## RESER2015 Programme and sessions

### A: Development and innovation in public and private manual services

Session 1: Public, private and social innovation in manual services (Thursday 11:15 - 12:45)

Chair: Brita Hermelin

NONE

Session 2: Manual service systematization and service values (Thursday 13:45 - 15:15)

Chair: Flemming Sørensen

- A2-1 Service culture and value experiences of everyday service : North-South divide  
**Anu Helkkula, Tiziana Russo Spina, Cristina Mele, Carol Kelleher, Valeria Improta**
- A2-3 Service Dominant Logic - how to systematize service business  
**Seppo Kuula, Erkkä Niemi, Harri Haapasalo**

Session 3: Bricolage and user-based innovation in manual services (Friday 10:45 - 12:15)

Chair: Mervi Hasu

- A3-1 How users are involved in business-to-business service innovation processes  
**Giulia Nardelli, Ada Scupola**
- A3-3 Employee critique as an impulse for bricolage in elderly care services  
**Sari Käpykangas, Mervi Hasu**

### B: Servitization

Session 1: Servitization (Thursday 15:45 - 17:15)

Chair: Thomas Meiren

- B1-1 Development of Smart Services in Manufacturing Companies  
**Thomas Meiren, Nicola Sacconi, Andrea Alghisi**
- B1-2 Servitization and Productization: two faces of the same coin?  
**Luna Leoni**
- B1-3 Standardizing the service delivery system for repetitive industrial services  
**Elina Poikonen, Miia Martinsuo, Sanna Nenonen**

### C: Innovative services, sustainability and value-creation

Session 1: Innovative services and innovation determinants (Friday 10:45 - 12:15)

Chair: Jon Sundbo

- C1-1 Determination of Innovation Capability of Organizations: Qualitative Meta Synthesis and Delphi Method  
**Mostafa Momeni, Susanne Balslev Nielsen, Mahdi Haghighi Kafash**
- C1-2 Service concepts from future - weak signals from different branches  
**Vitalija Petrulaitienė, Eelis Rytönen, Suvi Nenonen, Tuuli Jylhä**
- C1-3 Re-approaching the Meaning "Innovative Service" on Generating New Service Process: MEIJI Milk Express study case (fresh milk home delivery service) - Provider and User  
**Leisa Moreno**
- C1-4 Fruit wine festivals and producer visits as tourist attractions and marketing channels  
**Donna Sundbo, Jon Sundbo**

Session 2: Services and issues of sustainability (Friday 13:15 - 14:45)

Chair: Faiz Gallouj

- C2-1 Service innovation for sustainability: paths for greening by service innovation  
**Faridah Djellal, Faiz Gallouj**
- C2-2 Sustainable Development an Opportunity for Innovation in the Management Model of Public Organisations  
**José Aureliano Martín Segura, José Luis Navarro Espigares, César Pérez López, Guillermo Maraver Tarifa**

|  |                      |
|--|----------------------|
| Session 3: Values of services and their measurement (Friday 15:15 - 16:45) | Chair: Bent Petersen |
|--|----------------------|

- C3-2 Creating and Capturing Value for Different Types of Services - A Contingency Approach  
**Bent Petersen, Peter Ørberg Jensen**
- C3-3 Emotion measurement services for knowledge workers  
**Maiju Vuolle, Henna Salenius, Johanna Lintinen, Julia Mäkinen**

#### D: Changing geographies of services: Internationalisation, regional and local development

|  |                           |
|--|---------------------------|
| Session 1: Services and local, regional and national development issues (Thursday 11:15 - 12:45) | Chair: Laurențiu Tăchiciu |
|--|---------------------------|

- D1-1 Tyranny of Distance or Market Potential? Empirical Analysis on Service Sector Growth in Hinterlands of China  
**Liu Yi**
- D1-3 Host country impact of services FDI: the case of Visegrad countries  
**Zoltán Gál, Magdolna Sass**

|  |                      |
|--|----------------------|
| Session 2: Collaboration, networking and innovation (Thursday 13:45 - 15:15) | Chair: Lars Fuglsang |
|--|----------------------|

- D2-2 Towards a multi-level framework of collaborative innovation in tourism  
**Olga Høegh-Guldberg, Lars Fuglsang**
- D2-3 Evaluation of design thinking for the creation of service innovations in developing countries  
**Silvia Gliem, Astrid Boeger, Harald Goegl, Christiane Hipp**

|  |                       |
|--|-----------------------|
| Session 3: Services, regional and local development (Thursday 15:45 - 17:15) | Chair: William Beyers |
|--|-----------------------|

- D3-2 Dynamics of Trade In Services: Exports, Imports and Local Demand in Washington State and the U.S. 1963-2007  
**William B. Beyers**
- D3-3 Between the center and the margins: Services location, economic (re)structuring and quality of life in metropolitan periurban areas  
**P. Costa, T. Costa Pinto, M<sup>a</sup> F. Ferreira, F. Bernardo, C. Colaço, S. Santos, R. Lopes, R. Coelho**

|  |                     |
|--|---------------------|
| Session 4: Knowledge intensive services: geographic characteristics and development (Friday 13:15 - 14:45) | Chair Patrick Ström |
|--|---------------------|

- D4-1 International Financial Centre Development In Central And Eastern Europe - Role of Financial & Business Services Offshoring in IFC Formation  
**Zoltán Gál**
- D4-3 Outward FDI in financial services – the case of Hungary  
**Magdolna Sass**

#### E: Development, innovation and societal impact of knowledge intensive services

|  |                               |
|--|-------------------------------|
| Session 1: Innovation and new business models in KIBS (Thursday 11:15 - 12:45) | Chair: Christina Castro Lucas |
|--|-------------------------------|

- E1-1 Teaching Strategy of an Innovative Service: a Case Study in the Context of Cybernetic Simulated Scenarios  
**Víthor Rosa Franco, Cristina Castro Lucas Souza, João Gustavo Alcantara Guimarães**
- E1-2 From value propositions to business models: the case of diabetes self-care  
**Eija-Liisa Heikka, Salla Saraniemi, Pauliina Ulkuniemi**
- E1-3 Obstacles of Innovation and innovation capabilities in knowledge intensive business services in Palestine  
**Rabeh Morrar, May Abdelhadi**
- E1-4 Sustainable business model innovations in service: A study of Norwegian knowledge-intensive service companies  
**Erlend Aas Gulbrandsen, Sveinung Jørgensen, Lars Jacob Tynes Pedersen**

|  |                          |
|--|--------------------------|
| Session 2: Innovation and development in healthcare (Thursday 13:45 - 15:15) | Chair: Doris Schartinger |
|--|--------------------------|

- E2-1 Social innovation in Austrian health care: a conceptual approach  
**Doris Schartinger**
- E2-2 Non-Invasive Prenatal Test: An 'invasive' innovation in prenatal testing  
**Henni Tenhunen, An Chen**
- E2-3 The impact of service robotics on service work within a healthcare service system  
**Michaela Friedrich, Andrea Rößner, Anne-Sophie Tombeil**

|  |                      |
|--|----------------------|
| Session 3: KIBS and learning in clusters and networks (Thursday 15:45 - 17:15) | Chair: Morten Boesen |
|--|----------------------|

- E3-1 Learning in value networks as a challenge for digitalized service innovations  
**Eveliina Saari, Mervi Hasu**
- E3-2 KIBS and the Dynamics of Industrial Clusters: a Complex Adaptive Systems Approach  
**Benoît Desmarchelier, Faridah Djellal, Faïz Gallouj**
- E3-4 Serving mobile workers at university campuses – access to success  
**Eelis Rytönen, Vitalija Petraitienė, Suvi Nenonen, Tuuli Jylhä**

|   |                     |
|---|---------------------|
| Session 4: KIBS and internationalisation and outsourcing (Friday 10:45 - 12:15) | Chair: Grete Rusten |
|---|---------------------|

- E4-1 Building documentation for building operation - A study based on the theory of planned behavior  
**Jana Koers, Vanessa Platner, Torben Bernhold, David Serbin, Christian Junker**
- E4-2 Internationalization Services and KIS (Knowledge Intensive Services): Applicability of Traditional Models  
**Clara Belén Martos Martínez**
- E4-3 Current state and perspectives of 3PL outsourcing by SMEs  
**Laurențiu Tăchiciu, Vasile Dinu**
- E4-4 Which Factors Influence Formalization in the New Services Development Process? Empirical Findings from German Services Firms  
**Ilyas Khan, Thomas Meiren**

#### F: The role of services and service development in industrial policy

|   |                    |
|---|--------------------|
| Session 1: Policy issues (Friday 15:15 - 16:45) | Chair: Peter Smith |
|---|--------------------|

- F1-1 The impact of regulation of network and professional services on competition, growth and trade  
**Peter M. Smith**
- F1-2 Governance for collaborative development of service and system innovations  
**Kirsi Hyttinen**

#### G: Services and innovation in developing economies (REDLAS track)

|   |                     |
|---|---------------------|
| Session 1: Service innovation in development countries (Thursday 11:15 - 12:45) | Chair: Andrew Berry |
|---|---------------------|

- G1-2 Sectoral engines of growth in developing countries – are services a chance for catching-up?  
**Gisela Di Meglio, Jorge Gallego Martínez-Alcocer, Andrés Maroto, Maria Savona**
- G1-3 INNOVACIÓN, SERVICIOS Y DESARROLLO LOCAL: EL CASO DE LA ACUACULTURA EN MEXICO  
**Minerva Celaya, Araceli Almaraz, Alfredo Hualde**

|  |                     |
|--|---------------------|
| Session 2: KIBS and quality in services (Thursday 13:45 - 15:15) | Chair: Patrik Ström |
|--|---------------------|

- G2-1 The trade service in Latin America (2002-2012)  
**Suzana Quinet de Andrade Bastos, Melise Aline Saviotti Zille**
- G2-2 La compétitivité des entreprises locales face aux multinationales dans les pays sous-développés d'Afrique : le rôle de la qualité des services  
**Birahim Gueye, Dan Rani Guero & Chabi Benoit Kpassi Gobi**

|   |                               |
|---|-------------------------------|
| Session 3: Innovation dynamics in public services and governance (Friday 10:45 - 12:15) | Chair: Céline Merlin-Brogniar |
|---|-------------------------------|

- G3-2 Innovation in Public Services: A descriptive analysis of award-winning innovative experiences in Brazil  
**Lear Valadares Vieira, Antonio Isidro da Silva Filho, Mauro Célio Araújo dos Reis**
- G3-3 Service Innovation dynamics in solid waste sector: CDM landfill projects  
**Sílvia Cruz, Sônia Paulin<sup>2</sup>, Delhi Paiva**
- G3-4 A labour process approach to derived typologies for service innovations for Mexican KIB  
**Leonel Corona-Treviño**

#### H: ICT's role in service development (A)

|   |                          |
|---|--------------------------|
| Session 1: ICT based service encounters and innovation (Friday 13:15 - 14:45) | Chair: Flemming Sørensen |
|---|--------------------------|

- H1-1 Co-production of the Service Recovery – Embodiment Perspectives for the Innovation from the ICT-centric Service Encounter  
**Jannick Kirk Sørensen**
- H1-2 Online review site data in service innovation  
**Tuomo Eloranta**
- H1-3 ICT-based service encounters in e-service development  
**Hannamaija Määttä, Inka Lappalainen**
- H1-4 Comparing methods for involving users in ideation. The use of Future Scenarios and Blogs in Library Innovation  
**Hanne Westh Nicolajsen, Ada Scupola, Flemming Sørensen**

|  |                          |
|--|--------------------------|
| Session 2: ICT, learning and innovation in health care services (Friday 15:15 - 16:45) | Chair: Christian Bourret |
|--|--------------------------|

- H2-1 Gamification as an enabler of mutual learning in complex health care systems  
**Johanna Leväsluoto, Jouko Heikkilä, Kaupo Viitanen, Joona Tuovinen**
- H2-2 Transforming health care through niche service innovations: the perspective of new entrepreneurial ventures  
**Arto Wallin**
- H2-3 Frameworks towards a virtual co-creation tool for fuzzy front-end of service development in health care context  
**Katriina Lahtinen, Satu Aaltonen, Marika Järvinen, Outi Teittinen, Mikko Pirttimäki**
- H2-4 New approaches to patients' services and new uses of ICT in Co-operative Interface Organizations as a lever to improve the French Healthcare System  
**Christian Bourret, Corinne Nkondjock**

#### I: ICT's role in service development (B)

|   |                   |
|---|-------------------|
| Session 1: Mobile services (Thursday 11:15 - 12:45) | Chair: Ute Reuter |
|---|-------------------|

- I1-1 App communication on Instagram. A netnographic study of a young human brand Isac Elliot  
**Anu Helkkula, Apramey Dube, Maria Holmlund-Rytkönen, Tii Pylvänäinen, Arja Hallberg, Maria Hellberg**
- I1-2 Electronic auctioning of services  
**Ute Reuter**

|   |                     |
|---|---------------------|
| Session 2: ICT and the urban (Thursday 13:45 - 15:15) | Chair: Jan Bröchner |
|---|---------------------|

- I2-1 ICT use in delivery of uncertain and complex project services: the case of building refurbishment  
**Ahmet Anil Sezer, Jan Bröchner**

|   |                      |
|---|----------------------|
| Session 3: Improving customer loyalty and management through ICT (Thursday 15:45 - 17:15) | Chair: Jean Philippe |
|---|----------------------|

- I3-3 Evolving the online customer experience - Is there a role for online customer support?  
**Graeme McLeana, Alan Wilson<sup>b</sup>**
- I3-4 Unlocking new business potential in the field of digital services  
**Hanna Komulainen, Heikki Karjaluoto, Hannu Saarijärvi, Salla Saraniemi, Kaisa Still, Pauliina Ulkuniemi**

|  |   |                                 |
|--|---|---------------------------------|
| Session 4: Unlocking new potentials of ICT (Friday 10:45 - 12:15)                            |   | Chair: Jørn Kjølhøth Møller     |
| I4-1   | Use of equipment lifecycle data in industrial services<br><b>Moramay Ocaña Flores, Miia Martinsuo</b>   |                                 |

| J4-3   | Innovation management in healthcare services. Two countries in comparison<br><b>Laura Castrén, Markus Scheuer</b>   |                                 |

Industry Track: What creates succesful Service firms? Experiences from different countries and models to follow

NOT INCLUDED IN PROCEEDINGS

# **A: Development and innovation in public and private manual services**

# **A1: Public, private and social innovation in manual services**

*Chair: Britta Hermelin*

## **A2: Manual service systematization and service values**

*Chair: Flemming Sørensen*

# Service culture and value experiences of everyday service: North-South divide

Anu Helkkula<sup>1</sup>, Tiziana Russo Spena<sup>2</sup>, Cristina Mele<sup>2</sup>, Valeria Improta<sup>2</sup>, Carol Kelleher<sup>3</sup>

- <sup>1</sup>Hanken School of Economics, Finland, <sup>2</sup>Universita di Napoli, Italy,  
<sup>3</sup>University College Cork, Ireland

*The purpose of our study is to analyse individual service culture and value experiences of everyday services. Specifically, we understand service culture as the collective cultural dimension of individual service experiences. We focus on regional service cultures in Northern and Southern Europe and draw on Consumer Culture Theory (CCT) in order to understand how individuals make sense of their service experiences, meaning of resources and resulting value experiences within a collective cultural frame that affects their value experiences. We argue that service culture creates a foundation for current service and value experiences, expected service and value experiences, and imaginary ideal service and value experiences. We therefore contribute to service research in experiential value by extending service researchers' focus beyond individual service experiences to collective service experiences of service culture that creates a foundation for current and expected service and value experiences.*

## 1. Introduction

The study of culture has been an important topic across a number of business domains. For example, in organizational studies, culture is defined as “a set of values, beliefs, and norms that direct the thinking and decision making of a group” (Leininger and McFarland 2006). On the management side, this simplistic approach to culture in service experiences has been questioned due to increasing emphasis on the service economy (Pine and Gilmore 1998).

In the service research, culture has been dealt with both within the international service management literature and service research more generally. In particular the exploration of the service culture has interested researchers in the context of the internationalization of services (e.g. De Ruyter et al., 1998; Hyder et al., 2009), the role of culture of service organisations (e.g. Wilson, 1995, Webster and White, 2010; Akiko. 2012.), the impact of culture on service quality and recovery (e.g. Laroche et al., 2004; Ladhari et al., 2011; Wan, 2013 ). With some exceptions (e.g. Chan et al., 2012), the main corpus of service research seems to focus more on the perspective of provider service organisation, while less is said on consumers and how he/she makes sense of his/her service and value experiences within a collective cultural frame.

The more recent elaboration of Service-Dominant logic (SDL) (Vargo and Lusch, 2008) has greatly illuminated on consumer participation in value and service process. SDL scholars have argued for understanding value as exclusively, located within the phenomenological experience of beneficiary (Vargo and Lusch 2008), which extends beyond the dyadic provider-costumer relationship to include multidirectional resource integration (Chandler and Vargo, 2011). This has been followed by an increased emphasis on the embedded and contextual nature of value and the importance of shared institutional logics and socio-cultural ties that influence value co-creation (Vargo and Lusch, 2011, 2012; Helkkula et al., 2012, Edvardsson et al., 2011, 2012; Jaakkola et al., 2015).

Notwithstanding these studies, the socio-cultural dimension of service experiences has seldom been the focus of service research to date. In particular, less is known about the enabling and constraining interplay between socio-cultural context and individual sense-making of value experience. However, as service experiences are acknowledged to be social and context sensitive, service studies need to respond to the call for greater contextual sensitivity in service co-creation research (Chandler and Vargo, 2011; Akaka et al., 2015). Thus the socio-cultural dimension of service experiences has to be further investigated in service research.

In this study, we draw on Consumer Culture Theory (CCT) in order to understand individuals making sense of their service experiences, meaning of resources and resulting value experiences within a cultural frame that affects their social actions (McCracken 1986). The specific purpose of our study is to analyse individual service culture and value experiences of everyday services. Specifically, we understand service culture as the collective cultural dimension of individual service experiences.

We explore consumers' challenges in relation to the consumption of everyday service and how they use their culturally situated understanding of imaginary, ideal service in their everyday lives. We focus on two regional service cultures representing the European North-South divide: Helsinki in Finland and Naples in Italy. Collective cultural ideals in different socio-cultural contexts create a foundation for individual service experiences as they drive consumption choices (Arnould, 2006; Arnould and Thompson, 2005.).

The remainder of the article is organized as follows: First, we characterize the collective cultural dimension of service experience; next, we present the Event-Based Narrative Inquiry Technique (EBNIT) (Helkkula and Pihlström, 2010) used for understanding of cultural dimensions in service experience. Following this, we outline and discuss our key findings in relation to how service consumers individually and collectively make sense of challenges relating to their current service experiences, and how they create imaginary ideal service experiences using their culturally situated understanding. We contribute to service research by addressing the cultural dimension of service experiences and resulting value experiences that has gained little attention in experiential value research. We suggest future research directions and encourage both researchers and managers to analyse the collective cultural dimension in order to co-create valuable service that facilitates customers' everyday lives.

## **2. Cultural dimension of service experiences**

As previously outlined, in the service research, culture has been dealt with both within the international service management literature and service research more generally. However, extant insights from Consumer Culture Theory (CCT) help address this gap.

During the last decades, the socio-cultural aspects of consumption actions have gained momentum in the most of consumer research tradition, and in particular in CCT. Consumer studies have evidenced how consumers look for a complex mix of value from offerings including functional, economic and symbolic benefits, hedonistic experiences, and emotions (Holbrook, 1999; Sanchez-Fernandez et al., 2009). However, these studies remain still disconnected and scattered among different research fields with no unified perspective able to explain the complexity of consumer actions within the broader socio-historical frame of globalization and new market phenomena (Arnould, 2006; Arnould and Thompson, 2005).

An attempt towards a unified perspective has been recently provided by researchers grouped by Arnould and Thompson (2005) in the research tradition of CCT, which addresses the dynamic relationships between consumer actions and cultural meanings. According to Arnould (2006), the major contribution of CCT is the emphasis on studies on cultural complexity based on the assumptions of heterogeneous distribution of meanings and the multiplicity of overlapping cultural groupings existing within the market.

In particular, CCT research has provided a theoretical understanding of consumer choice and consumption in differing social and cultural contexts (Arnould, 2006; Arnould and Thompson, 2005; Holttinen, 2014). The ideologies and cultural ideals that drive consumption choices vary within in different socio-cultural context; in this sense culturally situated understandings influence service consumption (Arnould, 2006; Arnould and Thompson, 2005; Venkatesh, et al., 2006). Arnould et al. (2006) stress that consumers buy meaning and experience more than products. As cultural meanings are collective, and experiences individually determined, individual service experiences are co-created and embedded in a collective social context. Individual experiences may be different from those intended by commercial producers, who often aim for a specific type of a service experience (Cova and Dallı, 2009; Schau et al., 2009). In the CCT perspective, culture represents the real fabric of experience, meaning, and action (Arnould, 2006), and consumers are mainly seen as identity seekers (Venkatesh et al., 2006), who collectively co-create experiences in their daily lives. Thus, all kind of experiences - including of individual consumption - are inherently interactive and socially based (Arnould and Thompson, 2005; Schau et al., 2009). Consumers' belief systems and practices, together with their underlying structures, play central roles in building relationships with others and in their experience formation (Arnould and Thompson, 2005).

Many CCT researchers have distinguished in their empirical exploration the great variety of marketplace cultures built on the imbricated layers of cultural meanings and practices. The interest has been especially on the empirical analysis of fan communities (Kozinets 2001), brand communities (Muniz and O'Guinn, 2001; Schau et al., 2009) and consumer subcultures or tribes (Cova and Cova, 2002). Such

studies bring consumption practices into focus and illustrate how particular manifestations of consumer practices are constituted, sustained, transformed, and shaped in a social-cultural context.

Recently Thompson et al. (2013) put forward the idea that consumers may be seen as free and community embedded agents, who use consumption in meaningful ways in their everyday life contexts. Others stress the role of subcultures of consumption that offer co-creation opportunities for resource integration (Thomas et al., 2013). Thus, collective consumer culture and particularly sub-cultures denote the social arrangement in which the relations between lived culture and material resources including products and services are integrated in a collective co-creation experience.

Based on the assumption that people live in a social and culturally constituted world, overall these studies share a broad interest in the ways that culturally shared meanings and practices frame action and experience and are produced, reproduced, and transformed in market-related experiences.

More recently, highlighting the reflexive relationship between socio-cultural dimensions and consumer agency, culture has become a hot topic in CCT research. Scholars have investigated value-creation configurations and consumer actions that are not strictly tied to communities or similar closed groups of interest (Arnould, 2007; Peñaloza and Mish, 2011).

While service research and CCT can be seen as different streams of research, research, the alliance of SDL logic and CCT was already identified in 2006 (Arnould, 2006). For example, as highlighted earlier, SDL has presented the multi-layered and nested context of service ecosystems as a critical dimension in value co-creation (value-in-context) (Chandler and Vargo, 2011). This has inspired more authors to claim for a natural alliance between CCT and SDL, with cultural perspectives seen as the key mean to further elaborate on the value co-creation and market phenomena (Arnould, 2007; Peñaloza and Mish, 2011; Thompson et al., 2013; Akaka et al., 2015; Jaakkola et al., 2015).

Even if CCT and service research have found mutual interest in research, further elaborations on value and experience contextualization are needed. For example, Peñaloza and Mish (2011), Akaka et al. (2015), and Jaakkola et al. (2015) note that incorporating CCT informed cultural perspective to service research offers a promising point of departure for understanding the experiential view of value and contextual social and cultural aspects that frame consumers' experiences and practices.

### **3. Method**

As part of our empirical study, we conducted 78 narrative interviews using Event-Based Narrative Inquiry Technique (EBNIT) (Helkkula and Pihlström, 2010). The interviews were conducted in Naples (48) and in Helsinki (30), in Southern and Northern Europe in May-October 2013 in order to explore different service culture contexts indicative of the North-South divide. The duration of the interviews were

between 3 and 20 minutes, and covered the age range from 18 to 65 years. Overall, the interviews explored the challenges consumers have in their everyday lives and their innovative ideas how these challenges could be solved.

All 78 respondents were interviewed and contacted by Master students, who were asked to select respondents within different age ranges (see Table 1). The students were trained in the use of EBNIT in advance. The EBNIT interview technique combines narratives interviews, focusing on critical events, with a projective technique using metaphors. Projective techniques have been used to transfer narratives from their customary context, such as culture, to new contexts, interlining relationships of the contexts from which they are borrowed (Goodman, 1988). The purpose of each interview was to find out the everyday service experience that the respondent would like to revise or change in his/her life.

In relation to the interview format itself, firstly respondents were asked to recall a challenging service experience in their everyday life (critical event), and then tell a story about their experience. After that they were encouraged to create an imaginary story of an ideal service experience. The metaphor of a magic wand was used to trigger respondents to think about service consumption beyond their normal everyday experiences.

The following questions were posed in the interviews:

- Please tell me about a service related event that happened recently or a service related event that happened in the past that you can remember: what happened or what is it that you don't like in your everyday service experience?
- Why would you like to change this service experience in your everyday life, what is it about the service experience that you like / don't like?
- Now I will give you a magic wand. Everything is possible. No financial, technical, time or other restrictions. In relation to the service experience that you mentioned, please tell me what would happen in an ideal case, where your magic wand made everything possible? How might you live/experience that event?

The interviews were transcribed, and two researchers had discussions with the interviewers in order to elaborate their observations. Then two researchers read through the results several times. The experienced challenges in service experiences, imaginary ideal service experiences, themes and service culture dimension emerged from the data. We now use the North-South divide to present our findings.

## **4. Findings**

## 4.1 Finnish service experiences

In this section, we analyze and comment on the Finnish interviews in order to understand what are critical events in everyday service experiences and what constitutes ideal service experience. We take into consideration two main focal points: the challenging service experience highlighted by the respondent in question and how the respondent would like to change it, if everything was possible.

Respondents interviewed in Finland had challenging service experiences in relation to both public and private sector services. Finnish experiences underline that different types of public and private services were mainly functioning well. The challenge highlighted related mainly to the friendliness of customer service, or the human touch of the service.

For example, a middle-aged woman recounted her experience of using public buses. She recounted how a bus driver did not typically greet customers but, unexpectedly one morning, he said hello. Her ideal service experience is a service where bus drivers always say good morning and greet customers in a friendly way.

*“Normally when I take the bus here in Helsinki the driver never says anything and you just pass in silence. But today I was a bit slow, and when I passed the driver he looked at me. Then he stared at me, and he said “huomenta”, (good morning in Finnish). I was startled and thought “Oh my God! He said good morning to me!” So I started to say “Oh, yes. Good morning. Good morning”. Oh dear!” Normally they say nothing. But there was another woman and she didn’t first understand either what happened. The driver said “huomenta” to the woman and she answer back “Oh, sorry, sorry. Yes, yes.”. (Anna, 36-50, Helsinki).*

And she adds:

*“I would take my wand and I would strike it on all bus drivers every morning so the people would wake up and think ‘Ok, I have to remember to say good morning to every passenger’” (Anna, 36-50, Helsinki)*

She refers to her collective experience of this specific service culture in Helsinki:

*“I think it is an urban legend. Everybody has some story about these drivers, as they say nothing. In case they say “Hi!”, you don’t know how to react.”*

Lack of personal touch in service was also a challenge highlighted by the 50+-year old male Antti, who had had problems contacting a teleoperator’s customer service agent in order to correct a mistake in his invoice

*“They are losing a lot, they look at the bottom line in all that they do, they don’t look at you as an individual, they look at the percentages, the thousands or tens of thousands of euros that they lose - or as they put it, of turnover - and they forget that behind every thousand euros there are one thousand customers who are paying for it. They really don’t have much need to change their customer service. But, you know, people get really cheesed off by the non-responsiveness. So, I mean, it’s a simple thing, it would be a simple thing to solve. (Antti, 50+, Helsinki)”*

Some other respondents refer to unfriendly customer service in a fine dining restaurant/café; for example one respondent tells about his bad experience because the staff in the restaurant has a really bad attitude towards a young family, because they have their baby with them.

Another respondent in a fine-dine restaurant found that the waiter wasn't nice and seemed quite unwilling to serve. The wine served with the main course was really cold and the respondent didn't like it, because it was red wine and it's not supposed to be so cold. After a while, the respondent went to the kitchen and said that the wine is too cold, but they just answered: "we can't do anything about it, that's the temperature we have in here." And the respondent was sent back to his table.

Their ideal experience also related to a restaurant service, which would be service-oriented, meaning that the waiter was courteous and welcoming and offers laid-back and personal service, but which is not too meddlesome.

Also a young woman refers to unfriendly workers talking about poor service at the local supermarket, Valintatalo in Töölö, where staff members never say "hi" and are not nice with customers.

*"The checkout staff are not nice, and they don't even say "Hi". They just wander around and it is otherwise also a bad store." (Jola, 18-35, Helsinki)*

And her ideal experience is one in where personnel is kind:

*"In my ideal service someone is at all times at the cashiers' desk. Also, there would be a staff member in the store that you can ask if you search for something... Well normal customer service... Improvement in that. (Jola, 18-35, Helsinki)*

## **4.2 Italian service experience**

In this section we analyse the findings of the Italian interviews in order to understand what are the critical events about everyday service experiences and ideal imagined service faced by Italian consumers in Southern Italy. The majority of respondents refer to a poor performance in public service, in particular they refer to three main categories of service: public transport, public street maintenance, and public healthcare service. The major concern was the functioning of different types of public services, especially the mal-functioning of public transportation. For example, the unreliable schedules caused challenges in respondents' everyday lives.

A 44 -year old storeowner tells about her challenges using public buses and trains and her imaginary ideal experiences. In one instance, the respondent outlines the inefficiency of public transport.

*"I am a Neapolitan storeowner, I cannot organize my work because of the many train delays, bus delays, subway delays and often I am forced to take a taxi with expenses out of my budget (Anna, 44, Naples).*

Her ideal experience is about perfectly connected roads and enhanced service as the following illustration shows:

*“Streets would be perfectly connected, with adequate transport services, with more lines, more rides, better information. [...] tables and billboards suited to understand the times and rides during the day. Faster construction of new subway lines, and better maintenance of old lines (Anna, 44, Naples).”*

Also another respondent had difficulties organizing his work due to poor public services:

*“There was a delay of several minutes and I arrived late at night – then had problems to do my work” (Guido, 18-35, Naples)*

His ideal experience is about more trains, no delays, improved punctuality:

*“Greater focus, greater efficiency and quality. Trains on time, more controls, to have higher earnings, better punctuality” (Guido, 18-35, Naples)*

Some other respondents refer to the fact that roads were not in good shape. A man in the age range of 51+ tells of his bad experience due to the poor streets maintenance, which caused accidents and even punctured his tyre:

*“Once, after a storm, while I was driving the same stretch that I take every to the office, there was a hole hidden under a puddle of water that I went into, fully breaking the rim of my tyre. Of course I had to change the wheel in the first SOS area and this has led to a considerable delay in getting to work, a lot of stress and a certain fear caused not only by the unexpected blow, but also by the inability to quantify the damage. All this, of course under the effects of adverse weather conditions” (Claudio, 51+, Naples)*

In his ideal experience he would like to have people who make their work honestly using high quality materials and innovative techniques in order to restore radically road surface.

*“I would make a classification of all actions necessary to restore conditions of the streets. I would just like everyone carry their work honestly (Claudio, 51+, Naples)*

Also another respondent refers to his bad experience due to poor street maintenance:

*“There are consistently so many holes in the streets and roads that while driving I punctured the tire” (Antonio 26-35, Naples)”.*

His ideal experience is to have unlimited funds to repair the streets:

*“The funds at my disposal to improve city streets” (Antonio 26-35, Naples).*

Some other respondents tell about inefficiencies in public healthcare service. For example, a middle-age woman complains about her experience in a healthcare center:

*“I had a medical examination, there was a malfunction with the reservation system and I had to wait so long for my appointment.” (Simone, 51+, Naples)*

Her ideal experience is a more efficient service:

*“I would like that the service would be more efficient, that appointments would take place at the time that they were booked for ... and also increase the quality of service as the tools available are inadequate and not technologically advanced”. (Simone, 51+, Naples)*

While the narratives describe individual service experiences, many respondents emphasize their understanding of existing service culture being socially constructed. In the following extracts 24- and 35-year-old women, and a 51-year-old man open up the existing service cultures by referring to their friends and the notion of “we” or “everybody”.

*“I, like other people, was waiting for a train. Only after 30 minutes we started to talk about the discomfort. During the first 30 minutes we thought it was the usual delay. (Alessia 24, Naples).*

*“One of the services that we use every day and that usually brings us a lot of inconvenience is public transport, namely the service offered by the Circumvesuviana (Neapolitan train) line”. (Marina, 35, Naples)*

Also another respondent refers to the notion of “everybody” in the following extract:

*“Surely everybody knows that every time we drive our vehicles to work or another destination we are confronted with a quite difficult reality in which protagonists are our streets.” (Claudio, 51+, Naples).*

## **5. Discussion:**

Our findings show that existing regional service culture creates the foundation for sense-making of value (1) of current service and value experiences, (2) expected service and value experiences, and (3) imaginary ideal service and value experiences.

First, our findings show that existing service culture affects how people make sense of their service experiences of using that service. While respondents in Naples experienced public service, and especially the malfunctioning of public transportation as challenges in their everyday lives, respondents in Helsinki experienced the non-friendly service encounters as challenges. Even if the cause for not-so-good value experiences was different in both countries studied, both Naples and Helsinki respondents were disappointed with the value of service. Even if these experiences were individual, respondents both in Naples and in Helsinki referred to socially constructed service culture experiences. Accordingly, existing service culture, and how customers interpret it, creates a platform for individual service and value experiences. We contribute to service experience and value research by presenting an empirical study of regional service, and extend experiential service experience and value experience research that has mainly focused on individual service experiences. We provide empirical narrative data on public service, which has gained little attention in service culture research. We draw on recent service research that has extended its interest for collective service experiences and value experiences

(Jaakkola, Helkkula and Aarikka-Stenroos 2015) and research in consumer research focusing on co-consuming groups (Goulding et al. 2012; Carú and Cova 2015), especially for products, brands, consumer activities in brand communities (Schouten and McAlexander, 1995; Muñiz and O'Guinn, 2001; Cova et al., 2007).

Second, our findings show that existing service culture affects expected service experiences. For example, in relation to public transportation, the expected service experiences in Naples were very different from the expected experiences in Helsinki. While respondents in Naples had a pre-expectation of malfunctioning public transportation, respondents in Helsinki expected buses and trains to run on time. Accordingly, respondents in Naples expected buses and trains to be late or overcrowded, as in Helsinki a ten-minute-delay was considered to be a long delay and an unpleasant service and value experience.

In our study, we focus on the customer perspective as we study expected service experiences. The introduction of service economy as the foundation of business (Pine and Gilmore, 1999; Vargo and Lusch, 2008) has transferred the focus from service quality to service experiences and value experiences. We extend existing research on the Gaps-model, presented together with the SERVQUAL scale by Parasuraman, Zeithaml and Berry (1985) by focusing on service experiences and value experiences from the customer perspective. Accordingly, as the GAPS-model focuses on service quality, we address customer-experienced value. It has been shown that service quality affects customer satisfaction (Parasuraman et al., 1985; 1988; Howat and Murray, 2002). Quality has mostly been measured by standards, which are set by the service provider. Thus, quality does not measure a customer's subjective experience of the service or value. Instead, quality measures how the standards set by the service provider have been reached. In organization studies, Kumar and Kumar (2015) indicate that in addition to organizations, also customers may be influenced by different cultures and different regional cultures in their expected and perceived service. Our research extends previous research by focusing on customer service and value experiences instead of quality; and by emphasizing that regional service culture may be an essential factor when customers make sense of their service and value experiences.

Third, the findings show that customers' imaginary innovative ideas for an ideal service were strongly linked to the existing service culture. In Naples respondents imagined buses and trains running in time and not being too crowded to facilitate their everyday routines and actions. In Helsinki, imaginary ideal service experiences were related to better functioning of public transportation, as respondents' expected experiences were based on the existing service culture of well-functioning public transportation. We draw on recent service research on imaginary service experiences (Helkkula, Kelleher, Pihlström, 2012; Jaakkola, Helkkula, Aarikka-Stenroos, 2015) and extend individual experiences to collective experiences of service culture. Our study therefore contributes to service research on experienced value by emphasizing service culture as socially constructed foundation for sense-making of both lived and imaginary value experiences.

To conclude, this is one of the first studies to focus on the cultural dimension of service experiences and its implication to value and expected service innovations. We contribute to service research, and especially to SDL, by drawing on CCT by extending individual experiences to collective experiences of service culture that

creates a foundation for current service and value experiences, expected service and value experiences, and imaginary ideal service and value experiences. We argue that even if culture has received little attention in current service and value research, it opens avenues for understanding how customers make sense of their service and value experiences in relation to expected experiences, as well as their expectations and desires for future service experiences.

## **5.1. Implications**

The study has implications for service researchers and managers when they plan to develop and innovate service. Both local and global service needs to adapt to existing service cultures and its historical, socio-material and cultural context (Gherardi, 2008).

Respondents' service experiences indicate that existing service culture affects respondents' expected service experiences and their imaginary experiences of an ideal service event. As service experiences are the foundation to making sense of value experiences, existing culture in service affects customers' value experiences.

In case customers previously experienced mal-functioning service up to the extent that it has created a reputation for mal-functioning service culture, it affects customers' value experiences.

## **5.2. The limitations of this study and future research**

This study has focused on two empirical data sets on regional service cultures in Helsinki and Naples. Different regional service cultures offer a rich source of empirical data for future research. In addition to different types of regional service cultures, service cultures may relate to different consumer groups that may be geographically spread out and for example based on web-based interaction.

As sense-making of customers' imaginary, expected service experiences for future service are affected by existing service culture, we encourage research in service development and service innovation to consider service culture as they involve customers in co-creation of innovative service ideas. Existing service culture may indicate customers' expectations for improved service.

# Service Dominant Logic – how to systematize service business

Seppo Kuula<sup>1</sup>, Erkka Niem<sup>2</sup>, Harri Haapasalo<sup>3</sup>

<sup>1,3</sup>University of Oulu, <sup>2</sup>Aalto University

*Digitalization is changing the world quickly, industrial boundaries are vanishing, and competition is truly global. Digital transformation is disruptive, the new, unseen and born-global services are amplifying demand for service-oriented business- and marketing logic, where value creation between actors is a key element. The main aim of this paper is to describe cornerstones for systematizing co-creational service dominant business logic in the rapidly changing market environment. We review literature to find out what are the approaches behind service dominant logic and value co-creation in service marketing, how the value stream optimization based on Lean – philosophy was aligned with the other encountering theories, and then are creating the encountering framework for systematically utilizing the service dominant logic in business-to-business environment.*

## 1. Introduction

The baseline for Service oriented marketing is that customers consume service (plural), regardless of whether they buy goods or services, service is a value creative process, and service marketing shall be seen as relationships, networks and continuous close interaction (Grönroos, 1990: Lovelock; Gummesson, 2004: Vargo; Lusch, 2004). For the clarification Service in this context shall be seen as a perspective on value creation (value in use), not only as a part of offering (Edvardsson et al., 2012). The most significant difference between the industrialization driven product marketing and globalization driven Service marketing is seen in the definition of value creation. Most of the researchers are agreeing that in Service economy customer is always a value creator, but the definition of value co-creation is not exactly defined. Still we can see that Service Dominant Logic (Vargo; Lusch, 2004: Vargo; Lusch, 2008: Vargo; Lusch, 2014) is giving a sound foundational framework for exploring the ongoing encountering process between the actors in BtoB service economy, which is globally rapidly increasing business sector.

Value creation is difficult if not impossible to unambiguously define, but is used as a baseline for many world changing theories, like Lean thinking, which is described as a value creating process that's capable (value), available (value streams), adequate (perfection), flexible, flowing, and pulled (Womack; Jones, 1996).

Value co-creation requires a change in the dominant business logic from 'making, selling and servicing' to 'listening, customizing and co-creating'. This means it is also cross-functional: It assumes and requires alignment between all the operational or organizational functions. Later studies (Grönroos, 2008: Grönroos; Ravald, 2011) are questioning that supplier is always the value creator, but agreeing it can co-create value with the customer in certain alignment. This alignment and encountering cross

functionally between the supplier and customer organizations seems to be the enabler for later mentioned co-creative BtoB relationship.

Because customer is always seen as a value creator, value co-creation can be also seen as Pull System, which is an integral part of Lean Thinking and Lean management. In Pull System the control for flow of resources is determined by the end user, just like Vargo and Lusch (2004) are describing in one of the strongest SDL foundation points; “Value is always determined by beneficiary”. Lean thinking is eliminating wasteful practices and determinates and increases value-producing practices of the company, development or operations.

Encountering in this context means two-way actions between the customer and supplier, can also be referred as touch points, and can be initiated by either party. Encountering process is in the middle of the value creation (and co-creation), and is therefore taken to focus in this study. Theoretical foundation for our encountering – process definition is based on Payne et al. (2008) studies, but is taken to more practical level in use, and tweaked to fit into another value creation–related theories based on learnings over five years.

Lean approach for encountering is so called “Lean Startup” – model (Ries, 2011), which in brief is a process which is answering question; How can we learn more quickly what works, and discard what doesn't. Originally developed together with his mentor Steve Blank. Blank has told this methodology founding strong influences not only from Lean Thinking (Womack; Jones, 1996), but also value driven Entrepreneurial Management (Drucker, 1985; Stevenson; Jarillo, 1990), and Discovery Driven Planning (McGrath; MacMillian, 1999).

Testing of value creation in Lean Startup – model is done iteratively through so called Minimum Viable Product (MVP) – development process (Ries, 2011). This strategic MVP process is iterative, continuous and cross-functional. (Payne et al., 2008) presented all these three themes as common for the companies which have decided to utilize their SDL encountering process, which is one proof of the theoretical and practical connection between SDL and Lean.

Based on above the main aim of this interpretive case study research is to describe cornerstones for systemization of service business. Moreover, we aim at conducting a feasibility study of S-D logic and illustrate a practical application of the co-creation framework by applying Action Design Research (ADR) method. This can be condensed into following research questions:

- What are the elements Lean SDL Encountering framework to systematizing service business?
- How to systematically utilize the service dominant logic in business-to-business environment?

In this article, we first review literature to find out what are the approaches behind service-dominant logic. Second, we describe the research methodology and critically evaluate the quality of the research. Third, we study how to systematically utilize the S-D logic in practice in business-to-business environment using single case organization. Fourth, we discuss and analyze the findings in relation to existing theories in order to represent a generalized solution addressing a class of problems moving conceptually from an organization-specific instance onto a more abstract level. Finally, we conclude the paper with scientific and practical contribution of the research.

## **2. Literature review**

### **2.1. Service Dominant Logic, Service Marketing, Lean Thinking and Entrepreneurship are branches of the same tree**

The starting-point for Service oriented marketing is that customers consume service, regardless of whether they buy goods or services, and marketing shall be seen as relationships, networks and interactions. Service Dominant Logic (Vargo; Lusch, 2004: Vargo; Lusch, 2008a) can be seen as a foundational framework for Service Marketing, not as a new theory, like Grönroos (Grönroos; Ravald, 2011: Grönroos; Gummerus, 2014) was pointing out, and authors themselves concluded later (Vargo, 2011).

In Service Marketing, just like in SDL, the customer has been seen in the middle of value creation process (Sheth et al., 2000), and value creation is based on core competencies (Prahalad; Hamel, 1990). The value creation approach was introduced already by Michael Porter (1985).

Goods dominant logic had its roots in the industrialization, just like traditional management and organizational structures (Vargo; Lusch, 2014). Digitalization is accelerating the globalization, and is driving us away from the fallacy of mass-production. Digitalization is giving us more opportunities to get individual service for our individual needs, and is returning the appreciation towards craftsmanship.

Firm's ability to understand customers' value-creating processes, to create solutions that enable improved value creation, to create demand for these solutions, and to sell these to customers, receiving compensation based on customers' value in use (Bonney; Williams, 2009), is also baseline for both, Service Marketing and SDL.

Sawhney (2006) is describing how the product-centric view for marketing is too narrow and doesn't follow the evolution of human behaviour and thinking, and therefore is expanding the Solutions definition for covering the whole value creation chain. He complains, that solution - definition is loosely defined, and is defining solution as "an integrated combination of products and services customized for a set of customers that allows customers to achieve better outcomes than the sum of the individual components of the solution."

Solution marketing is defining outcome from customer's perspective, just like SDL and Lean. Customer needs holes no drills, benefits no features, and they do they not just are (Sawhney, 2006).

Customer liaison process in Solution Marketing is described as a sequence of activities that are logically connected, called a customer activity cycle (Sawhney, 1999: Sawhney et al., 2004: Vandermerwe, 1993, 2000).

The customer and supplier activity in Service Marketing relationship can be mapped in detail through an activity mapping process called activity blueprinting or customer experience mapping process (Seybold, 2001: Bitner et al., 2008).

Already in 1980's Drucker (1985) presented entrepreneurial management, which is responsive for value creation opportunities. He presented Entrepreneurial manage-

ment as a movement in which the economy is seen as biological process. He put innovation over invention, where Innovation was described more or less as creational process through co-creation and resource integration, and effectiveness over efficiency.

Lean thinking has its roots in Toyota Production System (Ohno, 1988). Lean thinking is based on incremental value creation, pull-directed value stream, effective flow of value creative particles (eliminating waste), and drive to perfection (quality is not a question but built into the system). Womack and Jones (Womack; Jones 1996) were describing value definition related to “specific product (service) with specific capabilities offered at specific prices through a dialogue with specific customers”, which can have translated as a co-creative resource integration.

In this article we conclude, that all of these ideologies are basically presenting the same idea; Industrialization was leading to productization, where all the offerings were compromises. Today all the economies are service economies, and value creation has become more complex. Service Dominant Logic is providing a good framework for understanding the process, where there are no barriers between the supplier and customer, and value creation is pull-directed and co-created.

## **2.2. Service Dominant Logic**

Service Science is seeing Service systems as value creational configurations of people, technology, value propositions and shared information (Maglio; Spohrer, 2008; Vargo; Lusch, 2008b; Vargo; Lusch, 2014). Originally Vargo and Lusch (2014) introduced the Service-dominant logic (SDL) through ten Foundational Propositions (FP). They were seeing Service as the application of competences benefitting each other (co-creation), and Service in the focus of economic exchange. This thinking is leading to the shift from operand resource exchange to operant resource exchange (competencies, knowledge and skills). Within this logic the operant resources are the fundamental source of competitive advantage. Goods are just a distribution mechanism for service provision.

According to Vargo and Lusch (2004; 2008a) Service Dominant Logic is based on the implication that value is defined, and co-created with the consumer (FP6), where core competencies are the competitive advantages (FP1). It means wide cross-organizational collaboration between the supplier and customer. Value co-creation means change through organization. Turning marketing logic from ‘making, selling and servicing’ to ‘listening, customizing and co-creating’ is requiring alignment between marketing, development and delivery organizations. Approach is based on customers’ strategic needs. Organizational foundation of SDL is in collaboration, and SDL is seeing all the social and economic actors as resource integrators, and therefore all economies as service economies.

SDL is defining value always determined by customer, and always created together. This definition is questioned in general (Grönroos; Voima, 2013), where service marketing based approach is seeing value creation to be shared sometimes as a value in use (SDL) but sometimes as a value in exchange, depending the maturity and relationship of organizations and actors. When value as a definition is not mathematically exact, and value creation therefore cannot implicitly be defined, SDL shall be seen more as a Service Marketing framework than implicit theory.

Applying Service-dominant logic means that the firm is not restricted to making value propositions only, but also gets opportunities to actively and directly participate in value creation with its customers.

Later the founding fathers of SDL have returned to further explore SDL, and presented that Service Dominant Logic is the reconceptualization of Service as the process where an actor is using its resources for the benefit of another (Vargo and Lusch 2014). They were presenting the original foundation points in four axioms;

- Axiom 1 was underlining FP1; Service is the fundamental basis of exchange. Service is always exchanged to service (operant serources).
- Axiom 2 was underlining FP6; The customer is always a co-creator of the value (interactive value creation process).
- Axiom 3 was underlining FP9; All economic and social actors are resource integrators. Value creation is network of networks.
- Axiom 4 was underlining FP10; Value is always uniquely determined by beneficiary; value is experiential and conceptual.

They were also presenting core conceptualization in more details, claiming that all actors (individuals, firms, nations) are fundamentally doing the same core activities in engaging to the the resource integration, exchanging service to service, and acting simultaneously as consumers and producers.

Akaka and SDL founding fathers (Akaka et al., 2013) were exploring the principles and management of Service ecosystem in the cultural context, talking again more about framework than theory. They were presenting Resource Integration in three levels, Micro (individual), Meso (firm), and Macro (nation). This framework was taking institutions along to the value creation with culture and norms. Interesting notion is, that while going deeper to the system perspective, they were seeing all marketing business to business related.

Service Innovation in the SDL framework is broadened to three different elements; service ecosystem, service platform, and value co-creation (Lusch; Nambisan, 2015). The study was seeing common worldview, architectural alignment, and structural flexibility of organizations required for co-creative service innovation. In our study these elements were at present when co-creative service innovation was occurred.

## **2.3. Lean Thinking**

Lean thinking is having its roots in Toyota Production System (Ohno, 1988). Lean thinking was studied, explained and popularized by Womack (Womack; Jones, 1996) and later explained in more details by Liker (Liker, 2004). The critical measure for Lean is value. Baseline is, that value is determined and defined by the customer.

The goal in Lean processes, from production through management, thinking, and processes to customer interface, is to get more value created with less waste, where waste (originally Muda in Japanese) can be defined as any activity which is usind resources but doesn't create value.

Value stream has always be pull-directed, as the value is defined by customer, and process has to be continuously improved, driving to perfection. In Lean process quality of service has to be built into the system.

Principles of Toyota Production System (TPS) are I) Respect for people, II) Continuous Improvement, III) Pull-directed process, IV) Solving root problems, V) Continuous learning in organization and partner networks, VI) Long term thinking over short term goals (Ohno, 1988).

In TPS personnel represent core competences, and core competence in a service society is a base of exchange. Good employee experience is the foundation for good customer experience. Continuous improvement has to be in the culture. This is leading to the iterative approach for process development and organizational learning. Visual controls and transparency are supporting the cross functional learning, titles are not important but respect for others, teamwork and mutual trust are.

Principles of Lean thinking are; I) identify value (value is defined by beneficiary, pull-direction), II) map value stream (seamless resource integration with customer), III) create flow (cross-functionality, culture), IV) establish pull (co-creation with customer), and V) seek perfection (iterative development) (Womack; Jones, 1996).

As already recognized, value is never easy to define, and every actor in the economy is wasting resources in some forms. In Lean thinking firms just have to think the created value from its customers' perspective, learn, iterate, improve, and revisit the value definition. When the value of service is defined, firm has to define the target cost for running the service when all the waste from the process is removed (Womack; Jones, 1996). In short this means that value for the service is co-created with the customer, price for the value is defined by customer, and cost for running the service is defined by supplier.

Eric Ries (2011) presented Lean Startup philosophy for answering the question How can we learn more quickly what works, and discard what doesn't. Learning process (Build-Measure-Learn) is clearly based on the value creation, and can be seen as Lean Encountering process. The iterative Build-Measure-Learn – process is the core part of the Lean startup methodology, explaining how the ideas can iteratively have turned into products, measuring value creation from customers' perspective, and then learn whether to persevere or pivot the idea. Haeckel's Sense-and-respond - centred view (Haeckel, 1999) is bridging Lean Startup philosophy to the Service Dominant Logic foundation. Main idea in Sense-and-respond – approach is to cultivate relationships that involve the customers in developing customized, competitively compelling value propositions to meet specific needs.

Ries' Lean Startup philosophy is also closely related to so called Design thinking (Brown, 2008), which combines deep end-user experience, systems thinking, iterative rapid prototyping and multi-stake holder feedback together (Inspiration – Ideation – Implementation). Maurya's Running Lean (Maurya, 2012) is filling Lean Startup approach with process for iterating the plan before running out the resources. It tackles to the co-creative value definition, where ideas and vision shall be tested with the minimal waste of resources.

## 2.4. Conceptual framework for value co-creation

Payne et al. (2008) explored the value co-creative encountering in the context of SDL and developed a conceptual framework for understanding and managing value co-creation between customer and supplier. The literature review and our empirical research confirmed the need for a practical value co-creation framework consisting of three main components, I) Customer value-creating processes II) Supplier value-creating processes and III) Encounter processes — the processes and practices of interaction and exchange that take place within customer and supplier relationships and which need to be managed in order to develop successful co-creation opportunities.

Figure 1. Conceptual framework for value co-creation (Payne et al., 2008)

In the value co-creation framework (Payne et al., 2008) Customer Processes are divided into three Relationship Experience based entities; Emotion (feelings), Cognition (thinking), and Behaviour (doing). In addition, Supplier Processes are divided into Co-creation and Relationship Experience Design entities. Finally, there are the Encounter Processes inbetween the Customer Processes and Supplier Processes.

In our research we used the Payne et al framework for data gathering and analysis regarding the customer encounters of the case organization. However, during the research period we ended up adding elements from two other frameworks (Bitner et al., 2008: Cova et al., 2002) and propose an improved version in Discussion section of this paper.

## 2.5. Lean SDL Encountering Process

In our empirical research we will use the Payne et al. (2008) framework for data gathering and analysis regarding the customer encounters of the case organization. However, during the research period we ended up adding elements from two other frameworks (Bitner et al., 2008: Cova et al., 2002) and propose an improved version in this paper.

In our synthetised framework all three are further divided into three subdomains (figure 2), Onstage, Backstage and Support – relations, based on the Service Blueprint

concept (Bitner et al., 2008). Solutions Sales – framework (Cova et al., 2002) is defining five stages in processing the customer network value proposition, Identification of actors, targeting actors, Identifying stakes for each actor, setting up an approach for the targeted actors, and a value creation approach, and our five years experience in co-creative value creation on the field. These three levels of Customer Relationship Experience based encountering processes are identified as in figure 2.

| CUSTOMER  | Emotion                        | Cognition                  | Behaviour                 |
|---|--------------------------------|----------------------------|---------------------------|
| <b>Onstage<br/>(co-creation,<br/>creating pull)</b> | Introduction<br>Creating trust | Service<br>Innovation      | Engagement                |
| <b>Backstage<br/>(resource<br/>integration)</b>     | Customer<br>Selection          | Service<br>Execution       | Identifying key<br>actors |
| <b>Support<br/>(service<br/>exchange)</b>           | Identification of<br>Value     | Cross-<br>Functionality    | Value Stream              |
| <b>SUPPLIER</b>                                     | <b>Learn<br/>(Ideas)</b>       | <b>Build<br/>(Service)</b> | <b>Measure<br/>(Data)</b> |

Figure 2. Lean SDL Encountering framework.

The Supplier processes are seen as a value steam, where core competences are the value particles, and suppliers' efficiency can be measured with value density (level of competency), and value stream density (optimizing utilization rate of value creating actions) based on Lean thinking (Hines et al., 2004: Liker, 2004: Womac; Jones, 2003). Therefore Supplier Processes, Co-creation and relationship experience – related entities, are shared following Lean Startup model to Learn, Build, and Measure (Ries, 2011).

Customer liaison process in practice can be seen as a sequence of activities that shall be logically connected (Customer activity cycle: Sawhney, 1999: Sawhney et al., 2004: Vandermerwe, 1993: 2000). We are targeting to short iterations in activity cycle, and to rapid prototyping cycles in service innovation for identifying the real value creation opportunities and best practices with the mini-mum waste of resources.

### 3. Methodology

#### 3.1. Research Approach & Case Description

This paper describes a longitudinal interpretive case study (Klein: Myers, 1999; Walsham, 1995: 2006) to provide in-depth knowledge about systematization of co-creational service-dominant business logic. The research was conducted in 2011 –

2015 as Action Design Research (Sein et al., 2011) in a publicly listed company providing professional services.

The case organization in this research is professional services provider Siili Solutions and its two customer encounters. Siili was founded in 2005 and has lately grown very rapidly and profitably: the average annual revenue growth has been 30% with about 10% EBITDA in 2009-2014. The initial public offering stock price was 7,00 euros (15.10.2012) and the all-time high stock price amounted to 20,25 (10.4.2015) euros, which equals to 189% increase. The cases are described in more detail in the Case Studies section of this paper. The cases are introduced anonymously without any detailed customer specific information for maintaining confidential relationship between the customer and the supplier.

The first and second authors of this research are 'involved researchers' and third author is 'outside researcher' (Walsham, 1995). The involved researchers are members of the management team of the case organization (since 2010 and 2013 respectively) and actively take part in the research & development (R&D) activities.

The primary objective of this case study was the design and implementation of new business logic and encountering process for the case organization. Since the beginning of this internal R&D initiative it was linked with academic research to improve credibility of the internal development, to guide development activities with systematic frameworks and to provide novel contributions for external practitioners and researchers.

## 3.2. Action Design Research & Critical Evaluation

### 3.2.1. ADR method

Action Design Research (ADR) is a research method for generating prescriptive design knowledge through building and evaluating an ensemble of IT artifacts in an organizational setting (Sein et al., 2011). The ADR method is described below and illustrated in Figure 3.

ADR consists four stages including several iterations (of stages 1-3) in order to provide participating researchers and practitioners with many opportunities for interaction:

- **Stage 1 Problem Formulation:** identification of a practice-inspired research opportunity based on existing scientific theories
- **Stage 2 Building, Intervention and Evaluation (BIE):** researchers design iterations of the artifact, which are consecutively improved with real-life organizational use. In BIE the initial problem and the design artifact are continuously evaluated in order to provide feedback for next iterations.
- **Stage 3 Reflection and Learning:** scientific reflection of the research problem, chosen theories, and the designed artifact. The intention is to enable application of the learning from building a particular practical instance to a wider

class of problems. This should result in new knowledge for other practitioners and researchers.

- **Stage 4 Formalization of Learning:** researchers formally describe the realized accomplishments and create general solution concepts or design rules.

Figure 3. ADR method: Stages and Principles (Sein et al., 2011)

### 3.2.2. Evaluation of Research

In order to improve the validity of research, it should be guided and evaluated by explicit quality criteria (Sarker et al 2013). In this section we critically evaluate our interpretive case study research according to the seven principles published by (Sein et al., 2011).

#### PROBLEM FORMULATION

1: Practice-Inspired Research. Our research team started from a real-life problem in the case organization, but did not settle for a simple consultant solution. Instead we created generalized knowledge that can be applied to a class of problems regarding encountering process in professional service organizations.

2: Theory-Ingrained Artifact. We used existing scientific theories in many ways during the research: I) we conducted a literature review to help the initial problem formulation and the design iterations of the artifact, II) we used several theories to analyze the customer encounters of the case organization, III) we enriched existing scientific knowledge with our research discussion and generalizations.

#### BUILDING, INTERVENTION, EVALUATION:

3: Reciprocal Shaping. We developed simultaneously Siili's organization and processes as well as the IT solutions of the case organization's customers.

4: Mutually Influential Roles. The involved researchers and the case organization em-

ployees brought practical knowledge and practices, while the outside researcher together with involved researchers brought their knowledge of scientific theories. As a result, both roles learned from each other.

5: Authentic and Concurrent Evaluation. We evaluated the research continuously during the research so that scientific knowledge was embedded in the process of building the artifact and not a separate stage following the building.

#### REFLECTION & LEARNING:

6: Guided Emergence. The resulting artifact of our research reflects the learning and continuous shaping during 2011-2015 in a real-life organizational setting and evaluation by research participants and external users.

#### FORMALIZATION OF LEARNING:

7: Generalized Outcomes. In this paper we represent a generalized solution addressing a class of problems moving conceptually from an organization-specific instance onto a more abstract level. In other words, our solution includes generalization of the problem and solution instances but leave derivation of design principles to further research.

### 3.3. Data Collection and Analysis

This research started in Finland in 2011 when a professional service provider company was looking for a unique competitive advantage and the first author was inspired by theories of Service-Dominant logic and Lean Thinking. The goal was to create an innovative service offering with supporting organizational structure and management and there have been several iterations by the publication of this paper in 2015.

The involved researchers are members of the management team in the case organization and, therefore, able to access all the internal material in the organization. The interaction and interviews in the case organization were not recorded, because it could have endangered the real-life setting and resulted in less truthful data collection (Walsham, 2006). However, the involved researchers wrote constantly research memos and collected secondary research material (e.g. management documents, reports, instructions, emails) while taking part in the development activities of the case organization.

We continued the interpretation of the data throughout the project, but decided to “step back and examine the interpretations of fellow participants” (Walsham, 2006) in June 2015 and to publish the findings in a peer-reviewed scientific conference for feedback. We aimed at analyzing and describing interpretations about encountering process rather than finding causal relationships (Gregor, 2006). Therefore, we mapped the empirical findings to the concepts of theoretical frameworks by (Payne et al., 2008; Vargo; Lusch, 2008a; Vargo; Lusch, 2004).

During the research process, the involved researchers conducted several exploratory workshops to analyze a vast variety of data and to construct a comprehensive view of current situation of the service offering between 2011 and 2015. The analyses

were later on validated in confirmatory workshops with the outside researcher. Results of the interviews and workshops are summarized in the following interpretive descriptions regarding previous development activities and the current situation.

The case company developed its offering from resource and project sales towards co-creative solution model and moved forward in the value chain from 2011 to 2015. Required organizational changes were implemented and the new enterprise system to support cross-functional skill-based competence management was developed. Value creation was a key driver in the iterative business development process, which we are proving through analysing two customer encounters of the case organization.

Based on Customer activity cycle we can identify Pre-phase (Learn), which can be seen as an Introduction, During-phase (Build) as creation of demand (Pull), and Post-phase (Measure) is covering the Leverage and Maintenance – phases. For making the different customer cases comparable we are using the previously introduced domains.

In our case the Physical evidence can be seen in Web, Reputation and Demonstrations, and actions can be shared to three different organizational dimensions; Business, Technology and Excellence, and all these three can again to be shared to operational, tactical and strategic levels.

Value co-creation requires a change in the dominant logic for marketing from 'making, selling and servicing' to 'listening, customizing and co-creating'. It is also cross-functional: It assumes and requires alignment between those organizational functions which make the customer promise and those which deliver the customer promise. In practice the required approach is relative to Lean Thinking, which is also optimizing value stream based on end user needs (pull).

We are studying and reflecting cases where the service provider is co-creating value in the professional service business environment, and are presenting the framework for systematic approach for encountering in such a relationship.

(Payne et al., 2008) explored the nature of value co-creation in the context of S-D logic, and developed a conceptual framework. They confirmed the need for a practical process-based value co-creation framework consisting of three main components; Customer value-creating process, Supplier value-creating process, and Encounter process. This framework is used as a foundation for our description.

We have combined the Lean Thinking based encountering process called Lean Start-up, which in brief is a process which is answering question; How can we learn more quickly what works, and discard what doesn't. Main principles in Lean thinking related encountering are; Focus on your customer, vision his need, describe the iterative approach how to get there, remove inefficiencies and waste, seek continuous improvement, empower the people operating in process and do all this in systematic way.

## **4. Case Studies**

In our research we used the Payne et al., (2008) framework for data gathering and analysis regarding the customer encounters of the case organization. However, during the research period we ended up adding elements from two other frameworks

(Bitner et al., 2008; Cova et al., 2002) and propose an improved version in Discussion section of this paper. We use the improved framework to analyse the following cases.

## 4.1. Case Organizations

**Siili Solutions Plc** (the case organization in this research) is a publicly traded management consulting and technology integrator company employing several hundreds experts in Europe. The company was founded in 2005 and has lately grown very rapidly and profitably. Siili is offering Digital Service creation and demanding information mgmt system integrations to various business fields like public sector, finance, media and industry. Siili assists its customers to define, develop and implement the most value creative digital service and software solution to their information systems, technology agnostically.

**Finance corporation (Case 1)** is one of the leadings in the Finnish financial sector, employing several thousands employees around of the country. It was founded more than 100 years ago, and has been able to renew itself after significant changes in Finnish macro economical situation, and after numerous mergers. This corporation is well aware of the ongoing Digital Revolution in its business sector, and has done continuous development for safeguarding its ongoing business and gaining its portion from the new digitized financial services.

**Insurance company (Case 2)** is one of Finland's most respected wealth management and insurance services provider, having hundreds of thousands private customers and tens of thousands corporate customers.

## 4.2. Case 1

Siili has been approaching this Corporation since 2011. Two first attempts were not successful, but after learning the value creative approach, Siili got the customer engaged to the value co-creation 2014. All three attempts are described below, only the last, successful one is described also at the cognition and behaviour levels.

### 4.2.1. Round 1 (2012)

**Emotion Onstage;** Siili was approaching this corporation already in 2011, when they were reorganizing their internal Enterprise software system (ESWS) development for increasing the operational efficiency. Siili was introduced to the highest technical level in the organization, using reputable references and SW architectural expertise in convincing its capability to challenge the existing suppliers. **Emotion Backstage;** Siili was seeing a co-creative value creation opportunity with Agile SW Development, and offered its services as the complementary for the existing suppliers. **Emotion Support ;** Customer was giving Siili an opportunity to challenge the existing supplier in standalone Digital Service creation. Even if Siili made a winning offer, it never entered to the Execution as the top management didn't see Siili as a strategic supplier.

#### 4.2.2. Round 2 (2013)

**Emotion Onstage;** Siili was continuing the collaboration, and gained new interest in the top technology management. **Emotion Backstage;** Siili found a sound opportunity in the interface between the new Digital Services and Legacy ESS. **Emotion Support;** Siili offered an innovative interfacing solution which was finalised in the co-creational service design iteration together with the customer, but because the involved customer liaison was too narrow, it never led to the execution.

#### 4.2.3. Round 3 (2014)

**Emotion Onstage;** Siili was getting stronger with an organic growth and a few acquisition, continuing the collaboration, and gained new interest from the top management. At this time there was wide presence from business, technology and marketing organizations listening the introduction. **Emotion Backstage;** Siili was listening customer need, understood customer organizational dependencies, and tailored its liaison meeting exactly customer expectations for the co-creative relationship. **Emotion Support;** Siili offered a lean startup – based approach for rapid digital service creation. The team was having interfaces to Business and Technology organizations.

**Cognition Onstage;** Siili was beginning with the rapid prototyping of possible new services. **Cognition Backstage;** When concept was proven, Siili offered not only the creation of service, but also integration to existing ESWS. **Cognition Support;** With the cross functional team from service creation to design, development, integration and information management Siili was proving its capability to support customer's value creation to all organizational entities (business, technology & excellence).

**Behaviour Onstage;** Relationship was beginning from the small amount of trust and small proof of concepting, but is growing steadily and now this customer is one of the 10 biggest of Siili's. **Behaviour Backstage;** Siili is now well known within the top mgmt, and Siili's liaison interface is growing steadily. Access to the mgmt team is giving Siili an opportunity to plan team member selections (required competencies) based on customer's strategy based expectations. **Behaviour Support;** Siili is learning continuously more about customer's business environment, expectations, technologies and way to work. At the same time customer is learning how to make iterative service creation effectively. Especially understanding architecture in many levels (business, information, enterprise) is enabling Siili to continuously increase its value in customer's value creation process.

#### 4.3. Case 2

Siili has been approaching this Company since 2011. The relationship has been growing from resource provider to the co-creative trusted digital service creation adviser. First two rounds are presented only on the emotional and cognitional level, but the third one is truly co-creative and therefore presented also on the behavioural level.

#### 4.3.1. Round 1 (2012)

**Emotion Onstage;** Siili was approaching this Company already in 2011. First introduction was done to the top mgmt level, where Siili was directed to Technology organization. **Emotion Backstage;** Siili was seeing a co-creative value creation opportunity with Agile SW Development, and offered its services as the complementary for the existing suppliers. **Emotion Support;** Customer was giving Siili an opportunity to challenge the existing supplier in technology agnostic sw service development.

**Cognition Onstage;** Siili was seen as a resource provider, not given a real opportunity for service innovations. **Cognition Backstage;** Siili was providing strong sw development competency to the customer's team. **Cognition Support;** Siili offered support technology agnostically and transparently.

**Behaviour Onstage;** Invoicing was purely time and material based, and volatility was following customer's needs and budgets. **Behaviour Backstage;** Siili was exploring opportunities to gain trust in the top management, and learned more customer's business and value creation. **Behaviour Support;** Siili was providing some add-on services like Agile coaching and problem solving, which was leading us to the next iteration.

#### 4.3.2. Round 2 (2013)

**Emotion Onstage;** Siili was continuing the collaboration, and gained new interest in the top technology management. **Emotion Backstage;** Siili found a sound opportunity in providing remote working team flexibly and cost effectively for supporting customer's urgent needs in the middle of budgeting session. **Emotion Support;** Siili was growing and acquiring more competence especially in digital service creation.

**Cognition Onstage;** Siili's business model was seen trustworthy and transparent. **Cognition Backstage;** Siili was maintaining the high level of competency with the remote team, and flexibility with the local on-site support. **Cognition Support;** Siili was still seen tightly as a sw system developer.

**Behaviour Onstage;** Business relationship was seen continuous, even if invoicing was following customer's needs and budgets there was some invoicing baseline always continuing. **Behaviour Backstage;** Siili was exploring opportunities to gain trust in the top business and marketing management, and learned more customer's business and value creation. **Behaviour Support;** Siili was offering some small digital service innovations, which was leading us to the next iteration.

#### 4.3.3. Round 3 (2014)

**Emotion Onstage;** Siili was getting stronger with an organic growth and a few acquisition, continuing the collaboration, and gained new interest from the top management. At this time there was presence from business, technology and marketing organizations. **Emotion Backstage;** Siili was listening customer need, understood customer organizational dependencies, and tailored its liaison to meet exactly customer expectations for the co-creative relationship. **Emotion Support;** Siili offered a lean startup – based approach for rapid digital service creation. The team was having interfaces to Business and Technology organizations.

**Cognition Onstage;** Siili was beginning with the rapid prototyping of possible new services. **Cognition Backstage;** Siili offered not only the creation of service, but also integration to existing ESWS. **Cognition Support;** With the cross functional team from service creation to design, development, integration and information management Siili was proving its capability to support customer's value creation to all organizational entities (business, technology & excellence).

**Behaviour Onstage;** Relationship was beginning from the small amount of trust and small proof of concepting, but is growing steadily and now this customer is one of the 10 biggest of Siili's. **Behaviour Backstage;** Siili is now well known within the top mgmt. Access to the mgmt team is giving Siili an opportunity to plan team member selections (required competencies) based on customer's strategy based expectations. **Behaviour Support;** Siili is learning continuously more about customer's business environment, expectations, technologies and way to work. At the same time customer is learning how to make iterative service creation effectively. Especially understanding architecture in many levels (business, information, enterprise) is enabling Siili to continuously increase its value in customer's value creation process.

## 5. Discussion – A Cross Organizational Approach for value co-creation

In service co-creation the Supplier processes are seen as a value stream, where core competences are the value particles, and suppliers' efficiency can be measured with value density (level of competency), and value stream density (optimizing utilization rate of value creating actions) based on Lean thinking. Ries (2011). created so called Lean Startup – framework for Lean encountering, which we have explored, proved working in our business environment, and integrated as a part of our encountering framework.

Business, Technology and Excellence (Emotional, Efficiency, Operational or Development) organizations are getting together in service related decision making, and therefore it is important to understand how strong the liaison is, and how the relationship can be leveraged and strengthened (figure 4). We would like to see this encountering to be tested in strategic, tactical and operational service offering, and in different business verticals.

In this process we have realized that cross organizational approach for value co-creation requires cultural backbone for common entrepreneurial customer service, and lean organization where people are respected and authorized for value creation. Personnel represent core competences, which in a service society are the base of exchange. Good employee experience is the foundation for good customer experience, which enables profitable growth. Employee commitment is the foundation for growth, and employee development is leading to the development of the company. The company's development creates the basis for a sustainable business, which creates trust among employees and customers.

Figure 4. Cross organizational value co-creation.

## 6. Conclusion

We conducted Action Design Research in a professional service environment in 2011-2015. The findings developed our understanding of this topic from the productization of services through servitization to Service dominant logic, its encountering, and finally to the Lean thinking and delivery process.

This research started in Finland in 2011 when a professional service provider company was looking for a unique competitive advantage and the first author was inspired by theories of Service-Dominant logic and Lean Thinking. The goal was to create an innovative service offering with supporting organizational structure and management and there have been several iterations by the publication of this paper in 2015. Original approach was based on productized service solutions and value propositions in 2011. However, the market environment, (consisting of the 300 biggest corporations in Finland) evolved towards product and technology agnostic software system integration. On this path during five years we have studied theory and practice (Learn), built an offering with organic and inorganic expertise development (Build), and measured constantly results for navigating towards right decisions with minimum amount of wasted resources (Measure). We found Service-dominant logic through Servitization theory, and have used it as a framework for our service innovation, creation and delivery processes.

Digitalization is feeding globalization, dismantling the industrialization driven business, management, and marketing logics. Industrial revolution was done for creating efficiency in scale, whereas Digital revolution is creating creativity in scale. Individual service creation is returning respect to craftsmanship, service innovation, and co-creative value creation. Service is the focus of economic exchange. Rapid and agile business development is required for responding to the change, no firm can create sustainable competitive advantage. Value creation is the baseline in service economy, and value is always defined by beneficiary. When offering is based on value

creation, the value stream is a measure for efficiency. This is how Lean thinking and Service dominant logic are clearly connected.

We believe that Service-dominant logic is a great foundational framework for understanding value creation in digital age, where service is the fundamental basis of exchange, and products only vehicles for service delivery. In digital economy supplier has to be able to provide real value to its customer, for understanding the value definition supplier has to be able to transparently collaborate and co-create the value offering. After that Supplier has to be able to provide fluent value stream, avoiding activities which don't create value. Service- and business development has to be iterative for being able to respond to the changes in business environment.

In this article we introduced Lean SDL Encountering Process as well as Cross Organizational value co-creation approach. We offer a broadened view to Service dominant logic, some of the latest Service marketing studies, and Lean thinking. Moreover, we connect these together for being able to explore value definition, value stream, and especially Encounter between the supplier and customer in service innovation, creation and delivery.

In summary we do believe, that the results of this study could help numerous organizations understanding the need for transparency and pull steered value co-creation in their business development process. We proved usefulness of these frameworks at least for the case organization with our empirical results. Our aim is to get deeper in details in the upcoming studies.

Kasanen et al. (1993) introduced the concept of market-based validation for constructive research. The research described in this paper fulfills the criteria of "weak market test" meaning that management of a single company has applied this construction and appreciates the usefulness. We encourage other researchers and practitioners to apply the same frameworks and constructions in other companies in order gain more scientific evidence. This would fulfill the requirements of semi-strong market test if the constructs would become widely adopted. In addition, the case company has profitably increased sales revenue and employee headcount as well as the stock market value during the research period, which also indicates that the strategic R&D initiative has been successful.

# USER INVOLVEMENT AND SUPPORTING TOOLS IN BUSINESS-TO-BUSINESS SERVICE INNOVATIONS: INSIGHTS FROM FACILITY MANAGEMENT SERVICES

## Abstract

**Purpose** – This article investigates and conceptualizes user involvement in business-to-business service innovations as well as the tools that are used to support interactions in such a service innovation process.

**Design/methodology/approach** – The paper uses a qualitative research approach to answer the research question. By following Miles and Huberman (1984)'s this study started with a literature review of studies investigating service innovation, service innovations models, user roles and tools in service innovation in general, to conduct an empirical investigation in facility management (FM) services.

**Findings** – The findings indicate that, in business-to-business services such as FM services, the involvement of users is variable depending on the offered services as well as on the specific role that users play with regards to the service being innovated since users might have different needs and expectations with respect to such service innovation. In addition the study reveals that face-to-face tools are preferred to ICT-based tools in business-to-business FM service innovations.

**Research limitations/implications** – As in all qualitative research, the main limitation of our study is the generalizability of the findings to other business-to-business service sectors. More research conducted both in FM services and other service sectors would help to shed light on the generalizability of these findings.

**Originality/value** – The study contributes with new and detailed insights into the complexity of user involvement and supporting tools in business-to-business service innovations.

**Paper type:** Research Paper

**Keywords:** business-to-business services, service innovation, customer involvement, user roles, tools for customer involvement, facility management services, Information and Communication Technology.

## Introduction

The service sector is an important economic sector of our society, employing about 70 % of the work force in most developed economies, and often characterized by complex service systems. A type of service that has developed over the last twenty years is Facility Management (FM) services. FM services are here defined as a diverse set of support services, which aim at enabling organizations to pursue the objectives and goals of their core business (Alexander 1992). Examples include building maintenance, catering, but also Information Technology (IT) services and cleaning. FM services, due to their supportive nature and to the fact that they are often outsourced to external providers, can be described as complex business-to-business service systems. They are in fact characterized by a complex value network, which includes top management, internal FM unit and employees of the client organization, along with the outsourced providers.

Facility management services require radical and incremental innovation not only to succeed and compete in the hectic contemporary markets, but also to affirm their increasingly importance within organizations (Goyal & Pitt 2007; Lindkvist & Elmualim 2010; Mudrak et al. 2005). However, the complex value network of FM services makes it difficult for internal and external providers to manage innovation processes, as heterogeneous needs and expectations require coordination among different innovation actors when planning and implementing FM service innovations. At the same time, it also implies that diverse internal and external actors get involved to various degrees throughout the FM service innovation process. This makes it particularly interesting to study innovation processes and, more specifically, user involvement in the innovation process of business-to-business FM services. Martin, Horne, and Schultz (1999) highlight that a major impediment to developing a business-to-business service innovation is understanding and adjusting to the change in role played by the client in a service dominant offering, as opposed to the role for one of product dominance. By drawing on Norman (1984) Martin et al. (1999) also emphasize that “the complexity is highlighted by the client playing two roles: that of the customer and that of a co-producer of the offering. In other words, clients not only receive and consume the service offering, but also serve as participants in its innovation, production, and delivery” (Martin et al. 1999:1). Such complexity of business-to-business services is further accentuated in FM services given the multiplicity of actors involved in the FM service system.

Kindstrom and Kowalkowski (2014) in point out that in business and industrial marketing, innovation research continues to focus mostly on products (e.g., Hsu 2011; Lettl & Gemünden 2005; Munksgaard & Freytag 2011), although some articles dealing with service innovation are getting published (e.g., Alam & Perry 2002; Nicolajsen & Scupola 2011). Nevertheless, Kindstrom and Kowalkowski (2014) suggest that B2B firms must embrace a broader perspective on innovation, moving beyond traditional product-centric views (e.g., Garcia & Calantone 2002). Given this background, the purpose of this article is to contribute to the literature on service innovation in a business to business context by: (1) conceptualizing and investigating user involvement in service innovation processes of business-to-business FM services and (2) mapping a number of tools, which support interactions in such a service innovation process. Therefore, the research question addressed in this paper is:

*How can users be involved in the different stages of the innovation processes of business-to-business services such as FM services and what kind of tools can be used to support such an innovation process?*

To answer the research question, the paper draws on literature on new service development and service innovation; literature on customer roles in new product and service development; and literature on tools for customer involvement to conduct an empirical investigation of user involvement in the business-to-business FM service field. Data collected in several FM organizations were used to answer the research question of the study.

The paper is structured as follows. The introduction presents the background, and the research question of the study. The second section introduces the empirical setting, while the third section outlines the theoretical background. The fourth section presents the research method. This is followed by the analysis of findings. Finally, the last sections provide a discussion of results and the concluding remarks.

## Empirical setting: FM services and FM innovation

In the last three decades, FM has established itself as a key service sector, with a diverse and highly competitive market of FM contractors, in-house teams, FM providers, FM consultants, and professional FM institutions (Cardellino & Finch 2006) that form complex FM supply chains (Nutt 2000). Coenen, Alexander, and Kok (2013) states that the provision of one or more FM services is usually outsourced to one or more external FM providers. The outsourced FM providers collaborate with the internal FM unit of the client organization to ensure the proper functioning of the organization as a whole, by providing FM services to the employees, i.e. the end-users. Table 1 below provides a description of the different actors and their role in the FM services outsourcing set up.

**Table 1: Stakeholders and stakeholder roles in the FM value chain.**

| FM Service Stakeholder                          | Role  | Explanation   |
|---|---|---|
| Organization, represented by the top management | Client  | Orders to the internal FM unit the services to support carrying out the core business.  |
| Internal FM unit                                | Double role of Customer and Internal Provider | Buys the services from the outsourced provider (in the role of customer) and/or provides services in-house to make sure that the organization can carry out the core business (in the role of internal provider). |
| Employees                                       | End-users                                     | Actually receive and consume the services while carrying out the core business of the "Organization".   |
| Outsourced provider(s)                          | Provider(s)                                   | Provide the services that allow the organization to function, by negotiating with the internal FM unit to serve the employees in the role of end-users  |

Borrowing the terminology from the marketing literature, in FM services the organization as a whole plays the role of the client, which, to properly function and carry out its core business, orders the service to the internal FM unit. The internal FM unit plays (1) the role of the internal FM provider from the perspectives of the client organization and end-users; (2) the role of the customer from the perspective of the outsourced FM provider, with whom it negotiates the terms of the FM service provision. The end users are the employees of the client organizations, i.e. the individuals that are provided the actual FM services.

FM services are combined in specific and ad hoc bundles of tasks, activities and services depending on the market and context in which the client organization operates. Due to their supportive nature, FM services have mostly been characterized as a secondary activity within organizations, and have been paid attention only in connection with the core businesses of the entities they support. However, FM organizations have often demonstrated the dedication and drive to implement new service development and exceed customer expectations, while adding value to the core business of the client organization (Pitt & Tucker 2008; Mudrak et al. 2005). Previous research has shown that FM organizations continuously manage innovation as a process and tend to have several projects under development at the same time (Mudrak et al. 2005; Cardellino & Finch 2006). However, they lack the ability to establish progressive innovation routines that would enable a successful innovation management. It can be concluded therefore that in addition to the complexity evidenced by Martin et al. (1999) in business to business service innovation in general, FM service innovation is further characterized by the need for cooperation between the different actors of the FM service system and the different roles played by top management and employees, along with the double role of the internal FM unit in the service innovation process (Coenen et al. 2013).

## Theoretical background

### *Understanding services and service innovation*

According to Bitner, Ostrom, and Morgan (2008) one of the most distinctive characteristics of services is their process nature. Unlike tangible goods, services are dynamic and unfold over a period of time through a sequence or constellation of events and steps. Moreover, services often require face-to-face interaction between the provider and the consumer as production and consumption often take place simultaneously. Although such simultaneity is not always true, services are perishable and cannot be stored, and their consumption usually starts right after production (Sundbo 1997; den Hertog 2010). The service innovation process has been defined as the process through which an idea for a new service, or for the renewal of an existing service, is developed and carried into practice to offer added value to the customer and provide benefit to the provider. To be classified as an innovation, the new service or the service renewal must not only impact the developer but involve elements that allow reproduction in different contexts (Sundbo 1997). There are several terms used in the literature to address the way new services are developed. New service development and systematic service innovation deal with the overall process of developing new services and are concerned with the complete set of steps from idea generation to commercialization of the service, even though some literature on service innovation only focuses on the idea generation phase.

In this article, the terms service innovation and new service development will be used interchangeably. In addition, for the purposes of this study, service innovations are defined according to the three Schumpeterian criteria, adapted to FM service innovation: (1) FM innovation is an idea, which is developed and carried into practice; (2) FM innovation brings benefits to its developer; and (3) FM innovation is reproducible, i.e. applied more than once (Toivonen & Tuominen 2009; Sundbo 1997). Not only new-to-the-world FM services are included in this study, but also new-to-the-firm (new-to-the-client) FM services, as (1) FM services are commonly adapted according to the characteristics of the client and thus require innovation management at the client side, but at the same time – in big organizations such as the ones involved in this investigation – new and improved services are reproduced across different FM services and areas of the organization, and therefore classifiable as innovation; (2) even when only new-to-the-firm, the new FM services originate organizational change processes in the customer FM unit and client (Nardelli 2013).

### *Customer involvement in service innovation and tools for involvement*

Whether service innovation processes are planned, or happen ad hoc (Gallouj & Weinstein 1997) the involvement of users is increasingly being recognized as potentially supporting of a successful innovation outcome. Service innovation literature has highlighted how the proactive and systematic involvement of users in new service development processes, if managed correctly, is able to support such development and implementation of ideas (Alam & Perry 2002; Alam 2002; Matthing et al. 2004; Magnusson et al. 2003; Nicolajsen & Scupola 2012; Scupola & Nicolajsen 2010). Customer involvement, in fact, is expected to provide a more complete and accurate list of customer needs, behavior, changing requirements, and deep-seated dissatisfactions with current alternatives, and therefore contribute and improve service innovation. In this study, customer involvement in FM service

development is defined as those processes and interactions where a development team collaborates with current (or potential) customers at strategic, tactic or operational level to uncover information such as latent needs, develop customer knowledge, and develop new services accordingly.

The literature on customer involvement has focused on the evolution and transformation of the customer from a passive subject to being an active player in the innovation process and the different roles that the customer can take in this evolution. Such roles have been characterized among others as collaborators, co-developers, competitors (Prahalad & Ramaswamy 2000). Table 2 below provides an overview of customer roles in service innovation.

**Table 2: An overview of customer roles in service innovation.**

| Von Hippel (1986)                         | <i>Lead users</i> .   |

Organizations use diverse tools to systematically involve users in service innovation processes, which have been discussed in existing literature (e.g., Prandelli, Verona, & Raccagni 2006). Face-to-face interactions in the form of, for example, workshops, focus groups, user visits and meetings have been found very important to successfully involve users in the service innovation process (e.g., Alam 2002; Magnusson et al. 2003; Matthing et al. 2004). However, ICT-based tools are increasingly gaining importance thanks to their ability to capture and store data and to their independence from geographical location. Prandelli et al. (2006) have, for instance, identified 28 different web-based tools that can be used in the different stages of product innovation. These web-based tools range from surveys and ‘complaint areas’ used in the idea generation phase to ‘virtual product tests’ in the product test phase. In addition, Prandelli et al. (2006) found that the web-based tools are mainly used by larger corporations in the first and last stages of the innovation process, and are mainly considered as substitutes for offline practices.

### *The Conceptual Framework*

To investigate how customers are involved in the service innovation process of business-to-business FM services, this study draws on the service innovation model developed by Alam and Perry (2002); the customer roles in the innovation process developed by Nambisan (2002) and a taxonomy of tools for user involvement in service

innovation developed by Scupola and Nicolajsen (2013). Alam and Perry (2002) presented a 10-stage model of the service innovation process, including: (1) Strategic planning; (2) Idea generation; (3) Idea screening; (4) Business analysis; (5) Formation of cross-functional team; (6) Service and process design; (7) Personnel training; (8) Service testing and pilot run; (9) Test marketing; (10) Commercialization (see the first column in table 3), and discussed user involvement in each of the stages. Alam and Perry (2002)'s contribution takes into account the core element of user involvement in service innovation and highlights the objectives, purposes, stages, intensity and modes of user involvement in new service development. Alam and Perry (2002)'s study is therefore useful to build the framework to investigate the heterogeneous user roles in the FM service innovation.

Nambisan (2002), on the other hand, has conceptualized three roles that can be played by customers in new product development: (1) customer as a resource; (2) customer as co-creator; (3) customer as user. Such roles have been previously applied to the context of business-to-business service innovation (Nicolajsen & Scupola 2011), and are here explained in relation to the NSD model by Alam and Perry (2002). Firstly, the contribution of customer as a resource is variable, and depends on the alignment of offered services with the customer base. One possible argument is that the more the provided services are aligned with the customer needs and expectations, the less the customers will actually contribute to the service innovation process, which will make the ideas generated by such role more incremental than radical. When playing the role as a resource, customers are usually passive: it is the provider that needs to find out about customers' opinions, needs and expectations through, for example, surveys or focus groups. Secondly, customers can be involved as co-creators, and thus participate in various activities, from design to development of the new service. Customer-firm interactions in this type of involvement tend to be more intense and frequent, and the support mechanisms for such interactions are expensive, time consuming and technology intensive. Finally, customers can play the role of users through service testing and service support. When involved as users, customers test the service and provide feedback based on their experience, which allows the service innovators to improve their offering when reproducing the service innovation.

Scupola and Nicolajsen (2013) have developed a taxonomy of tools to involve users in service innovations. They have distinguished such tools into direct vs. indirect and face-to-face vs. ICT-based. The direct tools (both face-to-face and ICT-based) such as workshops and online idea competitions require a direct and pro-active involvement from the users in the innovation process. The indirect tools such as ethnographic studies and virtual communities, on the other hand, require a more passive role, meaning that the users are mainly observed from outside actors to gain insights into their needs and expectations in relation to the service innovation process.

## Research method

To answer the research question, a qualitative research method has been chosen because qualitative data “are the source of well-grounded, rich description and explanations of processes [...] and help researchers go beyond initial pre-conceptions and frameworks” (Miles & Huberman 198:15). By following Miles and Huberman (1984)’s guidelines for conducting qualitative research, this study started with a literature review of studies investigating service innovation, service innovations models, user roles and tools in service innovation in general, which was followed by an empirical investigation in the FM field.

Data for the study were gathered from archival sources, interviews with companies as well as attendance in practitioner conferences and workshops on the topic of innovation in business-to-business FM services. In all, 19 explorative, semi-structured interviews with facility managers working in internal FM units and outsourced providers were carried out in 15 Danish companies (Table 4). Furthermore four in-depth interviews were carried out in two of the companies involved in the study, and aimed at gathering more details and examples of the innovation processes that were spotted during the initial explorative round of interviews. The themes of the interviews included company and respondent background, the management of FM service innovation and new service development in general, and, more specifically, the structure and characteristics of interaction among stakeholders, the features and impact of user involvement in service innovation, and the tools (face-to-face and ICT-based) that are used to support processes of FM service innovation.

**Table 4: Companies and interviewees involved in the study.**

| Company code | Role of company with respect to FM services | Core business      | # employees | Position of interviewees                      |
|--------------|---|--------------------|-------------|---|
| 1            | Client                                      | Financial services | 32500       | Head of Contract Management & IFM Development |
| 2            | Client                                      | Logistics          | n.a.        | Global Facility Management                    |
| 3            | Provider                                    | Cleaning           | 300         | CEO   |
| 4            | Client                                      | IT services        | 98000       | Facility Manager                              |
| 5            | Research group                              | Research group     | n.a.        | Expert  |
| 6            | Provider                                    | Hard FM services   | 8000        | Market Manager                                |
| 7            | Client                                      | IT services        | 430000      | Real Estate Site Operations Manager           |
| 8            | Consultant/provider                         | Consulting         | 6200        | Senior Project Manager                        |
| 9            | Client                                      | Industrial biotech | 5500        | FM Director                                   |
|              |   |                    |             | FM Manager                                    |
|              |   |                    |             | FM Project Director                           |
| 10           | Provider                                    | FM services        | 534500      | Head of Knowledge Sharing and Engagement      |
|              |   |                    |             | Commercial Director and CFO                   |
|              |   |                    |             | Director of Business Development              |

| 15 | Provider | FM services       | 7000   | Director of Business Development                              |

The interviewees were selected with a combination of convenience (at the beginning) and snowball (later on) sampling criteria (Eisenhardt 1989). All interviews were tape-recorded and transcribed, and notes were taken both during and after the interviews. To increase reliability, an interview protocol was used and a database was developed (Yin 2009). The respondents, all senior managers or directors, were somehow involved with FM innovation within their organizations.

To complement the interview data and ensure triangulation (Eisenhardt 1989; Yin 2009), archival data, i.e. reports, power point presentations, emails, newsletters, corporate brochures, were collected both from the interviewees and from secondary sources, such as corporate websites and during conferences, and were analyzed along with the interview data through subsequent steps of open and axial coding. The collected data were analyzed deductively by using the conceptual framework based on Alam and Perry (2002), Nambisan (2002) and Scupola and Nicolajsen (2013), with the support of the qualitative data analysis software Atlas.ti.

The setting in which we investigate user involvement is the business-to-business FM setting constituted by the relationship between the client organization and the outsourced FM service provider. Specifically, the data were analyzed from the perspective of the outsourced provider and the internal FM unit, which, within the FM service context, has the double role of being the customer (of the outsourced service provider) and the internal provider of the client organization. Therefore, when investigating user involvement in FM service innovation processes, it is interesting to look at how the internal FM unit (a) is involved as customer in relation to the outsourced FM provider; (b) involves top management and employees when developing new services together with the outsourced provider.

## Analysis and results

This study aims at understanding user involvement in business-to-business FM innovation processes in the setting of the client organization and the outsourced FM service provider. The perspective of the providers is taken to investigate which different user roles the stakeholders of the client organization, i.e. the users, play in the service innovation process. As explained above, within FM services two main stakeholders are to be considered as providers: the outsourced FM providers and the internal FM unit. Therefore, in FM services, innovation processes can be carried out by (a) the outsourced provider or (b) the internal FM unit individually, but also (c) in collaboration between the two parties. Given the focus of this investigation, the innovation processes considered in the data analysis are only those that were carried out in collaboration between the outsourced provider and the internal FM unit. The analysis shows that these service innovation processes can be initiated for different reasons, e.g., the contract obligations of the outsourced providers and/or the direct requests of internal FM units, and the

different actors take on different users roles (as defined by Nambisan 2002) with various degrees during the innovation process.

The data indicate, in fact, that the client organization (the one outsourcing the services to the external FM provider), the internal FM unit and the employees, i.e. the users, play the roles of resource and co-creator –although heterogeneously and to a various degree – throughout the new service development process, and up until the stage of service testing and pilot run. In the final two stages of the service innovation process (Test marketing and Commercialization), on the contrary, the study finds that the client organization, the internal FM unit and the employees are passively involved as users, if involved at all.

The next sub-sections will more in-depth present the results of the study, summarized in Table 5 according to (1) stages of the service innovation process (Alam & Perry 2002); (2) stakeholders of the FM service innovation; (3) user roles (Nambisan 2002); (4) supporting tools.

#### *User involvement and user roles in FM service innovation processes*

In FM services, the organization (client) as a whole, internal FM units and end-users of the client organization represent diverse sets of users each of which may play different roles in FM service innovation processes. Our analysis indicates that the internal FM unit cooperates with outsourced providers in most phases of the innovation process, and takes on the different roles of user, resource or co-creator. Top management and end-users of the client organization, on the other hand, mainly participate in innovation processes as user and resource, but on different levels. Top management is often involved by the internal FM unit to support and legitimate strategic decision-making, e.g., during the strategic planning and the business analysis stages of the FM service innovation process. End-users, conversely, are usually more or less directly involved in the more operational phases of the innovation process, such as idea generation and personnel training.

The stages of the new service development, during which strategic decision making takes place (e.g., strategic planning and business analysis) are those in which the most direct user involvement (as resource and co-creator) tends to be required, especially from the internal FM unit and the top management, who represents the interests of the client organization as a whole. Strategic decisions, such as the ones taken along the strategic planning or business analysis stages of the new service development, require the direct involvement of the top management, along with that of the FM unit, especially when significant investments and efforts are related to the service innovation. For example when the internal FM unit of company 1 (FM client) has decided to initiate an Integrated FM (IFM) project, they have done the strategic planning before going out and looking for suppliers, and have done so by constantly referring to and involving top management in decision making.

Moreover, regularly scheduled meetings are usually organized between the internal FM unit and top management to discuss the strategic development of the organization as a whole and the consequent adaptation needs of FM. The internal FM unit is then in charge of integrating all strategic considerations in the innovation processes developed by the outsourced providers. In case of sudden instance, e.g., a crisis, meetings between the internal FM unit and top management can also be called ad hoc, to discuss potential consequences and responsive counter-actions. In company 9 (FM client), for instance, top management has asked the internal FM unit to find a solution to reduce travelling costs for the organization (top management involved as co-creator). This resulted in a

shared strategic planning between the top management and the internal FM unit, who then took over the innovation process along with the outsourced provider.

The internal FM unit, gets directly and indirectly involved throughout most stages of the innovation process, not only as resource, but also, and even more, as co-creator. For instance, when the innovation process in question does not strategically and/or financially concern the organization as a whole, e.g., in the case of single service innovations, it is the internal FM unit that carries out the strategic planning of innovation processes. In such cases, the internal FM unit either influences the outsourced providers indirectly by setting the guidelines (involvement of the internal FM unit as resource) or works on the strategic planning and on its implementation together with the outsourced providers (involvement of the internal FM unit as co-creator).

On the contrary, operational stages such as idea generation and screening, among others, are left to the providers, unless the innovation process has a peculiar relevance for the client organization. In company 2, for example, an FM client stated how external providers should be in charge of the operational tasks of the innovation process, and especially idea generation, while the internal FM unit would rather be involved in the idea selection to make sure all needs and expectations of the end-users are taken into consideration. Innovation is, in fact, usually one of the activities, which the outsourced provider is expected by contract to carry out. The internal FM unit is thus not always keen on being directly involved in the operational phases. Therefore, the outsourced provider is usually in charge of the idea generation and the subsequent management of the innovation process.

The internal FM unit, however, may decide to be involved in operational activities for the new service development process either because of a specific interest in the upcoming project, or of a proactive entrepreneurial drive. The internal FM unit has two options for involvement in the innovation processes, initiated by the outsourced providers. It can either decide to be directly involved, by sharing ideas with the outsourced providers (co-creator); or send out idea competitions to their end-users to collect ideas, whose outcomes will then be shared with the outsourced providers. In the latter case, the involvement would be as intermediary, while the end-user would be involved as resource.

End-users, finally, tend not to be involved in the strategic decisions, as their heterogeneous needs are believed to (a) not correspond to those of the organization and (b) often be too operational. Their involvement would thus be too complex and resource consuming. Nevertheless, end-users seem to be involved, as resource and, most of all, as users, in various phases of new service development processes. Such involvement takes place through the intermediate action of the internal FM unit and/or the outsourced provider, which may decide to use ICT-based tools, e.g., email or Intranet, to distribute idea competitions and user surveys. In alternative, this may take place with face-to-face interviews, workshops and workgroups in the initial stages (idea generation and screening); and shared training and team building in the latter ones (formation of cross-functional teams and personnel training). For instance, company 14 (FM client) requires its providers to regularly distribute user surveys to ensure a specific level of user satisfaction, while company 10 (FM outsourced provider) carried out interviews with end-users to delineate their needs and expectations to generate ideas. The aim of such initiatives combines (a) collecting feedback on existing services to better match needs and expectations in the innovated ones; (b) asking for potential ideas for improvements and innovation; (c) build awareness on the activities of the FM unit. In addition, ideas and feedback

are continuously collected per email and/or customer relationship management tools. End-users use the ICT tools to submit their feedback and proactive ideas to the internal FM unit, which operates as filter, and pre-selects the ideas to submit to the outsourced provider for screening and, potentially, development.

**Table 5: Summary of findings.**

| Stages of the service innovation process | Stakeholders of FM service innovation                                  | User roles as defined by Nambisan (2002) | Supporting tools   |
|--|--|--|--|
| a) Strategic planning                    | Organization outsourcing FM services (FM Client)                       | Resource; Co-creator                     | Regular and ad hoc meetings; workshops                                       |
|  | Internal FM unit of Organization outsourcing FM services (FM Customer) | Resource; Co-creator                     | Workshops; trust-based relationships   |
|  | Employees of Organization outsourcing FM services (FM End-user)        | Resource                                 | User-surveys; interviews; workshops  |
| b) Idea generation                       | Organization (FM Client)   | Not involved                             | N.A.   |
|  | Internal FM unit (FM Customer)   | Resource; Co-creator                     | Workshops; ICT for information management and sharing                        |

|                      | Employees (FM End-user)        | User       | (observation by provider)                       |

#### *Tools for user involvement in the FM service innovation process*

Based on the findings, table 6 synthesizes the support tools that are and can be used to facilitate user involvement in new service development within business-to-business FM services. The tools are classified in relation to the roles of the users and their involvement within FM service innovation processes.

**Table 6: Classification of support tools in relation to user roles and involvement.**

|                                       | User   | Resource   | Co-creator  |
|---------------------------------------|--|--|---|
| <b>Organization as a whole/Client</b> | Ad hoc meetings                              | Transparency matrices and models<br>Workshops<br>Scenario analysis (with or without simulation IT)                       | Regular and ad hoc meetings<br>Workshops  |
| <b>Internal FM unit/Customer</b>      | Workshops                                    | Workshops<br>Shared training<br>Team buildings activities<br>IT for information management and sharing                   | Workshops<br>Face-to-face meetings<br>ICT for information management and sharing<br>Team building activities<br>Scenario analysis (with or without simulation IT) |
| <b>Employees/End-users</b>            | User-surveys<br>User workgroups<br>Workshops | User-surveys<br>Face-to-face interviews<br>Workshops<br>Idea competitions<br>Shared training<br>Team-building activities | Shared training   |

Among the support tools workshops appear to be the preferred tool for most user roles and involvements. The interviewees have depicted workshops as useful support tools in heterogeneous situations, as they can be adapted in the structure and functioning to specific contexts and needs. For example, workshops organized with outsourced providers and internal FM units are used to involve the latter as users (e.g., in test marketing), as co-creator (e.g., personnel training), and as resource (e.g., business analysis).

Top management needs to be involved through less “requiring” tools, such as regularly organized and ad hoc meetings, facilitated through scenario analysis and transparency models. This seems to be due to the need to

demonstrate the value of FM services, along with the non-strategic focus that top management tends to attribute to FM services.

ICT-based tools are mostly used to support information sharing and management, and, in some cases (e.g., scenario analysis and transparency matrices), to facilitate communication between different sets of users (e.g., between internal FM unit and top management of the client organization). On the other hand, the importance of partnership-like relationships with the outsourced providers, based on trust between individuals, is mirrored in the relevance of face-to-face meetings, especially to support involvement as co-creators, not only of the internal FM unit, but also of top management and end-users.

Finally, end-user involvement appears to be supported mainly through ICT-based user-surveys and interviews, which allow collection of end-user perspectives without direct involvement (requiring more intermediating effort by the internal FM unit). Nonetheless, end-users are sometimes involved as co-creators through idea competitions and workshops, which not only support the new service development, but also increase awareness of FM within the organization. Shared training and team building activities facilitate direct involvement as resource and co-creators and allow opening the innovation process while getting closer to the actual needs of the end-users.

## **Discussion and conclusion**

Given the peculiarity of FM services, it becomes important, when investigating FM service innovations, not only to look at the FM innovation process stages, as stated in the literature, but also to consider the different roles that different FM users might play when involved by the providers in such a FM innovation process. To investigate how FM service users can be involved with different roles through the FM new service development process, we have considered the user roles, i.e. resource, co-creator and user, presented by Nambisan (2002) in relation to the stages of the innovation process as described by Alam and Perry (2002). Furthermore, we have outlined the various tools, which FM organizations use to involve and engage the users in FM service innovation processes.

The results of the analysis indicate that, not only the involvement of users is variable depending on the offered services (Alam & Perry 2002), but also on the specific role that users play with regards to the service being innovated, when involved in FM service innovation processes. This is due to the peculiarity of FM services, where clients, customers and end-users do not represent a single typology of users, but rather have different needs and expectations with respect to the FM service innovation. These needs and expectations have to be matched and balanced for the service innovation to be successful, which is why the providers, who are in charge of FM service innovation, tend to involve different stakeholders in the same stage of the new service development process, but with different roles and variable degree of involvement. This implies that, for instance, customers, who buy the service, are involved as co-creator in the stages of new service development that require strategic decision making, to ensure a better match between the service innovation and the specific needs of the client, who orders the service, and the end-users, who finally receive the service. The client, represented in FM service systems by the top management of the organization ordering the services, is instead mostly involved as resource – to ensure a proper fit between the service innovation and the overall vision and mission of the organization. Finally, end-users are the least involved, called in as resource or user to ensure satisfaction, but without allocation of actual power in the new service development process. The data also indicate some trends in the use of face-to-face vs. ICT-based tools to

involve different types of users, and for different roles: the first are more common for user involvement as co-creators, while the latter support direct and indirect involvement as resource and user.

These results extend and contribute to the literature on service innovation and user roles by investigating user involvement in service innovation processes in complex services such as FM services, by highlighting which user involvement process might be followed, and which tools might be used to increase user satisfaction in the service innovation process. The study suggests that this might be achieved by involving different types of users in different stages of the service innovation process, with different roles and to a variable degree depending on what they can best contribute with, given their relation with the goal of the service innovation process. The focus on FM services depicts a setting, which was not addressed before in terms of user involvement in service innovation, but, and more interestingly, might be taken as an example for other business-to-business support services with complex value chain, such as IT services.

The theoretical implications of this study are linked to the importance of considering stakeholder roles when dealing with user involvement for business-to-business service innovation. This, in fact, might help to investigate user involvement in service innovation in more depth and details. For practitioners, on the other hand, this implies that, before involving users in service innovation, their role as clients, customers or end-users should be assessed to increase the potential of their contribution.

Nevertheless, this study also has limitations. Firstly, the focus on FM business-to-business service might limit the applicability of the results to other service contexts. Secondly, the data were collected among a relatively small amount of organizations in Denmark, which reduces the external validity of the study. Thirdly, theoretical models developed in business-to-consumer contexts were applied in a business-to-business FM context. To overcome the limitations, and increase the generalizability of these results, future research could for example replicate this study in other business-to-business services with multiple stakeholders. In addition, further studies could expand the focus to other aspects of service innovation, and look, for instance, at how the different stakeholders of complex service systems distribute and appropriate the value that is created through user involvement in new service development processes – and which tools can support such value appropriation.

# XXV. International RESER Conference: Employee critique as an impulse for bricolage in elderly care services

*Mervi Hasu, Sari Käpykangas*

Finnish Institute of Occupational Health

This paper analyzes critique expressed by front-line care workers on their work conditions as a potential impulse for change and innovation-oriented agency. By analyzing interview accounts and interactions of elderly care employees in municipal nursing homes it is possible to achieve new understanding of how employee critique can advance employee-driven innovation. In the paper we analyze connections between employee critique and daily routines of employees in the context of elderly care services. We see employee critique as a neglected topic of research as well as opportunity to develop elderly care services and care work.

## 1. Introduction

*"Employees has been involved in many changes at the work community. Sometimes the changes are accepted and occasionally refused. I can influence my team and its activities anyway." – Practical nurse Maria -*

The Nordic countries are very 'aged' societies, and they are set to witness further population ageing, with respective economic challenges, in the future. For instance in Finland, it is estimated that the number of employees in the elder care sector will need to increase by 30 000 by 2030, leading to additional expenditure amounting to 1.2 Milliard euro (Kiander 2009).

In spite of the increasing automation and digitalisation of contemporary work in the western world, care work, performed mostly by women, especially in public services, is continuously carried out in real-life, day-to-day encounters between the care worker and the person being cared for (Szebehely, 2005; Martela, 2012). As the economic downturn continues and service needs increase, mainly due to demographic ageing in Europe, the production of care – and care work – becomes a critical and debated matter.

Alarming research results are being reported concerning care workers' working conditions, plans to leave care occupations, management support, and professional development. Interestingly enough, little attention is paid on 'manual' care work, care workers and work communities from the point of view of innovations, especially bottom-up innovation (e.g. incremental innovation, bricolage). The dynamics of transformative, employee-initiated critique or resistive actions are not systematically addressed in public administration and service research. There is a need for studies which could inform critically reflexive, practice-based and employee-driven interventions in elderly care.

Care work is one of the most demanding fields in the labour market, both physically and mentally (e.g. Trydegård, 2012). Care work is mentally arduous while relatives support has declined especially in Finland. Due to this unfortunate trend, care worker may be the only social contact for ageing person. Care work is physically heavy, because technical nursing devices are not available or cannot be used in all client rooms.

According to the research results one out of three care workers had seriously considered quitting their jobs (Trydegård, 2012). The study was conducted on 2583 eldercare workers in Nordic countries. The care workers experienced their work as physically and mentally arduous, and felt that their opportunities to provide good quality care were weakening (ibid.). The majority felt that they did not receive support from their managers, and the workers lacking managerial support were twice as likely to want to quit their job (Trydegård, 2012; also Hansen, 2008). Thus, the development of competences in terms of professionalisation has stagnated in a few traditionally female occupations, surprisingly without much resistance on the part of the employees (e.g. Andrews & Waerness, 2011).

What if the majority of care workers really turned their thoughts into actions and quit when affected by the multiple changes that deteriorate their wellbeing and their ability to provide good quality care? Trydegård (2012: 125) proposes that thoughts of quitting may serve as a safety valve, and anticipates that most workers would end up staying in their jobs eventually. However, it is alarming if thoughts of quitting are the only way of coping – or practicing resistance - in care work (e.g. also Clegg & Courpasson, 2004). On the other hand, resistance may be useful for grassroots innovations and it doesn't signify intention to quit. Employee resistance may be mismanagement and misunderstanding (Waddell & Sohal, 1998). Employee resistance toward changes should be utilizing rather than overcoming (ibid).

In our view, it is ever more important to ask: *how* care workers question and criticize their situation at work, and what consequences does it have in the organization? In particular, what do the workers and their managers *do* when questioning and criticism arises? However, the dynamics of transformative, employee-initiated actions related to employee criticism at work are not systematically addressed in public administration research. Service innovation research and service design-oriented research especially in Nordic countries have advanced knowledge on grassroots employees' agency - in terms of everyday creativity and innovativeness - in solving organizational problems and developing new services (e.g. Fuglsang & Sørensen, 2011; Mattelmäki & Lehtonen 2006). Despite these advancements in service innovation research, there is a need for studies which could further inform critically reflexive, practice-based and employee-driven managerial interventions in services.

This paper analyzes critique expressed by front-line care workers on their work conditions as a potential impulse for change and innovation-oriented agency. By analyzing interview accounts and interactions of elderly care employees in municipal nursing homes it is possible to achieve new understanding of how employee critique can potentially advance employee-driven innovation. In the paper we analyze connections between employee critique and expressions of daily routines of employees in the context of elderly care services. We see employee critique as a neglected topic of service research as well as an opportunity to develop elderly care services and care work.

## **2. Employee critique – from resistance to agentive critique as a trigger for change and innovation in manual services Formalities**

Why employee criticism sometimes seems to manifest itself as unconstructive resistance, whining or slander, even mudslinging particularly from managers' point of view? Especially in many manual service occupations, people have not been educated interactively perform skills such as judging, building an argument and advocating for it. Continuous changes and declining resources i.e. shortage of staff in many elderly care organizations may cause serious constraints which may signal itself as problems in personal relations between employees.

A line manager in our case study also reported that employees tended to come to her one by one to present concerns, complaints or ideas for improvements. She interpreted that employees were very precautious to present their matters, even new ideas, in team meetings because they were suffering from bad relations between team members and thought that presenting ideas would mean criticizing openly work-mates' current ways of doing things. Presenting ideas openly may also be interpreted as deliberately seeking manager's favor, and a reputation of a 'smoothie' is something that many employees in manual service occupations try to avoid. Criticism and questioning among grassroots employees may be fragile and delicate question. Therefore, it is even more important to address employee critique as a manifestation of and an opportunity for agency that is able to cause positive change and innovation in service work.

### **2.1. Employee critique as agency for change and innovation?**

Criticism expressed directly to managers or work community by a service worker may be powerful – but perhaps neglected - vehicle for change and innovation in manual services. Also worker's self-criticism or self-critical assessment of the team's work patterns involves potential impulse for change and innovation. In addition, receiving criticism from customers and colleagues matters. But how "simple criticizing" or "receiving criticism" turns into agentive and constructive – or reflexive - action in the workplace?

Agency refers both to the motivation and the creativity that drive actors to break away from scripted patterns of behaviour. Agency is a temporally embedded process of social engagement and suggest that it reproduces and transforms the world through the interplay of the habits, imagination, and judgements of actors (Emirbauer & Mische 1998). Notion of breaking away from scripted patterns refer to prevailing practices, and term breaking away inherently involves some kind of critical assessment of behaviours/practices, i.e. questioning, criticizing, or judging. Agency is creative, temporal, it varies situationally, and it is individual and relational, simultaneously. Additional notions of agency address its action-relatedness and creative, transformational quality. Individual agency can be understood as the breaking away from a given frame of action and the taking of initiatives to transform it (Engeström & Virkkunen

2007). Notion of transformational agency captures the context-related, practice-based and experiential character of problem solving in agency. Conflicts, constraints and disturbances – typically causing a lot of criticism - in everyday service situations may simultaneously hinder and boost agency for change and innovation. Practitioners solve conflicts and disturbances during the development of their local activity and work practices (Haapasaari & Kerosuo 2014).

## **2.2. Employee critique as a springboard to bricolage?**

The concept of bricolage gives us a view of agentive *grassroots problem-solving practices of participants*. It suggests that when faced with resource constraints, employees may find innovative solutions in a situation based on ‘whatever is at hand’ (Baker and Nelson 2005, cf. Lévi-Strauss 1967). The participants create and combine their scarce resources and ideas in a novel way in order to develop some useful and novel outcomes (Baker and Nelson 2005, Fuglsang and Sørensen 2011, Salunke et al. 2012). Bricolage is a process of co-shaping an emerging path: participants offer inputs to generate a virtuous learning circle without much delay. The boundaries blur between design and implementation, and between rulemaking and rule following (Garud and Karnøe 2003).

Bricolage is not typically planned beforehand, but it requires situational individual agency. It emphasizes the significance of individuals’ actions and control over resources (Fisher 2012). In order to explore how ‘ordinary’ interaction between employees can lead to changes i.e. service improvements and innovations, we chose to use the concept of bricolage in the empirical analysis. Bricolage serves here as a practice-based, contextual and situational embodiment of agentive action. It may follow or be associated with employee critique and questioning, and it is targeted to solve the constraint with the use of resource integration, “what is at hand”. While being a theoretical concept, it is also a mode of individual or group practice which can be observed empirically. Bricolage incorporates contributions and resources of all participants in a given situation.

Drawing from the concepts discussed above, we explore the origin and nuances of employee critique and its potential connections to bricolage in a context of service work in elderly care. We tentatively suggest and aim to develop the concept of *agentive employee critique* in order to address the significance of agency inherent in mundane criticism that often lay unnoticed or even unvoiced especially among grassroots personnel. “Criticism hidden from managers” –phenomenon is well known in many work settings. Theoretical framework of the paper is depicted in Figure 1.

Figure 1. Theoretical framework of the paper

### 3. Case context with “low threshold” experiment, data and methods

The case context is publicly funded elderly housing facility in a Finnish city. The work in this context is relatively low-wage, physically strenuous, manual elderly care work in assisted living homes which include meals, laundry, cleaning, safety services, recreational activities and health care.

The elderly housing centre was founded in 1970 and it consist of four teams. We focused on one team in this empirical study. Elderly housing centre employs 92 registered and practical nurse and provides 83 house to customers in single and double rooms. The analysis is based on data from a team which consist of 26 employee vacancy and 42 house for the customers.

There is a high turnover of workers, which is typical in this field. Elderly housing centre has left customer apartments unoccupied because of shortage of staff. An increasing number of customers are weak with incurable illness. Residents’ poor condition is a load factor on care work. Personal care for the elderly takes more time from the nurses.

In this setting, each worker performs tasks in single-handed or autonomous pairs. The work is divided into three shifts. Few practical nurses takes care of the elderly in night shifts. Confidentiality matters and ethical issues are also part of the work. Employees deal with elderly peoples’ relatives and doctors daily.

The case data, gathered in 2014, included interview data and ethnographic observation in a team meeting. The data used in the paper are part of a larger data set which includes 110 interviews and 14 ethnographic observation situations in four elderly service organizations. The research design is depicted in Figure 2.

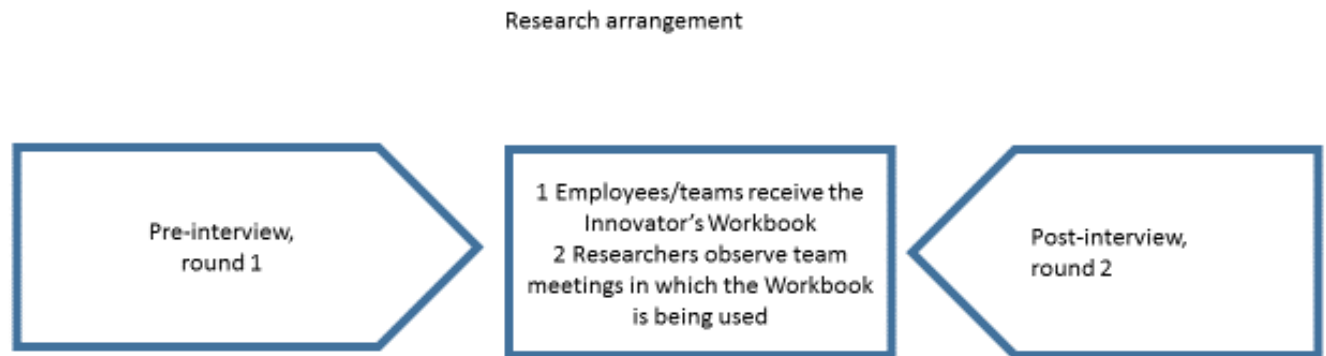

Figure 2. Research design. The research was based on interviews and observation

The thematic interviews lasted from 1.5 hours to 2 hours and included two rounds. Pre-interviews were carried out in April to May 2014 and second round lasted from November 2014 to January 2015. All the interviews were recorded and transcribed with the interviewees' written consent. Interviews traced the interviewees' perceptions of their previous, current and future experiences/expectations, roles, practical tasks/duties, benefits and ideas related to the development of their work. Pre-interviews themes covered the work tasks and role of the interviewee, service context and development, changes in work and management, patterns of team and client interaction and the interviewee's participation in various organizational or service development activities. Interviews also included narratives about problems in daily work and everyday life with the elderly. We tried to find out employees' agency related to development and innovating of work practices by way of pre- and post-interviews. We have picked up data from three employee cases for this paper, these employee's participated also in observation. Innovator's workbook was used in team meetings for eight months. We observed team meetings three time in June, September and November. The middle observation in the last day of September has been analysed precisely for this paper. Detailed field notes were written during the observation, and some meetings were audio- or videorecorded. At the end of each field situation, a detailed field report was written. General description of the data types and employee cases used in this paper is presented in Table 1.

Researchers observed the experiment in which a grassroots innovation-enhancing method, a printed book entitled as "Innovator's Workbook, was given to each em-

employee individually. We characterized the experiment as a “low threshold” and “grass-roots” innovation-enhancing experiment among care workers. The experiment was carried out as part of an ongoing research project TOIMI (Experimenting and evaluating the methods for promoting employee’s transformative agency).<sup>1</sup> In the case described in this paper, employees used the Innovator’s Workbook mainly in team meetings, but their supervisors also encouraged them to learn it and use it individually, since each team member had received their own piece of the book. Innovator’s Workbook included 19 different themes and assignments associated with development and employee innovating at work. It helps for instance employees look at the work from a different perspective, question their current work practices and to find a new enthusiasm for work. One theme (number 10) which is related to this paper deal with critique and innovation. The idea of that theme is to encourage employees to provide feedback and express constructive criticism to others. The aim is to increase employee’s initiatives and proposals. In the related assignment employees were able to practice the giving and receiving of criticism. We have brought this theme in a review because of illuminating and vivid research data.

| Data type   | Number of data   | Date | Case characteristics  | Code in the text |
|---|--|------|---|------------------|
| <b>Thematic interview</b> , altogether 6 interviews | 2 interviews with Employee A; pre-interview (1) and post-interview (2) |      | Age 50 female elderly care worker in practical nurse position. Table 1. Summary of data analyzed in-depth in the paper

## 4. Case description

The work community is dominated by women employees. Practical nurses make a large proportion of daily work. There was two nurses in team at the beginning of the research project, but one of them left her vacancy. The remaining employee had the workload of two and she was responsible over twenty customers care daily.

The care work involves emotional work and the ability to adapt changing client situations. Care workers are co-operating with relatives daily. Some clients doesn't have relatives or they are disinterest in elderly person's condition, therefore nurses makes all decisions concerning clients' life. Nurses may be the only responsible social contact to elderly person what makes their work emotionally heavy.

There has been big challenges in the case organization. The workers were forced to work in a hurry. In addition, the use of substitutes has strained employee's and increased their work pressure. There has been a lot of reorganization and change in this setting. Workers interpersonal relations has been occasionally tense and these experiences the team members described in the interviews. These organizational and relational factors may have affected employee's willingness to make grassroots innovations.

The elderly house facility in question is originally an apartment building, which severely limit practical care work and the implementation of new practices. Dining and injection are constantly chafing specific matters in this case. Lack of space is workers continuous concern, although client rooms and dining rooms have been reorganized during last years.

## 5. Results

We first present an overview and summary of the interview accounts of employees' critique, and of agency on development and bricolage, before and after the experimentation with the Innovator's Workbook (5.1). Second, we provide an overview and summary of discussion on a critique-related assignment among service workers during one team meetings (5.2).

## **5.1. Employee critique in interview accounts**

We selected three interviewees for in-depth analysis. Two of them are practical nurses and one of them is nurse. They are different-aged and different stages of their careers. Firstly we looked at how they expressed their transformative agency and secondly how they self-evaluated their own, their work community's and their line manager's agency on a scale of one to ten. Thirdly we sought illuminating quote of agency expressed by employees themselves and finally we formulated researcher's interpretation on each employee case (see Table 2-3). Analyzes have been made from two rounds of interviews.

Employees regarded organizational changes with suspicion in the first round of interviews (see Table 2). The workers expressed different degrees of resistance and strong critique against organizational changes. The biggest target of resistance was a new team division. It seemed that developing new working pattern as one team turned out to be very slow process, possibly because of team member's unwillingness to break the boundaries. Resistance against workplace settings represented in employee's action. The workers solved the problem pragmatically in their own way. For instance, one of the practical nurses insisted not to follow general rules and retained her own way of caring related to nutrition. This action could be interpreted as a clear protest and it highlights very active individual agency.

The workers expressed individual agency, as they often reported how they tried to individually influence work conditions related to caring practices by making initiatives to line manager only. On the other hand employees' agency was relational, as they expressed criticism directly in team meetings (for instance as depicted in Table 4).

Interestingly enough, the workers were more satisfied with their work and working conditions in the second round of interviews (see Table 3). Criticism toward working conditions decreased. Interesting observation was that the employees expressed more social support to each other as well as courage to voice their ideas and initiatives aloud in team meetings. Employees also gave better grades of their own agency on development. In addition, they referred work atmosphere improved during the year 2014.

| Employee                             | Characteristics and objective of agentic critique   | Self-grading of agency on development of (1) one's own (2) work community (3) line manager (scale 1-10) and (4) number of bricolage accounts  | Summary of agency expressed by (1) employee and (2) researchers' interpretation   |
|--------------------------------------|---|---|---|
| <b>Emp A 'Maria' practical nurse</b> | <p>Partially negative expressions towards ongoing changes, no clear expressions of self-critique or self-reflection</p> <p>Critique on structural and organizational issues in care work, and on lack of resources and high turnover of staff (large amount of deputy personnel)</p> <p>Also adaptive and agentic views: <i>"however I feel that I can influence the team and activities"</i></p>   | <p>(1) Oneself: 7</p> <p>(2) Work community: 8</p> <p>(3) Line manager: 9</p> <p>(4) No substantial descriptions of bricolage (Finnish not her mother language)</p>   | <p>(1) <i>"I have a few ideas. I take responsibility and try out new ideas. I'm not shy or quiet person"</i></p> <p>(2) Socially active caregiver, positive attitude on work development, she does not make many initiatives individually, but likes to be part of putting new ideas into practice</p>  |
| <b>Emp B 'Anne' practical nurse</b>  | <p>Expresses strong resistance and critique towards organizational and work-related changes (i.e. particular manager), reports even her individual action of protest towards manager's orders</p> <p>Also lot of reflexive self-critique and questioning of one's own orientation to customers and time allocation between customer care and other duties</p> <p>Partially also optimistic future orientation on personal learning and adaptation</p> | <p>(1) Oneself: 7</p> <p>(2) Work community: 7</p> <p>(3) Line manager: 7</p> <p>(4) 5-6 relatively detailed and rich descriptions of bricolage, mostly employee-initiated examples of using one's personal resources, also one customer-initiated case</p> | <p>(1) <i>"I admit that I do have strong resistance to change, and actually I'm surprised about that... I do express my points of view, and I take positions... I have a lot to learn, though, especially on how to take account of the residents' views more and more"</i></p> <p>(2) Ethically reflexive caregiver, a lonely rider, who applies individually-oriented thinking and actions towards changes and new ideas, she is also capable of expressing self-critique</p> |
| <b>Emp C 'Silja' nurse</b>           | <p>Reports previous critical attitudes towards changes, now expresses mainly positive attitudes: <i>"I feel serene about ongoing changes"</i>, no clear expressions of self-critique or self-reflection</p> <p>Critique on amount of work and task distribution, and on leaders failing to put organizational change (teams integration) into practice in a right way</p>   | <p>(1) Oneself: 7</p> <p>(2) Work community: 9</p> <p>(3) Line manager: 8-9, Upper manager: 6</p> <p>(4) 2-3 descriptions of bricolage</p>  | <p>(1) <i>"I have never been much an idea-generator. Therefore I would not be able to be in a supervisor position or alike. But I do achieve a lot in my work, I really can achieve."</i></p> <p>(2) Quiet achiever and bearer of responsibility, strong tendency to under-value or underestimate her own innovativeness, since she also do make initiatives and gives support to others' ideas</p>   |

Table 2. Pre-interview (1. round): agentic critique, agency on development and bricolage, based on interviews of three employees (preliminary analysis)

| Employee                             | Characteristics and objective of agentive critique  | Self-grading of agency on development of (1) one's own (2) work community (3) line manager (scale 1-10) and (4) number of bricolage accounts (5) mention of Innovator's Workbook  | Summary of agency expressed by (1) employee and (2) researchers' interpretation  |
|--------------------------------------|---|---|--|

Relational and co-creative view towards changes and innovation |
| <b>Emp C 'Silja' nurse</b>           | <u>Changes:</u> A larger number of proposal for resolving daily work problems, mention of the importance of colleagues' support, expresses strong courage on grassroots innovations, 'entrepreneurial' employee<br><br>More critique against line manager, tired of the work situation. | <u>Grading improved, except of manager's clearly declined</u><br>(1) Oneself: 8<br>(2) Work community: 8<br>(3) Line manager: 6<br>(4) No particular change: 1-2 descriptions of bricolage<br>(5) Critical comments about the Innovator's Workbook, expression of reservations towards the situation in the organization in which such method was applied | (1) <i>"I develop work with nurse -oriented thinking. I propose a more flexible solutions than others. I'm equitable to everyone and I know the customer's best."</i><br><br>(2) <u>Clear change:</u> Employee has taken bigger developer role. She is one of the initiators of the new practices. She underestimates her valuable contribution.   |

Table 3. Post-interview (2. round), changes in agentic critique, agency on development and bricolage based on interviews of three employees after the experiment, use of the Innovator's Workbook (preliminary analysis)

We interpreted that at least partial explanation for improved satisfaction and decreased criticism was due to the fact that there had been advancements in getting and keeping enough manpower in the organization. There was less experiences of severe hurry at work. It may be also that personnel had finally adapted to new team arrangements.

What we could not quite explain with improved personnel situation and adaptation was the observation that employees expressed more social support to each other as well as courage to voice their ideas and initiatives aloud in team meetings, and that they gave better self-evaluation of their own agency on development.

In order to further explore these changes in interview data, we now turn to look at a piece of analysis based on observation in one team meeting in which the Innovator's Workbook was used to deal with theme that was specifically related to critique and criticism at work.

## **5.2. Bricolage-related accounts and interactions during a team meeting**

The ethnographic observation of the team meeting in which the Innovator's Workbook was used took place in the afternoon, in the meeting room that was used also as a social gathering place for the employees during lunchtime and breaks. The three employees whose interviews were analyzed above participated in the team meeting. Altogether nine employees participated in the meeting led by line-manager (head nurse).

Two researchers also participated in the meeting to observe the situation, discussions and interactions. They were supposed to do as less interruptions as possible, i.e. clarifying questions. The meeting was audio-recorded with participants' written consent, and detailed memo was kept during the meeting. The meeting lasted approximately 1,5 hours. The preliminary analysis in this paper is based on memo.

Theme number 10 in the Innovator's Workbook that deal with critique was discussed in the meeting. A few employees had the book with them when they arrived. The theme was agreed upon and decided among the employees in the previous meeting. The idea of that theme and related assignment was to encourage employees to provide feedback and express constructive criticism to others in matters of work and service development. The aim was to help understand questioning and criticism not as something to be avoided but as potential source for development, and help increase employee's initiatives and proposals. In the related assignment employees were able to practice the giving and receiving of criticism.

Six turning points were found in the discussion on critique-theme (Table 4). We call these turning points as 'bids', kind of invitations to some other person or persons to join in, i.e., add something, comment on, or answer to a question. Especially at the start the line manager put forward 'bids', but as the meeting proceed, also team members such as practical nurses became active. The most significant turning point,

number 2 (see Table 4), was made by one employee, as she reacted relatively strongly to researcher's question and corrected researcher's wrong information.

The workers' discussions and interactions during the team meeting supplements the analysis based on the interview data. Table 4 presents an overview of the preliminary analysis. Critique as potential impulse for new ideas and initiatives was demonstrated in an interesting way in the meeting. Criticizing was intentionally addressed as term in speech for instance by one employee in her voicing that "I am criticizing... [the matter debated on]. Expressions of criticism was linked with new ideas and quick experimentation, bricolage, on work practices. In a way, participants rehearsed expressing their criticism and ideas openly and publicly.

Line manager praised the discussions and ideas several times during the meeting. As reported by the line manager immediately after the meeting, she was surprised by the active participation and rich ideation of the employees. Almost all participants took part in the discussion. Several new ideas and initiatives were dealt with in the meeting. It was also revealed that quick change and experimentation on dining arrangements, as bricolage, (i.e. with resources at hand), had already taken place by the employees' own decision, and in the meeting they informed the line manager about the results and debated on them together (see Figure 3). In addition, later on the line manager reported that the team has continued to speak openly in team meetings.

In a way, criticism-theme turned into powerful agentive critique in the meeting, as it was constructively shared and developed into new solution-ideas by the work community in a form of bricolage. Collective agency on development seemed to strengthen during the meeting between team members and between line-manager and the team.

We interpret that the use of Innovator's Workbook method have had an effect on the employees' transformative, developmental agency, as observed in the changes of the interview accounts after the intervention. The employees expressed more social support to each other as well as courage to voice their ideas and initiatives aloud in team meetings, and they gave better self-evaluation of their own and their work community's agency on development.

| Key phases of the meeting   | Introduction of new topic and its initiator   | Subject matter of 'bricolage'  | Action points, participants  |
|---|---|--|--|
| 0 Private insights of the line manager shortly before the meeting | Negative: almost the whole staff changed within short period of time<br><br>Positive: staff shortage has been almost resolved   | -  | -  |
| 1 Preparing team discussion                                       | LM informing, reminding the staff about their duties during her leave of absence (forthcoming)  | -  | LM's managerial speech associated with deadlines   |
| 2 Discussing on the topic   | <p><b>1<sup>st</sup> "bid"</b> LM's direct question as opening of the group discussion [referring to topic in the booklet]: <i>How do you feel about criticism, how does it feel to receive critique?</i></p> <p><b>2<sup>nd</sup> "bid"</b> a turning point revoked by R's question leading to E's interruption: <i>But it is not dropped to taking off!</i> [E using powerful expression, followed by several small questions, and a few expressions of praise by LM]</p> <p><b>3<sup>rd</sup> "bid"</b> LM's suggestion and praise: <i>It is good that you</i> [referring to individual employee] <i>despite the criticism drove this matter forward</i></p> <p><b>4<sup>th</sup> "bid"</b> LM's new question to all: <i>What other matter should be changed, any thoughts?</i></p> <p><b>5<sup>th</sup> "bid"</b> E: <i>I am criticizing how this is now arranged ...</i></p> <p><b>6<sup>th</sup> "bid"</b> E introducing of new subject matter that needs development</p> | <p>Referring to Innovator's workbook, assignment no 10 (receiving and expressing critique)</p> <p>Customer dining arrangements in the facility, mainly from employee point of view, but also customer point of view</p> <p>LM dominating, 2-3 employee participants in the discussion, one E initiating a turning point</p> <p>New question, looking for new topic/ideas to discuss</p> <p>E's initiative: customer hygiene matter, new showering practices, mainly customer point of view</p> <p>E's initiative: new ordering practice of customer's personal care equipment, mainly employee point of view</p> | <p>-</p> <p>Dining arrangements experimented and in a process to be sustained, new practice under discussion (employees' informing LM)</p> <p>LM's suggestion to expand experimentation</p> <p>LM connecting topic of the workbook to new daily practices</p> <p>No clear decision</p> <p>Several employees participating</p> <p>Several employees participating</p> <p>Decision by LM, marked in the memo</p> |
| 3 Closing team discussion (scheduled time running out)            | LM's question to all: <i>What subject in the booklet shall we work with in our next meeting?</i> E's initiative: <i>We should take seven (no 7),</i> LM's comment: <i>Yes that is a good subject.</i>   | -  | Decisions: next subject from the booklet, setting the date for next meeting  |
| 4 Private insights of the line manager shortly after the meeting  | LM being surprised by the active discussion and employees' direct initiatives, also reporting an employee previously saying to her that "we shall take this seriously" which LM had interpreted to mean serious use of the book in development of work practices, 'innovations'   | -  | -  |

Table 4. Preliminary analysis of team meeting in which the Innovator's Workbook was used as a resource. One topic and related assignment (expressing and receiving critique in ones work) had been picked up from the book in the previous team meeting and decided to be discussed in this meeting (30.9.2014). Participants: line manager and 9 elderly care employees (one male), two researchers observing. Duration approx. 1,5 hours. E=employee, LM=line manager, R=researcher

Figure 3. Employee-driven innovation in customer's dining arrangements.

## 6. Discussion

The interest of the paper was on *how* elderly care workers question and criticize their situation at work, and what consequences does it have in the organization? In addition, we aim to investigate what do the workers and their managers *do* when criticism arises? We suggested an integrative framework for exploring the nuances of employee critique and its potential connections to bricolage in a context of manual service work in elderly care. We tentatively suggested the concept of *agentive employee critique* in order to address the significance of agency inherent in mundane criticism that often lay unnoticed or even unvoiced especially among grassroots personnel in manual service work.

In the introduction we referred to negative research results on experienced wellbeing of elderly care workers. Low resistance against the poor working conditions and shortage of resources was being observed as well. On the other hand, it has been suggested that resistance may be useful for grassroots innovations and it doesn't signify intention to quit. Our explorative study supports observations made by Waddel and Sohal (1998) that employee resistance toward changes should be utilized rather than trying to overcome it (ibid). We observed that despite arduous working conditions, care workers expressed active agentive critique, and they were able to turn it into constructive and innovative solutions in order to improve their working conditions

and customers quality of life. The employees' actions and interactions represented transformative agency discussed in the beginning of this paper. This is positive and important research results although it was shown in small data set. Evidence included data from interviews and ethnographic observation that supported each other.

Managers of manual work may need to consider employee critique as an important and potentially innovative resource in the workplace and in customer relations. As public organizations tend to lower hierarchies and integrate services, employees acquire new responsibilities, and co-creating of services becomes more usual. In addition to managers' roles, there also existed other responsible roles in our study significant for bricolage. Our findings support observations of Fuglsang and Sørensen (2011) who pointed out that many potential innovations in the form of bricolage occur without the perception of managers. The combination of frame, freedom, control of resources and responsibility for implementation supports the employees to utilize opportunities and perceived competences. These observations have implications for practical applications of service-dominant thinking, as most earlier research addressing co-creation of value have either focused on planned activities or practices at the upper organizational level.

# Development of Smart Services in Manufacturing Companies

Thomas Meiren<sup>1</sup>, Nicola Saccani<sup>2</sup>, Andrea Alghisi<sup>2</sup>

<sup>1</sup>Fraunhofer IAO, Stuttgart (Germany)

<sup>2</sup>University of Brescia (Italy)

*The digitisation of products and processes is an important trend in manufacturing companies. This also changes business models and influences the offering of product-related services. In particular, a new type of highly IT-based services, the so-called “smart services”, will provide various new possibilities for companies. A reference framework consisting of a process-activity model, methods and tools as well as organisational arrangements shows, how such complex services can be developed in a structured way.*

## 1. The rise of smart services

Information and communication technology has become an integral part of manufacturing industries. In particular, the increasing digitisation of products and processes is triggering new business models and the associated organisational systems, networks and consumption patterns. This paves the way for a new type of highly IT-based services, the so-called “smart services” (Kagermann et al., 2015) like advanced status and diagnostics applications, new control and automation solutions as well as profiling and behaviour tracking. They are making use of the growing volume of data that is being captured every day and are combined in innovative ways in order to create on-demand, personalized solutions for customers. Moreover, product performance and customer behaviours will get visible as they have never been before. Due to the high complexity of smart services, systematic approaches for their development are required, and first promising research can be found in the area of New Service Development, Service Engineering and Service Design (Papastathopoulou; Hultink, 2012, Fähnrich; Meiren, 2007).

Based on two empirical studies – one within the European Project “T-REX” (Saccani; Adrodegari; Alghisi, 2014) and another within a joint initiative of European service researchers (Edvardsson et al., 2015) – the current business models and service offerings of manufacturing companies have been analysed. It has become obvious that their service business has undergone extensive structural changes within the last decade and, also today, they are still facing many challenges, in particular, when it comes to the use of information and communication technologies. Many manufacturing companies are, however, hindered by the fact that their present corporate structures and processes are not designed to enable complex IT-based services to be efficiently developed and launched on the market. Difficulties are frequently encountered because appropriate business models are missing, requirements of customers are not clear, new services are not accurately defined and tested, IT integration is challenging, and the service staff is not sufficiently trained.

## 2. Framework for the development of smart services

Taking into account existing knowledge in the area of New Service Development, Service Engineering and Service Design, a reference framework for the development of smart services has been elaborated. In particular, it explains the creation of a new service from its first idea at the beginning to the market launch at the end by reflecting an external perspective (e.g. customers, competitors), an internal perspective (e.g. management, service staff), and an economic perspective.

The aim of the framework is to provide companies with extensive support in developing new smart services or redesigning existing smart services. It puts a particular focus on the economic perspective, i.e. the systematic approach is intended to lower both the costs of the smart services and the total cost of ownership for the products to which they relate.

In addition to a (level 1) typology to distinguish between basic scenarios for the development and refinement of smart services, the framework consists of a (level 2) process-activity model, (level 3) methods and tools, and (level 4) organisational arrangements (see Figure 1).

Fig. 1: Structure of the reference framework

The individual levels of the reference framework are explained in detail in the following chapters.

### 2.1. Level 1: Typology

The reference framework aims to help companies develop more professional smart services. This may include the improvement or redesign of existing services, or the development of completely new services. Moreover, it is crucial regarding the choice of process and methods whether the revised or new services are being offered to existing markets or customers, or whether they are to address new target groups. These considerations then provide, on the one hand, the dimension of smart services (existing vs new) and, on the other hand, the dimension of the target market (existing vs new). The resulting typology is depicted in Figure 2.

Fig. 2: Typology for development activities

The typology is based on the well-known Ansoff Matrix (e.g. Kotler; Keller, 2012). While this nevertheless serves as a tool for strategic management and is primarily used as an aid for planning corporate growth, the modified typology in the reference framework should pursue operative aims. In particular, the typology is intended to provide support in making key decisions on defining areas of focus and selecting necessary activities right at the start of the development process.

The four basic categories of typology and the ensuing consequences for the development process are explained below.

### Type A

What is undoubtedly the most demanding category is the development of new smart services for new markets, where a new range of services is developed for clients with whom the company has not previously worked. In order to ensure success in the development process and to mitigate risk, conducting a run-through of the complete development process is recommended. In particular, the information collated in the development of the initial business model should be supplemented by an extensive market analysis. It is also advisable to adopt a strongly external perspective in the course of the development process and to integrate potential customers on an ongoing basis where possible (e.g. through interviews and workshops).

### Type B

Like Type A, the second category is concerned with the development of new smart services, but for existing markets rather than new ones. This has the advantage that market structures (customers, competitors, multipliers, etc.) are generally already familiar, making the communication of the relevant information much less complex. Similar to Type A, conducting a complete run-through of the development process is also recommended, although individual methods that adopt the external perspective may be conducted in a simplified way or even skipped completely. However, they should only be skipped completely if the markets and customers are already very familiar (as is the case, for example, if a new smart service is only to be developed for one lead customer).

## **Type C**

The third category is based on existing smart services that need to be adapted to new target groups. This is a very typical case that often gains importance with the increasing internationalisation of many companies, i.e. existing services need to be adapted to local conditions (e.g. language, cultural requirements, different logistics and new partners). As for Type A, the external perspective is also very important for Type C, and conducting the associated activities consistently is recommended. By contrast, tasks described in the development process that affect the internal, operative design of the service can be skipped – as long as this does not result in any change requests.

## **Type D**

The supposedly simplest category is the redesign of existing smart services for existing target groups. This generally concerns selective adaptations to the range of services (e.g. adapting the delivery process, cooperation with new partners, use of new IT or communications technology). For Type D, a comprehensive requirements analysis should be conducted first and then only those activities from the development process that actually affect the improvements to or the redesign of the smart service should be selected.

The aforementioned typology provides an initial tool for the classification of the development task and for making the first selection decisions with regard to the process and methods to be used in the development.

## **2.2. Level 2: Process-activity model**

The core element of the reference framework is what is known as the process-activity model. This takes the form of a detailed description of the entire development process for smart services and the tasks to be conducted.

As a result of a literature analysis and requirements derived from practice (i.e. from a study conducted of 95 companies and a workshop with 12 practitioners), the basic type selected is known as a stage-gate model, which describes the development of the service from the requirements analysis to market launch. Stage-gate models are characterised by the linear sequence of the individual, consecutive stages in the process (Cooper, 2008). By doing this, there are clearly defined results after each stage, which can then be used in subsequent stages. For companies, particularly SMEs, stage-gate models are advantageous because they are clearly structured and easy to understand, and the pending development activities are ordered in a clear and logical way.

The process-activity model for the development of smart services is summarised in Figure 3.

Fig. 3: Process-activity model

This model follows the important development stages of requirements analysis, service design, service test, service implementation and market launch. It has also been supplemented by three perspectives (internal, external and economic), which must be taken into account in each phase.

### Development phases

As discussed at the start of the chapter, the model is based on a clearly described service concept, including the relevant business model. Generally, the information collated here tends to be of a strategic nature, however (e.g. to which markets and which customers will the smart service be offered? Which are the most important value propositions of the service?) It is also necessary to collect information about the operational design of the service.

The actual development work begins with the *requirements analysis*. Requirements are collated and assessed from a company perspective (“What form should the smart service take for the management and staff?”) and from a customer point of view (“What form should the smart service take for the customer?”). The aim is to obtain a clear picture of the details of what the smart service needs to be able to do in order to be successful. It is also important to identify critical factors that must be avoided in order to prevent the failure of the service. Fulfilment of those requirements evaluated as the most important provides a clear guideline for the subsequent stages in development.

The next stage is *service design*. Here, the service features to be developed are described, the processes for the later provision of the service are defined and the use of resources planned. In addition, a marketing concept should be developed at this stage in order to integrate market and customer aspects for the subsequent market launch of the new service from an early stage of the development process, as well as carrying out a detailed price and cost calculation of the service.

The *service test* is then the next step. As the previous results are of an overwhelmingly conceptual nature, this stage focuses on carrying out a practical test of the smart service. Even if services seem to be predominantly intangible by nature, a range of approaches are available. They include everything from acceptance tests among staff and customers, partial implementation of the concepts (e.g. IT demonstrators, user interfaces) to initial tests with the actual customer.

*Service implementation* follows the test phase, and this is where the previous tasks are now implemented within the company. This primarily affects technology/IT tasks (e.g. hardware/software), implementation of organisational measures (e.g. assigning responsibilities, preparing operational instructions and procedural guidelines) and the implementation of HR measures (e.g. filling newly created vacancies, training staff). This stage also includes implementing the previously developed marketing concept and establishing essential KPIs for monitoring and managing the subsequent fulfilment of the service.

After a successful internal implementation of the new service, it is now ready for *market launch*. This predominantly concerns the roll-out of the service, i.e. providing the necessary resources and the approval of the service for the customer. Internal and external information and communication measures should also be conducted in parallel. This stage requires start-up monitoring and checking the success of the service. Final adjustments may have to be made on the basis of customer or staff feedback (e.g. through surveys and the evaluation of complaints).

Once the market launch is complete, the development process has come to an end and the new smart service may be handed over to the relevant department.

### **Internal, external and economic perspectives**

In addition to the chronological sequence of the development stages, the process-activity model also integrated a second structuring level. This involved three different perspectives that have to be taken into account at each stage in order to ensure the most comprehensive process possible and, ultimately, the success of the service.

The *internal perspective* looks at the company's point of view. This primarily focuses on operational aspects of the smart service. Typical examples include the planning of processes and resources. The work carried out should be compared with the requirements of internal stakeholders (staff, management, etc.) on an ongoing basis.

By contrast, the *external perspective* describes the market or customer's point of view. For services that are characterised by the close integration of the customer by their very definition, it is essential that they are not developed from a purely internal perspective. In the same way as internal stakeholders are included in the development process, external stakeholders – primarily, the customer, but also partners, suppliers, etc. – should also be integrated.

The *economic perspective* is the third and final level. As the cost perspective is important for every company – both for the smart services and for the associated (tangible) products – the economic perspective was also integrated into the model. Even in business practice, it is clear that services are not only seen as a 'necessary evil' in order to maintain product business but increasingly also as an opportunity to boost the company's financial results (Neely, 2009).

## **2.3. Level 3: Methods and tools**

Although the process-activity model forms the 'backbone' of the entire process, it does not describe in detail *how* the tasks described are to be accomplished. Practitioners, in particular, would have difficulty at this point knowing exactly what it is they have to do in order to successfully complete a task. For example, if a task such as

the analysis of market and customer requirements seems obvious, the question still remains as to how exactly it should be carried out and which methods are available.

The third level of the reference framework addresses precisely this challenge and provides a selected set of methods, templates and tools. These are listed according to the specific stages of development in Table 1.

| Development phases     | Methods  |
|------------------------|--|
| Requirements analysis  | Visualisation of service ideas<br>Interviews<br>Workshops<br>Requirements list<br>Target pricing and target costing  |
| Service design         | Service description<br>Process steps for smart services<br>Service blueprinting<br>Role concepts for service delivery<br>Interaction design<br>Marketing mix<br>Cost calculation |
| Service test           | Service FMEA<br>Service concept testing<br>Pilot customers and test markets<br>Lab approaches for service testing<br>Simulation of prices and cost                               |
| Service implementation | Implementation planning<br>Training<br>Marketing measures<br>Key performance indicators  |
| Market launch          | Roll-out planning<br>Customer satisfaction survey  |

Table 1: Overview of selected methods

The focus is on methods that are specific to services. In addition, methods for project management are also relevant for service development projects, but they can easily be transferred and applied, so that they are not explicitly mentioned in the methods part of the reference framework.

## 2.4. Level 4: Organisational arrangements

In contrast to product or software development, the systematic development of services remains uncharted territory for most technology-based companies. There are often no specific units within the company to take on this task, or no clearly defined responsibilities as to who is responsible for which individual activity (Schäfer, 2014; Meiren, 2006). For this reason, the reference model was supplemented by a fourth level in terms of organisational arrangements.

## Organisational structures

For larger companies that already have organisational structures in place, the question soon arises as to who will be responsible when it comes to new services. This might be the service department, but it could also be marketing, sales or the strategy department or business development if there is one in the company. Or should an internal R&D department be established in order to develop the service, as is the case for product and software development?

If the issue of organisational structure is abstracted, it is possible to determine whether the company should set up an internal unit for the development of the service or not. In addition, a decision must also be made as to whether such a business unit would work on this task continuously, or just periodically. The possible alternatives are illustrated in Figure 4.

|  |   |  |
|--|---|--|
| Service development<br>as a permanent task | Existing organisational unit<br>to develop services | Special organisational unit<br>to develop services       |
|  | External development<br>of services                 | Service development by<br>cross-functional project teams |
| Service development<br>as a temporary task | Service development<br>as an additional task        | Service development<br>as a main task                    |

Fig. 4: Basic organisational alternatives for the development of smart services

Empirical evidence shows that there is no ideal solution here. Rather, it is a business decision that largely depends on the value that is given to new services and the degree to which the company is prepared to invest in them.

## Roles and responsibilities

The basic anchoring of service development within organisational structures is a strategic decision for the company. Furthermore, the question also arises from an operational level as to which persons should take care of which tasks and which skills are required for this.

The following comments focus, however, on resource planning for service development projects because in practice it is usually necessary to resort to existing resources, and bottlenecks on the human resource side can often arise very quickly. Furthermore, many service development projects are so complex that they typically involve a large number of employees from different parts of the company. What are frequently referred to as role concepts are explained below as a suitable instrument for assigning personnel to development tasks (Bullinger et al., 2003). Role concepts describe the human resource skills necessary to develop a particular service in the form of roles. These roles are defined on the basis of the experience, expertise and skills required to perform each individual task. They do not, however, make any recom-

mendations as to who will actually fill them. A role is characterised by competencies and responsibilities. It is quite possible for one person to be assigned several roles, or for several persons to be responsible for one and the same role.

The fact that the tasks themselves are considered separately from the persons appointed to perform them, make role concepts an extremely flexible planning instrument. Skills and responsibilities can be specified at an early stage, qualification requirements can be estimated and suitable qualification measures initiated. Capacity bottlenecks can be anticipated sooner and, if necessary, new staff taken on in good time.

Role descriptions form the basis for every role concept. They might be structured as follows:

- *Meaningful name:*  
Roles can be given any name depending on the specific requirements of each firm. Possible role names for service development projects could include: project manager, marketing planner, process designer or roll-out manager.
- *Tasks and outcomes:*  
Description of the responsibilities assigned to each role or role owner in connection with service development.
- *Skills:*  
These can be subdivided into various categories, such as technical skills, methodological skills, social skills and media skills.
- *Relationships with other roles:*  
Each role is characterised by relationships with other roles: for example, relationships of a cooperative nature or where one role is considered to be a special variant of another, more general role.

Roles should not be confused with positions. In other words, they are defined solely for the purpose of service development. A 'controller', for instance, does not necessarily have to come from the company's financial controlling department, but simply needs to be someone with the necessary skills in financial controlling to handle the specified project tasks.

The following generic roles (Table 2) could be used for a broad range of service development projects. Nevertheless, it is strongly recommended to adjust the set of roles to the company situation.

| <b>Roles</b>             | <b>Responsibilities</b>   |
|--------------------------|---|
| Project manager          | <p>Schedule project (incl. activities, responsibilities, time-table, milestones)</p> <p>Allocate the required resources to each activity (e.g. persons, tools, equipment)</p> <p>Define of all methods and tools to be used in the project</p> <p>Estimate costs on the basis of available key figures</p> <p>Contract external partners</p> <p>Establish basic reporting for the project</p> <p>Coordinate and supervise all project activities, including initialising the process phases and activities as well as decisions about measures to rectify problems</p> <p>Monitor the project (completion dates, effort, costs and activities)</p> <p>Document of projects activities</p> |
| Marketing manager        | <p>Coordinate customer involvement into the project</p> <p>Support the collection of internal and external requirements</p> <p>Support the price and cost calculations</p> <p>Design and implement the marketing mix (brochures, presentations, publications, trade fairs etc.)</p> <p>Support the collection of feedback from customers and employees</p>  |
| Manager prices and costs | <p>Execute the price and cost calculations of the service</p> <p>Execute the lifecycle cost calculation of the related products</p> <p>Prepare and evaluate make-or-buy decisions</p>   |
| Service product manager  | <p>Analyse current and future markets trends</p> <p>Collect internal and external requirements</p> <p>Support the price and cost calculations</p> <p>Specify and describe the service</p> <p>Plan and execute service tests</p> <p>Document the service</p> <p>Collect feedback from customers and employees</p>  |
| Operations manager       | <p>Plan and implement suitable organisational structures for the service</p> <p>Plan and implement suitable delivery process for the service</p> <p>Determine and provide the operating resources necessary to deliver the service</p> <p>Plan and deliver the required operating resources for the service</p> <p>Define KPI's for the service</p>   |
| HR manager               | <p>Coordinate employee involvement into the project</p> <p>Define roles for the delivery process of the service</p> <p>Identify qualification needs</p> <p>Recruit new staff for the service</p> <p>Plan and organise the training of the staff for the service</p>   |
| Systems manager          | <p>Plan and coordinate IT-related activities of the service</p> <p>Test IT components of the service</p>  |

Table 2: Roles for service development

In many cases, it could also make sense to define customers as a role as well, in particular, if they are directly involved in development projects (e.g. as lead users).

A role concept should be clearly linked to the process-activity model as it is shown for the generic role concept and the process-activity model of the reference framework (see Figure 5).

| <b>E</b> Execute<br><b>S</b> Support<br><b>A</b> Advise | Company requirements | Market requirements | Target pricing & costing | Service concept | Marketing mix | Calculation of prices & costs | Conceptual tests | Market tests | Simulation of prices & costs | Operational measures | Marketing measures | Key performance indicators | Roll-out | Feedback collection |
|---|----------------------|---------------------|--------------------------|-----------------|---------------|-------------------------------|------------------|--------------|------------------------------|----------------------|--------------------|----------------------------|----------|---------------------|
| Project manager   |                      |                     |                          |                 |               |                               |                  |              |                              |                      |                    |                            |          |                     |
| Marketing manager                                       | <b>S</b>             | <b>S</b>            | <b>S</b>                 |                 | <b>E</b>      | <b>S</b>                      |                  | <b>S</b>     |                              |                      | <b>E</b>           | <b>A</b>                   | <b>S</b> | <b>S</b>            |
| Manager prices and costs                                |                      |                     | <b>E</b>                 |                 |               | <b>E</b>                      |                  |              | <b>E</b>                     |                      |                    | <b>A</b>                   |          |                     |
| Service product manager                                 | <b>E</b>             | <b>E</b>            | <b>S</b>                 | <b>E</b>        | <b>S</b>      | <b>S</b>                      | <b>E</b>         | <b>E</b>     | <b>S</b>                     | <b>S</b>             | <b>S</b>           | <b>S</b>                   | <b>S</b> | <b>E</b>            |
| Operations manager                                      |                      |                     |                          | <b>S</b>        |               |                               | <b>S</b>         | <b>S</b>     |                              | <b>E</b>             |                    | <b>E</b>                   | <b>E</b> |                     |
| HR manager  |                      |                     |                          | <b>S</b>        |               |                               | <b>S</b>         | <b>S</b>     |                              | <b>S</b>             |                    | <b>S</b>                   | <b>S</b> |                     |
| Systems manager   |                      |                     |                          | <b>S</b>        |               |                               | <b>S</b>         | <b>S</b>     |                              | <b>S</b>             |                    | <b>S</b>                   | <b>S</b> |                     |

Fig. 5: Role concept and process-activity model

Within a real project the next step would be the definition of the project team, i.e. the assignment of real people to the defined roles. The objective should be that each project member has the skills that are defined in his role descriptions. If not, qualifications measures should be initiated for the project member. Other alternatives could be the outsourcing of project tasks to external partners that have the relevant competencies, or even the recruitment of new staff according to the role profiles.

### 3. Outlook

Smart services offer companies which produce machines and equipment an interesting possibility to develop their service business. The advantages are being able to connect with almost every point on the earth through the medium of the internet without additional interruptions. Above all, internationally active companies offer additional services to their customers which could not be achieved previously. For example, small and medium sized companies which do not have the resources for a comprehensive world-wide presence can now deliver services to their customers like remote monitoring, online documentation and online training sessions.

The challenges which are to be overcome with the development of smart services may however not be underestimated. A service is then perceived as excellent by the customers if the details add up, and even small irregularities in the service process, in customer communication or in information technology can lead to the displeasure

of the customer. As shown, it is recommended that a structured procedure with the development of services should be established in order to secure an efficient, customer oriented process and to avoid possible weak points.

Fig. 6: Internet-based guideline

The reference framework including more detailed descriptions of the single levels will be published on the Internet, so that a broad number of companies could make benefit of it. A first prototype of this online guideline has already been developed (see Figure 6). It will go public at the end of 2015.

## Acknowledgements

The framework described in this document has been conducted as part of the project T-REX (Lifecycle Extension Through Product Redesign And Repair, Renovation, Re-use, Recycle Strategies For Usage & Reusage-Oriented Business Model), research project funded by the European Union Seventh Framework Programme (FP7/2007-2013) under grant agreement no 609005. # Servitization and Productization: two faces of the same coin?

Luna Leoni<sup>1</sup>

<sup>1</sup>“Tor Vergata” University of Rome

*The ongoing convergence and integration between manufacturing and service sectors involves the firms' adoption of new strategies, namely: servitization and productization. Despite servitization having already been discussed in depth by scholars, little has been said on productization. The thematic analysis of 27 peer-reviewed journal articles lead to define productization as the process of transforming a service company offering by adding tangible products or by decomposing service components into combinable modules. Moreover, productization and servitization need to be considered as “two faces of the same coin”, which acting reversely lead to considering the existence of a new company type: the solution provider.*

## 1. Introduction

The companies of our time compete in what has been defined as a “Customer Economy” (Seybold *et al.*, 2001). This means that society is controlled by customers, who exercise their power over all types of firms, reshaping and transforming their businesses. Therefore, *satisfying customers' needs* has become the mission and purpose of every firm.

In order to survive in this new scenario, companies – both product- and service-centred – have to reinvent themselves and their offering in a way that allows the complete fulfilment of customer needs.

The alignment between *company offer* and *customer needs* involves a profound organizational culture transformation; because for customers it no longer makes sense to distinguish between tangible and intangible goods, the same has to become true for companies. Obviously, a firm's cultural shift requires a strategic change. Evidence of this is the development and dissemination of two new strategies, namely: *servitization* and *productization*, adopted by product-centred and service-centred companies, respectively.

Despite servitization having already been discussed in depth by scholars – starting from the milestone paper written by Vandermerwe and Rada in 1988 – there has been little discussion about productization. Thus, as it is becoming increasingly difficult to ignore the ongoing convergence and integration between manufacturing and service sectors, a deeper understanding of the productization strategy seems to be necessary.

Therefore, the purpose of this paper is to address the following research questions:

RQ1: How is productization defined in the existing academic literature?

RQ2: Can productization and servitization be considered as “two faces of the same coin”?

For the sake of clarity, it is important to highlight that a literature review on productization has already been conducted by Harkonen *et al.* (2015). However, the different aims and methods adopted limit the risk of the results overlapping.

Through a thematic analysis of 27 journal articles (identified by a systematic literature review), this paper aspires to move forward the body of knowledge on productization, while at the same time contributing to the servitization field.

Following this introduction, the paper has been divided into five sections: the first explains the methodology adopted; in the second section the descriptive findings are reported; the third section is devoted to the thematic analysis; in the fourth section, discussions, conclusions, implications and future research avenues are jointly presented.

## **2. Methodology**

Having regard to the aim of this paper, this study is founded on a systematic literature review (SLR). This method – widely used in management literature (Crossan and Apaydin, 2010; Newbert, 2007; David and Han, 2004) – differs from traditional narrative reviews (Huff, 2009; Cooper, 1998) and can be considered the most suitable research approach in order to identify, review, and synthesize – in a transparent and rigorous way – all the literature currently available (Victor, 2008) on the productization topic.

The research process has been carried out following the three steps suggested by Tranfield *et al.* (2003), namely: planning, conducting and reporting. The first step has been devoted to the scope definition and protocol development. The conducting and reporting steps are, instead, accurately described in the next paragraph. In particular, the reporting phase has been divided in two sub-stages:

1. A descriptive analysis: to provide, through the use of graphics, simple summaries of the relevant literature (Sandelowski, 2000); and
2. A thematic analysis: to identify key themes between papers, in order to provide the major findings of the systematic literature review.

### **2.1. Search strategy**

In order to identify the relevant literature related to productization, the search strategy was developed by first choosing the online research databases: i.e., “EBSCOhost”, “Scopus”, and “Web of Science”.

During the second phase, and according to their direct association with the topic analysed, the keywords were identified. To avoid the possibility of losing significant articles, all the possible grammatical forms and spelling differences of “productization” were considered.

The selected keywords within the chosen online databases allowed the identification of 788 papers.

In the third phase specific inclusion and exclusion criteria were applied (see Table 1).

| Inclusion criteria                           | Exclusion criteria   |
|--|--|
| Articles published in peer-reviewed journals | Articles containing the keywords only in the list of references or in the biographies    |
| Articles written in English                  | Articles dealing accidentally with the selected topic                                    |
| Articles published until December 2014       | Articles showing a poor awareness of existing literature and/or a flawed research design |

**Table 1. Inclusion and exclusion criteria.**

Moreover, the research results have been further refined considering the “document type” and “subject area” of the papers that were found. In particular, the former limit allows considering only “articles and reviews”, while the latter limit helps to refine the results coming from the following areas: “business, management and accounting”, “decision sciences”, “social sciences”, “economics, econometrics and finance”, and “environmental science”. Through the application of these restriction criteria, 307 potentially relevant articles were identified.

In the fourth phase, after removing any duplicates, the abstracts of all the articles were reviewed to ensure their relevance to the research goal. Careful reading of the abstracts resulted in the selection of 34 articles.

In the fifth phase, the full text of all the papers selected through the previous screening was read, corroborating the articles’ relevance to the research questions and aim. In particular, for determining the articles’ substantial relevance, the fit for purpose approach of Denyer *et al.* (2008) was adopted. Indeed, the dataset includes only those articles that were directly relevant to the research inquiry; this yielded a total of 24 papers.

Finally, both reference and citation tracking (i.e., the snowballing technique) were applied. The former requires scanning and crosschecking the list of all the 24 previously identified papers, while the latter identify articles that had cited those papers (Greenhalgh and Peacock, 2005). The first approach works back in time from the article, whilst the second approach works forward in time from that article, but both are useful in order to ensure that any other possible relevant publications were also captured. This allowed for the conclusive identification of a final dataset composed of 27 relevant articles.

The review procedure is summarised in Table 2.

| Phase         | Description                                    | Articles |
|---------------|--|----------|
| 1             | Selection of databases                         | 788      |
| 2             | Identification of keywords                     |          |
| 3             | Application of restriction criteria            | 307      |
| 4             | Removal of duplicates and reading of abstracts | 34       |
| 5             | Full-text reading                              | 24       |
| 6             | Snowballing technique                          | 3        |
| Final Dataset |  | 27       |

**Table 2.** The systematic literature review process.

In line with Tranfield *et al.* (2003), the 27 identified articles have been deeply analysed through descriptive and thematic analyses, discussed in the following two sections.

### 3. Descriptive analysis

The descriptive analysis – through the use of graphics – offers a snapshot of the subject being studied, by simply summarizing the relevant literature (Sandelowski, 2000).

In particular, the 27 articles identified through the SLR have been analysed according to the year of publication, journal distribution, geographical distribution, and authors' contribution. Each category is hereafter discussed.

#### *Articles by year of publication*

Productization literature could be considered as in a nascent stage, and the publication trend – illustrated in Figure 1 – is proof in this sense.

**Figure 1.** Time-line distribution of the papers.

In fact, starting from Levitt's paper, in 1972, it is only in 2011 that the academic interest towards productization shows any real expansion, reaching a peak of six publications in that same year. Despite this, in 2012 the trend starts to decline, until reaching only a single specific publication on the topic in 2014.

The scarcity of publications is not attributable to any specific explanation. For the sake of completeness, it is necessary to point out that there is much “grey literature” (i.e., academic literature that is not formally published, such as theses, conference proceedings, etc.) on productization (as demonstrated by the number of papers found in the first phase of the literature review process showed in Table 2). However, the rigorous methodology applied and the author's intention of ensuring the analysis is of a high quality grade, do not allow the inclusion of literature that has not been formally published.

#### *Articles by source*

Even though the productization literature is scarce, the subject is treated by scholars of different disciplines, therefore determining the involvement of 19 different journals for the 27 published articles (see Figure 2).

**Figure 2. Journal distribution of the articles.**

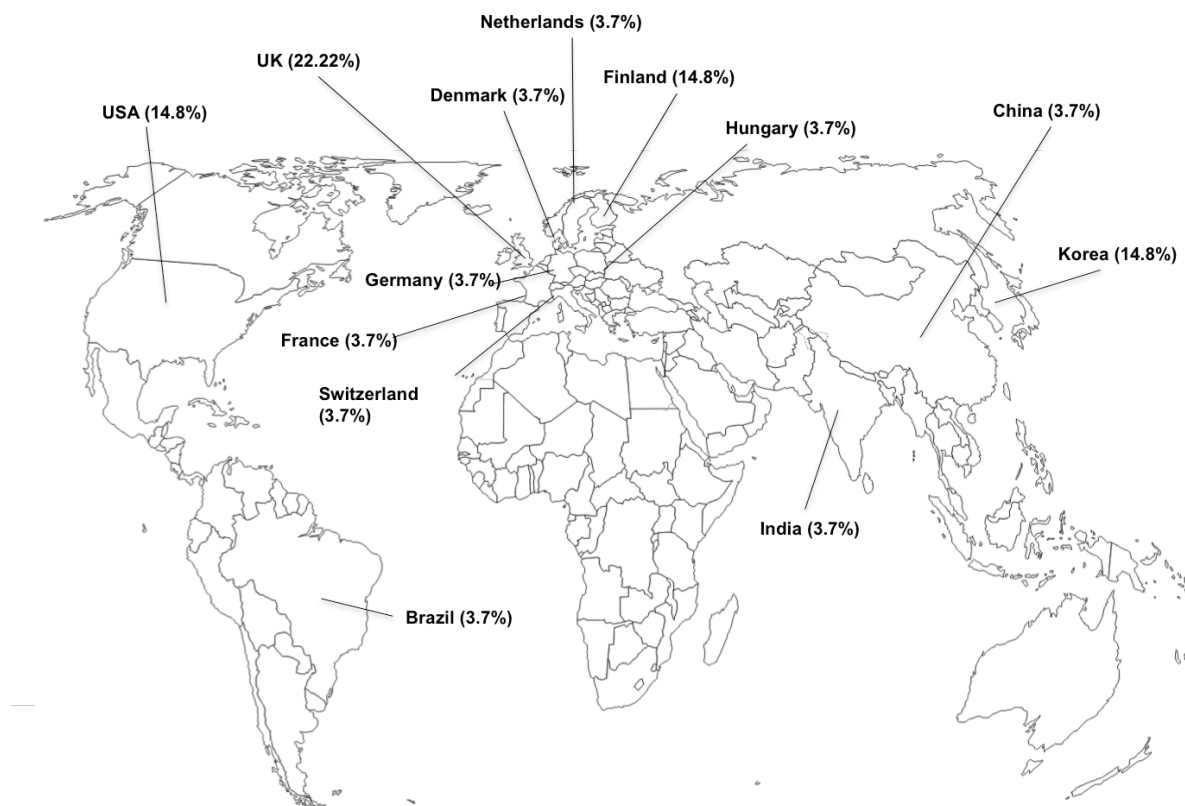

The different research fields (e.g., management, marketing, engineering, technology, etc.), in various ways are involved in the study of the phenomenon, let us therefore assume that the same will develop not only extensively but also comprehensively in the foreseeable future.

However, it is surely not a coincidence that the journal containing the highest number of publications is the *International Journal of Production Research*.

#### *Articles by country*

Not only many different journals but also a wide range of countries seem to be involved in the articles being published on productization.

Figure 3 shows a world map with the indication (given in percentages) of the number of publications from the various countries. The origins of the journal articles have been determined by the first author's affiliation.

**Figure 3. Country distribution of the papers.**

The largest proportion of journal articles that refers to productization (almost 60%) were produced in Europe, while another 22% originates from Asia, and the remainder from America. The most involved country is the UK (more than 22% of articles) followed by Finland, Korea and the USA on a par (with almost 15% of articles).

#### *Articles by author(s)*

The last point is devoted to a descriptive analysis of the productization literature that deals with the number of authors that have contributed to the topic development.

A total of 79 different authors published articles on productization. Of these, only four authors appear in more than one contribution. They are: Durugbo, Geum, Lee S., and Park. In particular, Durugbo appears in two articles, one as sole author and one as first author. Geum, Lee S. and Park published, as co-authors, two articles (in both cases with Geum as first author). Finally, Geum and Park published together another article (in which, however, Park is the first author).

Also this last point – the absence of ‘leader author(s)’ – confirms what has been already said, namely that the productization literature is still in a nascent stage.

## 4. Thematic analysis

The main findings of this SLR emerge through the application of a thematic analysis approach to the dataset.

The thematic analysis approach allows an author to accurately describe a phenomenon (Daly *et al.*, 1997) and consists of the identification of common themes through “careful reading and re-reading of the data” (Rice and Ezzy, 1999, 258), “where emerging themes become the categories for analysis” (Fereday and Muir-Cochrane, 2006, 82). According to Braun and Clarke (2006), it is performed through six different phases: 1. familiarization with data, 2. generating initial codes, 3. searching for themes among codes, 4. reviewing themes, 5. defining and naming themes, and 6. producing the final report.

Due to the aim of this paper, the systematic theme’s development has been performed through the inductive (data-driven) approach (Boyatzis, 1998), according to which codes are derived bottom-up throughout the researcher’s reading of data.

Hence, through the codes that emerged, four themes have been identified and are hereafter presented and discussed. Table 3 shows the corresponding references for each theme, highlighting the contribution of each item to the subject through the use of a 3-points asterisks range (\*=little contribution; \*\*=medium contribution; \*\*\*=strong contribution).

| Author(s)                      | Themes                  |              |                         |                          |
|--------------------------------|-------------------------|--------------|-------------------------|--------------------------|
|                                | Defining productization | Case studies | Productization features | Link(s) to servitization |
| Levitt (1972)                  | **                      | **           | **                      | **                       |
| Vandermerwe and Rada (1988)    | ***                     | *            |                         | **                       |

**Table 3. Key themes identified in the productization literature.**

## 4.1. Defining Productization

In order to understand the productization concept, the first theme has been devoted to the analysis of the different definitions given in the literature.

In the analysed literature, it is possible to find the first direct reference to the term productization in Flamholtz (1995, 42) who describes it as “the process of analyzing the needs of current and potential customers in order to design the products or services that will satisfy their needs” and it “includes not only the design of a product (defined here to include services as well), but also the ability to produce it”. This definition can be linked up to the claims by Vandermerwe and Rada (1988, 136), who – although not explicitly referring to the term productization – state that “the classic service companies [...] began to use more product to facilitate and deliver their services and take more control in the design specification of the products used to produce and deliver these services”.

After more than ten years, productization has been redefined by Baines *et al.* (2007, 4) as “the evolution of the services component to include a product or a new service component marketed as a product”. Since then different authors have also referred to it (e.g., Park *et al.*, 2012; Beuren *et al.*, 2013).

Authors such as Chattopadhyay (2012), Valminen and Taivonen (2012), and Nagy (2013) describe productization as the process of making the service offering more product-like through a systematization of its different components.

Nevertheless, there are other terms directly associated with productization. These are:

- “Technocratic thinking” (Levitt, 1972): in order to improve the services quality and efficiency, services companies must consider themselves to be manufacturers;
- “Modulization/modularization” (Sundbo, 1994; Ritala *et al.*, 2013): services are standardized through the creation of specific modules (one for each element of the services), which could be differently combined, depending on the customers’ needs;
- “Commodisation/commodification”: these terms originate from the consideration that ‘ideas’ could be marketed and consumed (Fincham, 1995; Heunsinkveld and Benders, 2005). In this vein, Ukko *et al.* (2011, 127) state that “productisation is a process in which an idea is developed into a marketable entirety that has highly standardised and well documented production phases and product elements”; and
- “Tangibilizing” (Reddy *et al.*, 1993; Jaakkola, 2011): the creation of a physical image of the service offering by adding to it some physical evidences.

Despite the different definitions and terms presented in the literature, they have different but common points that lead towards answering the first research question, and converging towards a more complete and detailed definition.

RQ1: How is productization defined in the existing academic literature?

*A1: Productization is the process of transforming a service company offering by adding tangible products to core services or by decomposing service components into combinable modules, with the aim of fulfilling customers' needs and improving service quality and efficiency.*

## 4.2. Case studies

The case study methodology is widely used in the productization literature and is devoted to the analysis of different types of companies (e.g., Davies *et al.*, 2007; Chattopadhyay, 2012; Alter, 2012; Valminen and Toivonen, 2012; Durugbo, 2014).

Sometimes cases are not deeply explored within a paper but they are presented as successful examples of productization practices (e.g., Levitt, 1972; Vandermerwe and Rada, 1988; Sundbo, 1994). Moreover, some of the cases analysed do not mention the company name, only its business sector (e.g., Chattopadhyay, 2012; Alter, 2012; Valminen and Toivonen, 2012; Ritala *et al.*, 2013; Durugbo, 2014).

An overview of the key examples is provided in Table 4.

| Company                           | Source  | Field                   | Productization process  |
|-----------------------------------|---|-------------------------|---|
| Atkins                            | Davies <i>et al.</i> (2007)                                   | Consultancy             | It moves into integrated solutions becoming a systems integrator of externally supplied product components.   |
| ATM (Automated Teller Machine)    | Geum <i>et al.</i> (2011a)<br>Geum <i>et al.</i> (2011b)      | Bank                    | The use of technology to the banking system allows its automation, which evolved until becoming a self-service offering (production and consumption do not need to be simultaneous any more). |
| Cable and Wireless Global Markets | Davies <i>et al.</i> (2007)                                   | Telecommunications      | In their offering there were also product components (supplied by external manufacturers) and network facilities (provided in-house).   |
| Danish ISS                        | Sundbo (1994)   | Cleaning                | The internationalization has been possible because the 'cleaning service concept' has been made recognizable through the standardization of some components.                                  |
| DHL                               | Vandermerwe and Rada (1988)                                   | Logistics               | In addition to core services, they offer a high quality telex and laser-printing bureau. They designed their own computer and telecom network in order to track the parcels movement.         |
| Hilton                            | Sundbo (1994)   | Accommodation           | Internationalization has been possible because the 'hotel service concept' has been made recognizable through the standardization of some components.   |
| McDonald's                        | Levitt (1972)<br>Vandermerwe and Rada (1988)<br>Sundbo (1994) | Food                    | It industrialized its processes, making them highly structured and repetitive.  |
| McGraw Hill                       | Vandermerwe and Rada (1988)                                   | Printing and publishing | Customers have the possibility to mail order diskettes because core elements of services have been standardized.  |

**Table 4. Companies examples of productization.**

The case studies allow considering different aspects related to the productization, both in terms of theory and practice.

First of all, it is interesting to note that only one unsuccessful case is presented in the literature, i.e., Cable and Wireless Global Markets: “It was unable to force its internal regional business units to relinquish control of profitable corporate accounts and faced strong competition from major systems integrators” (Davies *et al.*, 2007, 190). This leads to two possible considerations: 1. The productization process is (almost) always a successful strategy; or 2. The literature lacks a deep analysis of the phenomenon. Considering the relatively young age and paucity of contributions related to productization, it is possible to consider as valid the second assumption.

Secondly, McDonald's, ATM and small-KIBS (Knowledge Intensive Business Services) companies are those most considered by authors when referring to productization practices. Thus, leading practices in the adoption of productization can be found both in small and large companies. This can be considered a clear sign of how all service companies – whatever their size – recognize the need to make changes to their offering. Moreover, the fact that even small businesses are able to put in place productization strategies might suggest that this process does not require huge monetary investments. Unfortunately, the lack of quantitative studies in the literature (devoted to the measurement of costs linked to this practice) does not provide answers; although this does offer a great opportunity for future research development.

### 4.3. Productization features

Despite productization literature not having been extended so far, it is already possible to identify some specific features, together with their mutual relations.

The adoption of a productization strategy by a service firm implies the creation of a ‘new service offering’. According to Ritala *et al.* (2013), this involves two phases: a) service-offering visualization, and b) service-offering modelling and modularization. In order to perform these phases, Jaakkola (2011, 224) suggests “three key practices: (1) specifying and standardizing the service offering, (2) tangibilizing and concretizing the service offering and professional expertise, and (3) systemizing and standardizing processes and methods”. The adoption and implementation of these practices inevitably produce changes in ‘*the way of being and doing*’ of the company. Such changes could be facilitated by the adoption of technology. In particular, if the new service offering includes tangible products, technology can act as an interface between them – especially in the design phase (Geum *et al.*, 2011a and 2011b). Moreover, “the increased use of technology has the consequences that service production becomes more like manufacturing” (Sundbo, 1994, 253), and this occurs both with hard and soft technologies (Levitt, 1972). Once the new service offering has been developed, the efficiency and success (Valminen and Toivonen, 2012) of the productization strategy depends on the “firm’s success in defining its market segment and potential niche” (Flamholtz, 1995, 42). The correct formulation both of the new offering and the competitive positioning is reflected – with a positive effect – on firm performance. Productization benefits have been clearly stated by Chattopadhyay (2012, 198): “Service companies attempt Productisation of service for improving competitiveness and performance. Defining, systematizing and concretizing a service make its production more profitable and efficient. When the production process is well defined, the quality of the service becomes more stable. In addition, the possibilities to

accumulate knowledge systematically are improved. Productisation often intensifies the transfer of knowledge and enables the division of work. Finally, Productisation makes the pricing of the service easier". Obviously, achieving these results is positively and inevitably reflected in the customers' satisfaction and loyalty.

Each aspect encompassed in this theme, due to its importance, need to be further and deeply explored in the future.

#### 4.4. Link(s) to servitization

In order to answer the second research question, the last themes collect all the articles in which it was possible to identify links between productization and servitization. In particular, it is interesting to point out that connections have been found in 18 journal articles (out of 27), corresponding to 67% of the literature analysed. This preliminary finding allows the author to state that productization and servitization are strictly related but the existence of the link is not sufficient to determine if productization could (or not) be regarded as the opposite approach of servitization. Thus, the 18 articles included in this last theme have been fully and deeply explored.

First of all, in the academic discussion it is possible to identify three levels of convergence; i.e., between sectors (service and manufacturing), offerings (services and products), and strategies (productization and servitization). Table 5 shows the corresponding authors for each convergence level, with related statements.

| Level of convergence | Author(s)                    | Statement   |
|----------------------|------------------------------|---|
| <b>Sectors</b>       | Levitt (1972)                | "they [service companies] must think of themselves as performing manufacturing functions [...] only then will they begin to make some significant progress in improving the quality and efficiency of service" (p. 42)            |
|                      | Vandermerwe and Rada (1988)  | "manufacturers and service companies are thinking and behaving like one another" (p. 321)   |
|                      | Sundbo (1994)                | "similarities between the organizational forms of the firm in the two sectors" (p. 261)   |
|                      | Wang <i>et al.</i> (2011)    | "the traditional boundary between manufacturing and services is becoming increasingly blurred" (p. 6865)  |
| <b>Offerings</b>     | Gallouj and Savona (2009)    | "the boundaries between goods and services become more blurred" (p. 162)  |
|                      | Clayton <i>et al.</i> (2011) | "the consideration of the product and service as a single offering" (p. 2)  |
|                      | Geum <i>et al.</i> (2011a)   | "integration of products and services has been a matter of grave concern for both manufacturers and service providers" (p. 129)   |
|                      | Nagy (2013)                  | "services will increasingly behave as physical products [...] in contrast, physical products incorporate more services than before" (p. 103)  |
| <b>Strategies</b>    | Aurich <i>et al.</i> (2009)  | "servitization of this product [...] reverse approaches implementing productization of services" (p. 593)   |
|                      | Alter (2012)                 | "ideally, servitizing should be treated symmetrically with productizing" (p. 27)<br>"servitizing and productizing should be viewed as opposite strategy directions" (p. 29)   |
|                      | Kim and Yoon (2012)          | "many manufacturers [...] are trying to change their business model through servitization [...] similarly, service providers are also making efforts to deliver high quality of services to customers by productization" (p. 324) |
|                      | Durugbo and Riedel (2013)    | "servitization closely connects and integrates services with offered products for servitized products, whereas productisation does the reverse for offered services" (p. 599)   |
|                      | Durugbo (2014)               | "servitization [...] and productization that does the reverse" (p. 2885)  |

**Table 5. Levels of convergence in the academic discussion.**

The link between productization and servitization has been recognized by scholars and can be regarded as the result of the existing correlation and convergence between service and manufacturing sectors, on the one hand, and services and product into a single offering, on the other.

The above-mentioned integration between services and products into a single offering entails also taking into account a part of the studies dealing with the product-service system (PSS) concept. In particular, the existence of a link between the three research communities (i.e., productization, servitization, and PSS) can be noted by examining these concepts' definitions:

- Servitization: “bundles consisting of customer-focused combinations of goods, services, support, self-service, and knowledge” (Vandermerwe and Rada, 1988, 316);
- Product-service system: “a marketable set of products and services capable of jointly fulfilling a user’s need” (Goedkoop *et al.*<sup>1</sup>, 1999, 18);
- Productization: the process of transforming a service company offering by adding tangible products to core services or by decomposing service components into combinable modules, with the aim to fulfil customers’ needs and improve service quality and efficiency.

The three definitions have two important common points: 1) creating an offering that simultaneously combines products and services; and 2) creating an offering that will satisfy customers. In this sense, the assumption of Baines *et al.* (2007) and Beuren *et al.* (2013), which considers PSS as a special case of servitization, seems not to be valid any more. The PSS concept cannot be restricted to manufacturers’ offering; it also seems usable for service companies (e.g., Clayton *et al.*, 2011; Kim and Yoon, 2012). On the other hand, it can be useful to define new terms, as Park *et al.* (2012) do. They define “integrated product-service” (IPS) as “any offering in which products and services are integrated, regardless of its type(s), objective(s), and feature(s)” (p. 529).

The verified relationship among the three research communities also reinforces the already verified lack of literature specifically dedicated to productization. In this sense, it is worth noting that of the 18 papers considered within this theme, only two are exclusively devoted to productization (i.e., Chattopadhyay, 2012 and Valminen and Toivonen, 2012).

Moreover, by analysing only the articles that jointly consider productization and servitization, it is possible to identify which kind of relationship scholars recognize between the two concepts. The adjective most used to describe this relationship is “reverse” (Aurich *et al.*, 2009; Durugbo and Riedel (2013); Durugbo, 2014). Thus, productization is seen as the exact opposite of servitization, and this answers the second research question.

<sup>1</sup> The article by Goedkoop *et al.* (1999) is not included in the 27 journal articles derived from the SLR. It has been cited here due to its importance to the context.

*RQ2: Can productization and servitization be considered as “two faces of the same coin”?*

*A2: Productization and servitization can be considered as “two faces of the same coin”. In particular, positioning manufacturers and service companies at the far ends of an imaginary continuum, servitization and productization strategies acting reversely lead to the convergence of firms’ offering and sectors.*

## **5. Discussion and Conclusion**

This study set out with the aim of assessing the importance of productization practice in the modern economy.

The application of a thematic analysis to 27 journal articles – derived from a systematic review of the literature on the topic – allows us to clearly define the productization concept and its relationship with servitization.

In particular, productization has been defined as the process of transforming a service company offering by adding tangible products to core services or by decomposing service components into combinable modules, with the aim of fulfilling customers’ needs and improving service quality and efficiency. Moreover, productization and servitization can be considered as “two faces of the same coin”, which acting reversibly lead to the convergence between manufacturers and service companies.

The overall understanding and specific findings of this research have both practical and theoretical implications.

Firstly, the analysed journal articles show that the productization concept is still not well established within academic discussion, so much so that it is not possible to identify a specific research community dealing with this topic. More productization-specific studies are needed and significant work remains to be undertaken.

Even though a wide range of future research questions can be posed, there are at least three specific aspects that – more than others – need to be addressed:

- Customer role (e.g., changes to customer participation in the offering creation);
- Design issue (e.g., engineering aspects related to the practical combination of tangible and intangible goods); and
- Guidelines (tools and techniques) for managers (e.g., empirical investigations in order to provide best practices).

Secondly, the conducted research seems to suggest the existence of a new type of firm, namely the solution provider, shown graphically in Figure 4.

**Figure 4. The solution provider firm.**

Both manufacturing and service companies are facing important transformation processes, in order to maintain a successful competitive position. This requires the implementation of new strategies and changes in the offering provided. Practically: the application of servitization and productization processes by product- and service-based firms, respectively; and the simultaneous presence of tangible and intangible goods into a single offering. Therefore, it is possible to state that firms have to provide *solutions* (the main purpose of the new offering is to solve a consumer's problem, regardless of what it is). Servitization and productization strategies perform this task. Along the axis, each level of service/product infusion generates a new offering capable of fulfilling a specific customer requirement.

As a result, achieving a successful competitive position will be possible only through the creation of a balanced mix of products and services according to the customer expectations.

Although this study has been conducted in a rigorous manner, it contains several limitations, and – as with all research methods – is susceptible to critical observations. Limiting sources to peer-reviewed journals – even though increasing the validity of the investigated articles – does not allow for the exploration of the contribution on productization available in other publication media. Moreover, the adopted inclusion and exclusion criteria, together with the selected keywords, may also have influenced the results.

Due to the extensive search possibilities still open, the increased knowledge on productization topic gained through this study represents only the first step towards a deeper and more complete understanding of the phenomenon.

# Standardizing the service delivery system for repetitive industrial services

*Elina Poikonen<sup>1</sup>, Miia Martinsuo<sup>2</sup>, Sanna Nenonen<sup>3</sup>*

Tampere University of Technology

*Manufacturers need to develop efficient service deliveries that can be used for multiple customers with different equipment. The service delivery system can support service repetitiveness through standardization. The objective is to increase understanding on features and requirements of standardization in the service delivery system and identify means for efficient service delivery in triadic settings. The qualitative multiple-case study with three manufacturing firms reveals different relevant factors for standardization for reactive and proactive services and highlights certain practices in triadic customer participation. Equipment and remote technologies both challenge and enable standardization and require new competences.*

## 1. Introduction

In order to produce industrial services efficiently for multiple customers with multiple pieces of equipment including different technologies, a manufacturing company has to develop its service delivery system carefully. According to Roth and Menor (2003) different service concepts and markets require different management and service design approaches. They propose a framework for studying service operations management issues (Roth; Menor, 2003). This framework enlightens the critical aspects in service delivery systems. Ponsignon et al. (2011) have used this framework to develop service delivery system design characteristics and contingencies.

The efficiency of a service delivery system requires that the system is standardized at some level. Standardization in service delivery means the use of generalized processes to multiple customers and services with little or no customization. It also refers to the means companies use to systematize their service deliveries. Standardization may imply a tradeoff between customer satisfaction and efficiency. The challenge is to manage service quality and productivity at the same time (Wang et al., 2010).

Competitive performance includes outcomes of cost, quality, flexibility and cycle time (Jacobs et al., 2007), and standardization can be a means to improve these performance measures. Service process designs, service modularization, and e-service systems have been studied both in industrial and knowledge-intensive service contexts already (Carlborg; Kindström, 2014). Even if service repetitiveness for diverse customers is a priority to suppliers, previous research has not covered standardization in service delivery systems sufficiently.

As industrial service business becomes global, the complexity of customers' demands in multiple channels increases and the entry of nontraditional competitors in

markets are possible (Roth; Menor, 2003). For example a supplier may enter into competition with its customers in service business, if it takes increased responsibilities as part of customers' processes. Customers' needs have become more heterogeneous and diversified (Bask et al., 2011). Also the service deliveries are more complex and there are multiple parties involved. Companies have to be able to manage the service delivery system, including various structural, infrastructural and integration choices (Roth; Menor, 2003).

When moving towards service business, the supply chain often changes into a network. A triad, i.e., collaboration of three companies, is the smallest example of this network setting (Choi; Wu, 2009). By examining triads the relationships between different players and their power positions can be researched. The understanding of a supply network phenomenon has been limited by the lack of empirical evidence of managing different triads (Peng et al., 2010). In particular, there is a research gap concerning the service production to end users in service triads. More knowledge is needed on how industrial companies can promote industrial services towards customers in a triadic setting with third parties such as equipment dealers and logistics providers. In this research we are examining how a manufacturing firm acts in a triad and how it can promote service production for end customers.

The purpose of this study is to examine the standardization of service delivery systems when producing industrial services to customers in a multi-equipment environment. The goal is increased understanding on features and requirements of standardization in the service delivery system, and particularly manufacturing firms' roles in service triads in such systems. The research analyzes the need for standardization caused by multiple customers, multiple pieces of equipment and multiple technologies embedded in the equipment. The study focuses on three research questions:

- 1) What are the critical features requiring standardization in manufacturing firms' service delivery systems?
- 2) How do manufacturing firms manage customer participation and end-customer information in service production?
- 3) How do manufacturing firms use technology to promote service delivery system standardization?

The study is focused on manufacturing firms and their service delivery systems towards customers in global, industrial settings. The settings are characterized with complexity: each piece of equipment is unique, the customers are multi-equipment and multi-service users, and various third parties may be involved, including dealers, external service providers, and software firms.

## **2. Literature review**

Service sector grows fast and many manufacturing companies are transforming their business towards service-dominant logic. This means that the nature of value creation transforms. Producers and customers do not have separate roles anymore but they are co-creating value in their interactions (Vargo; Lush, 2008). The customer value does not depend merely on the main product anymore. The relationships be-

tween the supplier and customer in order to ensure the product's effective use are also affecting the customer value. (Grönroos, 2011)

The configuration and design of the service delivery system is the way to provide the target customers the service concept and the value proposition. This part of the service business' competitiveness is contingent (Verma et al., 2002; Johnston; Clark, 2005). To achieve expected levels of performance in overall profitability and customer satisfaction, an alignment has to be found between target market, service concept and service delivery system design (Ponsignon et al., 2011; Roth; Menor 2003).

According to Roth and Menor (2003), companies need to consider their strategic choices in target market, service concept and service delivery system design that are linked with each other through service encounters. The target market is related to selecting the right customer. The service concept consists of two parts: core service and peripheral services. The peripheral services supplement the core service and offer additional benefits that add value for the customer. The service delivery system is the process how the service is delivered to the customer. (Roth; Menor, 2003) It includes for example the technology, equipment, procedures, people and management that are needed in the service delivery (Heskett, 1987). The focus of this study is in service delivery systems.

## **2.1. Service delivery system design**

In the design of service delivery systems, the extant literature emphasizes the role of technology, people, equipment, facilities and layout, location, and processes and procedures (Heskett, 1987). Ramaswamy (1996) discusses the matter in a more general way. He proposes that the service delivery system design choices are related to the service delivery processes and the facilities where the service is produced. Roth and Menor (2003) divide the strategic service delivery system design choices into three aspects: structural, infrastructural and integration choices. The structural choices relate to facilities and layout, equipment and technology, and service product-process interfaces and capacity planning. The infrastructural choices concern such issues as practices, people, performance systems, policies and processes. Finally the integration choices relate to operations coordination and organization, service supply chains, learning and adaptive mechanisms, and integration technologies. (Roth; Menor, 2003)

Ponsignon et al. (2011) have used Roth and Menor's service strategy framework in an empirical study with a market leading electricity supplier in UK. As a result they propose service delivery system design characteristics and contingencies. The nature of the target market and the service concept affect the service delivery system design. Customer requirements can either be heterogeneous or homogeneous. The service concept can be highly customized or standardized. It can be typified by contract with configurable parameters and the nature of customer relationship. For example level of technical and interpersonal skills, potential of automation, level of employee discretion and routineness can be higher or lower depending of the nature of the target market and service concept. Also the delivery process is affected and it can be either decoupled or coupled. (Ponsignon et al., 2011)

An important part of service delivery is the supplier's cooperation with subcontractors and various other parties. The service supply chain is a network of suppliers, service

providers, consumers and other supporting units that performs transaction functions of the resources needed in the service production. It also performs the service deliveries and changes the resources into core and supporting services. (Baltacioglu et al., 2007) According to Ellram et al. (2004) service supply chain management is process, information, service performance, funds and capacity management throughout the whole chain. Service supply chain management is a critical aspect to ensure the efficiency and the profitability of service production. Services also differ from products in such ways that traditional supply chain management has to be revised to meet the requirements services cause.

## **2.2. Standardization of service processes and supply chains**

When a company produces services to multiple customers in a multi-equipment environment, standardization of the service delivery system is needed to some extent. Some important issues in service delivery system standardization can be found from previous research. A summary of relevant previous research is shown in Table 1, and key issues are discussed further.

*Formalization vs. flexibility in service processes.* Wemmerlöv (1990) and Carlborg and Kindström (2014) divide service processes into rigid and fluid processes. According to Carlborg and Kindström (2014) the rigid processes are standardized and they do not require a high level of information exchange between the customer and the supplier or technical skills. The rigid processes are also highly centralized and formalized. The fluid processes on the other hand are customized and a high level of information exchange and technical skill are required. Also Ostrom et al. (2010) propose same kind of classification. According to them services can be designed to be flexible, dynamic and created together with the customer or rigid, standardized and produced without customer participation. However, in many cases the suppliers customize their services even though they have a modular service portfolio. This kind of behavior complicates the standardization of service delivery system. Nevertheless in order to be efficient, the supplier should aim to standardize its service processes to some extent.

*Service concept and process modularity.* Earlier research has already shown that service concepts may be highly standardized, whereby the customer-specific delivery of services may be supported through the use of modular service components (Jacobs et al., 2007). Roth and Menor (2003) divide the service concept into core service and peripheral services. The core service has five elements: supporting facilities, facilitating information, facilitating goods, explicit services and implicit services. The peripheral services are supplementary to the core service and they offer additional value-adding benefits for the customer (Roth; Menor, 2003). When a company creates new services in addition to their core product business, they have to balance meeting of the customer needs and acceptable level of service development efficiency (Carlborg; Kindström, 2014). As customer needs are becoming more diversified and heterogeneous, this may hinder the balancing of those aspects (Bask et al., 2011). Modularization can be used to manage the balance between the customer needs and efficiency.

In modularization an object is divided into components. These modules then can be combined differently and thus create customizable offerings (Carlborg; Kindström, 2014). In service business there is often a process point of view into services. When

using this viewpoint, service is a mixture of physical and non-physical elements. Different customer-specific configurations can then be created by integrating these elements. (Davies et al., 2007; Pekkarinen; Ulkuniemi, 2008)

Table 1: Summary of previous research and its gaps concerning standardization in industrial service delivery systems.

| <b><i>Viewpoint to standardization and key sources</i></b>   | <b><i>Key conclusions; possible gaps</i></b>   |
|--|--|
| <b>Formalization vs. flexibility in service processes</b><br>Wemmerlöv, 1990<br>Carlborg; Kindström, 2014<br>Ostrom et al., 2010<br>Carlborg; Kindström, 2014<br>Yu; Zhang, 2008 | Services can be designed to be flexible, dynamic and co-created with the customer or rigid, standardized and produced by the supplier only.<br>Flexible service processes cause requirements for technical skills and tasks vary highly, rigid service processes are highly formalized and task variety and the level of technical skills are low.<br>Industrial service process is related to the production planning, customer demands and maintenance demands. Because predicting the exact sequence of a service process is often impossible, the process must be flexible in order to be able to answer changes in the three aspects.<br><i>Gap: How can co-created service processes be standardized to increase efficiency?</i>   |

It has three main parties: the supplier, the service provider and the consumer.<br><i>Gap: How can understanding the service supply chain ease standardization of the delivery related processes?</i> |
| <b>Customer participation</b><br>Carlborg; Kindström, 2014<br>Xue; Harker, 2002<br>Tuunanen; Cassab, 2011  | There are three different production modes: firm production, customer production and joint production.<br>Customer participation in service production has mainly been viewed as minor and supplementary.<br>In a few existing studies that have usually an internal supplier-oriented point of view, the customer's co-producing role is often neglected.<br><i>Gap: How does customer participation affect the service delivery system and how can it be managed?</i>  |

*Supply chain reference models.* Consulting firms and information system providers have developed various modular reference guides to promote the design of standardized product and service processes in companies. Ellram et al. (2004) combine the SCOR (Supply Chain Operations Reference) model and the GSCF (Global Supply

Chain Forum) framework to create a service supply chain model. The SCOR model is a tool for charting supply processes and activities. The GSCF framework conceptualizes supply chain through three features: the structure of the chain, the management components and the business processes. (Croxtan et al., 2001) Ellram et al.'s service supply chain consists of five main parties. These are supplier, purchasing, internal user(s)/stakeholders, finance and ultimate customer. The management issues through the chain relate to service delivery, capacity, customer relationship, supplier relationship, demand and cash flow. (Ellram et al., 2004)

Baltacioglu et al. (2007) introduce a framework for service supply chains called the IUE-SSCM (Izmir University of Economics Service Supply Chain Model). The IUE-SSC model is based on the SCOR model and Ellram et al.'s model. It has three main stakeholders in the service supply chain: the supplier, service provider and consumer. In the model, information flow and technology management are important issues through the chain. Service delivery happens between the service provider and the consumer or between the supplier and the consumer. Also this model has several management issues related to demand, capacity and resources, supplier relationship, service performance, order process and customer relationship. All of these management issues have their own sphere of influence in the chain. (Baltacioglu et al., 2007) By using these kinds of models companies can understand better the natures of service supply chains. Also Ellram et al. (2004) highlight that their model can be used to notice red flags of hidden cost sources in the service supply chain. The IUE-SSC model has been implemented to the healthcare industry which is facing notable growth with increasing costs. To be able to manage the growth and the costs, service supply chain management is vital for the industry. In this context the IUE-SSCM was successful tool for identifying important managerial aspects. (Baltacioglu et al., 2007)

### **2.3. Customer participation in service deliveries and service triads**

One distinct feature in service production is customer participation. The dominant understanding is that the supplier and the customer both participate in the joint production of the service (Carlborg; Kindström, 2014). Customer participation increases the variation in the system and makes demands on the facilities, technology and design of staff (Safizadeh et al., 2003). In many cases the supplier cannot avoid customer's participation in the service delivery system (Zomerdijs; de Vries, 2007). This means that one critical aspect in the service delivery system standardization is the customer's role and it has to be considered when the company develops standards and standardized processes.

In the existent literature on industrial services, customer participation in service production has mainly been seen as supplementary and minor (Carlborg; Kindström, 2014). Also the customer's cooperation role in service production is often neglected (Xue; Harker, 2002). Customer participation in service production is, however, a reality and companies have to be able to manage it well to achieve efficiency in the service delivery system.

Service delivery in supply networks implies that multiple parties may be involved in service delivery. Service triads engage suppliers, customers and certain third parties into service delivery (e.g. Wu; Choi, 2005). Dubois and Fredriksson (2008) and Wu

and Choi (2005) have studied triadic networks where one buyer interacts with two suppliers. Dubois and Fredriksson (2008) propose a type of sourcing called “triadic sourcing” where the buyer utilizes a joint sourcing strategy for two distinct suppliers, based on a single case study in car industry. Wu and Choi (2005) concentrate on supplier-supplier relationships in their research, using a multiple case study in eight companies from different industries. They define archetypes of these relationships in triadic networks. Rossetti and Choi (2008) have surveyed triadic networks where the supplier interacts with an intermediate player and an end customer in commercial aerospace industry. They focus on a phenomenon where the supply chain disintermediation takes place between the supplier and the customer (Rossetti; Choi, 2008). The third type of triadic network is a chain where one supplier interacts with two buyers. Choi and Kim (2008) have done a literature review of this kind of a network. They highlight the importance of structural embeddedness in a buyer-supplier relationship. This means that the buyer should evaluate its suppliers in the network context and not in isolation.

Peng et al. (2010) have taken a different kind of approach into triads. They identify six types of triads from which they chose three and focus on them, based on their specific research sample. These three triads are as follows:

- 1) The company has a bridge role in the triad which means that it is connected to two disconnected partner companies.
- 2) The company has a peripheral role in triad. It is connected only to one of the connected partners.
- 3) The company has an equal role in the triad. All the companies are connected to each other.

In this research we are especially interested in such a triadic setting where the supplier has a peripheral role. The supplier sells its products to the end customers via distributors or integrators. We are inspecting the means that the supplier has to promote the service sales to these end customers. When using these kinds of sales tactics, the supplier in many cases does not know the end customer. This complicates the supplier's service production and after sales opportunities.

## **2.4. The role of technology in service deliveries**

In the past decades, the rapid development of information and communication technologies and the internet has had enabled standardization both in service processes and products. Such technological developments for example enable companies to collect data and keep record of their installed base remotely at the customers' locations efficiently (Jonsson et al., 2009). Remote monitoring is done by adding sensors into the equipment. These sensors produce real-time data about the equipment that can for example be related to signs of breakdown, current status or unusual use of the equipment (Westergren, 2011). The companies can use this kind of data to develop and offer new services to their customers, including preventive maintenance and optimization services.

The sensors are placed on the critical components. When remote monitoring system (RMS) is installed in multiple factories, the manufacturer has an opportunity to collect and analyze data from several components and production systems across organiza-

tional boundaries. (Jonsson et al., 2009) RMS provides also other benefits for the manufacturer. By monitoring the components and equipment the manufacturer is able to track where its pieces of equipment are. Also the knowledge about the products increases, which enables the manufacturer to predict and identify its customers' service needs. (Jonsson et al., 2009) This is a major competitive advantage for the manufacturer as it is essential for the service provider to understand its customers' needs.

To sum up, the above literature review has scanned the key issues relevant to standardizing the service delivery systems. Earlier research has largely focused on the design parameters of service delivery systems inside manufacturing firms and drawn attention to flexible and rigid processes. To complement previous research, we have highlighted the importance of the customer's and network's role as part of standardization efforts, as well as the role of modern remote technologies. Customer participation in service production has been noted in the literature but its effects on the service deliveries have to be studied more, particularly in demanding industrial contexts. Also the ways to manage the customer participation in the service context is an important issue that needs to be enlightened more, particularly when various information and remote technologies are used, to monitor the installed base of equipment.

### **3. Research methods**

#### **3.1. Research design**

This research was conducted as a qualitative multiple case study. According to Yin (2009) a case study is a suitable method when the aim is to understand a real-life situation holistically. The case study can also be used to collect knowledge of a group, individual or phenomenon (Yin, 2009). The benefit of a multiple case study is that the results of the first case can be verified in the next cases.

In this research three manufacturing companies were studied. All the case companies are product oriented and active in the engineering industry. In order to maintain the anonymity of the companies, they are called CompanyA, CompanyB and CompanyC. Table 2 offers background information of the case companies.

All the case companies operate in a global environment. They are product-oriented manufacturing companies, with a primary focus on the delivery of fairly complex technology-based systems and recent expansion of offerings into industrial services. At the moment all the companies are showing an interest in remote services. However, only CompanyC is actively selling these kinds of services at the moment and even in their case remote services play a minor part.

The biggest differences between the case companies are their customer bases and service processes. Every company has their own working methods and different technological systems. Also the technology embedded in their equipment causes variation between the companies and their service deliveries.

Table 2: Information of the case companies

|                            | <i><b>CompanyA</b></i>  | <i><b>CompanyB</b></i>   | <i><b>CompanyC</b></i>  |
|----------------------------|---|--|---|
| The nature of the industry | Mostly project deliveries but also transactional deliveries. Focus area is component manufacturing. | Mostly project deliveries but also transactional deliveries. Focus area is assembly manufacturing. | Mostly project deliveries. Focus area is both component and assembly manufacturing. |
| Typical customers          | Customers vary from company clients to consumers  | Customers vary from small to big companies   | Customers vary from small to big companies  |
| Service offering           | Traditional product related services, consulting  | Traditional product related services, process integration and optimization                         | Traditional product related services, process improvement                           |
| Net Sales (million euros)  | >30000  | <5000  | <5000   |
| Number of employees        | >100000   | >10000   | >10000  |

### 3.2. Data collection

The data collection was done using multiple methods. In this research semi-structured interviews were used as the primary data collection method. The interview outline development was based on the literature review and the general information of the case companies. The interview outline included similar questions for all the case companies. However some modifications were made depending on the case companies. The main themes of the interviews were: service delivery processes, the company's customers and their role in service deliveries, service delivery system standardization, sales processes, customer interaction, remote data collection and background information. The service delivery process theme included questions for example about the structure of the process, its level of standardization and the participants involved in the process. The customer's role theme had topics such as communication between the supplier and the customer, customer's participation in the service delivery and customer satisfaction. Questions about sales processes on the other hand were related to the order-delivery process, cooperation of product and service sales teams and sales tools.

In total, 19 interviews were performed. Five interviews were carried out in CompanyB and seven interviews in both CompanyA and CompanyC. They lasted between 25 to 111 minutes (53 min on average). The persons that were interviewed were working mostly in middle management in service business related operations. All the interviews were audio recorded and transcribed. Most of the interviews were conducted at the case companies' premises and some at the university premises. This offered also an opportunity to learn about the interviewees' working environment and to observe the premises and working habits.

Observation and documentation provided by the company were used as secondary data collection methods in the CompanyA. The company's repair shop's operations - the repair process, personnel's working habits and the facilities - were observed.

They also offered some documentation about their service processes and information systems. These documents were mainly presentations and the documents were used to acquire a complete understanding about the company's services and service processes. This was analyzed and used in the research for purposes of validation.

### **3.3. Data analysis**

Data analysis included several steps. The audio-recorded interviews were transcribed by an external service provider. The first author reviewed the transcripts to find and correct mistakes and gaps. After this, the data was categorized. The categorization was thematic and based on the interview structure.

Each company's data was initially analyzed separately before a cross-case comparison. The aim was to develop case-specific results as well as to find the similarities and differences between the case companies. Workshops were held with all the case companies to discuss the case-specific results and get feedback from them. The aim of these workshops was also to ensure the correctness and validity of the results. Additionally, the case-specific narratives were sent to the company contact persons, for validation and potential corrections. After the feedback of the companies, a cross-case analysis was made to compare and combine the results. The analysis was inductive within the core themes, enabling the emergence of key issues unique to the case contexts. Excerpts from the interviews and cross-tabulation are used in the Results chapter to demonstrate the key findings.

## **4. Results**

### **4.1. The case companies' service delivery processes and their standardization**

There are similarities and differences between the case companies regarding their service delivery processes and how well they are standardized. All the case companies use ERP systems to standardize the steps in their service deliveries. However, the interviewees have identified various needs for improvement, and a need for further standardization can be noted. According to the interviewees, particularly the reactive service deliveries and communication with the customer include good potential for enhanced standardization.

All the case companies have both reactive and proactive services in their service portfolio. The service delivery systems vary between these service types. In case of reactive services, interviewees in all the case companies noted several domains in which standardization could be enhanced. The issue most commonly mentioned by interviewees is problem solving concerning the equipment in the customer's use. It can take a long time and it requires sufficient background information from the customer. A manager at one of the case companies highlighted: *"We have to know so much about the situation that we can send that kind of maintenance technician there who can audit the right piece of equipment."* This means that communication with the customer is important for the service delivery. Another manager noted that when a maintenance technician faces a piece of equipment that is not familiar to him, the

problem solving is challenging and it can take a long time. In general, allocating the right resources for the right tasks is a relevant resource management issue that requires planning and anticipation.

In the proactive services, interviewees reported good experiences with managing the service delivery systems. A manager explained: *“We know at least two months before the time of the delivery, how long it will take and what is the size of the team we are going to send to the customer’s premises.”* When the service deliveries are planned and scheduled beforehand, the uncertainty of the service delivery system decreases. For example spare and wear parts can be ordered straight to the customer’s premises depending on the service and the expected time the delivery requires decreases. Yet, the case companies have also different challenges regarding the proactive services. The identified factors relevant to standardization in the case companies’ delivery of reactive and proactive services are summarized in Table 4.

Table 4: Factors to be taken into account in standardization in different service type deliveries, as identified in the interviews

| <i>Challenges in reactive services</i>   | <i>Challenges in proactive services</i>   |
|--|---|
| <ul style="list-style-type: none"> <li>• Service delivery system variation case-by-case</li> <li>• Resource management</li> <li>• The costs increase</li> <li>• The delivery time increases</li> <li>• Defining the problem and its cause</li> <li>• Unexpected changes in the service specifications</li> </ul> | <ul style="list-style-type: none"> <li>• Unique challenges, depending on the service, customer, context and other factors</li> <li>• Customer participation in information collection</li> <li>• Unexpected changes in the customer’s premises or the environment where the delivery takes place</li> <li>• Spare parts are not at the right time at the customer’s premises even though ordered in time</li> </ul> |

Particularly in proactive services, the pursuit of standardization faces different factors in the manufacturing firm’s delivery system, varying between the customer requests and the companies much more than the challenges in reactive services. Overall, the interviewees felt that the management of proactive service deliveries is at a relatively good level in the case companies and the challenges emerge from such unique aspects as the customer base, the service concept or organization structure. The interviews highlighted challenges in customer participation, the importance of locations and environment in service deliveries, and timely spare part deliveries from the sub-contractors. These were the issues that were most important according to interviewees own experience in proactive service deliveries.

The standardization of service processes differs between the case companies. Some processes are well standardized but others vary depending on the customer and the piece of equipment. For example a manager at one of the case companies noted that their wear part service deliveries are well standardized but their field maintenance service deliveries vary a lot and the manager compares them to a car repair. Every piece of equipment requires a bit different maintenance tasks and the processes are different. Some main challenges related to the lack of standardization were expressed as part of the interviews. A manager at one of the case companies noted: *“Because the service processes are not standardized and the services are not productized enough, the pricing and the offering of the services is much more difficult than products.”* Another manager explained that they have had cases where spare parts have delayed and the service delivery has failed. They are now trying to ensure that these kinds of situations will not happen again. Also, the interviews revealed that

certain parts of service processes may be better standardized whereas other parts may still be quite customized.

## **4.2. Customer participation in service deliveries**

Customer's participation in service deliveries was experienced as crucial particularly in case companies A and C, and important also in CompanyB. In CompanyA and CompanyC the most important thing emphasized in the interviews is the information the customers offer. Customers have to give certain information for the companies so that they are able to properly plan and schedule the service deliveries. This information includes for example knowledge of the piece of equipment in question, details of the problem or need and possible information about planned stoppages. A manager noted: *"In my opinion we could give more responsibility to the customer regarding the validity of background information. There could be some kind of automatic procedures because there often are quality errors."* In CompanyB's case the importance of customer participation varies. In some service deliveries the customer participates highly in the service delivery and for example does some maintenance tasks by itself. In other cases the customer may participate only to necessary extent.

In all case companies the customer participation highlights the importance of communication. The means the case companies use to communicate with the customers are both formal and informal. Most important means of communication for the case companies are email and meetings. However, even though in many service deliveries the information is a crucial aspect, the case companies have standardized the communication models only little or not at all. For example, a manager at one of the case companies explained that they have certain information that they ask from the customer every time, but still in many cases there is a lack of information and they have to contact the customer several times. This leads to delays in the service deliveries.

Particularly in one of the case companies the need to promote end-customers' service use through sales intermediaries was highlighted in the interviews, and it deserves further attention as it illustrates the triadic setting in service delivery. The company uses several sales channels and in some cases they are facing challenges to know who the end-customers of their products are. This issue originates from the supply chain management and the fact that the chain is not transparent enough.

The company has tried to promote the end users to inform about the pieces of equipment by offering additional guarantees. However the guarantees have not been successful incentives for the end users. A sales manager noted: "Typically our products are such that if they have a two year guarantee, they break right away or last 15 years. Half a year additional guarantee is not a very big benefit." At the moment the company is developing a software system to ease the registration of the equipment. The end user would just scan the serial number of the piece of equipment with a mobile phone or tablet and the registration would go through the software system.

The company also considered incentives for their distributor partners and integrator customers to inform them who their customers are. In case of distributors the company could develop into repetitive concepts such services that would be easy to sell and they could offer some kind of compensation for the distributors to sell their services with the products. Integrators are more complex case because some of them

compete with the company in the service area. If the integrator is a competitor, they have no means to promote the integrator to inform them of the end-customers.

Also the organization structure of the company has been considered as a relevant issue. Their product and service departments are separate and it hinders their service sales because the cooperation between the departments is not sufficient. According to a manager they do not offer the customers services at the same time as products. This is a sales problem and it could be solved by adding cooperation between the departments. At the moment the company is trying to integrate the departments at some level in order to ease the sales process.

Furthermore, the company example demonstrates increased complexity due to the use of several different information systems and even the different departments' use of different systems. Due to the complexity in such support systems, cooperation between the service and product departments is not always easy. If the sales departments had common systems, it would be easier for them for example to inform the other department of leads.

#### **4.3. Use of remote technology and its requirements on the service deliveries**

All the case companies can produce some services for multiple customers at the same time. The technologies in the customer's use and remote technologies to monitor equipment generate unique requirements toward the manufacturer. Interviewees had experienced that both core equipment technologies and remote technologies to monitor them are relevant in service delivery, and the development toward technology-related services is currently ongoing.

The different technologies embedded in the equipment causes requirements for the service deliveries. Interviewees in all the case companies highlighted that the technologies require different competencies and resource management becomes more complex. In all the companies, supervisors in each team or unit are in charge of resource and competence management. Also the technology embedded in the customer's premises can cause requirements for the case companies. A manager explained: *"In some customer premises the maintenance technicians working in there have to have security certificates. This means that all our maintenance men cannot work in all locations."* This adds the complexity of the resource management.

The interviewees in the different companies had somewhat different experiences related to technology and its role in standardization. For example the long lifecycles of the equipment are a central issue when pursuing standardization as there are multiple generations of the same equipment category in use all the time. A manager at one of the case companies explained: *"Some of the customer's pieces of equipment can be several decades old when others are new. Challenges arise when we have to compare substitutive products to these pieces of equipment."* Also the size of the piece of equipment can affect the service deliveries. One manager had experience of spare part deliveries and he noted: *"It is a logistic nightmare to replace thousand parts that weight 400 kilos."* The technology embedded in the equipment can have traditional and surprising effects on the service deliveries and its role has to be remembered when managing a service delivery system. Some of the interviewees emphasized the competences needed for handling technologies in customer's use and

the need for internal knowledge of these competences. To achieve customer satisfaction, it is quite crucial to find the right experts for service delivery when equipment lifecycles are long and generations of equipment differ from each other.

All the case companies showed interest in the interviews for monitoring the equipment and using the gathered data for predicting customers' service needs. A manager at one of the case companies told: *"There are lots of opportunities to exploit the data. -- The idea behind it has to be the willingness to help the customer."* All the case companies gather installed base data from their customers. The most highlighted issue in the case companies at the moment is the management of the data. Different information systems across units cause challenges and in many cases the data has to be added into several systems. At the moment CompanyC has the most developed remote service offering. They are actively gathering remote data and use it in their service production. Their biggest challenge is that in theory remote services are enabled but in practice development in the processes is still ongoing.

## **5. Discussion**

### **5.1. Standardization of delivery systems in industrial services**

The first research question relates to the features that need standardization when developing a manufacturing company's service delivery system. This study reveals that the important features in standardization can be divided into reactive service factors and proactive service factors. The identified reactive service factors include resource management, cost and time management, problem solving and information management regarding service specifications. In reactive services, therefore, standardization appears to require actions on a very operative level in the processes and practices governed by the manufacturing firm. The proactive service factors, in turn, consist of customer participation management, facility management and spare part delivery time management. Therefore, in proactive services, standardization is considered in terms of how the customer interface is managed and how customer requirements are fulfilled in the service delivery. In all, these factors agree with earlier literature relatively well, but point out the necessity to consider standardization at multiple levels: customer interaction, service delivery system, and micro-level operations of the manufacturing firm.

Many of the factors found in this study have been noted in Roth and Menor's (2003) study of service delivery systems. For example resource management, information management in service specifications and customer participation management can be considered as infrastructural design choices. Facility management and spare part delivery time management on the other hand are related to structural design choices. Cost and time management and problem solving have not been covered in Roth and Menor's framework because they can be considered as more specific than the framework. Our findings, thereby, contribute by highlighting some of the micro-level operations that complement the general framework on service delivery systems, particularly in the reactive services of engineering firms.

Some of the factors relevant to service delivery system standardization can be related to the service supply chain models of Ellram et al. (2004) and Baltacioglu et al.

(2007). For example customer participation management has been considered in both of the previous models. Information management regarding service specifications and resource management can be related to Baltacioglu et al.'s model. The other factors have not been covered in the supply chain models because the models are made on a more general level. Therefore, our findings on the industrial services of engineering firms contribute by highlighting the focus on proactive services, when seeking standardization at the customer interface activities.

Both in reactive and proactive services, the results showed unique challenges, depending on the service type, customer, context and other factors. Variation occurred in the service delivery systems, as well as situation-specific service delivery. The findings, therefore, promote the idea that different service delivery systems are needed for different situations even within the same manufacturing firm.

## **5.2. Customer participation and end-customer information in service production**

The second research question inquired the manufacturing firms' means to manage customer participation and end customer information in service delivery. The interviews showed that even in the case of proactive services, customers have an important role in enabling and even driving standardization possibilities. Customer participation and information provided by customers may either advance or challenge the standardization of services. If customers are willing to provide information that suppliers need for service standardization, they can be enablers of the standardization process. However, in the opposite case suppliers may be powerless regarding their standardization objectives.

The results lend support to Safizadeh et al.'s (2003) claim that customer participation increases the variation in the system and causes requirements on many aspects. The study also reveals that in many cases the customer participation is an essential part of the service delivery, thereby agreeing with Zomerdijs and de Vries' (2007) research. However, customer participation was experienced as somewhat more central in the standardization of service delivery than what is proposed in some earlier research. For example Carlborg and Kindström (2014) claim that customer participation has mainly been seen as minor and supplementary. Also Xue and Harker (2002) explain that the customer's cooperative role in service production is often neglected. In this study, engineering firms considered customer information and customer participation as quite relevant in the pursuit for standardization.

In particular, one of the case companies demonstrated a clear triadic setting where the cooperation through sales intermediaries with customers made the access to customer information and participation especially challenging. Such intermediaries have been identified in earlier research particularly in terms of service providers between the equipment manufacturer and customers (Finne & Holmström, 2013). The findings in this study complement earlier research in revealing the importance of the transparency of the service supply chain, organizational structure and partner management in a multiple sales channels situation.

Certain practices were emphasized in the results, in attracting customer participation in service delivery. For example, the incentives for the end-customers have to be significant enough so that they are willing to register their pieces of equipment. The

case company has offered additional guarantees but these have not been significant enough for the end-customers' business. Organizational structure was considered as relevant to the end-customer service promotion. If the service and product sales departments are separate, the communication between the departments is crucial. The literature regarding triadic settings mainly concentrates on the structure of the triad, and this study has revealed practical ways in which the transparency and cooperation in the triad can be enhanced.

### **5.3. The role of technology in service delivery system standardization**

The third research question dealt with the role of both equipment technologies in the customers' use, and remote monitoring solutions as prospective means of service delivery system standardization. According to the results, the low or limited degree of standardization may hinder offering of services and the efficiency of service delivery, which in turn make the pricing and marketing of services complex. Thus, standardization of services can be considered as a necessity for large-scale service provision.

The technology embedded in the equipment causes requirements for the service delivery system. The most important requirement is resource management. According to the results, different technologies require the availability of different competencies. This has been noted also in the previous studies. For example Roth and Menor's (2003) service delivery system framework highlights the importance of resource management. This study was focused on engineering firms with multiple different complex systems, with different generations of equipment in use globally at the customers' locations. This complex setting and its requirements to resource and competence management draw attention to the organizational arrangements in service delivery systems. Further research is needed, to map and analyse with more detail how resource and competence management should be configured, to meet the needs of global engineering firms in their industrial services.

One promising means for service standardization seems to be the use of remote technologies even though it also requires investments into development, as the results show. As the interviewees commonly noted, in particular, in the case of reactive services they are reliant on the information given by the customers. Use of remote technologies would decrease this dependency, and reliable information about the equipment and its malfunctions and repair needs would be readily available for the supplier. Moreover, it would shift the focus more toward the direction of proactive services. Remote technologies would also establish a connection between the supplier and the end-customer even though the supplier would be a peripheral partner due to the intermediary retailer. This way the supplier could promote better the use of services among end-customers.

Even if the remote technology can provide a means to promote standardization of services the diversity of the equipment poses still challenges for this process. Hence, a question remains whether the data obtained from divergent equipment is uniform enough to be useful for service standardization.

## **6. Conclusions**

### **6.1. Contributions and managerial implications**

This paper contributes to the research of service delivery systems by discussing the standardization of delivering repetitive industrial services and promotion of service use in triads; topics only bypassed in the previous research. The topic was approached through a qualitative case study in three manufacturing companies offering industrial services.

Based on the results, two main points regarding the standardization of service delivery systems were highlighted. First, even though the case companies are already experienced in industrial service business and can be considered as unique in their settings, standardization in the service delivery systems was perceived as relevant, necessary and feasible. Standardization possibilities were identified both in reactive and proactive services and on three levels: micro-level operations of the firm, customer interaction and the service delivery system. Second, proceeding in the standardization process is problematic and some aspects require special attention. Differences in standardization practice exist across service types, contexts and organizational structures. In addition, the results showed that wide-ranging technologies and multiple customers set requirements for wide-ranging competencies and resource management. This study contributes to the topic particularly by considering complex settings in which all equipment are unique and multiple customers are serviced in cooperation with various third parties.

This study has featured some factors that need standardization in manufacturing companies, potentially to be taken into account in managerial practice. The importance of customer participation in service production was highlighted and the results can be used to understand the relevance of customers in the service delivery system. Furthermore, technology has various roles as a means to promote service delivery system standardization. This study has explored how equipment technologies drive changes in the service delivery system, and how remote monitoring services can ease the development.

### **6.2. Limitations and ideas for further research**

The main limitation of this study relates to the research design choice of a case study in three manufacturing companies. The results cannot be generalized as such to cover all other manufacturers offering services even though the results were validated in workshops in the case companies. Detailed analysis would require more extensive data collection among a larger group of manufacturing companies offering industrial services.

Further research is needed particularly on: 1) the details of remote technology use in complex and global service contexts; 2) triadic customer cooperation in alternative partner configurations; 3) implications of the lifecycle of equipment technologies on service delivery, and 4) the practice of resource and competence management in industrial services in global engineering firms, particularly when equipment lifecycles are long. As this study was focused on the manufacturers' operations only, it would

be interesting to expand the study to 5) cover also the customers' and third parties' viewpoints, to provide a more comprehensive outlook of the subject.

## **7. Acknowledgements**

This research has been conducted as part of the Service Solutions for Fleet Management (S4Fleet) research program funded by the Finnish Technology and Innovation Agency Tekes, companies and research institutes, and coordinated by FIMECC (Finnish Metals and Engineering Competence Cluster). We gratefully acknowledge the support of the financiers and the companies that participated in this study.

## **Abstract:**

*Characteristics of firms, especially service firms, are defined by rapid change, globalization, hyper innovative competition, etc., and recent research shows that one of the most dynamic capabilities that lead to the strongest competitive advantage in the organizations is the innovation capability. The innovation capability is associated with other organizational capabilities. So, many organizations have focused on the need to identify innovation capabilities and resources or strengths in relation to external opportunities and threats according to inside-out view because innovation capability has consistently been defined as a new service, a new product, a new technology, or a new administrative practice and process. Developing the innovation capability as an important aspect of dynamic capabilities of a firm is an important research project and it can help to achieve competitive advantage in this rapidly changing world.*

*This research focuses on recognition of the aspects of innovation capability and proposes a conceptual model based on a qualitative Meta-Analysis of academic literature on organisations innovation capability. This is proposed for the development of the concept of innovation capability in the organizations and this paper includes an expert based validation in three rounds of the Delphi method.*

*This research proposed a direct relationship between Innovation Capability and three main capabilities that is called Structural Capability, Personnel Capability and Operational Capability (S.P.O. Model). Also, it offers the most important indices which directly influence and are related to the Innovation Capability.*

**Key words:** Organizational Capabilities, Dynamic Capabilities, Innovation Capability, Personnel Capability, Structural Capability, Operational Capability.

# 1. Introduction

To maintain the survival of organizations in the competitive context of the world today, organizations have no way out except attaining a competitive advantage (Porter, 1980; Barney, 1991). In order to explain the competitive advantage in organizations, two viewpoints are to be considered: The first approach which is based on the Industrial Organization Theory (Bain, 1968) in Michael Porter's ideas regards attainment of competitive advantage as resulting from environmental opportunities and is called the Market Based View (MBV). The analytical instruments utilized in this point of view are analysis of the value chain, analysis of competitive forces, generic strategies, competitiveness, clusters, competitive advantage of nations, etc. (Porter, 1980). Another approach the issues of which became common in the strategic management literature since the publication of the article "Resource Based Theory" by Wernerfelt 1984 is called the Resource Based View (RBV). This viewpoint has been investigated and developed by other experts and the related models have been appraised in organizations (Barney, 1986). Numerous studies in the last two decades have indicated that the competitive advantage based on internal capabilities of organization is the best origin for generation of success (Crook et al., 2008). The capabilities approach constitutes an extension to the resource based perspective (Helfat et al., 2007). In this conception, resources change through the action of capabilities approach, while some capabilities may deal specifically with adaptation, learning, and change processes. All capabilities have the potential to accommodate change (Helfat et al., 2003). Capabilities refer to the firm's ability to alter the resource base by creating, integrating, recombining and releasing resources (Eisenhardt & Martin, 2000). Also, many theorists have focused on the need to identify organizational capabilities and resources or strengths in relation to external opportunities and threats according to inside-out view of resource based approach in the firms (Bryson et al., 2007). So, capability translates to dynamic capability for Interaction of internal resources of organization with environmental opportunities (Teece et al., 1997-2009) and the innovation capability is one of most important dynamic capabilities that orientates the organization to adapting with environmental opportunities (Saunila et al, 2014). The innovation capability can be either a new product, a new service, a new technology, or a new administrative practice (Hage, 1999). This approach defines a capability for innovative organization as one that is intelligent and creative, capable of learning effectively and creating new knowledge (Lam, 2004).

An Investigation of scientific articles shows that most articles in the area of capabilities do not usually offer any recommendation concerning the procedures for management of the development of capabilities (Borjesson & Elmquist, 2011). In the innovation literature, researchers have pointed to the lack of a comprehensive theory or model of innovation and the related capabilities with a capacity for organizational understanding (Khalil, 2002).

For this purpose, this research follows to find factors influential on innovation capability of organizations through a procedure with provision of a comprehensive model and the theoretical confirmation of the model.

## 2. Research Method

This research is descriptive and non-experimental and employs a qualitative research method. Data collection is obtained through the following two ways:

- A. Qualitative Meta Synthesis of literature. The researchers reviewed most of valuable and scientific papers and articles in Innovation Capability field with critical consideration (Maxwell, 2013), so this research made a critical review on all of the articles that focused on innovation capability in the past decade. At last, the conceptual model proposed for the development of innovation capability in the organizations, and thus
- B. Delphi method, for the conceptual confirmation of the conceptual model (Boynton & Zmud, 1984) of innovation capability, an expert panel formed in three rounds (first round interview, 2 rounds of questionnaires). The panel include 20 innovation experts (number Academic Scholars and number Practitioners; which were elected as experts in organisational capabilities due to their research field or their Managerial role in an organisation with innovation as key business e.g. an entrepreneurship organisation; but also their availability).

The qualitative collected data (from both A and B) was coded and classified. Then the questionnaire data analysed by statistical analysis with Arithmetic Mean (Average in Statistics). The statistical measurements come out from five-step Likert questionnaire.

Table 1: Overview of the applied research design

|                   |   |
|-------------------|---|
| In this research: |   |
| Research Paradigm | Qualitative Research Paradigm   |
| Methodology       | Multi method: Meta Study and Delphi   |
| Research Strategy | Qualitative Meta Synthesis and Delphi Panel   |
| Data Collection   | Documentations, Literature Review, Past Review, Structured and Semi Structured Interviews, Questionnaire Survey |
| Data Analysis     | Open Coding and Statistical Analysis  |

As illustrated in table 1; the general research design is a multi-method study. It consists of step one: the generation of a conceptual model of innovation capability through the critical review of other researches by qualitative meta synthesis. In step two, a Delphi panel is set with innovation capabilities experts utilizing the snowball technic. Then, as the first round of Delphi, short structured interviews with individual experts. This was followed up by a second and third rounds of Delphi using a questionnaire. For data analyses of the answers, open coding (for literature review and interviews and statistical analysis (for structured interviews and questionnaire survey). Based on the prior knowledge experts of capability, we proposed a final conceptual model to describe and improve organisations innovation capability. Which consists of dimensions, components and indices.

### 3. Innovation Capability

Innovation capability consists of internal reinforcement procedures and processes. This process is a key mechanism for stimulation, measurement, and reinforcement of innovation (Lawson & Samson, 2001). Many authors consider innovative capabilities equal with being innovative or even innovative performance of aspects that could be quantitatively assessed (e.g. the number of inventions registered or the number of operations of a new product). Although these measures are useful pieces of information on the performance of the firm, they do not offer a picture of innovation capability of the firm. The concept of capability is not a performance parameter but it is an index of preparedness of the firm and the development through innovation forces (Borjesson & Elmquist, 2011). This research believes innovation capability is a great ability to provide innovative services and products continuously through the organizational capabilities, capacities and competencies. This definition is utilized by some other researches (Saunila et al., 2014; Saunila & Ukko, 2012; Sáenz et al., 2009; Lawson & Samson, 2001).

With reference to the summarized literature and the research paradigm of this study which is formulated on the systematic definitions of innovation, it is understood that innovation capability is dependent upon other capabilities in the organization which may be classified into three groups of Structural Capability, Personnel Capability and Operational Capability (S.P.O. model) as the main dimensions. The operational capability is very much dependent upon technological capacity and support capacity, and the personnel capability is dependent upon the individual knowledge capacity, finding of business environmental opportunity and idea generation ability which is based on creativity of human resources, and the structural capability is dependent on internal processes of organizations as managerial capacity, cultural capacity, communicative capacity and organizational knowledge capacity.

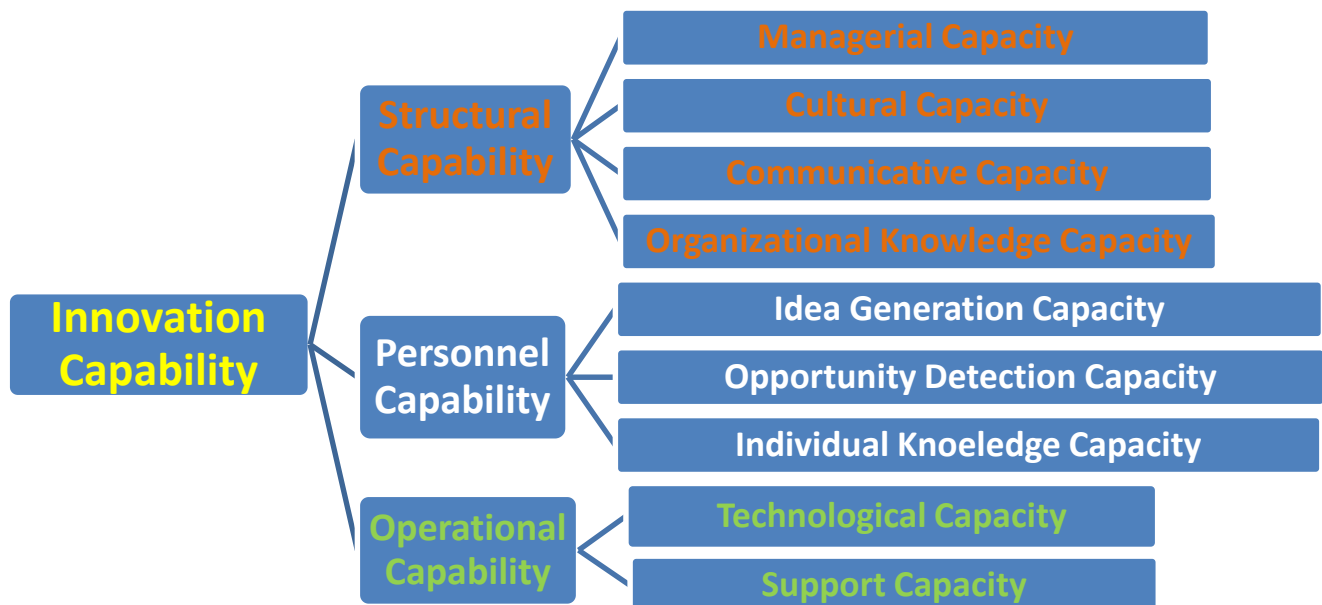

Figure 1: The S.P.O. Model of Innovation Capability (Structural Capability, Personnel Capability and Operational Capability).

### **3.1. Dimensions of Innovation Capability**

Innovation is a complex technological, social, and economic process. Therefore, success is not measured through just one or two factors and no factor could be effective alone. As such, no management or technical tool or instrument can establish an efficient environment for innovation. In fact, what we obtain in research is a collection of different factors which should regularly establish and improve an innovation environment so as to guarantee the innovation success in an organization (Barnano, 2005). Innovation capacity completes as the result of several relationships and communication among organizational, resources, qualifications, and connections with other organizations (Hii & Neely, 2000).

Therefore, the innovation capability of a firm is not the result of one of its abilities but it flows from a collection of abilities and other capabilities, which means an internal potential for generation of new ideas, identification of new market opportunities, new services and products through resources and capabilities of a firm. Considering the literature reviews, this research believes innovation capability has been dependent on other capabilities in an organization and classifies them into three groups including: structural capability, personnel capability and operational capability.

#### **3.1.1. Structural Capability**

Structural capability is effective in the provision of organizational innovation capability since organizations should take the most advantage of their internal organizational situation and structures for development of new capabilities and reconstruction of the existing capabilities (Colarelli O'Connor & DeMartino, 2006). Structural capability states that in addition to operational dimension, the structural changes of an organization toward the establishment of a capability that causes the flow of the innovation capability in the organization plays a significant role for achieving success. Some define this as the capability for the formation of a stable structural mechanism for modification of all activities toward common goals for the purpose of an effect on the speed of innovation process through infrastructure for developmental projects (Guan & Ma, 2003) and some others refer to it as a structural mechanism of an organization for realization of innovation (Lichtenthaler & Lichtenthaler, 2009).

Of course, this research is of the opinion that structural capability is dependent upon four capacities in an organization: managerial capacity, cultural capacity, communicational capacity and organizational knowledge-based capacity which is based on the storage and generation of organizational knowledge and organizational learning.

With the emergence of large companies in the early twentieth century, many attractions have come up around the role and functions of managers (Chiesa et al., 1996). The issue has been dealt with in different scientific areas such as operation theory utilizing scientific knowledge on production systems, vertical and horizontal assimilation of provisional chains. They claim that the management of firms are able to carefully plan and coordinate

resources and capabilities of an organization (Zawislak et al., 2012). Structural changes of an organization toward establishing capabilities for the purpose of developing competitive superiority is understood only through managerial capacity (Zawislak et al., 2013). The innovation capability relates directly with managerial capacities such as planning an appropriate organizational structure, planning a mechanism for relationship with mainstream of an organization, multilevel management and a proper decision-making mechanism, use of innovation networks, budget and reward system based on innovation, strategic planning, and leadership style (Colarelli O'Connor, 2008). Also, studies show that there will be no improvement in the development of capabilities without an explicit and coordinated support by managers regarding the origin and outcome of capabilities (Borjesson & Elmquist, 2011). Certainly, Innovation increases the competitive advantage of firms, but for this purpose, a procedure is required for the management of new knowledge and skills which are applied for the daily management of firms (Tidd et al., 2005).

On the other hand, the management system which applies the innovation capability as a strategic capability for activating the cycle of innovation strategy and couples the existing trade with the strategic innovation system can achieve more success in the innovation capability (Kodama & Shibata, 2014). Also, it is necessary to emphasize that integration and coordination among other capacities for the establishment or development of organizational innovation capability is carried out by the management of an organization (Lichtenthaler & Lichtenthaler, 2009), this is combined in this study under the title of managerial capacity.

One of the other most important components of innovation capability is the knowledge of organization which are accumulate in personnel and information systems of organizations and firms (Skiltere & Jesilevska, 2013). Organizational knowledge refers to accumulated skills and expertise (Hefat et al., 2007) but many authors and theoreticians distinguish between exploration and creation of knowledge on the one hand, and exploitation of knowledge on the other (Bansal & Bonger, 2007). Moreover, some believe that organization of knowledge processes takes place beyond the boundaries of firms (Cassiman & Veugelers, 2006) and, of course, some authors have laid stress on the significant role of the combination of internal and external knowledge in the process of innovation. It is necessary to emphasize that restoration of the internal knowledge refers to generation of new knowledge within the firm and restoration of the external knowledge refers to the description of the acquisition of knowledge from outside sources (Lane et al., 2006). Exploitation of the internal knowledge is the description of the internal innovation and exploitation of the external knowledge refers to the transfer of knowledge to outside of the organization (Lichtenthaler, 2007).

Also, exploitation of knowledge involves repetition of new methods in different situations and implementation of the internal and external programs in various circumstances since organizations are different by nature and for survival in environmental changes make different choices for utilization of their innovations. And it is to be emphasized that maintenance of internal and external knowledge is related to organizational processes and guarantees the constant transfer of knowledge through which the best start for exploration, maintenance, and exploitation of knowledge takes place (Zollo & Winter, 2002).

For the purpose of the development of the concept of the capacity of organizational knowledge that refers to re-creation of dynamic capabilities, it is emphasized that dynamic capabilities provide for the capacity of an organization for the establishment, development, and change of its resources (Helfat et al., 2007). In accordance with this approach, firms

should dynamically embark on development of capacities for knowledge to benefit from the innovation (Chesborough, 2006).

Also, in the maintenance of knowledge, an organization confronts the issue of integration or dependence of knowledge which is a reference to the likelihood of the combination of internal and external knowledge. Of course, the complementary nature of internal and external processes of knowledge requires coordination in the organization (Cassiman & Veugelers, 2006). An organization needs reconstruction in its knowledge for boosting conformation ability or modifying environmental conditions earlier than competitors in order to be successful (Lichtenthaler & Lichtenthaler, 2009).

Absorption and maintenance of external knowledge for transfer to the organization should be considered seriously. Of course, for the purpose of gaining and having access to external knowledge, a firm should often provide for the transfer of a part of its knowledge to outside (Grant & Baden-Fuller, 2004).

In fact, the organizational knowledge capacity contributes to the revision of the source of innovation with the goal of surviving over time since the necessity for transfer and renewability of resources is considered a significant principle in dynamic capabilities (Lichtenthaler & Muethel, 2012) and also because organizations should activity renew and rearrange their innovative processes over time (Helfat et al., 2007).

Cultural capacity is represented by the organizations which have structured flexibility into their organizational culture to embed and encourages teamwork, creativity, learning and collaboration which creates value collectively (Verma et al., 2014). Cultural capacity is the culture executed by a learning organization with the aim of creating a culture to contribute to a valued outcome by enhancing organization's ability and thereby boosting innovation capability (Hung et al., 2010). Emphasizing cultural facets which impart comprise management backing for inspiring employees to work together, search, interact, and seek support toward innovation will lead to acquisition of capacity resulting in innovation (Verma et al., 2014).

Innovative activity may arise from any part of the organization process such as organizational communication abilities, entrepreneurial ability, adaptability, etc. Also communicative capacity contributes strongly to innovation, especially in services and in organisational innovation. A communication channel is a structural characteristic that can be used by a decision unit to achieve successful innovation implementation within organizations (Fidler & Johnson, 1984). The communicative capacity refers to organizational ability for networking and cooperating with other organizations (De Marchi, 2010).

### **3.1.2. Personnel Capability**

This research believes that personnel capability is dependent upon three capacities in an organization: capacity for finding opportunities, capacity for generating ideas and capacity for individual knowledge which are based on the creativity and other abilities of human resources.

Finding and exploiting environmental opportunities has always been a big challenge for the organizations in confrontation with the dynamic environment (Lichtenthaler, 2007). Therefore organizations and firms need to develop new and special abilities and capacities

for exploitation of new environmental opportunities (Phillipset et al., 2005). This is because the firms which show more potential for exploitation of new ideas are said to possess more innovation capability compared with competitors (Francis & Bessant, 2005). So, the first step in the innovation process is finding, considering and establishing innovation opportunities for the organization (Lichtenthaler & Ernst, 2012). Also the dynamic capabilities approach has paid particular attention to exploration of new opportunities as a dynamic principle in capabilities and has described it under the title of sensing capacity (Lichtenthaler & Muethel, 2012). As a result and with precedence, innovation capability, which is the core capability concerning dynamicity, requires finding new ideas in the midst of opportunities. Thus, it can be stated that even more important than technical capacities, provision of applicable innovative pathways is the centroid of the innovation capability of any organization (Zawislak et al., 2012).

On the other hand, formulation of new ideas can be presented in the framework of a model, concept or program. New ideas can be a new service, a new product, a new technology, or a new technique for the management of staff (Soltani Tirani, 2008). Of course, exploration and generation of ideas include two major phases: A) Thinking of ideas as possible clues, and B) Selection of ideas, addition of other ideas, and re-implementation through change and combination of ideas (Sborn, 1992). Moreover, innovation capability is an internal stimulating energy for production and exploration of new ideas in utilization and examination of solutions for the detected environmental opportunity in the atmosphere of market, and it is argued that one way to develop this capability is to increase the absorption capacity of firms for these opportunities (Assink, 2006). Of course, for the purpose of idea generation activities, it is not enough to be creative; the whole process of survey, development, integration and implementation should be considered (Borjesson & Elmquist, 2011). Thus, the seizing capacity referred to in dynamic capabilities which attempts to create source values for the organization, assumes the role and responsibility for idea generation and conceptualization concerning availability in the process of innovation capability in an organization (Lichtenthaler & Muethel, 2012).

Also, should emphasise that the idea detection and generation capacity directly refer to personnel and staff abilities (Saunila et al., 2014; Raffai, 2014).

On the other hand, it is to be emphasized that the innovation capability refers to the ability of a firm to innovate through internal knowledge that is it indicates generation of knowledge within the personnel and staffs. This process of knowledge exploration starts with the understanding of particular opportunities by the ingenuity of expert personnel, and after the generation of the new knowledge, they have to maintain a relationship between this new knowledge and the environment opportunity (Shane, 2000). Of course, the process of knowledge generation usually requires time since an invention is more than a mere idea and the generation of new knowledge generally occurs in response to a need (Khilji et al., 2006).

For the purpose of recognition of environmental opportunities, personnel knowledge should be reactivated and assimilated with the new knowledge. Moreover, it should be internalized again through experience. Knowledge can be traded and changed since new knowledge over time so that they could employ and activate it later again (Pandza & Holt, 2007).

### 3.1.3. Operational Capability

The operational capability of an organization, which focuses on technological and operational activities and abilities of an organization, contributes to the achievement of organizational goals and is under the direct influence of a techno-loop. This is formulated in this study in the frame of operational capability in accordance with the researches carried out by other researchers as technological innovation concept (Figueiredo, 2002; Acur et al., 2010; Zawislak et al., 2012).

Among a collection of abilities which all firms utilize for the generation of various innovated products and services, technological capacity have achieved a prominent position in different studies. The concept of technological capacity of a firm is defined as the ability of a firm in the use of technology and combination and recombination of parts and constituents, and the relationship among constituents, procedures, processes and techniques (Afuah, 2002). Therefore, the development of technological capacity requires investment of time and resources to establish a structure for the development and maintenance of this capacity (Ho et al., 2011).

Among various capabilities of a firm, the technological capability is necessary to a greater degree. This is because it makes it possible for the firm to establish new concepts, processes, and solutions. For this reason, firms with innovative capabilities are more likely to increase their profit compared with the competitors (Patel & Pavitt, 1997).

With reference to the present features of competitive environments, while the level of competition is on the increase in the industry, the technological capability has increasingly been seen as a vital factor for the maintenance of long-term competitive advantage for firms (Acur et al., 2010).

Technological capacity of a firm is the result of learning processes (Jonker et al., 2006) which require ample use of knowledge and mobilization of scientific and technological resources so as to make the generation of the innovative products and services possible (Garcia et al., 2007). Therefore, the firms that have developed their technological capacity boost their chance of success compared with those who have less-developed technological capacity. It goes without saying that increase of this capability does not happen by chance but absorption, concordance, and change of the existing technology is necessary for the development of technological capability (Madanmohan et al., 2004).

Studies show that four basic aspects are inherent in the technological capability: A) Learning processes, B) Strategic focus on technology, C) Difficulties of abilities' transfer, and D) ability of Dynamics (Figueiredo, 2002).

In other words, the firm should be able to change its abilities, skills, and technological know-how. When this happens, it may be claimed that has technological capacity (Tello & Zawislak, 2013).

In addition, it may be stated that operational capability is also dependent on the transactional abilities of an organization. Achievement of competitive superiority through sales is facilitated by what is called transactional ability. Transactional ability is, in fact, all the activities that a firm performs to reduce marketing, bargaining, and delivery costs. In other words, reduction of transaction costs becomes possible through transactional ability. Of course, the role of transactional ability in the establishment of innovation capability for the firm is justified on the condition that when the firm can produce a product or a service with innovative superiority compared with similar goods and services on the market, it should be able to bargain it on the market. And because all firms permit the use,

management, and processing of their technology for the explicit and clear goal of positive economic income, they should have a certain abilities for trading their products and services (Zawislak et al., 2012).

Transactional ability should act in a way that this innovative technology does not transfer to competitors to make sure that it results in the maintenance of competitive advantage for the firm (Barney, 1991) and also the firm can absorb technological innovations in the industry. Of course, like all capabilities, capacities and abilities, transactional ability should be established, developed, and changed. In this process again learning plays a key role (Mayer & Argres, 2004). In fact, development of transactional ability will contribute to the development of innovation capability (Zawislak et al., 2012).

Also, the supportive capacity of an organization such as logistical and supportive process and the work place situation of an organization do an important role for developing of operational capability in order to innovation capability (Mello et al., 2008; Shan & Jolly, 2010; Zawislak et al., 2012).

### 3.2. Index

All the theoretical concepts should be segmented into dimensions to understand their various aspects. And on the next level, dimensions should be broken down to components. Also, for certain empirical aspects of a subject, components should disintegrate to indices (Bhattacharjee, 2012).

In this research innovation capability is the core concept of research, so the personnel capability, structural capability and operational capability are the main dimensions. Also, the main components and indices are listed in Table 2.

Table 2: Indices of Innovation Capability

| Concept               | Dimension             | Component                      | Index                             |
|-----------------------|-----------------------|--------------------------------|-----------------------------------|
| Innovation Capability | Personnel Capability  | Opportunity Detection Capacity | Business Environmental Survey     |
|                       |                       |                                | Accuracy, Attention, Intelligence |
|                       |                       | Idea Generation Capacity       | Creativity                        |
|                       |                       |                                | Practicality                      |
|                       |                       | Individual Knowledge Capacity  | Knowledge                         |
|                       |                       |                                | Experience                        |
|                       | Structural Capability | Managerial Capacity            | Strategy And Goals                |
|                       |                       |                                | Management Style                  |

|  |                        |                                   |                         |
|--|------------------------|-----------------------------------|-------------------------|
|  |                        |                                   | Stability of Management |
|  |                        |                                   | Resource Availability   |
|  |                        | Cultural Capacity                 | Flexibility             |
|  |                        |                                   | Diversity               |
|  |                        |                                   | Risk Acceptance         |
|  |                        | Communicative Capacity            | Networking              |
|  |                        |                                   | Cooperation             |
|  |                        | Organizational Knowledge Capacity | Organizational Learning |
|  |                        |                                   | Knowledge Storage       |
|  |                        |                                   | Knowledge Absorption    |
|  |                        |                                   | Information system      |
|  | Operational Capability | Technological Capacity            | Research & Development  |
|  |                        |                                   | New Technology          |
|  |                        | Support Capacity                  | Logistics               |
|  |                        |                                   | Work Place              |

## 4. Results and Discussion

This research focuses on the main factors of Innovation Capability in organizations, which could be seen as new services, new products, new processes, etc.

The outcome of the Qualitative Meta Synthesis of literature, is a first version of the conceptual model; which was modified due to expert's comments in the first two rounds of the Delphi method. The first round was done by structured interviews, and we identified the dimensions and components as figure 1. Then at the second and third rounds, they confirmed components and indices as table 3 and table 4.

It should be emphasised that the agreement within the expert panel is significant. The scientific domination was as minimum 84% that was measured by some questions. It means that the data provided through the panel is very reliable for further studies and other researches and empirical applications. In addition, the participation of panel members has been rated as 90%, 85%, and 85% in the first, second and third rounds respectively.

The statistical measurements come out from Likert (5 steps) by the structured questionnaire in the first and second rounds. Also, the measurements are done for the components and dimensions through the "accept" or "not accept" (2 steps) questionnaire in the third round. Also, the measurements for indices are carried out through the five-step Likert questionnaire.

Table 3: Delphi Results, Dimensions and Components

| Does Innovation Capability depend on: |                                   | Round 1 | Round 2 | Round 3 | Result   | Source   |
|---------------------------------------|-----------------------------------|---------|---------|---------|----------|--|
| Dimensions                            | Personnel Capability              | -       | 4.3     | Yes     | Approved | Interview  |
|                                       | Structural Capability             | 4.7     | 4.2     | Yes     | Approved | Literature   |
|                                       | Operational Capability            | 3.9     | 4.1     | Yes     | Approved | Literature   |
| Components                            | Opportunity Detection Capacity    | 4.7     | 4.2     | Yes     | Approved | Literature   |
|                                       | Idea Generation Capacity          | 4.7     | 4.4     | Yes     | Approved | Literature   |
|                                       | Knowledge Based Capacity          | 4.5     | -       | -       | -        | Came from literature, but has been broken down to Individual Knowledge Capacity and Organizational Knowledge Capacity due to the expert's comments |
|                                       | Individual Knowledge Capacity     | -       | 4.4     | Yes     | Approved |  |
|                                       | Organizational Knowledge Capacity | -       | 4.7     | Yes     | Approved |  |
|                                       | Managerial Capacity               | 4.7     | 4.6     | Yes     | Approved | Literature   |
|                                       | Cultural Capacity                 | -       | 4.5     | Yes     | Approved | Interview  |
|                                       | Communicative Capacity            | -       | 4.7     | Yes     | Approved | Interview  |
|                                       | Operational Capacity              | 3.8     | -       | -       | -        | Came from literature, but changed to support capacity by the expert's comments   |
|                                       | Support Capacity                  | -       | 4.4     | Yes     | Approved |  |
|                                       | Technological Capacity            | 4       | 4.5     | Yes     | Approved | Literature   |
|                                       | Transactional Capacity            | 2.8     | -       | -       | Refused  | Literature   |

Table 4: Delphi Results, Indices

| Component                         | Index                             | Delphi | Result   |
|-----------------------------------|-----------------------------------|--------|----------|
| Opportunity Detection Capacity    | Business Environmental Survey     | 4.2    | Approved |
|                                   | Accuracy, Attention, Intelligence | 4.6    | Approved |
| Idea Generation Capacity          | Creativity                        | 4.8    | Approved |
|                                   | Practicality                      | 4      | Approved |
| Individual Knowledge Capacity     | Knowledge                         | 4.5    | Approved |
|                                   | Experience                        | 4.4    | Approved |
| Managerial Capacity               | Strategy And Goals                | 4.6    | Approved |
|                                   | Management Style                  | 4.4    | Approved |
|                                   | Stability of Management           | 4.1    | Approved |
|                                   | Resource Availability             | 4.2    | Approved |
| Cultural Capacity                 | Flexibility                       | 4.4    | Approved |
|                                   | Diversity                         | 4.1    | Approved |
|                                   | Risk Acceptance                   | 4.4    | Approved |
| Communicative Capacity            | Communication Network             | 4.7    | Approved |
|                                   | Cooperation with others           | 4.3    | Approved |
| Organizational Knowledge Capacity | Organizational Learning           | 4.7    | Approved |
|                                   | Knowledge Storage                 | 4.3    | Approved |
|                                   | Knowledge Absorption              | 4.6    | Approved |
|                                   | Information system                | 4.2    | Approved |
| Technological Capacity            | Research & Development            | 4.5    | Approved |
|                                   | New Technology                    | 4.2    | Approved |
| Support Capacity                  | Logistics                         | 3.8    | Approved |
|                                   | Work Place                        | 4      | Approved |

## 5. Conclusion

Recent research shows that one of the most dynamic capabilities that lead to strongest competitive advantage in the organizations is innovation capability. The innovation capability is connected with to other organizational capabilities. The innovation capability is defined as a great ability to provide innovative services and products continuously through the organizational capabilities and capacities.

This research focuses on the recognition of the facets of innovation capability and proposes a comprehensive model of Innovation Capability in three main capabilities that is called Structural Capability, Personnel Capability and Operational Capability (The S.P.O. Model).

There are found to be nine components under these three dimensions; Structural Capability is dependent on Managerial Capacity, Cultural Capacity, Communicative Capacity and Organizational Knowledge Capacity. Personnel Capability is recognized as Opportunity Detection Capacity, Idea Generation Capacity and Individual Knowledge Capacity. And the Operational Capability is through determined Technological Capacity and Support Capacity. In addition, this research identifies 23 indices as the most important elements which directly influence and are related to Innovation Capability.

This research aim at developing the innovation capability as a significant aspect of dynamic capabilities of an organisation. Organizations and companies can apply the suggested conceptual model to review their organisational innovation capability and to continuously improve their internal resources.

The generic character of this study calls for further research in this research topic and in specific empirical domains. This research could investigate the practical implementation of the SPO model and generate more specific recommends of how to apply this model in organizations and firms.

# Service concepts from future - weak signals from different branches

*Vitalija Petrulaitienė, Eelis Rytkönen, Suvi Nenonen, Tuuli Jylhä*

<sup>1,4</sup>Aalto University, Department of Real Estate, Planning and Geoinformatics

<sup>2,3</sup>Aalto University, Department of Civil and Structural Engineering

*In order for facilities management (FM) to proactively support organisations and distinguish their service requirements a deep understanding of future is needed. This paper introduces five branch-specific (retail, senior housing, industry, wellness and well-being, and knowledge work) scenarios in order to predict future challenges for FM. The results suggest that FM should consider: (1) FM in virtual worlds; (2) responsibility, wellbeing and sustainability factors as business drivers; (3) new ways of conducting daily activities, which require new ways of supporting clients; and (4) mixed and multi-use space segments in order to act proactively. These findings might be useful for FM service providers in Nordics and globally.*

## 1. Background

Facilities management (FM) aims to support the core business of an organization in a rapidly changing operating environment. FM should be perceived as a set of strategic proactive actions that support the future of the organization instead of a set of reactive technical and operational services. Deep understanding of the changes in the core businesses of clients in the future is essential in order to understand the future service requirements.

The megatrends in demographic changes, ICT-development and well-being are affecting rehabilitation by changing the customers, products, processes and places for the future. The services provided by FM need to shift from facilities-centric to client-centric throughout (Hinks, 2002) in order to meet ever-changing requirements of businesses. The current socio-demographic changes are creating an enlarging customer group of elderly people. The rapid development of information and communication technologies (ICT) runs parallel to these societal changes and offers possibilities to cope with the above-mentioned challenges.

These megatrends affect resources directly related to FM services in organisations – management of people, business, property and knowledge (Nutt, 2000). People and human resources (HR) are facing the most radical changes, among others, new ways of working, organisational changes, and IT development. Flexible work environments that allow working independent of time, place, and location, require strategic approaches to HR as well as better management of the supporting facilities. Physical resources are the least changing because of slow nature of changes in built environment.

One of the biggest challenges for the future is managing the existing properties by i.e. improving utilization, disposing and facilitating alternative mixture of tenancies (Nutt, 2000). Facilities businesses tend to perceive designs as standardized for single purposes – be it re-

tail, senior housing, industry, wellness, wellbeing or knowledge work, every branch has its own standards and rules of the game. However, due to digitalization, barriers between the branches blur in terms of facilities, as the activities taken in physical environments become increasingly varied.

In order to understand how these changes will affect FM industry, a systematic and more innovative approach to real estate must be taken. Traditionally, real estate research was empirical and retrospective and many times physical properties were considered separately from wider economic, social, environmental and cultural aspects which many times led to oversight of significant connections thus ineffective strategy development (Saurin; Ratcliffe 2011). Latest research (i.e. Jensen et al., 2014, Ratcliffe, 2002, Saurin; Ratcliffe, 2011) suggests that futures studies can provide opportunity for FM professionals to explore the future in a more structural way and strategically prepare for changes by positioning different expected developments through scenario creation (Jensen, 2014). Futures thinking is different from long-term planning in a way that it recognizes that the future is not an extension of the past, there might be different possible scenarios due to a various relationship between factors and it is led by innovation (Saurin; Ratcliffe, 2011).

This paper introduces five facility branch-specific scenarios in order to predict future challenges for facilities management. The branches in question are retail, senior housing, industry, wellness and well-being and knowledge work. The scenarios have been constructed based on research projects which investigated the futures of a variety of space segments that are relevant to the selected branches. Facilities under investigation are shopping centres, residential buildings, offices, wellness centres and industrial production facilities.

## **2. Trends affecting the FM industry**

To understand the development of FM as an industry in more detail, this section explores the megatrends that affect FM the most. It combines industry and academic aspects in an attempt to find interlinkages between the forecasts of ISS (2014), Bev Nutt (2000) and John Hinks (2002).

Hinks (2002) states that IT development combined with the management of knowledge has a huge impact to organisations' core operations, their supply chains, business support and their customers. IT development and virtualisation of operations affects the location of workforce, their usage of facilities as well as the management of knowledge in organisations. Organisations and FM service providers need to acknowledge the interdependency between core business processes and the business support role. Dispersed locations mean that the support functions that previously were provided in one building now have to be duplicated for each individual or delivered at a distance. It brings flexibility to organisations, hence, improving their competitiveness although it might not be economically efficient. Global sources of expertise and increasing need of collaboration and communication leads FM towards a broader resource management role and change from facilities-centric business to a communications-centric virtual business. Successful linking of the right knowledge with the right people at the right time becomes a challenge that FM industry needs to deal with.

Nutt discusses ideas presented in the conference "Futures in Property and Facility Management II" (2004) which again points out the belief that FM services can no longer be consid-

ered as secondary functions but need to take an active and central role by connecting FM, IT and HR together to support people who are driven by a “work is where you are” culture.

The megatrends that will have an effect on FM industry in the upcoming 20 years were identified by Hamish (Nutt, 2004) and they included demographical changes, technological development, social attitudes, ethical pressures and regulations. Ten years later, ISS forecasted nine largest megatrends that will affect the FM industry the most and they were highly corresponding with the previous forecast: economic growth, globalization, demographic trends, and sustainability, technological development, growth of knowledge society, individualization, focus on health and wellbeing and commercialization (ISS, 2014). The main points of the megatrends are summarized in Table 1.

Table 1: Summary of megatrends and their implications to FM industry

| <b>Megatrend</b>   | <b>Implications to FM industry</b>  |
|--|---|
| Economic growth  | Shift towards emerging markets (ISS)  |
| Globalization  | Localization (ISS, Nutt); Duplicated, virtual services (Hinks)                              |
| Demographic trends   | Variety of global workforce needs (ISS, Nutt)   |
| Sustainability or ethical pressures                          | Supply and value chain, systemic design (ISS, Nutt)   |
| Technological development                                    | Automation and intelligent ways of working (ISS, Nutt); Big data in built environment (ISS) |
| Growth of knowledge society                                  | Communications-centric virtual business (Hinks)   |
| Individualization  | Tailor-made solutions (ISS)   |
| Change in social attitudes and focus on health and wellbeing | Promoting active, healthy and productive lifestyles (ISS, Nutt)                             |
| Commercialization  | Agile specialization, differentiation and innovation (ISS)                                  |
| Regulation   | Building use strategies, versatility, re-differentiation, flexible tenures (ISS)            |

These megatrends influence changes in all FM functions: management of finance, HR, properties, and knowledge. Due to properties’ inertia to change (according to Nutt (2000), only 4% of national building stock changes each year), built environment is the most predictable segment of FM industry and can be used as a basis for exploring future scenarios for FM industry in five branches where facilities are in diverse use.

### 3. Methods and sample

In order to explore the empirical field of FM, five research projects were conducted during 2006-2014. The data consists of a set of five clusters of future scenarios collected during five research projects around usability and productivity of built environment in Aalto University. These projects are shortly described in Table 2.

Table 2: Five research projects analysing FM service future scenarios

| Project name | Project focus                       | More information and reports   |
|--------------|-------------------------------------|--|
| Induspace    | Usability of Industrial places      | <a href="http://www.ttl.fi/fi/tutkimus/hankkeet/induspace/Sivut/default.aspx">http://www.ttl.fi/fi/tutkimus/hankkeet/induspace/Sivut/default.aspx</a>  |

| KUNTO        | Usability of Rehabilitation centres | <a href="http://www.ttl.fi/fi/verkkokirjat/Documents/KUNTO_loppuraportti.pdf">http://www.ttl.fi/fi/verkkokirjat/Documents/KUNTO_loppuraportti.pdf</a><br><br>Suvi Nenonen, Heidi Rasila, Veera Romppainen (2012), Wellness and Well-being in the Future – Scenarios for Well-being Centres.<br><br><a href="http://conferences.chalmers.se/index.php/ARCH/arch12/paper/view/429">http://conferences.chalmers.se/index.php/ARCH/arch12/paper/view/429</a> |
| SELMA        | Senior housing                      | No published work  |

All five projects had two common aims. First, each aimed to develop tools and methods to assess the usability of the built environment in different use-specific space segments. Second, each aimed to develop future scenarios in order to understand the role of the spaces and FM in the future. The scenarios were created according to the space type in project focus as follows: Industrial places, Knowledge workplaces, Shopping centres, Rehabilitation centres, and Senior housing.

Futures approach is a structural way for different actors to proactively prepare for possible future pathways (Jensen, 2014) and deal with uncertainty (Saurin et al, 2008). Futures approach is trans-disciplinary in nature (Saurin, Ratcliffe, 2011) and considers interactions between technological, social, economic, political and cultural variables and focuses on information and knowledge flow instead of money and goods (Jensen, 2014).

Scenario development allows to learn about the future by understanding the nature and impact of the most uncertain and important driving forces affecting our world. It is a group process that encourages knowledge exchange and development of a deeper mutual under-

standing of central issues important to the future of business. The goal is to craft a number of diverging stories by extrapolating uncertain and heavily influencing driving forces. The stories together with the work process have a dual purpose of increasing the knowledge of the business environment and widen both the receiver's and participant's perception of possible future events (Schoemaker, 1995).

The development of scenarios is based on Future workshops which consist of different methods which structure the imagination of participants (Jungk and Müllert, 1987) such as: Future Wheel, ACTVOD, PESTE, and Delphi survey.

In the project of *Usability of Rehabilitation centres in Finland*, the future workshop aimed to investigate the future by creating an understanding of the nature and impact of the most uncertain and important driving forces affecting the physical wellness centres. In *Prowork* project, three sets of workshops were conducted in order to understand the change of work and physical and virtual workplaces.

Future wheel was used in workshops of *Usability of Rehabilitation centres* and *Senior housing*. The participants worked with the Future wheel in order to capture the past, present and future phenomena in connection with the rehabilitation/senior housing. Future wheel is a structured brainstorming method used to organize thinking about future events, issues, trends, and strategy and visualising interrelationships between variables (Jackson, 2013).

Additionally, the Futures table exercise was conducted based on differing systematics, e.g. questions like to whom, what, how, where, what are the enablers, what are the hindrances and so called ACTVOD table was used. The acronym comes from first letters of the six variables: Actors, Customers, Transformation process, Values, Obstacles, and Drivers. This is a tool that allows creating network operating models for structuring and development and is based on CATWOD methodology (Hietanen, 2009). The futures table was used in the *USAB* (*Usability of the shopping centres*) and *Induspace* projects.

*Induspace* project also included PESTE (otherwise known as STEEP) analysis which consists of five aspects: P for Political, E for Economic, S for Social, T for Technological, and E for Environmental. It gives a bird's eye view of the whole environment from many different angles that one wants to check and keep a track of while contemplating on a certain idea/plan (Laihonen, 2005).

The Delphi study was performed in the project of *Usability of Rehabilitation centres in Finland*. It included two rounds of surveys which aimed to clarify the well-being services of the future. The Delphi survey was structured according to four themes: 1. Rehabilitation of working life in the future, 2. Rehabilitation of the ageing people in the future, 3. Rehabilitation for self-paying customers in the future and 4. The facilities of the rehabilitation and wellbeing services in the future (Rasila et al., 2013). The Delphi method is usually used for producing different views, ideas and justifications on which one can base planning and decision making. The method is relevant when the object of research and the problem are open. With help of the Delphi technique, one can start contemplating and choosing between the future alternatives (Pill, 1971; Jackson, 2013).

Table 3 summarises the methods used in different projects. It also includes information about the participants of the workshops.

Table 3: Methods used in Future workshops and participants in five projects

|               | Industrial places   | Knowledge workplace   | Shopping centres  | Rehabilitation centres   | Senior housing  |
|---------------|---|---|---|--|---|
| Future wheel  |   |   |   | x  | x   |
| ACTVOD        | x   |   | x   |  |   |
| PESTE         | x   |   |   |  |   |
| Delphi survey |   |   |   | x  |   |
| Participants  | Users (employees)<br>Facility managers, Architects, Researchers<br><br>N=15 | Users (globally), ICT managers, Human resource managers, Facility managers, researchers<br><br>N=20 | Users (different age groups) Experts, Shopping centre managers, Researchers<br><br>N=40 | Users (visitors, different age groups), Experts (e.g. healthcare experts, representatives of different association), researchers<br><br>N=70 | Users (habitants of senior houses) , Facility managers, architects, researchers<br><br>N=15 |

In each project, the participants were selected based on their role – the aim was to take different perspectives into account. Participants can be divided to five core roles: users, experts, facility managers, architects and researchers. The main priority was to have users involved in each workshop. Experts were engaged to get insights on the knowledge from the field from past to the future. Facility managers were invited to represent the supply side of the services. Researchers were facilitating the workshops and summarizing the reports. All scenarios despite the Senior housing scenario are published.

The last phase of the Future workshops included the future narratives which summarized the outcomes of the results produced by different methods (Table 4). Each analysed branch had four scenarios drawn except the *Industrial Places* which had five scenarios in total.

Table 4: Future scenarios developed for five different branches

| Scenarios                        | Description   |
|----------------------------------|---|
| <b>1. Industrial places</b>      |   |
| 1.1. Monumental industrial space | The old industrial piece of architecture has been taken into new use or the new industrial building is retrofitted to a monumental wow-architecture object. |
| 1.2. Modular container factory   | The number of modules can be adapted based on production volume.  |
| 1.3. Multiuse pro-               | Loft is used as a factory for production only for certain phase of time and   |

|                                      |  |
|--------------------------------------|--|
| duction loft                         | can be transformed to other uses easily  |
| 1.4. Mobile virtual production space | Fully automatized and controlled from a remote white-collar control centre mobile virtual production space   |
| 1.5. Mountain top production space   | Space which is based on consideration of all the issues connected to sustainability, energy-use and environmental care.  |
| <b>2. Knowledge workplaces</b>       |  |
| 2.1. Safety box                      | <p>It is based on a decreasing role of physical place.</p> <p>Environment is highly polluted and the mankind has not succeeded in decreasing the carbon footprint. Virtual world is the most functional reality and social connections take place mainly in the second and third life. Physical space exists only to protect people.</p>   |
| 2.2. First life                      | <p>It is based on a decreasing role of virtual place.</p> <p>Physical spaces are in full use. Ecocatastrophe has taken place in digital reality and the information and communication infrastructure did not overcome the climate changes. Real estate platforms for living and working and different generations struggle to relearn old ways of working. There are lots of trainings for writing letters and new kinds of time management trainings are famous. Social places are important in order to transfer old ways of working to younger generations who have never seen mobile phones.</p> |
| 2.3. Care and love                   | <p>It is based on an increasing need of social place.</p> <p>Knowledge intensive society has caused a variety of symptoms for knowledge workers and they gather to workplaces in order to be re-treated. The driving force for working is sharing the work to achieve the goals. Individual performance is rewarded only as part of a collective outcome. Physical and virtual places are designed to enforce a variety of social activities and to provide all possible support for well-being of knowledge workers.</p>  |
| 2.4. Network no-mad                  | <p>It is based on a decreasing role of organizations as infrastructure.</p> <p>Working takes place in networks and individuals manage themselves. Physical places are providing platforms for different networking activities, while virtual place is an office base for individual entrepreneurs. Social places occur in both realities.</p>  |
| <b>3. Shopping Centres</b>           |  |
| 3.1. Wellness circus with user zip   | User profile is in zip and the user is identified by smart and responsive environment in shopping centres. After arriving to a shopping centre, instructions for the recommended user journey is made for the customer – the proposal is based on the status of wellbeing of the individual and the services are tailored according to the profile.  |
| 3.2. Virtual interface in the living | No one visits shopping centres but shopping is an individual or social amusement through simulations and haptic experiences in ubiquitous  |

|                                  |   |
|----------------------------------|---|
| room                             | world.  |
| 3.3. Community                   | Community is developed around a shopping centre – shopping centre is a new form of old village with all the services in the near distance.  |
| 3.4. Tradition centre            | A place to go when disappeared tradition of going to shop needs to be experienced. It is a nostalgic environment, where one can try how it feels to push shopping trolley or to encounter a real shop keeper. |
| <b>4. Rehabilitation centres</b> |   |
| 4.1. Experience centre           | The experience centre for sustainable well-being. The centre provides experiences with all spices provided through local resources.   |
| 4.2. Balancing training          | Balancing training for the veterans of work life. The disseminated service network for free choice – customers will collect their own training program from different modules.                                |
| 4.3. Special expertise centre    | The provided service focus on high expertise in one or two narrow fields and is recognized internationally.   |
| 4.4. Delivery centre             | The local well-being services are delivered to the places where the customers and needs are.  |
| <b>5. Senior housing</b>         |   |
| 5.1. Living as a world citizen   | The climate change has changed the globe so that it is impossible to identify one's own roots anymore as they are scattered around the world because of high levels of mobility and travelling.               |
| 5.2. Social entity               | The network is your family – family is constantly recreated within the community in which an individual is involved.  |
| 5.3. Virtual entity              | Seniors can be active even though there are physical restrictions. Social digital network is an essential part of daily life.   |
| 5.4. Long life                   | Senior citizens live longer and need longer term places because the medical science has successfully lengthened our lives dramatically.   |

## 4. Analysis of the scenarios and results

After the analysis of the content of scenarios, four scenario clusters were identified: ICT-driven, New practices to conduct work processes, Sustainability-driven, Well-being-driven, and the New use of spaces. Table 5 indicates how the different scenarios are allocated to different clusters. The number presents the number of scenario from earlier descriptive illustrations.

Table 5: Clusters of the scenarios of different space segments

|  | New practices in work processes | ICT | Sustainability | Well-being | New use of space |
|--|---------------------------------|-----|----------------|------------|------------------|
|--|---------------------------------|-----|----------------|------------|------------------|

|                                       |               |          |          |          |               |
|---------------------------------------|---------------|----------|----------|----------|---------------|
| <b>Industrial place scenarios</b>     | 1.4           | 1.4      | 1.5      |          | 1.1, 1.2, 1.3 |
| <b>Knowledge work-place scenarios</b> | 2.2, 2.4      | 2.1, 2.2 |          | 2.3      |               |
| <b>Shopping centre scenarios</b>      | 3.2           | 3.1, 3.2 | 3.3      | 3.1, 3.3 | 3.4           |
| <b>Rehabilitation scenarios</b>       | 4.2, 4.3, 4.4 |          | 4.1, 4.4 | 4.2      | 4.4           |
| <b>Senior housing scenarios</b>       | 5.2, 5.4      | 5.3      | 5.1      | 5.2      |               |

The analysis of scenarios in accordance with four identified clusters show that the *New practices in work processes* seem to be the main driver of the scenarios of future work and living environments. Change of work practices was driving future development in all spaces and one to three scenarios in each space. However, the quantitative grounding can be used only as a weak signal. From content analysis, the following propositions can be drawn:

*New practices in work processes* cluster suggests that the part of work processes and practices are shifted towards digital environment. This affects both the behaviour and the environments where we act: virtual shopping in living room with simulations and haptic possibilities (*Scenario 3.2.*) has widened the traditional uses of living rooms to uses of cinemas, amusement centres or adventure parks. Will these actions take place at home in the future? Or are we going to do our shopping in science centres with the latest technology? Also, due to the new practices in work processes service concepts of spaces have evolved and are still evolving exponentially. The service offer for *Network nomad* (*Scenario 2.4.*) provides aspects of fully different service provision than traditional office concepts were able to offer in 2006 when the workshops were conducted.

*ICT-driven* cluster of scenarios indicates that there are two implications of the use of technological possibilities: development of smart environment which guides our activities or transformation of ways to conduct processes and it is partly interlinked with the cluster of new ways to conduct work processes. ICT-technologies and Internet of Things (IoT) affects how actors communicate with one another and enables better quality of both service delivery and operational management of built environments (*Scenario 2.1*). *Scenario 5.3* in *Senior housing* takes a similar approach in stating that, i.e. social needs can be fulfilled with virtual interface. However, because of vulnerability of ICT-technology, old practices can be adapted to new uses, which is proposed in *Scenario 2.2* of *Knowledge workplaces*.

*Sustainability-driven* cluster indicates that the environmental crisis can affect the global level and the climate change possibly resulting in dramatic changes in different continents and districts. This was discussed greatly in the *Scenario 5.1. Living as a world citizen* in *Senior housing* and in *Scenario 1.5. Mountain top production space* in *Industrial spaces*. The other aspect is related to energy-efficient and environmentally friendly behaviour and solutions and emphasized the significance of local resources. This was highlighted in scenarios in *Re-*

*habilitation centres (Scenario 4.1. Experience centre and Scenario 4.4. Delivery centre) and in Shopping centre's Scenario 3.3. Community.*

*Well-being* driven cluster covers different perspectives of the well-being of the user of spaces. It is a primary service offer in *Shopping centre Scenario 3.1. Wellness circus, Knowledge workplace Scenario 2.3. Care and love* and in *Scenario 4.2. Balancing training (Rehabilitation centre.)*. The significance of another aspect of well-being – community - has increased in scenarios in *Shopping centres (Scenario 3.3. Community)* and *Senior housing (Scenario 5.2. Social entity)* as well as in *Knowledge workplaces (Scenario 2.3. Care and love)*.

The *New use of spaces* cluster is highly important in *Industrial place* scenarios (*Scenario 1.1. Monumental industrial space, Scenario 1.2. Modular container factory, and Scenario 1.3. Multiuse production loft*). It indicates the need for spaces to be adjusted and used for different purposes, designed with different principles than traditionally or designed based on the principle that one actor, function or purpose takes place in a space for only a certain amount of time. The traditional value of the former use can be a new product as is indicated in *Scenario 3.4. Tradition centre in Shopping centres*. The *New use of spaces* is connected also to a *Scenario 4.4. Delivery centre in Rehabilitation centres*.

## **5. Discussion**

In order for FM to proactively support organisations' core business and develop their services, a deep understanding of changing organisational environment is needed. Megatrends discussed by ISS (2014), Hinks (2002) and Nutt (2000) such as technological development, globalization, sustainability, demographical change and others affect the future of organisations, thus different needs for FM services arise.

Future research methods that are used in this paper represent how they can support the future orientation and proactive approach of facilities management. Futures approach promotes forward-thinking, widens perspectives which then increase the number of options available for decision-makers to prepare and manage the upcoming change (Saurin; Ratcliffe, 2008). The short response time to future events is important for organisations and FM service providers in order to stay competitive in global and fast-changing markets.

This paper analyses different future scenarios in five different spaces – Industrial Place, Knowledge Workplace, Shopping centre, Rehabilitation, and Senior housing. Based on the main drivers for future change, these scenarios are then clustered into five different categories: ICT development, New practices in work processes, Sustainability, Well-being and New use of spaces. These driver categories, recognized in this study, are consistent with the trends identified by Hinks (2002), Nutt (2004) and ISS (2014) and have an effect on all different spaces, thus all FM industry.

The development of ICT and Internet of Things (IoT) has influenced not only how built environment is treated but especially it changed and continues to change the ways how work is done. It empowers employees to work from any place and any time, thus changing the demand and usage of buildings. Remote and virtual work means more individualization and creates the need for tailor-made solutions (ISS, 2014). Diminished demand for industrial spaces and office buildings creates the need to reconsider and create new building use

strategies, thus, in many cases, change regulations in very conservative construction sectors. Overall focus towards sustainability and well-being leads towards system re-design and creates the need for services promoting active and healthy lifestyles.

Based on the literature and results of this study, we suggest that there are four topics for proactive facilities management to be taken into account. They are:

1. FM in virtual worlds

FM service providers can support this by e.g. studying the virtual paradigm and its opportunities and implications for the FM applications. Managing knowledge sharing within users on a global scale easily and quickly becomes strategically important for FM. Virtual communications and document sharing is exponentially increasing which might also cause some ethical and security issues like: which data belongs to who? Who is responsible for securing the data transfer? And similar. Ability to provide services remotely and fast becomes a competitive advantage for FM service providers and geographical location of customers has less effect on service delivery.

2. Dissemination of activities and new ways of doing daily activities, which require new ways of supporting clients

Facility managers can take a user-centric approach to developing services that support the tasks-to-be-done of the users instead of supporting each branch as we know it. Personalisation of FM services to support each user according to ones needs should become a main priority for FM service providers. The Internet of Things will bring opportunities to automate more activities for FM as well as to better understand the users and provide more productive spaces.

3. Responsibility and wellbeing factors as business drivers

FM service providers can support well-being by emphasizing individual user and his/her personal well-being in service offerings. Highly flexible spaces, better designs and new maintenance approaches are becoming more and more available due to a better understanding of the users and the building itself. FM has to get even closer to their customers and their core businesses in order to provide user-oriented services. Flexibility of work (time and location-independent work) creates challenge for FM and requires a new approach for FM to their own operations and service delivery.

4. Mixed and multi-use space segments

It is important for FM to break free from the standards and seek for synergies between different branches. The buildings are not anymore single-use buildings but the mixed-use spaces and it creates challenges for FM providers as their services are too segmented and traditional. Synergies between different services, service providers as well as ways of providing a service are needed in order to fully support client organisation. Facility managers should experiment with contemporary solutions and rethink the fixed physical construction paradigm in order to go hand in hand with the changing organisations and their needs.

The research is based on futures studies and scenarios are developed by the limited amount of participants. In order to receive different perspectives on developed futures, various ac-

tors (from users to researchers) were invited to future workshops. Still, the number of participants was small (15 people) and the results might be debatable. Even though the findings are limited to the Finnish business environment and context, the future scenarios of different branches and the future of FM may offer some insights to global level too. These results closely correspond to the trends and implications identified in previous literature, therefore it is possible to state that they are valid.

## 6. Conclusion

More and more facility managers understand the need of changes in FM field. A new, proactive and more strategic approach towards FM needs to be taken in order to meet ever-changing needs of their services' users. In order to plan, design and manage facilities strategically, a deep understanding of future trends and users' requirements is needed. To provide a dynamic view and help planning future FM strategies, future scenarios are created based on identified trends. These different future scenarios help organisations to prepare for possible changes and avoid the situation when "probable" future does not appear. Few megatrends, such as ICT development and globalisation, are affecting the FM industry in every branch and every scenario, and they need to be closely looked at to understand what it will mean not only for FM but also for other businesses and all society.

# **Re-approaching the Meaning “Innovative Service” on Generating New Service Process: MEIJI Milk Express study case (fresh milk home delivery service) - Provider and User perspectives as innovative/innovated service**

*Leisa Moreno*

Ryukoku University, Graduate School of Economics

*This paper adopted two research methods: systematic literature review to identify how has been services defined as innovative beside the novelty determinant component identification allowing such definition; and single-case study, demonstrates the need of such clarification for services which indeed belongs to the past and re-introduced in present time. The analysis focuses on the MEIJI Company “new” delivery service and explores how the provider and users are able to identify the service as innovative. The findings here after reported give the degree of how it urges the need to identify novelty determinant components on the present time for similar cases.*

## **1. Introduction**

What is an innovative service?

Shall it be understood as service that “innovates” verb predominance approaching sense or innovation on/in even for the service? For non-native English speakers like different Latin based language: “service qui innove ou service (re)innovée ou service innovant”; “serviço que inova ou serviço (re)inovado ou serviço inovador”; once again in English: “Innovative service”, service that have been innovated or that innovates. Looking to questions introducing the conference it is easy to lead comprehension focus to newly generated services. But reflection towards novelty in and for (insisting on the difference language leading understanding matter) services available in this century. Appearing now a day or coming from the past?! In a simple analogy we can take reference of “fashion cycles”: inspirations of past (re-introducing renewed and improved version).

“Innovative”: verb or adjective (action, attitude, behavior or characteristics)?!

Meaning “New” or “Renewed” Service?!

Shall in this paper all notions, definitions and specificities of service be taking in importance: as process as product as well as set of characteristics in a product (Gallouj 1984) .

Service: comes from to serve, letting others do it to you, for you. So is that any “personal gesture” turn out in to an economic activity synonymous of innovating in service’s sector?!

It is convenient to talk about innovative services because services providers decided to do it for the user/client instead of letting it to be done by the client or only because it never was done before.

Taking in account details in a service as process and enlighten it as new when one of innovation types (radical, improvement and incremental) operates over specific detail.

Re-evaluating user/consumer’s decision on “participating” versus “non-participating” at the **Genesis** of innovative services – social dimension of co-creation of value; can we consider be in front of an infinity source of potential service? For that as soon as de future user decide to no longer do it on his own and waits for a service provider to take hand and do it for him.

How to measure the degree of novelty under such considerations?

Service engineering and R&D in services shall be the main way/place to identify innovative characteristic of.

But R&D in services is not adequately reflected in the productivity statistics and so underestimated. Here is an interesting concern to put at light researches on what to qualify as innovative service (Djellal et al 2003). Impossible to do not take on pair the productivity matter related to.

User/client/market-oriented services instead of traditional sense administrative public services got its word on innovative services: extending into complementing or not activities.

Food industry does not stay behind on the world servitization adaptation process. The new type of value creation is based on the offering product-service system (PSS). In an economy such as the Japanese one focused on the changing order: the proof MEIJI a very well-known and owner of an honorable reputation brings back to the light of the day an old fashioned service: Fresh Milk Delivery Service.

This subject pushes a review through all concerns around defining innovative service.

Let’s then apply evaluation modes suggested by previous reflections on this matter.

## **2. Research Methods**

For the common sense believe: “Innovative Services” are those awaking the attention of the user (actual ones as well as potential ones) by a “difference” caused by an element not recognized by the user up until the moment the refereed service is available.

This paper essence idea is: a given innovative service can be considered as such by the moment it is seen by users alike and then become reproduced for the potential and future users.

Two methods have been used:

1. Systematic Literature Review: based on rigorous and reproducible steps that allow the linking of future research to questions and concerns posed by the past research (Thorpe et al. 2005):
2. Case Study Research: producing first-hand understanding (Yin, 2004), its ability to examine in-depth a case within its real-life context (Tavoletti,2007).

## **2.1. Systematic Literature Review**

### **Data collection**

Based on traditional systematic review process, the following set criteria have been established:

- EBSCOhost as the research database;
- All chosen articles were published in English;
- All articles were from 2000;
- Keywords used were: service, innovative, definition;
- Abstracts helped on final selection;
- Full reading of articles;

A total of 15 papers suggested by the database composed the dataset regarding to identify how has been services defined as innovative adjacent to the novelty determinant component identification allowing such definition.

### **Dataset analysis**

Analysing the dataset there are some considerations to take in account: fully dedicated papers to innovative service definition are “inexistent”; the number of papers ranged by the database related to the keywords increased after 2010; topics were of a multidisciplinary nature but management predominance is easily noticed.

### **Results**

Deepening the analysis it is possible to identify a lack of studies examining explicitly innovative services definition. Furthermore the generating process of new services also suffers same scarcity.

Focus was about innovations *in* service often entitled as “innovation service”. And this takes us back to preliminary distinction made for semantic matters.

However a brief and dual categorization allows ranging the read articles as follow:

- Innovation basis: all the literature measuring the degree of novelty.

AND

- Management basis: all the organizational structure support.

## 2.2. Case study

“Single-case studies can richly describe the existence of a phenomenon” (Siggelkow, 2007).

Through the diversified, performing and crowned by novelty Japanese service universe two cases were picked to embody this paper.

Adopting a descriptive introducing method the case is here by presented. Then follows the data analyse. In order to follow an ideal evaluation of the respective “Innovative” characteristic/adjective/behaviour questions ruled by a multidimensional approach supported the interviews.

### Data collection

In order to respond to the paper aim the Case Study Research method was used to produce a “first-hand” understanding due to the ability it provides on examine in-depth a case with real-life context (Yin, 2004).

Interviewing (the “how”) service provider and service users by the belief only the lived experience by both side shall reveal the novelty (the “why”) degree contained by the chosen service.

All the interviews (providers and users) were guided by a pre-elaborated questionnaire which the targets could have in hand along interview moment.

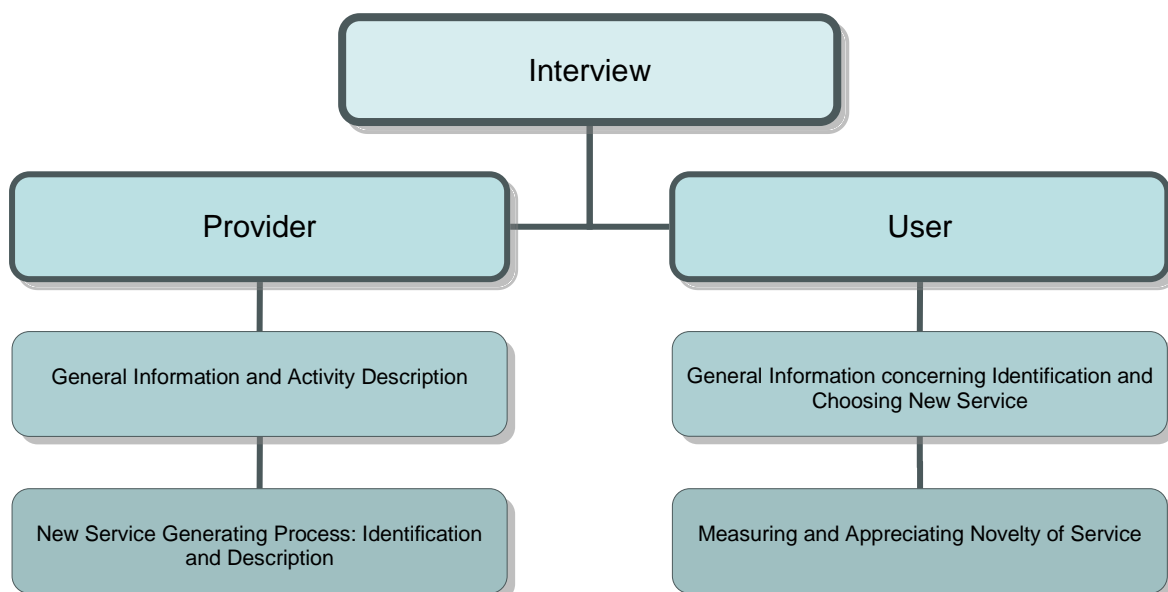

Figure 1: Interview key points. Source: Own elaboration.

## **Data analysis**

A cross-interview analysis allowed insights from each interview compared to one and another.

## **3. Findings**

Up-and-coming findings from the data analysis are here reported.

Service research universe after strong empowerment still have room for improvements on novelty degree measurements aside of continuous hard work on productivity measurements.

The paper insights aim to contribute on future brain storming(s) dedicated to improve construction of solid tools for innovative service identification, definition, classification, evaluation and so on.

### **Innovative service generating process**

Every and any process is considered as a series of actions or steps taken in order to achieve a particular end in general. Here in particular to generate services that is new, original and introduces changes taking in consideration respective creative origin. Undeniable additional perspective shall be taken when facing brand new services; especially when using existing tools for identification, definition, classification, evaluation and so on.

Despite the semantic distinction concern launching the essence idea of this paper, data indicated in the case for MEIJI Corporation decision to introduce answered the market demand of servitization.

The innovative service generating process appears here like obeying to context and conjuncture exigencies. And in simple way we approached this process by the angle of value co-creation by users' deliberation on self doing (or not) versus service provider make of users decision a business opportunity.

### ***Cyclical Momentums* definitions of innovative services**

Timing for questioning overcame changes seems discarding any order or regent law.

Suggesting to revisit or to make a retrospective analysis of "new" or "renewed" or "re-introduced" service among existing analyses supported by this paper aims to call attention up on innovative service distinct from service innovation. To be ranged as revisiting a concept or notion paper shall belong to future readings.

Cyclical momentums definitions get its "inspiration" by the time line simple observation: In a moment at high demand and supply response is followed by dropping aside for alternative solution; and contextual reconfigurations re-bring on vogue former solution.

What to say for the milk delivery service staging and solid comeback?

Looking at the choice made by MEIJI Corporation to bringing back from past a service instead of suggesting fully brand new creation of service type suggests new insights regarding innovative service identification, definition, classification, evaluation and so on. This makes questions the use of fashion cyclical returns as analogy for this specific case.

### **Become a servitization strategy applied success company on Food Industry**

Innovating and integrating successfully as moving into service universe is usually made facing difficulties. This is said because mutations on management must be done. Service businesses come into the long living different kind of organization.

MEIJI Corporation (re)introducing the delivery service made use of its market needs knowledge following business strategy and niche opportunities on Food Industry. A whole management section of Meiji Dairies Corp.'s home delivery was created. Moreover a social dimension is to be taking in account: aging population matter. Therefore the market could and still can expect further growth in sales and profits as the population still ages.

We here assist to an adoption of the servitization strategy making full use of knowledge acquired by MEIJI Corporation. Being a hard core food industry organization, the company could by adding a service add knowledge of its own market: servitization strategy adoption requires the acquisition of new knowledge (Leoni 2015). This implies that information and knowledge management systems have to support the dissemination, gathering, and application of knowledge (Ward and Graves, 2007).

It would be very interesting to make a comparative analyze between types of delivery services on food industry available for users. A good example and alternative reason of dropping aside on time of the milk delivery: grocery delivery service. The milk being an item to certainly belong the list, we shall not forget some requirements to have such service: punctual need, over determined amount of purchase, distance from store, etc. according to provider's means to provide such service. In contrary, milk delivery service for MEIJI is a specific kind of item, on a daily basis, using shops as distribution points covering an identified perimeter. Another good example is the convenience stores. First on line to represent Japanese service universe they are everywhere with a logistic system defying any and every activity. Any user could just go for his milk at the street corner. And still delivery milk service can step out the scene once the delivery channels provide highly predictable and stable demand according to providers and they play over food safety winning hearts among users and costumers.

### **Users and costumers perspective**

The success of any novelty is related to the market reaction.

After discovering the novelty a major concern for respective suppliers is the taking in of the solution as alternative among existing choices.

Following MEIJI Philosophy of extreme importance attached to clients' feedback we can make direct appreciation of the value of co-creation as well as an improvement of knowledge concerning this specific service. At same time it allows the Corporate a boost on delivery outlets' promotional activities as it is easier to pitch new products.

Another plus for this service is the client advising potential ones to become actual clients. Positive experiences benefits from the neighbors "bouche-à-oreille" information divulgation current.

#### **4. Discussion and conclusions**

There is always room for growth in producer services activity, particularly in the information field and chiefly for those related to R&D functions: innovative services just come from it tricking mind as for the question what comes for "the egg or the thick-en".

In further and deeper multidisciplinary analyses this revisiting proposal can reveal policy implications, for example. And this can be of different nature: social (aging population), environmental ("milk man" dislocation versus all service users' dislocation to purchase the item), etc.

The chosen case might have a prime individual "wellbeing" contribution and "solving problem" visage as above different nature policy implications can refer to. The system offered by the delivery service has more than primer social effect. As they have shops centralizing the departure point of fresh product environmental issue has also its dimension taken in account. Same for the employment economic one: the more the number of clients grows, the more employees will be needed to respond with service quality.

We hope to see more and more analyzing study cases adopting "multi-criteria and system dynamic perspectives" evaluation. This empowering evaluation of the evolution through the "Innovative Services" universe we now live in. Details can be revealed and handled by accurate tools as they're caught by their mutating shapes in the ongoing generating new service process.

#### **Acknowledgments**

Gratefull acknowledges are here addressed to all MEIJI professionals that gave time and attention to the study. Special acknowledgments goes to Yasuyuki Nishigaki Sensei and Elie Mizokami for academic help and support.

**Key Words:** Fruit Wine, wine tourism, festivals, entrepreneurship, experience

## 1. Introduction

In this paper we investigate how fruit wine festivals (Cavicchi and Santini 2014) and producer visits (Croce and Perri 2010) are used to promote the new field of modern fruit wine (including gastronomic cider) and whether these promote local tourism. Fruit wine has been re-invented, particularly in Denmark, by a new scientific approach to cultivation and production methods resulting in a new type of gastronomic products. Hitherto, fruit wine in Denmark has mostly been used in the low-to-medium priced forms of cider and dessert wine. But modern fruit wine may be considered parallel to grape wine and can be used more widely as an aperitif, an accompaniment to meals or even used in food. This wider use and the basic idea of fruit wine as an alternative to grape wine is new. The use of grape wine and wine tourism has been investigated extensively (e.g. Osmond and Anderson 1998; Hall et al. 2000; Williams 2001; Carlsen and Charters 2006; Hall and Sharples 2008; Croce and Perri 2010; Mason and Paggiaro 2011; dal Bianco et al. 2013; Nella and Christou 2014; Cavicchi and Santini 2014), but not the use of fruit wine and its relation to tourism. The purpose of this investigation is to see how some fruit wine producers in Denmark attempt to use festivals and producer visits to create an interest sphere

and promote sales, to find the drivers and barriers behind such attempts, and to see how effective fruit wine festivals and producer visits are in creating a new interest sphere. Further, we analyze how much this contributes to development of local tourism and the possible barriers for this.

The festivals and producer visits are results of entrepreneurial activities (Binks and Vale 1990; Fletcher and Watson 2006; Fuglsang and Sørensen 2013). Some of the activities are even carried out in entrepreneurial networks (Johannisson 1988; Klyver and Hindle 2007), for example the fruit wine festivals. The focus of this paper, however, is not on the entrepreneurship per se or the technical innovations, but on how the entrepreneurs attempt to promote the fruit wine. Our approach is to see this as a market innovation by creating a new interest sphere of fruit wine in a part of society – which is a marketing innovation (Nyström 1990) – by using established, locally oriented tourism means (festivals and producer visits).

The investigation is carried out through case studies in Denmark of four fruit wine producers and of two annual instances of a fruit wine festival.

In the paper we first present the background – the development of modern fruit wine as a new gastronomic field and the fruit wine producers' attempts to create a new interest sphere and promote sales of the fruit wine. Next, we present the theoretical elements that are needed to understand and explain the producers' use of festivals and producer visits as means to promote modern fruit wine. In the next section we analyze the data material and finally a conclusion with a discussion of the innovative theoretical perspectives this investigation leads to will follow.

## **2. Background**

### **2.1 Modern fruit wine**

Fruit wine is undergoing gastronomic renewal. New, scientific cultivation and productions methods and the use of local varieties of fruit, primarily apples and cherries, based in local "terroir" (Groze and Perri 2010) are bases for new types of fruit wine with high gastronomic value. Producers are experimenting with new fruit varieties, new cultivation methods (using different fertilizing methods, land areas, harvest times, apple and cherry varieties etc.) and new production methods (storing temperature, fermentation, chemical control etc.). For example, they experiment with apple ice wine by storing the wine outside during the winter. University scientists are investigating and developing cultivation and production methods that the producers use. The development from craftsmanship to scientifically based production which grape wine has undergone the last fifty years (emphasizing oenology) is also happening in modern fruit wine production. Many of the fruit wine producers embracing such a new approach have been producing fruit wine for less than ten years.

This development has led to new fruit wines with a higher gastronomic quality than traditional cherry and apple wines. The nuances of flavour and combinations of sweetness and acidity have improved resulting in a variety of refined sophisticated tastes. The producers experiment with wine from many kinds of fruit including rhubarbs, gooseberry, elderflowers and black and red currants, however cherries and apples clearly are the most used fruits. Apple cider has internationally been developed to a high gastronomic level; however, the Danish fruit wine producers have even develop it further into a sparkling wine that can be used similar to champagne.

Fruit wine has traditionally been seen by users as having limited use, mostly as aperitif or as a beverage suited for certain specific dishes such as “galettes”. A challenge for the modern fruit wine producers thus is to widen the field of use so that the wine is connected to food consumption. For example, to make it mainstream to drink fruit wine with many kinds of food and use it in dishes to increase the gastronomic value of them.

For the entrepreneurs who produce the new type of fruit wine, the marketing and storytelling about the wine is crucial to put fruit wine on the consumers’ consciousness and establish an interest sphere and a business. Wine tourism is one means of doing this. The production of fruit wine is carried out locally and the tourism that the fruit wine production may generate is also partly local (except the fruit wine festival, which, however, brands the localities as the fruit wines are often presented as “from locality x”).

## **2.2 Creation of a new fruit wine experience Interest Regime**

The producers use fruit wine festivals to simultaneously market their own products and create a general interest in modern fruit wine – an interest sphere, which we here shall term Interest Regime using a concept from the French sociologist Laurent Thévenot (2006, 2007). Both the festival and producer visits are local and thus can be classified as tourist activities that contribute to development of the general local tourism and the destination (Leiper 2000). However, as promotion of fruit wine sales and creation of a modern fruit wine Interest Regime, the festivals and producer visits also have the wider aim of promoting fruit wine sales and export.

Consumption of fruit wine is part of the experience economy (Pine and Gilmore 1999; Sundbo and Sørensen 2013) as it is purely hedonic (Caru and Corva 2003). Festivals and producer visits are experience activities as well as promotion means based in the currently hyped experience economy (Pine and Gilmore 1999; Boswijk et al. 2007; Mossberg 2007; Sundbo and Sørensen 2013). The festival and producer visits are also used to get publicity in national and international media. These activities can be understood as experiential

marketing (Smilanski 2009), aiming at promoting sales of fruit wine and a general fruit wine Interest Regime through the creation of experiences.

### **3. Theory**

The paper is primarily empirical with an inductive interpretation of the results. However, some theories are bases for our understanding of the development of local fruit wine production and fruit wine tourism. Three theory traditions are bases for the empirical analysis. One is Thévenot's theory of Interest Regime (Thévenot 2006, 2007) which can explain the attempt to create a wider interest sphere in the society. Also, the producers intend to promote and create sales via festivals and producer visits and the theory of experiential marketing (Smilanski 2009) is used to understand this part of their behavior. Finally we emphasize the emerging research tradition of food and wine tourism. This tradition does not contain one fundamental core theory, but rather consists of scattered generalizing conclusions on empirical research (Hjalager and Richards 2002; Hall and Sharples 2008; Groce and Perri 2010). Nevertheless, these conclusions can be used to ask research questions for the new fruit wine tourism phenomenon and assess whether our analysis can contribute to this tradition.

#### **3.1 Interest Regime**

The theory of Interest Regime is suitable to understand how a group of people develop a common interest – in this case in fruit wine as a gastronomic field with all the aspects of taste, use and knowledge about cultivation, production and so forth. The idea of Interest Regime is based in the idea of social practice, which has been a concept and approach within sociology that has emphasized empirical social construction by groups of people of social phenomena (Gherardi 2006; Corradi et al. 2010). The theory used here is based on Laurent Thévenot's (2006, 2007) theory of regime of engagements. Thévenot develops his and Boltanski's earlier theory on economies of worth (Boltanski and Thévenot 2006) into a theory on how individuals are engaged in political and market activities. He defines three regimes of this engagement: familiar engagement where the individual's interest is personal and the social practice carried out in small, tight communities; engagement in a plan where the individual carries out an interest as a plan in common with other people outside the community; and justifiable engagement where the individual is engaged by the public order, which is the strongest determinant.

We can not apply Thévenot's regimes directly on the development of fruit wine as an Interest Regime. His theory is oriented towards explaining political power and discourse while the explanation of development of interest for fruit wine concerns a more personal sphere (wine consumption and meals) and experiences, which often have a hedonic element (Pine and Gilmore 1999; Jantzen et al. 2012; Sundbo and Sørensen 2013), which is not explicit in Thévenot's theory. However, we can base the understanding of interest regimes on his two first regimes. The regime of engagement in a plan contributes the

elements of understanding individuals' engagement in fruit wine as a common social movement, while the regime of familiar engagement contributes an understanding of wine consumption and meals as a social activity in the family or group of friends and an enjoyment of fruit wine that has hedonic elements.

The formation of the fruit wine Interest Regime is a social process in which individuals and common structures interact (cf. Giddens's (1984) structuration theory). Media – mass media and ICT-based social media – play a main role in the formation of the Interest Regime.

### **3.2 Experiential Marketing**

One of the newer developments within the field of marketing is the idea of experiential marketing (Schmitt 1999 and 2003; Elliot and Percy 2006, Lenderman 2006). The idea of involving experience elements in marketing in order to influence or create an emotional impact on potential or actual consumers is far from new. This has been an important element in creating a recognizable brand to which consumers can relate (Schmitt 1999, Elliot and Percy 2006). Likewise, marketing has played a role in creating the overall customer experience (Pine and Gilmore 2002; Schmitt 2003). However, in experiential marketing an event or similar live experience forms the central core element of the entire marketing strategy.

Experiential marketing exists in various different theoretical and practical conceptualisations. Here we use that of Shaz Smilanski (2009). In most marketing approaches there can be a multitude of marketing communication channels. In experiential marketing, the central element is the live brand experience. It should be an experience in order to leave a lasting imprint in the memory of the customer; it should be a brand experience as it relates not only to a product, service or experience offering per se, but more so to an overall desired impression of the offering and the producer behind it; and it should be live to be simultaneous and allow for interaction with the customers. As for experience content, it should communicate what Smilanski (2009 p. 6) refers to as "the big idea" which is the intended impression on the end consumer. This stems not only from the properties of the product, service or experience being marketed, but also from the brand personality or intended identity of the producer. The live experience often includes one or more memorabilia.

Such a live brand experience can either be direct and take place face-to-face with customers, or it can have an indirect form, for example live television broadcasts or through online virtual worlds. What is important is that the event is live. It should immerse the customer in the brand offering by surrounding the customer with multi-sensory inputs creating a live involvement and pre-occupation with the offering. In this case of investigation, the brand offering is

replaced by the overall phenomenon of modern fruit wine. Thus the customer should be immersed in multi-sensory inputs during the live event.

This does not exclude other more traditional marketing channels. In fact, quite the contrary: It includes a variety of other marketing channels such as advertising, word-of-mouth, digital marketing and field marketing. But experiential marketing is a holistic and integrated approach in which the live brand experience forms the central core element and the other marketing elements serve as amplification channels around the core element. This constellation can allow the core element to be used in all other touchpoints with end customers.

Importantly, this integrated methodology built around a “big idea”, the live brand experience, should not be a tactical aftermath or supplement, but rather a strategic element planned from the beginning and forming the central point of origin for the overall marketing effort. It should combine asynchronous mass marketing raising awareness more generally among potential consumers with more live direct marketing aiming at creating a stronger, more personal bond between the producer’s offering and the end customer (Smilanski 2009 p. 28). The ideal is to transform the end customers into advocates or even evangelists for the offering, in this case modern fruit wine in general.

### **3.3 Wine and food tourism research**

A quite comprehensive literature on research of general food and wine tourism demonstrates that gastro-tourism (tourism where people travel with the aim of experiencing meals, food and wine) is a growing field (Tourism Recreation Research 2001; Journal of travel and tourism marketing 2003; Groze and Perri 2010; Cavicchi and Santini 2014). Without the concept being used, the research demonstrates that the gastronomy Interest Regime is a growing field in many societies (Hjalager and Richards 2002). Wine tourism has also been researched particularly (Carlsen and Charters 2006), which has led to models for managing and marketing wine tourism. Nella and Christou (2014) have segmented wine tourists according to their involvement with wine. They found that the more involved winery visitors are in wine interest, the more they were interested not only in the wine, but also visiting other wineries and buy wine afterwards. The low-involved people’s motive for visiting wineries was rather that they were part of a group. Mitchell and Hall (2003) found that high-involvement visitors are more likely to visit wineries year-around (and thus create year-around tourism and wine sales). These results indicate that the Interest Regime concept is useful in understanding customers’ engagement with fruit wine and that the producers should emphasize particular segments in their attempt to create a fruit wine Interest Regime to market their fruit wine.

Wine festivals have been investigated as a wine marketing as well as a tourism activity (Hall and Sharples 2008). Yuan et al. (2004) made a survey to visitors at a wine festival and found that interest in wine was the most important motive to visit the festival followed by interest in experiencing festivals. Family togetherness and socialization were motives of less importance. This indicates that wine festival attendants mostly are people involved in the wine Interest Regime. These had higher education and income than those mostly interested in festival and social activities (Yuan et al. 2004). Mason and Paggiaro (2012) introduced a stimulus-response model to explain visitors' behavioral intention in a food festival to re-visit the festival or buy products afterwards (which is an effect of their satisfaction). This intention is dependent on a positive emotional experience, i.e. what happens to them during the festival. The festivalscape (the physical environment) is only influencing their satisfaction indirectly via the experiences of what happened in the festival. This underlines the importance in an experience marketing approach to understand wine festivals. Robinson and Clifford (2007) found that authenticity is an important factor in creating a good experience in food and wine festivals. Beverland et al. (2001) have introduced a theoretical life cycle model for wine festivals which says that in the beginning wine festivals are local and focused on selling the local producers' products. Later they become more national or global, emphasizing media interest and mass marketing.

Producer visits have also been investigated. Sparks (2007) has studied potential wine-tourists' intention of taking a wine vacation. These intentions are determined by general wine interest, experience with wine and the destination. This may be interpreted as a wine Interest Regime. Carlsen and Boksberger (2015) in a literature review conclude that success of producer visits, i.e. that the visitors get a good experience, depends on the personnel's knowledge and skills about all aspects of wine production. This underlines that wine marketing via tourism should be addressed to an audience with a particular Interest Regime, not to tourists in general. Mitchell and Hall (2001) have studied the purchasing behavior related to producer visits. They conclude that females are more receptive to the visit experience than males, however, they do not buy more wine in place, but do so in the future. Telfer (2001) demonstrates that clustering, for example establishing a wine route or a wine village, is more efficient for wine sales than single producers marketing their wine visits. To understand how this is done Dodd and Beverland (2015) have proposed a wine tourism life cycle model according to which cellar door sales in the first phase is used to survive by increasing sale from the winery. Later on, greater distribution channels and wider promotion to build brand awareness is introduced and is connected to events (such as wine festivals) branding wine in general and the particular producer.

Although they attract a particular wine Interest Regime segment, Festivals and producer visits may attract tourists more generally to local communities (Williams 2001). This may, however, also imply dangers for the communities. Too intensive food and wine tourism may destroy environmental, social and economic sustainability (Poitras and Getz 2006).

#### **4. Methods and material**

The methodology used in this study is inductive consisting of qualitative observations and interviews, as well as quantitative survey analyses. The research consists of two parts: 1) The festival is investigated through visitors surveys and observation. We have interviewed the visitors using a structured questionnaire with descriptive variables that we have predefined, and this was supplemented with observations. We have investigated two instances of the festival, one in 2014 and one in 2015. 2) We are engaged in a long-term development project with four fruit wine producers, which also involves a group of biologists who help the producers develop new fruit wines, and engineers who are developing a device that can measure the chemical components of fruit juice and fruit wine. We have made observations of the destinations (Gans 1982) and interviews with the producers. This is the basis for the investigation of tourist visits to the producers.

##### **4.1 Material from the investigation of the festivals**

The fruit wine festival took place at a manor house (Frederiksdal) in Western Lolland, an island in the south-east peripheral region of Denmark with extensive tourism activities. The manor house is the largest and most well-known fruit wine producer in Denmark. The festival, which lasted one day each year, was open to all, an admission fee was charged and in the festival area were many producers that presented and sold their fruit wine and cider, guided tours to a cherry orchard, demonstration of food with fruit wine (the food could also be bought as meals) and presentations on fruit wine. Each festival was visited by about 700 people.

The survey was carried out as follows: The interviewers (2 in 2014, 6 in 2015) were placed at different spots and selected visitors that passed by randomly. Thus the selection criteria were mainly simple random selection. However, they had instructions to select different types of visitors according to age, sex and whether they came in large or small groups or individually. The sample should thus be representative. The sample in 2014 was 44 visitors (about 6% of the visitors) and 93 in 2015 (about 13%). 3 wine merchants, 2 professionals (chefs, cooks, sommeliers etc.), 2 journalists and 37 consumers were interviewed in 2014. 7 wine merchants, 11 professionals and 75 consumers were interviewed in 2015. The interviewers performed an oral conduction of pre-

printed questionnaires. The reliability of the survey was ensured by the random selection of interviewees and the survey was repeated in 2014 and 2015.

The survey with fixed questions and answering categories was descriptive. It investigated the following factors (each factor measured by several variables): Background (occupation, age, gender, residence). Whether visitors were professionals (wine retailers, chefs, journalists etc.) or consumers. For professionals: Whether they sell/use fruit wine, which type, how they use it (chefs and restaurant owners), whether they would serve/sell more if the quality increases and which price they charged for the wine. For consumers: How often they drink fruit wine, which type, and the field of use they see (aperitif, drink to meals, use in food), and how much they will give for a bottle. The validity of the survey is tested by comparing to results of the qualitative investigation.

In the survey we have observed a bias in the 2015 material as 60% of the interviewees were male (see table 1) (while the gender distribution in 2014 were equal). This cannot be seen as an expression of more males visiting the festival in 2015; it could also be a bias in the sample. This methodological bias has been controlled by analyzing whether the two genders had different results in the other variables. This was not the case, thus this gender bias does not influence the overall results significantly.

A number of qualitative observations (Veal 2011) were also made at the festival. These were carried out in the entire festival area throughout the day to see how visitors interacted with the producers and with the fruit wine. The observation process was partially formal and systematic involving different observers making iterative sampling regularly in the form of photographs; but it was also partially unsystematic as the observers improvised according to the festival activities and behaviour of the festival visitors. The observers used ad hoc criteria, albeit within the predefined frame of observing how visitors interacted with the producers and products. Besides the photographs, data recording was in the form of schematic drawings of the festival layout including an assessment of the distribution of visitors at various times, and qualitative field notes. After the festival days, the observers and interviewers were themselves interviewed on tape during a debriefing by the researchers.

## **4.2 Material from investigation of producer visits**

We have followed four producers during two years by visiting and interviewing them, made conversations, organizing experience and marketing activities for them, participated in project meetings with them and exchanged information about the producers with the other researchers in the project (the biologists). We have thereby collected material, which is observation (Veal 2011), short, informal interviews, producers' presentations at meetings and documentary material.

One of the issues that we have investigated in this course is the producers' attitude towards visits and other promotion arrangements in their place. Only one of the producers has used producer visits as a more extended and regular activity. This producer has been interviewed for one hour about his producer visit activities using a structured interview guide.

The validity and reliability of this material has been ensured by the different methods used, which makes it possible to cross-control the information.

## 5. Results

### 3.1 The fruit wine festival

The festival, which has taken place three times, lasts one day each year. Though relevantly located at the production place of the largest producer of modern fruit wine in the country, its remote geographical location in a sparsely populated area means that many visitors are local. Having paid an entrance fee, visitors are given a glass for wine tasting, which they can keep and take home when they leave. They are then admitted into the manor area, which is not normally open to the public. In this area, two large barns are converted into temporary market places in which each producer has a booth. There are also a few booths selling food as well as several booths doing demonstrations such as how to cook or make desserts with fruit wine. There are also special areas in which presentations and group discussions can take place. At the end of one barn are cherry wine production facilities which the visitors can see up close. Outside the barns is a lawn with a few benches. There is also a tractor pulling a little wagon, and with regular intervals it offers visitors a guided tour of the manor grounds including an oral presentation on the history and current status on fruit wine production at the manor.

Most visitors were consumers. The results in the following tables and figures only concern consumers. At the end of this section we will briefly describe the attitudes and use of fruit wine for the merchants and professionals.

In table 1 are characteristics of the interviewed festival guests in 2014 and 2015 listed.

**Table 1      Interviewed fruit wine festival visitors (consumers)  
Percentage**

| <b>Age – years</b> | <b>2014</b> | <b>2015</b> |
|--------------------|-------------|-------------|
| Under 31           | 23          | 15          |
| 31-50              | 42          | 35          |
| 51-70              | 26          | 44          |

|                                     |    |    |
|-------------------------------------|----|----|
| Over 70                             | 9  | 10 |
| <b>Gender</b>                       |    |    |
| Male                                | 48 | 60 |
| Female                              | 52 | 40 |
| <b>Adress</b>                       |    |    |
| Copenhagen (metropole)              | 41 | 37 |
| Town                                | 16 | 43 |
| Countryside                         | 34 | 20 |
| Abroad                              | 9  | 0  |
| <b>Occupation</b>                   |    |    |
| Servants in higher position         | 32 | 38 |
| Servants in lower position, workers | 29 | 18 |
| Self-employed                       | 16 | 18 |
| Housewife, retired                  | 13 | 18 |
| Student                             | 10 | 9  |

In 2014 a little less than half of them came from the local area and a little less than half from Copenhagen. About 10% came from abroad. Most visitors were between 31 and 50 years old in 2014 while they were between 51 and 70 years in 2015. The visitors had become older from 2014 to 2015. They also came from different urbanized areas: 34% came from countryside (mainly around the manor house) in 2014 and only 20% in 2015. The occupation of the visitors was slightly changed towards a higher status level in 2015. All this indicates that the visitor group has become more “urbanized” from 2014 to 2015.

This demonstrates that the fruit wine producers have succeeded in getting middle aged (and thus able to buy) peoples’ attention to the fruit wine. All occupation types were represented. However, employees at managerial levels were over-represented. This demonstrates that the interest for fruit wine is quite socially widespread but with the supposed front runners or elite (middle age high salaried employees and managers) as the most interested and possible opinion leaders (Katz and Lazarsfeld 1955).

We have asked the visitors’ attitudes towards, and use of, fruit wine, particularly how often they drink fruit wine and their understanding of what it can be used for. Mostly people drink fruit wine rarely (once a month) (figure 1). More people in 2015 answer “often”, but more also answer “never”. Most people in 2014 only see the possibilities of using fruit wine as apéritif while more people in 2015 see a wider use – to meals and in food (figure 2). The visitors

use apple and cherry wines, which are the most commonly produced ones. Very few interviewees mention other berries or fruits. To most of the festival guests, fruit wine still is a new, experimental experience. They have no traditions for, and most of them no clear idea of, how to use the fruit wine

**Figure 1      How often do you drink fruit wine?**  
**Percentage**

**Figure 2      Use of fruit wine**  
**Percentage answering**

A few professionals (wine merchants, chefs, food journalists etc.) visited the festivals, which got much publicity in a couple of Danish food magazines in 2014. The professionals were in 2015 not more frequent users of fruit wine than the consumers. Neither did they see a more wide use of fruit wine. They also came looking for inspiration. They believed that there is an international niche market for fruit wine and they will sell/serve more fruit wine if the quality is further increased.

### **5.1.1 The festival as experiential marketing**

The approach of the festival had many experiential marketing elements. As a live brand experience it had a central role supplemented by other amplification channels. For example, it had been advertised beforehand in the press. It also attempted to create a lasting impression not only through memories but also by offering every visitor a memorabilia in the form of a wine glass. It did not aim at promoting a particular brand (not even that of the hosting manor, though it of course got a proportionately higher share of mentions), but rather modern high quality fruit wine as a collective phenomenon.

Observation data showed that the live format induced a lot of interaction between visitors and producers giving ample opportunity for conversation

about the wine as well as tasting it. While survey responses show that visitors did not use fruit wine very often (see figure 1), the “big idea” or core message of modern fruit wine being of a high quality and that there are several producers who can provide such pleasurable experiences was successfully conveyed to the visitors, as expressed in conversations between them and the interviewers. Observation data also show that visitors were immersed in the phenomenon of modern fruit wine, being surrounded by multi-sensory stimuli including not only tasting and smelling the wine, but also seeing the wine. For example, one booth had a spectacular method of pouring the wine which involved raising the bottle high above the glass to oxidize the liquid. The sounds of the many wine glasses could also be heard throughout the festival. Furthermore, the interactive format inviting visitors to have discussions with the producers succeeded in not only interaction but also involvement and at least a temporary preoccupation with modern fruit wine in the visitors.

Many came because they had heard of fruit wine or were interested either in fruit wine in particular or gastronomy in general. Others were locals who came mostly to support events in the local community or to socialize with family and friends. Visitors could be roughly split into these two groups, locals interested in a local live experience and non-locals interested in a fruit wine live experience. This can be discerned from survey responses on motives for visiting (see figure 3 below), and observation data showing that many visitors were casually dressed while some had dressed up for the occasion indicates some further evidence of a bisection of visitor groups. The festival worked as experiential marketing for both groups albeit for different reasons. Williams (2001) has demonstrated that over the past decade, there has been a shift in wine country imagery from an emphasis on wine production processes and related facilities to more of an emphasis on aesthetic and experiential values associated with more leisurely recreational and tourist pursuits. These values and the opportunities to socialize appealed to the locals many of whom during survey interviews expressed that their motivation for visiting was to experience the place of fruit wine production and sale as a leisure and tourism destination. For the other group, the enthusiasts and hobby producers, the live brand experience satisfied a different motivation. For example, observation data showed that several hobby producers and enthusiasts spent considerable time observing and discussing details of production processes with the producers.

In some ways the festival needs some further development as experiential marketing. The big idea of using modern fruit wine was only partially conveyed to the visitors. The visitors mostly saw modern fruit wine as an exotic aperitif (92% in the survey) or dessert wine or gift item, and not as something to be consumed as a natural daily beverage or a drink to meals. These visitors were also exposed to fruit wine and thus both awareness and knowledge were

spread. However, observation data and survey results indicated that many visitors expressed a lack of knowledge of how and when fruit wine should be used. They appreciated the festival and expressed that they learned much about fruit wines, and the festival may be assessed as a success as a tourist activity. However, we also observed some lacking elements in promoting fruit wine as a daily consumption phenomenon. For example, there was very little food at the first festival, and therefore the visitors had difficulties in tasting the combination of food and fruit wine and learn which dishes that go well with the different wines (see e.g. Figure 2).

Observation and survey data also indicate that there was still a tendency among visitors to see fruit wine as primarily for desserts (in contrast with the intentions of the producers interviewed). During the debriefing, both interviewers and observers also mentioned that several visitors had expressed dissatisfaction with the lack of availability of fruit wine in conventional supermarkets. So to many guests it was not clear where they could buy the fruit wine when they came home thus this part of the marketing was not successful. Finally, according to observation data, some visitors were also dissatisfied with the price level of the fruit wine, which they found too high. Several visitors hypothesized that the low number of producers was the cause of this, and that as more producers entered the market, prices would fall.

As a live brand experience supported by other marketing channels, the festival succeeded in immersing the visitors and engaging them with modern fruit wine in multi-sensory ways. The core messages of the big idea were also conveyed successfully, but other messages such as use and availability were not communicated successfully to the visitors. Therefore the festival can be seen as a success overall, but with some important elements missing.

### **5.1.2 Fruit wine festivals and Interest regime**

An issue to investigate is whether the visitors are part of a fruit wine Interest Regime (Thévenot 2006) and whether the festival contributes to develop such one. We have asked the visitors in the survey about their motives for coming to the festival (Figure 3) and have investigated this issue in the observations and qualitative conversations. The qualitative material suggests that three different motives as expression of three different Interest Regimes exist. One is an interest in fruit wine. This may be combined with an interest in wine in general and people with this interest are primarily coming from urban areas. This Interest Regime can be seen in figure 3 as “special interest in fruit wine” (43% mentioned this in 2014, 25% in 2015), and the wider interest in wine and use of wine in the categories “interest for wine in general, “gastronomic interest” and “inspiration” (15-30% mentioned these motives); “to support fruit wine production” (22% said in 2014, 14% in 2015) is also part of this Interest Regime.

Another Interest Regime is support of the local community. This is represented by people coming from the festival area (local countryside and towns); they do not care for fruit wine, but want to support local development (production of fruit wine and tourism). This Interest Regime can be seen in figure 3 as “want to support local initiatives” (27% answered this in 2015). A third Interest Regime is a general experience Interest Regime – people are coming for the experience of the festival and social get together, and fruit wine is not a primary interest although it for the occasion can be interesting part of the total experience. This Interest Regime can be seen in figure 3 as “curiosity” (52% answered this in 2014 and 58% in 2015) and “social get together” (39% answered this in 2014, 23% in 2015).

**Figure 3      Motives for visiting the fruit wine festivals**  
**Percentage**

A part of the visitors are driven by the local community support (or just local curiosity) Interest Regime. This Interest Regime neither increases sales of fruit wine (as these people are not particularly interested in using fruit wine) nor local tourism. As such, the festival is not very successful in its aim. The fruit

wine Interest Regime is a less mentioned motive in 2015 than in 2014 and more visitors never use fruit wine. The festival seems on its way to be counter-productive in increasing the fruit wine Interest Regime. The general experience Interest Regime is the largest motive and it may support local tourism if visitors are coming from far away. The residence of the visitors suggests that this is not case. Less people are coming from Copenhagen in 2015 than in 2014, only 2 people from abroad have been found as interviewees (in 2014) and, although less people come from countryside, more people are coming from towns (which, according to the qualitative material, are mostly locals). The festival does not seem to support an increase of local tourism.

### **5.1.3 Fruit wine festivals and local wine tourism**

As the survey results and observation data indicate at least two different motivation patterns for visitors to attend the festival, this seems to support the results of Nella and Christou (2014) segmenting wine tourists into more and less involved groups, the motivations of the former being wine and wineries and that of the latter being socializing. Both segments belonged to their own Interest Regime which was catered to satisfactorily, indicating that the festival succeeded in offering something for various visitor groups. However, the producers' aim is primarily to promote modern fruit wine and a general fruit wine Interest Regime, not to promote local tourism. Thus the organisers face a decision on whether to target the festival more to the fruit wine Interest Regime or to keep it broad. On the other hand, the fruit wine festival and producer visits may support local tourism as a side-effect. Evidence was also found to support the conclusions of Mason and Paggiaro (2012) that a positive emotional experience, such as that offered at the festival, not only increased satisfaction but also induced visitors to return and to purchase. This can also explain the dissatisfaction that some visitors had that they did not know where to purchase it outside of the festival. As the festival has only existed for three years, it is yet too early to see if it confirms the wine festival life cycle model of Beverland et al. (2001).

### **5.2 Producer visits**

Producer visits are generally not used by the four fruit wine producers. Only one of the producers, who is an extrovert person, has developed quite comprehensive visitor activities. According to interview responses, several tourists visit his growery, but he has discovered that it is difficult to attract normal holiday tourists. The growery is placed in an agricultural area outside normal tourist areas and his wine is not yet so world-famed that many people will make a journey, or maybe not even a detour to visit him. He has been more successful

in using business tourism by organizing seminars and events for firms and their employees and customers, who see the visit as an extraordinary experience.

The other three producers do only receive visitors occasionally. They express in conversations and interviews two reasons for not doing this. One is that the wine growery is a production place and it will be a disturbance to have visitors and they do not have visitor facilities. The other reason is that they do not like to give experiential presentations. One of the three non-visitor-receiving producers – the largest one in whose manor house the fruit wine festival was organized – has planned to develop visitation facilities and introducing organized visits. Particularly via the festival, he has built up ability in storytelling and organizing visits. He is a good story-teller and gives the visitors an extraordinary experience.

## **6. Conclusion**

Festivals and opening for visitors can be means for entrepreneurs within food and wine industries to create awareness of a new product area and do marketing. However, these means also have some challenges: The entrepreneurs should have an extrovert personality to stand for open visiting. Festivals can attract tourists who could be market opinion leaders, but it is difficult to increase sales after the festival (for example because the food and wine product not leave the “exotic” first stage in the consumers mind, or the products cannot be purchased in the visitors normal shops).

This paper contributes with new knowledge to both experience theory (Mossberg 2007; Smilanski 2009; Sundbo and Sørensen 2013), and an emerging food and wine tourism theory (Mitchell and Hall 2006; Hall and Sharples 2008). It shows that the effect of the fruit wine festivals and producer visits on local tourism has been limited. To create a larger effect on local tourism probably demands a wider, permanent and more organized effort that includes many producers who can be visited, several festivals that also appeal to foreign tourists, and fruit wine experiences becoming a part of the general tourism marketing of Denmark. Fruit wine routes could be an example of such an activity. To support the fruit wine Interest Regime, it can be recommended to move the festival to a more urban area where those belonging to this regime live. Or the festival could be expanded with social activities and other initiatives to give it an even higher experience status (similarly to what the Roskilde music festival has done, Sundbo 2004). This could both attract more experience Interest Regime visitors and perhaps make them interested in fruit wine (cf. Sørensen and Sundbo 2014) and attract more fruit wine and other wine enthusiasts.

The festival could increase local tourism, but mostly within a limited timeframe. Producer visits have the potential to increase local tourism to a larger extent, but more experiences would need to be included. For example,

more producers within the same area could give basis for fruit wine routes; consumption of modern high quality fruit wine could also become a more widespread and common phenomenon (including in local restaurants and shops); and it could to a larger extent be incorporated in the overall marketing of local areas.

## XXV. International RESER Conference:

# Service innovation for sustainability: paths for greening through service innovation

*Faridah Djellal and Faïz Gallouj*

Clersé, University Lille 1 - Science and Technology

### **Abstract:**

*The purpose of this work is to examine the extent to which services and service innovation can contribute to sustainable development in its environmental dimension. The supposed immateriality of services seems to argue in favour of their natural sustainability. This is actually just a myth – one we examine the roots of, and which we refute. This calling into question of the naturally-green-services myth does not, however, mean that the greening of the economy cannot rely on services. On the contrary, greening also fundamentally depends on innovation dynamics being implemented in or by services.*

## **Introduction**

More than two decades of research in economics and management science, have helped to make service innovation a relevant, legitimate and increasingly important issue in the field of innovation studies. The (recent) maturity of this field of research is illustrated, to some extent, by the rising number of both qualitative and quantitative literature reviews covering the topic of innovation in services, in both its general and its specific (sectoral or thematic) aspects. A recent review of these reviews is provided in Gallouj and Djellal (2015).

Research efforts have naturally mainly focused on two (often related) issues, namely the nature of innovation in services, and its production modes. Does innovation in services (in terms of form, how it is produced) differ from innovation in goods? This is the main question that has long guided the emerging field of service innovation studies. Depending on how this question is answered, the literature considers three analytical perspectives used to address innovation in services: a technologist/industrialist or assimilationist perspective (negative response to the question), a demarcation/differentiation perspective (positive response) and an integration/synthesis perspective (reconciling goods and services, their differences and similarities, within a single analytical model) (Gallouj 2010). A fourth perspective, labelled inversion perspective, focuses on the strategic role played by certain services (KIBS) in the their customers' innovation.

In recent years, innovation studies have been bolstered, in various ways, through the exploration of new themes (e.g. KIBS in innovation, social innovation, public-private innovation networks, public policies for service innovation, etc.) and through empirical investigation in new sectors. They have also been reinforced by complementary qualitative work using quantitative surveys, relying in particular on the revision of OECD Manuals (Oslo and Frascati Manuals) as well as on the launch of national surveys (see Community Innovation Surveys in particular).

However, the maturity and legitimacy of service innovation studies also depend on their ability to be in line with the great contemporary socio-economic issues. From this point of view, sustainability is undoubtedly a key issue. Contemporary economies are certainly *service economies*, and if they are - or truly aspire to be - *sustainable development economies*, then the question of the relationship between *services* and *sustainable development* has to be addressed. However, in spite of certain notable exceptions - such as reporting on the adverse effects of transport and tourism on the environment - little attention has been paid to this question so far. Sustainability is still seen as a predominantly industrial issue (Djellal and Gallouj, 2010, 2015).

The purpose of this chapter is to examine - mainly from a theoretical angle at this stage - to what extent services and service innovation can contribute to sustainability in its environmental dimension (in other words to 'economic greening') - that is, to the satisfying social needs while leaving the smallest possible ecological footprint. Our focus in this work is thus not (or at least not directly) on the economic and social dimensions of sustainability.

Some intrinsic characteristics of services - especially their immateriality - seem to argue in favour of their natural sustainability. This is actually no more than a myth<sup>1</sup> - and one we propose, in Section 1 of this chapter, to examine the foundations of, achieving its deconstruction. This calling into question of the myth of 'naturally green' services does not mean that the greening of economic activity (at either micro or macro level) cannot rely on services. On the contrary, in section 2 we show that greening also fundamentally depends on innovation dynamics implemented *in or by* services.

## **1. Services are green by nature: the foundations of a myth, and its deconstruction**

The idea that services would be greener and more sustainable, that is, less damaging to the environment than goods, is not uncommon in the literature (Claval, 2006; Illeris, 2007; Rifkin 2000; OECD, 2000; Ellger and Scheiner 1997). It even seems to be confirmed by some statistical analyses at both international and national level. For example, the International Energy Agency (2008) estimated that, in 2005, services (excluding the transport sector) accounted for 12% of CO<sub>2</sub> emissions and 9% of total final energy consumption, worldwide. In the case of France, although the services sector (excluding transport) accounted for almost 75% of GDP and

---

<sup>1</sup> It should be noted that this is a positive myth, while the service economy is more verbose in negative myths: for a discussion of these myths, see Gallouj (2002)

employment, it was responsible for only 7% of CO<sub>2</sub> emissions in 2008<sup>2</sup> and consumed 15% of total energy in 2010 (CEREN, 2012).

This idea of the 'natural greenness' of services is based on their immateriality, which is meant to provide a relatively satisfactory criterion with which to distinguish services from goods (§ 1.1). Because they are supposed to be immaterial, services would, the thinking goes, be less harmful to the environment than material goods - whose manufacturing process gobbles up natural resources and is a source of pollutant emissions, etc. The tertiarization processes at work in contemporary economies should therefore automatically lead us to more immaterial/intangible - and therefore more sustainable economies (Ettighoffer 1992; Romm et al., 1999).

This attractive hypothesis is, however, debatable. It is possible, for example, to note that the most tertiarized contemporary economies are also the biggest polluters, and that certain service sectors (transport in all its forms, for example) are among the top sources of negative environmental externalities. Beyond simple fact, our purpose is to reconsider the myth of immaterial and therefore green services, from an analytical angle. Step 1 in this reconsideration process is an attempt to identify a certain number of (forgotten or neglected) sources of service materiality (from a static point of view) (§ 1.2). Step 2 is the highlighting of the socially-constructed (and therefore changing) nature of service materiality/immateriality, depending on the output convention adopted (§ 1.3) and Step 3 consideration of the search for materiality as the subject of active strategies carried out by service organizations (§ 1.4). Inverse dematerialization strategies will be considered in the second section of this work, which is exclusively devoted to them.

## **1.1. The foundations of the green services myth**

Across the board, from economics to management science, works on services ritually recall a list of technical characteristics that are supposed to be intrinsic to services, namely: Intangibility (immateriality), Heterogeneity, Interactivity and Perishability. This is particularly true in marketing, where the IHIP acronym is common knowledge. These characteristics have long been considered quasi-genetic criteria (a kind of DNA) serving to distinguish services from goods.

This definition of the essence of services by their immateriality is rooted in the history of economic thought, particularly among classical economists (Smith, 1960 [1776]; Say, 1972 [1803])<sup>3</sup>.

He does not explicitly use the term 'immaterial', yet Adam Smith is considered the precursor of the definition of services by their immateriality. This intrinsic technical characteristic of services comes from the distinction Smith made between 'productive' and 'unproductive' labour. Only productive labour (for example, the labour of the workman in a factory) creates wealth, because it adds value to the material it processes and it brings about material results, which are likely to lead to

---

<sup>2</sup> Data from CITEPA: Centre Interprofessionnel Technique d'Etudes de la Pollution Atmosphérique [interprofessional technical center for the study of atmospheric pollution] concerning CO<sub>2</sub> emissions, excluding LULUCF (Land Use, Land-Use Change and Forestry).

<sup>3</sup> For a review of the debates on services in economic thought, see Delaunay and Gadrey (1992).

accumulation. In contrast, services<sup>4</sup> are performed by unproductive labour, that is to say, which “does not fix or realize itself in any permanent subject, or vendible commodity, which endures after that labour is past, or for which an equal quantity of labour could afterwards be procured” (Smith, 1960 [1776]). The immaterial nature of services is often derived (in a way that is perhaps somewhat unsatisfactory) from the idea formulated by Smith (and taken up by Alfred Marshall) that the “work of all [the services] perishes in the very instant of its production” (ibid.). Admittedly with some ambiguity, then, the unproductivity of service work (its inability to create wealth) is, in Smith’s words, a synonym for immateriality.

It was another classical economist, Jean-Baptiste Say (1972 [1803]), who first explicitly introduced the ‘immaterial’ qualifier to the definition of services. Jean-Baptiste Say called into question the implicit and ambiguous identity established between *unproductivity* and *immateriality* (*the evanescent nature of the output*). According to him, services, while immaterial, are not unproductive, since they are useful, the source of visible and enduring (accumulative) results (changes) - for example the healing produced by the work of doctors. In Smith’s analysis, Gadrey (2000) identifies the premises of a distinction between immediate or direct output on the one hand, and the mediate output on the other - the outcome or long-term or indirect result (‘change of state’ in the reality subjected to the services provided). Only the immediate output is evanescent, the outcome itself is lasting: for example health, education and culture have durable effects on the mind or body. To take another example provided by Smith himself, though the immediate work of the domestic servant may be evanescent, the resulting cleanliness does not vanish once the work is done, but endures some time.

The reasoning which, in modern economies, involves translating this genotype (that is, these technical characteristics) into an environmentally-friendly phenotype is obvious. Since the output of services is immaterial, evanescent and transient, it is supposed not to harm the natural world, unlike industrial and agricultural production which transforms raw materials into physical goods, damaging the environment in both their production and their consumption. Such reasoning is clearly mistaken. Services are both less immaterial, and less green than they seem – it all depends on how the materiality issue is addressed. Services are of course immaterial in the sense that they are not intended to produce tangible goods as final output. However, their relationships with materiality may take a range of forms, in line with the types of services envisaged. In the following paragraphs, we examine these different relationships.

## 1.2. The (neglected) sources of service materiality

Given the link established between the level of materiality and the sustainability of services, in calling into question the principle of intrinsic immateriality of services (genotype), we also query its supposed positive effects in terms of sustainability (phenotype). We therefore propose, in this paragraph, to seek to identify neglected sources of service materiality which undermine the myth of its natural sustainability.

---

<sup>4</sup> Smith provides a number of examples of service providers including domestic servants, servants of the state, servants of the church, artists, lawyers, doctors...

Service materiality may manifest itself in different places: (a) in the service medium or target; (b) in various estate facilities, that is the physical spaces of production/consumption; (c) in the production factors deployed in the service relationship. While it is important not to neglect the (physiological) materiality of the human factor, it is of course on the capital factor that we focus here. A further significant source of (direct and indirect) materiality stems from another intrinsic characteristic attributed to the service - its interactivity, its coproduced character (d). Indeed, interactivity is often associated with mobility, which requires implementation of a certain number of transport facilities and infrastructure – these being highly material and damaging to the environment.

### ***a) Materiality of the service medium***

The diversity of services in their relationship to materiality is obvious. Even intuitively, it escapes no-one that transportation, waste processing, cleaning, catering, hostelry, and car repairs are more 'material' services than are consultancy, training, insurance or psychotherapy. Even within the confines of these few examples alone, we might add that nothing is more material than the dishes prepared in a restaurant's kitchen, whereas psychotherapy is primarily a verbal exchange.

Beyond plain intuition, by mobilizing theoretical works devoted to definition of the service concept (Hill, 1977; Gadrey, 2000), this difference in materiality between services can be interpreted by the difference in materiality between their mediums. Indeed, drawing on Hill, Gadrey (2000) defines the service as a "set of processing operations seeking to change the state of the service medium". The service medium is in turn defined by the target or reality modified or worked upon by the service provider on the customer's behalf. It may take different, more or less material forms: (i) a material good, (ii) codified information, (iii) individuals (customers, users) themselves having physical, intellectual or locational characteristics, and iv) organizations, again in their various aspects (technologies, structures, collective competences and knowledge).

The 'change of state' effected by the service can be considered immaterial (healing for the sick, satiety for the guest of a restaurant, repairs to a car, improved cultural awareness, knowledge and employability for a student). Such a change of state can neither be stored nor surrendered, regardless of the medium to which it is consubstantially linked. The service medium may, however, be more or less material, leading to the service itself in turn being considered more or less material.

The degree of materiality of the medium is the basis for a number of service typologies. Thus – when focusing on the difficulty of defining and measuring productivity in services – Gadrey (1996) has proposed a typology which can be extrapolated without difficulty to the services sustainability issue. This typology includes three groups of services whose differences are marked by their main medium:

- 1) Services that mainly involve the physical processing of technical mediums. These differ little from the conventional production of physical goods, which is the category to which the statistical conventions would in any case have assigned them (passenger and goods transportation, repair of goods, catering, hostelry, retailing,

various rentals, standardized processing of codified information (e.g. some functions of banks and insurance companies...).

2) Intellectual services applied to organized productive knowledge - often referred to as 'intangible' or 'pure' services because, unlike those of the previous group, these services are not primarily focused on goods (engineering, consultancy services, R&D, software production, advertising/PR services, etc.).

3) Services applied to individuals' knowledge and capabilities, in final consumption, and posing significant problems with regard to the identification and measurement of output (education, health, leisure, culture, etc.).

In the previous typology, the service is defined by the *main* medium that is the subject of the 'state change process'. This means that in reality every service activity operates, to varying degrees, on *several mediums*, so that every service activity is in fact a combination of functions associated with these different mediums (material, informational, cognitive, relational, etc.). These combinations vary across space, and especially over time (we will return to this issue in point 2.1a).

### ***b) The materiality of service production/consumption spaces***

Another key expression in the materiality of services is the materiality of their production/consumption spaces. The service economy is often associated with the absence of factories and heavy-duty production lines. However, services do also require production/consumption spaces such as offices, classrooms, hospitals, railway stations, and airports. It would clearly be wrong to conclude that these spaces are environmentally benign – one has only to consider the space taken up by such service facilities as supermarkets, airports, logistics platforms, university campuses, hospitals, landfills, etc. The environmental damage attributable to these production/consumption spaces manifests itself in a variety of ways: use of space, energy consumption, waste generation, emissions, noise, visual and olfactory disturbances, etc.

From an organizational perspective, the question of the production space materiality is often considered via making a distinction between two different spaces: the back office and the front office. The back office is where the material or informational transformations of service mediums take place in the absence of the customer (for example, the restaurant kitchen or the various departments within a company). The front office is the customer-facing area (for example, the floor of a restaurant, the bank counter or the hotel lobby).

In management science, and in marketing in particular, an extensive literature has developed in recent years, seeking to take full advantage of these production/consumption spaces and enhance their materiality. This aspect of materialization strategies will be discussed in paragraph 1.4.

### ***c) Materiality of the production factors deployed***

Even though the labour factor has an evident physical existence, here we are addressing the issue of capital materiality. The third sector theory is built upon the idea that services are low capital-intensive, and primarily based on the mobilization of

labour. Colin Clark, a founding father of the theory of the third sector, observes that “most service businesses require far less in the way of capital goods than industry or agriculture” (Clark, 1940). This low capital- intensity lies at the heart of the first positive (rather than residual) definition of the tertiary sector. According to Fourastié (1949), the service sector includes activities for which productivity growth rate is low due to weak mechanization. Baumol (1967) relies on the same assumption in his unbalanced growth model which defines services as a stagnant sector, whereas goods belong to a progressive sector. It should however be noted that in a later work, Baumol et al. (1985) qualified this analysis by introducing an asymptotically stagnant sector combining a progressive and a stagnant component. An example of this is provided by the IT sector, whose hybrid nature (hardware + software), starts out progressive, while the hardware element is proportionately dominant, then evolves towards stagnation as the software component grows stronger.

This negative assessment of the capital-intensity (and materiality) of the services (and conversely, the positive assessment of their sustainability) must be qualified and called into question - both statically and dynamically. First of all, it is undeniably true that some services have long been characterized by their high capital-intensity: this is the case not only of transport in all its forms (passenger and goods transport, air, rail, land and sea transport, etc.), but also of energy and water supply activities (public utilities) for which the question of their belonging to ‘industry’ or ‘services’ continues to be a matter of debate (Broussole, 2014). Yet it is clear, from a dynamic perspective, that services are increasingly capital-intensive. They fall within the scope of natural technological trajectories in the sense of the evolutionary theory (Nelson and Winter, 1982), i.e. trajectories of increasing mechanization. We will return to this point in paragraph 1.4.

#### ***d) The material dimensions of interactivity***

Interactivity is another essential (intrinsic) technical characteristic of services. It refers to the different forms of interaction between service consumer and service producer (different modalities of the service relationship), which reflect various levels of co-production of the service by the consumer. Like immateriality, this technical characteristic of services also has its roots in the history of economic thought. Storch (1823) is often cited as its precursor.

This service interactivity is also a source of materiality - and therefore of adverse effects to the environment. It often presupposes a physical encounter, which entails travelling on the part of service relationship protagonists. These journeys are material-intensive because they mobilize not only transport infrastructure and technical systems, but also different encounter venues, depending on the nature of the mobility in question. Interactivity thus has an effect on materiality, especially through the two above-mentioned vectors of materiality (see § b and c) - namely the factors of production and production/consumption spaces.

Several types of journeys can be distinguished (Gadrey, 2010; Fourcroy et al., 2015): (i) journeys by consumers or users to the place of service production/consumption (for example, in trade, catering, hostelry, education or health, at least in their traditional dominant form); (ii) journeys by service providers to the customer, be this a firm or a end consumer (e.g., consultancy, certain sales formulas, home services);

(iii) simultaneous journeys by service providers and clients (passenger transportation in all its forms); (iv) journeys made by service organization employees to their workplace.

These different types of journeys involve individuals whose mobility is required for the establishment of the service relationship, that is the encounter between client and provider. The mobility can however also concern material goods: material inputs required to produce the service, as well as the goods that are the subject of the service transaction (e.g. supply to stores in retailing, delivery of goods to customers in mail-order selling).

Service-associated journeys are a major source of energy consumption. In 2007, in France, they represent approximately 40% of official tertiary sector energy consumption (Fourcroy et al., 2012). The scale of these journeys and their impact on sustainability are such that Gadrey (2010) has no hesitation in predicting the decline - and even the demise - of whole swathes of the tertiary sector, unless appropriate solutions (innovations) are found. Examples of such activities are transportation and all services relying heavily on transportation - including international tourism and business travel, hostelry, postal services, etc.

### **1.3 A materiality/immateriality that depends on the output convention adopted**

Immateriality is not an (objective) intrinsic technical characteristic of services, just as materiality is not anymore always seen as a fundamental dimension of goods (see § 2.2). The degree of materiality is a social construction, which depends on the output conventions adopted. The materiality of the service and its impact on the environment differs, depending on the delineation of the border of the service, according to its topographical and temporal coordinates.

In the following paragraphs, we consider the output convention at three different levels:

- the technical (topographic) delimitation of the boundaries of the service activity as such (this level essentially reflects the direct materiality of the service);
- the focus on the indirect dimensions of the materiality of the service, particularly (but not exclusively) from a time perspective, involving an analysis in terms of life cycle;
- the focus on the universal nature of the "service provided" as an ontological characteristic of both services and goods.

#### ***a) The physical scope of the service***

It is obvious that, depending on the border that is drawn to delimitate the service, the level of its materiality and therefore of its sustainability can vary considerably. This relationship between the output convention adopted and sustainability can be illustrated in the case of the evaluation of energy consumption. Such an exercise was performed by Fourcroy et al. (2012), who propose to break down the service into three components (basic services), which give rise to different energy needs (see Figure 1): conditioning, service operations and travel.

According to the definitions of the service previously mentioned (§ 1.2a), *service operations* consist in the mobilization of competences and techniques in order to make transformations on the various mediums of the service (material object, information, knowledge, the individual). These operations require technologies, particularly technologies for material and information processing, which are energy consuming. *Conditioning* refers to the whole set of energy-consuming activities achieved for the preparation of the physical space of the service activity (fitting out, cleaning, heating, air conditioning, lighting, etc.). These activities take place upstream of the service operations, but also during the operations and partly after them. *Travel* refers of course to the different configurations of the journeys made by the service protagonists before, during or after the service operations (see section 1.2d). It is a major source of energy consumption and pollution. It should be noted that conditioning activities and service operations could take place in the premises of the company or outside the company.

**Figure 1. The Scope of Energy Consumption in the tertiary sector as assumed in CEREN statistics (source: Fourcroy et al. 2012)**

However, the official energy statistics (for example, in France those of CEREN<sup>5</sup>) limit the scope of energy consumption to *conditioning activities* and *service operations within the service firm*. The only energy consumption taken into account are those of the equipment used within the premises of the service organizations. Therefore, the measurement conventions underestimate the energy consumption and more generally the negative environmental externalities in the tertiary sector. They exclude, in fact, on the one hand, the energy consumption of conditioning activities and of service operations performed outside the service firm, and on the other hand, the consumption related to travel activities.

By adding to the official statistics, the energy consumption generated by the whole set of journeys related to the consumption or production of services (journeys the service consumers in order to consume the service, journeys by service organizations employees from home to their workplace, journeys by service providers for professional reasons), Fourcroy et al. (2012) estimate, in the case of France, and for 2007, that the energy consumption is multiplied by a factor of 1.4.

<sup>5</sup> CEREN: Centre d'Etude et de Recherches Economiques sur l'Energie [Centre for study and research into energy economics]. This is the major French organization supplying energy statistics on the tertiary sector.

## ***b) The direct and indirect sources of materiality***

The discussion of the materiality of services (and of its negative effects in terms of sustainability) is often restricted to its *direct* sources. But there are also *indirect* sources of materiality. Taking them into consideration would contribute to scale up the adverse environmental effects of services.

Direct sources of materiality (and corresponding negative externalities) are those which appear immediately within a given service provision. They reflect the negative externalities directly generated by the use of the different material elements (service medium, production factors, production/consumption spaces, etc.), within the different component of a service (operations, conditioning, travels).

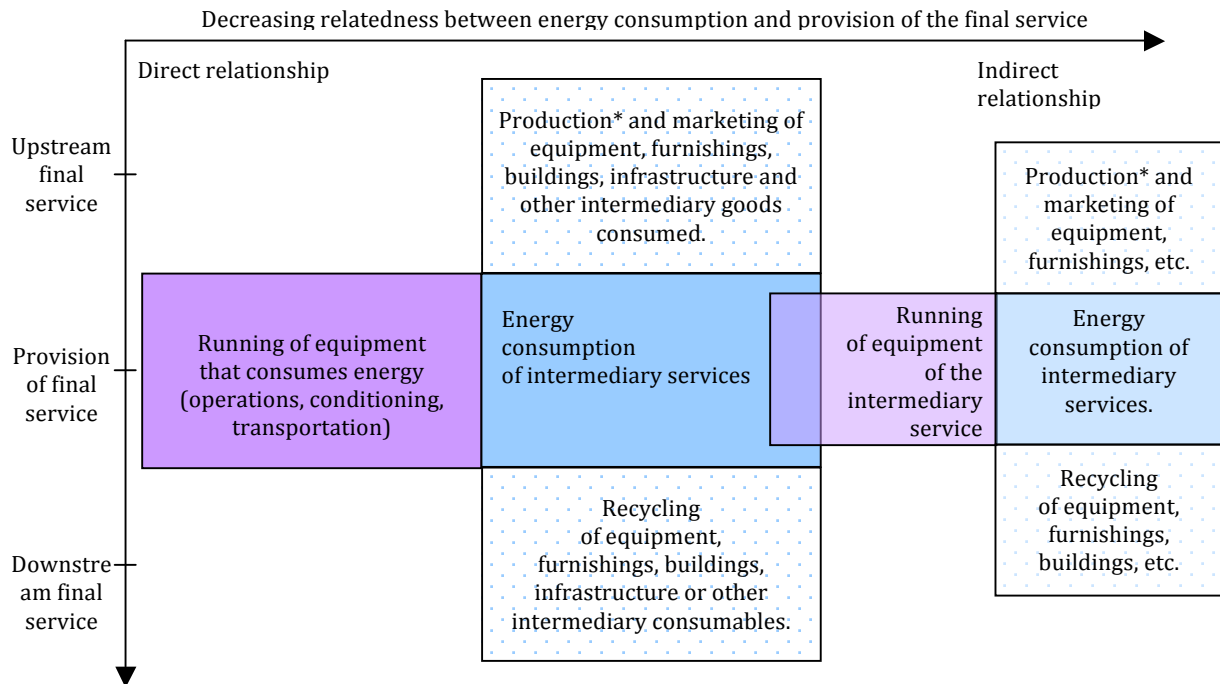

Indirect sources of materiality, for their part, are those that are induced by the service in question in the rest of the economy and/or at other times, upstream or downstream the service. There are (at least) two different types of indirect sources of materiality (Fourcroy et al., 2012).

The first type can be addressed by an analysis in terms of life cycle, applicable to the whole set of material goods mobilized during the service provision: technical equipment of course, but also buildings, furnishings, intermediate consumption of various goods, goods sold (e.g. in retailing). These different material goods are not only sources of materiality (and externalities) during their use (direct materiality previously mentioned), but also, upstream, at the moment of their own design, production and selling, and downstream, when they are maintained or repaired and possibly recycled at the end of their life. By analogy with grey energy, this incorporated materiality can be labelled "grey materiality".

The second type of indirect source of materiality of the service corresponds to the materiality associated with the different types of intermediary services, necessary for the provision of the final service in question. These may include, for example, cleaning services, catering services, consultancy services. These intermediary services also, recursively, involve direct and indirect sources of materiality. The former correspond to the negative externalities that appear immediately during the delivery of the intermediary services in question and which are generated by the different vectors of materiality of these intermediary services (equipment, furnishings, buildings, etc.). The latter correspond to the grey materiality of these intermediary services themselves and, recursively, to the materiality of the intermediate services necessary for the provision of these intermediate services themselves, etc.

Figure 2 provides an illustration of the distinction between direct and indirect sources of materiality, in the sole case of energy consumption. It can easily be generalized to all direct and indirect sources of materiality. Using an input-output method, Fourcroy et al. (2015) estimate that in France, for 2009, taking into account grey energy multiplies the energy consumption in services by a factor of 1.6 (it is even doubled in certain service sectors such as the information and communications sector).

**Figure 2 The total direct and indirect sources of energy consumption in a final service**

 Grey energy of equipment, furniture & furnishings, buildings, infrastructure, etc.

\*Production in the broad sense. This includes: the design of the project, the extraction and transportation of the necessary raw materials, the processing of raw materials and fabrication of the product.

### ***c) The service as a common ontological characteristic of both goods and services***

The idea of the subjective and conventional nature of the border of services (of the difference between goods and services) probably culminates in the recent theoretical work, which consider that the search for specificity (materiality of goods vs. immateriality of services) is counter-productive, since in fact "everything is service".

These works share the idea of a certain (observed or desired) blurring of the boundaries between goods and services and the need for common theoretical models. They actually rediscover the principles of consumer microeconomics: the utility, the value in use, the service or final characteristic as an ontological characteristic of both goods and services. This common immaterial nature of goods and services, which militates in favour of integrative or unifying theoretical analyses, is at the heart of all the following theoretical constructs: the functional economy theory (Stahel, 1997; Du Tertre, 2007; Boutillier et al. 2014), which defines any output (goods or services) by the function (service) it provides, the experience economy theory (Pine and Gilmore, 1999), which defines the output by the experience it provides to the consumer, the "Service-Dominant Logic" (SDL) (Vargo and Lusch, 2006) which defines the value by the value in use, therefore erasing the difference between goods and services, and the "Service science" (Maglio and Spohrer, 2008) which is a science of both goods and services. Another formulation of this integrative theoretical perspective is more directly focused on the innovation issue. This is the approach (of the product and of innovation) in terms of

characteristics developed by Gallouj and Weinstein (1997) and extended by a number of other works (De Vries, 2006; Garcia-Goñi and Windrum 2008; Gallouj and Toivonen, 2011, etc.).

However, if they share a common desire of theoretical synthesis, these integrative theories do not pursue the same key objectives. Thus, the main initial project of the functional economy theory (Stahel, 1997) is to develop a theory of sustainable development. Therefore environmental issues occupy a central place in this theory. The analysis in terms of SDL (Vargo and Lusch, 2006) and the experience economy theory (Pine and Gilmore, 1999) essentially fall into the scope of a perspective of service marketing. They rediscover and operationalize the use value, and the new consumer economics (Lancaster). The approach in terms of characteristics (Gallouj and Weinstein, 1997) is also of Lancasterian inspiration. Its main purpose is to provide a theoretical model that accounts for the diversity of the innovation dynamics in both services and goods. But of course, these theories can add (or have already added) to their research agenda, purposes other than their original purpose. Thus, for example the functional economy theory and SDL are increasingly addressing innovation issues (Ordanini and Parasuraman, 2011; Vargo et al., 2014). The approach in terms of service characteristics strives to integrate environmental and more generally sustainability issues (Djellal Gallouj, 2015; Cruz et al, 2015).

#### **1.4 The rise in materiality as an active strategy of service organizations**

In management sciences, real or supposed immateriality of services has long been regarded as a weakness to be corrected. This immateriality of the service and its associated heterogeneity/variability character, are the origin of performance evaluation issues (service quality, cost or labour productivity) concerning both the client and the service provider (Gadrey 1996; Djellal and Gallouj 2008a). Therefore different (innovation) strategies have been implemented to introduce material elements in services or optimize existing ones. Some authors (especially Levitt, 1972) established this rise in materiality as a strategic imperative for service organizations, advocating for a systematic "industrialization" of services.

The increase in material intensity of services and their industrialization can take different forms that are closely related, but that we present separately, in order to highlight the different materialization (and industrialization) mechanisms at work.

The first form of materiality rise is the introduction of material technical systems in service companies and organizations. The information and communications technologies that spread invasively in services are (especially in their hardware dimension) an essential source of this materialization process. But other technologies also play a key role (often by hybridization with ICTs): cooking, cooling and ventilation technologies, transportation technologies, medical technologies, etc. As highlighted by a certain number of works (Berkhout and Hertin 2001; Faucheux et al., 2002; Gadrey, 2010), these technical systems are intensive consumers of exhaustible natural resources (rare metals) and energy. They also raise formidable problems related to the treatment of waste. Their development is often artificially supported by extremely short life cycles associated with quasi-programmed obsolescence (Desmarchelier et al., 2011).

The second form of materiality rise is, paradoxically, the implementation of what may be called soft or "immaterial" technologies. This is the standardization of work processes, the implementation of industrial production methods, models, blueprints (Levitt, 1972; Lovelock, 1992; Kingman-Brundage, 1992), which are veritable production "manuals" of the service. These invisible technologies lead to a standardization of the service itself. The product, in this case, is not a good, but a quasi-product: for example, a standard insurance contract or a standard financial product, a tourist standard package, a standard menu item identical throughout a fast food chain (McDonald's is often cited as the archetype of the industrialization of catering). Industrialization means, then, eliminating cases that are not standard cases.

The third form of materiality rise involves the physical spaces of production/consumption of the service. It can be addressed in two different ways. The first reflects the development, in possibly innovative forms of these spaces defined as architectural entities (*external or 'property' materiality*). The icons of this property materiality are large shopping centres, logistics platforms, transportation hubs, etc. It should be noted that this property materiality can even, in certain cases, rely on industrial production processes, since some modules of the building infrastructure are pre-fabricated in a factory (this is the case, for example, of Hotel Formule 1 of Accor Group). The second way to address the rise of materiality of the physical spaces is to look at the materiality that manifests itself within the infrastructures. This *internal materiality* is critical to customers, who are sensitive to the aesthetic and functional qualities of the internal architecture and of the furnishings: accessibility to spaces, signage, appearance, decor, comfort, ergonomics, etc. All these elements contribute to make tangible the immaterial and the heterogeneous, and are the subject of intense innovation efforts. The strategies implemented to optimize the internal materiality may have different but complementary goals: communication/advertising, improving access and mobility, optimizing the client-provider interaction, reducing uncertainty about the quality, etc.

The last form of materiality rise that we evoke does not concern the production but the consumption sphere. It manifests itself by the rise of the self-service in Gershuny's meaning (1978), that is to say the replacement of services by industrial goods used at home: for example, the replacement of the laundry service by the use of one's own washing machine, the replacement of the cinema by the DVD at home, etc.

## **2. Greening the economy by innovation *in* services and *by* services**

In the first part of this work, we have argued that, contrary to an old assumption, the service is not green and sustainable by nature, but that it includes direct and indirect sources of materiality, which serve to increase its ecological footprint. We have raised the innovation issue only in addressing these sources of materiality in dynamic terms, that is to say by focusing on the materialization/industrialization strategies implemented in service companies and organizations.

In this second part, we address innovation from a different angle, that of dematerialization strategies. In a service economy, innovation in services and by services plays a key role in the process of dematerialization and greening. This greening of the economy by services and service innovation can take two different but complementary paths: first, the greening of the services themselves through the implementation of dematerialization strategies and green innovations trajectories within services sectors (§ 2.1); then, the greening of goods by services and services innovation (§ 2.2).

## **2.1 The greening of services themselves: the green innovation trajectories in services**

We consider here how, through appropriate innovations strategies, services can dematerialize and green themselves. To account for these *internal or endogenous dematerialization* strategies, we rely on the different dimensions of the materiality of the service previously considered, namely the materiality of (i) the service medium, (ii) the production/consumption spaces and (iii) the production factors. We will not discuss here separately dematerialization strategies associated with the interactivity of the service, to the extent that they are actually special cases of dematerialization strategies related to production factors (transport systems) and production and encounter spaces. This analytical approach is simplifying since the different materiality sources separately addressed here are interdependent in reality.

### ***a) Dematerialization and greening of the service medium***

As we mentioned in paragraph 1.2, the medium of the service can take different more or less material forms: a (material) good, the individual himself, codified information, knowledge. If, in theory, a service activity may be defined by the nature of its main medium (therefore several types of services are distinguished: material, informational, cognitive, relational services...), a service organization is mostly processing simultaneously these various mediums, combined in varying proportions. These combinations are not static but dynamic, and in particular, they may evolve according to dematerialization trajectories.

Depending of the analytical level adopted (macro, meso, micro), the dematerialization of services, considered in terms of the dematerialization of their mediums, can be interpreted in different ways.

At the macro or mesoeconomic level, the dematerialization of the medium may manifest itself by a rise of informational, cognitive and relational services at the expense of material services. This structural change is reflected by concepts such as 'information economy' or 'knowledge economy'. It is also at the heart of the post-industrial society as defined by Daniel Bell (1973), namely, a society that is moving towards the higher-level services in which the mediums of service provision are human beings and knowledge (in particular health, culture, leisure, research and public administration) to the detriment of so-called lower-level services characterized by the processing of tangible goods (transport, retailing, etc.).

At the micro level, this dematerialization is expressed by the rise, within a given organization (or activity), of processing operations of immaterial mediums

(information, knowledge and relationship with the individual) to the detriment of processing operations of physical mediums. The outsourcing of certain material services activities (e.g., catering, transportation, cleaning) can contribute to this process of dematerialization. However, as highlighted by Djellal and Gallouj (2008b), the various mediums of the service and the various corresponding functions (operations) can be associated with different technology families: material processing technologies (robotics, mechanics,...), information processing technologies (IT, telecommunications), knowledge processing technologies (soft technologies, methods...). Thus, in a given activity (or service organization), the rise of the immaterial mediums and functions with respect to material mediums and functions is bound by a reciprocal causality to the change of relative weights of technological families and corresponding innovations trajectories. The dematerialization of the service is thus associated with the rise of immaterial innovation trajectories (pure service, cognitive (methodological) and informational (in its software dimension) at the expense of material innovation trajectories (see section c).

### ***b) Dematerialization and greening of production/consumption spaces***

The dematerialization and greening process of production/consumption spaces fall into the scope of two distinct groups, which are not fully independent. The first group includes the different operating modalities of the dematerialization and greening of traditional production/consumption spaces, while the second group consists of "alternative spaces" to these traditional spaces.

In the first group, dematerialization and greening of the traditional production/consumption spaces can be operated in different ways, which, essentially, refer to building engineering and architecture (including interior architecture). Thus dematerialization and greening cover, first of all, innovation efforts to build sustainable property infrastructure (ecoconstruction, HQE approach) whether these efforts focus on the nature of the materials used, the non-intrusive inclusion of infrastructure (the buildings) in the natural environment or the configuration of interior spaces, etc. They also cover, in some respects<sup>6</sup>, "architectural and spatial" facets of the so-called low-cost or service regression strategies (Djellal and Gallouj, 2005, 2008b). Indeed, these service regression strategies simplify not only the service offer (by limiting it to the central service and eliminating peripheral services), but also the physical environment of this offer. They are less demanding in volume and quality of reception areas (see, for example, the frugal reception areas of low-cost airlines companies at airports, the Spartan material organization of shelf spaces in discount retail chains) and, according to Fourcroy (2015), less energy consuming. Dematerialization and greening of traditional production/consumption spaces finally also covers the experience of "smart buildings", reflecting a hybridization of real estate techniques and information technologies (see following item c).

In the second group, dematerialization and greening of production/consumption spaces are obtained by the introduction of spaces, alternative to traditional production/consumption spaces. Some of these alternative spaces are not new, but

---

<sup>6</sup> In other respects, and primarily, regression strategies aim more, as we have already stated (see § 1.4) to industrialize the service, to make it less intangible, less interactive.

they are experiencing a significant development. These include, for example, alternative spaces associated with the following services: 1) home services (e.g., home care services, especially elderly care); 2) remote services relying on post mail, telephone, but especially Internet; 3) services in shared space (e.g. village shop that provides postal services). These alternative spaces can contribute, in varying proportions, and all things being equal, not only to reduce the production/consumption spaces but also the amount of travel.

### ***c) Dematerialization and greening of the production factors***

The process of dematerialization/greening production factors (limited here to technical systems) can be addressed by focusing on the different ways that innovation trajectories at work in service organizations may evolve: (i) the rise of immaterial innovation trajectories at the expense of material trajectories; (ii) the strengthening of the immaterial dimension within a given innovation trajectory; (iii) the hybridization of several trajectories. The process of the dematerialization of production factors can also be addressed (iv) through changes in material goods ownership and use regimes.

#### *Changing relative weight of innovation trajectories in favour of immaterial trajectories*

First, within a given service company or service activity, the dematerialization/greening process can be considered (as we have already pointed out above) to be a rise in immaterial innovations and technologies at the expense of material innovations and technologies, alongside the rise of the intangible components of the service provision, which is at the expense of its tangible components. In other words, material innovation trajectories reflecting technological developments relating to the transport and transformation of material substances, whether human or physical<sup>7</sup>, become less important than immaterial innovation trajectories which reflect, on the one hand, the production and evolution of formalized methods of knowledge processing<sup>8</sup> and, on the other, the implementation and evolution of 'pure' services innovation, independent of any technical medium.

#### *Strengthening of the immaterial/green dimension within a single innovation trajectory*

The dematerialization process may also be considered at the level of any one component of the service (material, informational, cognitive, or relational) or at the level of the corresponding innovation trajectory, whether material or immaterial. The idea here is that the innovation trajectories, whatever form they take (material or immaterial), are becoming more environmentally-friendly, meaning that efforts are being made to develop and adopt cleaner, more energy-efficient technologies. For example, within the logistics material innovation trajectory, efforts are made in favour of cleaner transport technologies (electric and hybrid vehicles). Within the material and information innovation trajectories, efforts are also made to reduce the volume (materiality) of new technical systems, so that they are more compact. This trend towards miniaturization and integration is not, however, new. Though evolutionary economics (Foray and Zuscovitch, 1988) has described it as a specific natural technological trajectory insofar as it characterizes the technological evolution of a particular sector (electronics), it is tending to become a generic natural technological

---

<sup>7</sup> For example, passenger or goods transportation systems, cooking and refrigeration systems, cleaning systems, various kinds of dispensing machines, visitor attractions, bio-medical or bio-pharmacological innovations, etc.

<sup>8</sup> For example, new consultancy methodologies, new health or cleaning protocols.

trajectory (concerning many sectors). In the specific case of the informational trajectory describing the dynamics of information systems, it is generally assumed that (immaterial) 'software' dimensions tend to outweigh the (material) 'hardware' dimensions as the trajectory evolves. Acceptance of this hypothesis thus means that the informational trajectory will evolve in line with a growing dematerialization process. It is on the basis of this hypothesis that Baumol et al. (1985) introduced an asymptotically stagnant sector in the so-called unbalanced growth model.

#### *Hybridization of material and immaterial innovation trajectories*

Dematerialization and greening can also happen through the hybridization of innovation trajectories. In the most common case - the hybridization of material and informational innovation trajectories - the question arises as to whether hybridization helps reduce the level of materiality of the new hybrid technical systems formed (to which the answer is probably yes, assuming that the software dimension overrides the hardware dimension). However, beyond this hypothetical dematerialization, there is no doubt that some hybridization strategies, all other things being equal, do have a greening effect: this is the case where the introduction of ICTs helps streamline use of a technical system with a view to sustainability -and in particular to energy-saving (smart grid solutions) (Hyytinen and Toivonen, 2015). This is also the case where ICTs are used to carry out service transaction without travel (e.g. remote surgery). Conversely, it should be noted that the hybridization of immaterial (pure service and methodological) innovation trajectories and informational innovation trajectories – that is, the introduction of ICTs to both pure service and methodological innovations, contributes to the pro-materialization dynamic in services (see § 1.4).

#### *Changes in production factor ownership and use regimes*

Dematerialization of production factors (and more generally of material goods) may be achieved through changes in ownership and use regimes. Within the sphere of production, as in that of consumption, individual ownership and private use may give way to different service consumption patterns that do not include ownership (or do not include exclusive ownership) of the goods: leasing, renting, sharing, pooling (see also § 2.2c below). Examples include car sharing (such as BlaBlaCar), shared use of certain sophisticated and expensive technologies, possibly within the context of public-private partnerships (e.g. scanners in hospitals), etc. This fall in materiality, voluntary though it may be, can also be fortuitous, a joint by-product of the pursuit of other objectives. This is, for example, the case of the pooling of heavy equipment in hospitals, which primarily pursues an economic objective.

## **2.2 Dematerialization/greening of goods (and of the whole economy) through services**

As we noted in the previous paragraph, services (as activities or organizations) may themselves be subject to dematerialization and greening dynamics. Here we look at another relationship between services and greening, namely the potential role these activities may play in the greening of other economic activities than their own. These greening (dematerialization) strategies can be described as *external or exogenous*. Within the framework of the so-called economy of functionality, and within a servitization perspective (Vandermerwe and Rada, 1988), the concept of Product-Service System (PSS) (for a literature survey, see Goedkoop et al., 1999; Mount, 2002; Tischner et al., 2002; Tukker, 2004; Baines et al., 2007; Beuren et al., 2013)

occupies an important place in this issue of the greening *by (rather than of) services*. Although it is becoming catch-all and ambiguous as it seeks to gain theoretical consistency, this concept has undeniable heuristic value. Indeed, the concept of PSS (initial, pared-down definition: a combined offering of goods and services) has extended to cover more abstract content, and in particular the idea that everything is service.

In this section, we begin by discussing the analytical ambiguities introduced by enriching the concept of PSS (§ a). We then examine the implications in terms of the dematerialization/greening of different PSS formulations, distinguishing two cases: (i) Product-oriented PSS and dematerialization through the addition of services to products (§ b); (ii) Use-oriented PSS and dematerialization through the substitution of services for products (§ c).

### ***a) Different PSS concepts, and some ambiguities***

Strictly speaking, Product-Service System can be defined as the association (the joint supply) of products and services to meet consumer needs. Such systems existed long before the concept of PSS was explicitly introduced. Although other denominations reflecting the same idea (the combination of products and services to meet consumer needs) preceded PSS, these have been less successful (Bryson 2010). Examples include 'goods-services complexes' (Barcet, 1987) and 'compacks' - a neologism (from 'complex packages') coined by Bressand, 1986, (see also Bressand et al., 1989), comprising 'bundles of services and manufactured inputs'.

In the literature, the 'mechanical' definition of PSS soon gave way to a more complex definition, going beyond the combination of products and services to include utility and environmental issues. Thus, according to Manzini and Vezzoli (2002), "the concept of PSS promotes a focus shift from selling just products to selling the *utility*, through a mix of products and services while fulfilling the same client demands with less environmental impact".

On the whole, in recent literature, the PSS concept seems to be a heterogeneous category, covering various modalities of the (real, theoretical or even rhetorical<sup>9</sup>) integration of products and services. These modalities are described in the following terms (Mont, 2002; Tukker, 2004; Bryson 2010 Vandermerve and Rada, 1998 Boutillier et al., 2014): the association of physical products with intangible services; the definition of the product by the services it renders; the sale of the use of a product rather than the product itself (leasing, renting); the sharing or pooling of the use of a product, and repair rather than disposal. Such a broad and open definition of PSS introduces an ambiguity related to the confusion between the service as an activity (as opposed to a product) and the service as utility or use in the sense of economic theory. A PSS connects products and services. But the ambiguity arises, on the one hand, out of the semantic shift that characterizes the term 'service', and on the other, out of the nature of the relationship which causes a system to exist.

In an attempt to formally summarize these semantic ambiguities, Let's call P the product, S the service, s the final characteristic (utility, use value, service

---

<sup>9</sup> This is sometimes a marketing discourse

characteristic),  $\sigma$  the general (generic) function attributed to a product, a service or a combination of products-services,  $\Sigma$  the service uses that can be made of the product P.

In contemporary literature, as we have just stressed, the PSS concept now, in an ambiguous and catch-all way encompasses a broad set of relationships (which are not always systemic), associating a product (P) and an expression of the service from among those just mentioned (S, s,  $\sigma$ ,  $\Sigma$ ). The main relationships in question are as follows:

- P + S. This is the PSS in the strict sense, combining tangible products with intangible services.
- $\Sigma$  (P), which expresses the service uses of a product. These service uses include leasing, renting, sharing, pooling, etc. While a relationship between  $\Sigma$  and P does exist here, it can only be called a PSS via erroneous use of language.
- P ( $\sigma$ ) or S ( $\sigma$ ), which formalize the idea that a product or service is defined by the general function it performs: mobility, leisure, health, or education, for example. The relationship between P and  $\sigma$  and S and  $\sigma$  is not itself systemic. In reality a system exists only when P and S are combined to satisfy a function, which can be formalized as follows: (P + S) ( $\sigma$ ).
- P (s) or S (s), which, in the Lancasterian tradition, reflect the idea that any product and service is defined by the service characteristics it provides. As in the previous case, the general idea is that products (like services) are defined by the service provided. The difference lies in the fact that the service is not approached in general terms (as a function), but rather broken down into more specific basic service characteristics (e.g. the transport or mobility function is replaced by a vector of service characteristics: speed, security, comfort, etc.). Both approaches to the relationship between products and services can have critical implications on both perception of the level of materiality and the definition of innovation. However, the relationship between P and s or S and s is not systemic. Indeed the service characteristics (s) are consubstantial to P and S; these are not external components capable of creating a system.

The first of the above relationships (P + S) reflects what the literature on PSS (Tukker, 2004) calls 'Product-oriented PSS', while all the other relationships fall within the scope of the 'Use-oriented PSS'.

### ***b) Product-oriented PSS: dematerialization and greening through the addition of services to products***

Product-oriented PSS are established by the addition of services to products. They may, however, take more or less sophisticated and integrated forms, featuring more, or fewer, added services. Within this product-oriented PSS diversity, it is possible to distinguish two main sub-categories, according to the knowledge-intensity of added services.

#### *The addition of (relatively) low knowledge-intensive services: services around the product*

The best-known form of product-oriented PSS is that which entails adding traditional services (generally those having (relatively) low knowledge-intensity) to a product.

These PSS are similar to what Furrer (1997, 2010) calls “services around the product”. Examples include the addition of different pre- and after- sales services, financial and insurance services, etc. which made Fordist economies so successful. Such PSS may be considered at micro level (the same company provides the combined supply of products and services) or at meso level (the joint offer is the result of a partnership between different actors). In the latter case, the PSS is more than just a design and product engineering concept since it also reflects a production and innovation network dimension.

It should be acknowledged that the original purpose of such a system is not ecological. By adding services to products, the objective pursued by companies is to gain a competitive advantage. Companies seek to improve the quality of goods, reduce costs, boost sales and thus increase profits. In some cases, the services added to the product can even be more profitable than the products themselves (Furrer 1997). By adding services to products, companies may also seek to lock down the relationship with the customer - in other words, to generate customer loyalty (Bryson 2010). The multiplication and tightening-up of service relationships (i.e. customer interaction) help keep the provider attentive to client needs, favouring adaption and innovation. It is now possible to state that the addition of services to products, and the concept of PSS, have enriched innovation theory, ahead of sustainable development theory. The two fields (innovation and sustainability) are now reconciled within this concept.

In this PSS approach, dematerialization arises out of multiple sources. First and foremost, it is mechanical (passive), a result of the rise of intangible services in the PSS. In other words, by adding services or service to products, the degree of immateriality of the entire PSS rises. In this way, the ratio between the ‘volume’ of material products and the ‘volume’ of intangible services serves an indicator of the degree of the service’s materiality/immateriality. Within the supply of a given industrial firm, the volume of intangible services may increase, outweighing the volume of material products. This development, which raises sectoral allocation issues, is illustrated by the case of iconic industrial companies (particularly in IT) that have essentially become service providers. It should be noted that in this simple PSS approach, the reverse process of adding products to services also contributes to the creation of a PSS. Such a process, however, helps increase materiality, rather than reduce it.

Dematerialization is also active for some added services. This is, of course, the case of repair and maintenance services, as well as of take-back and recycling services at the end of product life. All of these contribute to dematerialization through the expansion of the lifespan of either the products or some of their components, and by reducing use of virgin materials in the production process (Agri et al., 1999).

#### *The addition of KIBS: the P-KIBS System*

A product-oriented PSS can also be constituted through the addition of Knowledge-Intensive Business Services (KIBS) (various types of consultancy services, engineering, training, and research) to products (and services). The Product-KIBS system also contributes to dematerialization of the system, in a mechanically (passive) way, by the simple juxtaposition of intangible services and physical

products. This is not, however, the most important dematerialization/greening mechanism. Above all, KIBS contribute via an active role. Indeed, in this type of PSS, KIBS are primarily mobilized as agents of change. They can accompany and support the greening/dematerialization efforts of a business and corresponding innovations, whether technological or non-technological. A number of consulting companies have thus either specialized in providing greening services, or included this expertise in their service supply.

### ***c) Use-oriented PSS: dematerialization through the real or theoretical substitution of services for products***

The currently dominant PSS approach is broader than the previous one, since - beyond the systemic dimension (linking products and services), it is the distinction between products and services (and paradoxically between components of the system) that is called into question. Indeed, the main idea here is that, by nature, everything (including the product) is service and that material goods are subject to service uses. This PSS approach is called 'Use-oriented PSS'.

- From the theoretical (and sometimes rhetorical) point of view, this PSS approach falls within the scope of a perspective that reflects a radical change in perception of the nature of goods and services. In this vision "everything is service". Agricultural products, industrial products and services alike are of value only based on the service(s) or function(s) they provide.
- From the operational point of view, this PSS approach reflects, then, a change in the way products are used by consumers, associated with a change in the producer's business model. The company no longer provides products, and the consumer no longer acquires ownership of a product – rather, both respectively sell and buy the use of the product and the service it provides. From this perspective, products (such as cars, photocopiers, and machines) are no longer what are sold, but rather kilometres travelled, the number of photocopies made, hours of operation, and so on. This purchase of the service provided by the products can take many forms: renting and leasing (potentially even going as far as a 'pay per service unit' model<sup>10</sup>), as well as sharing and pooling.

In this PSS approach, dematerialization and greening are not limited to the rise of mechanical immateriality through the addition of intangible services. Here the sources of immateriality and greening are more complex and difficult to grasp. They are linked to the decline in consumption of durable goods and the efforts made by producers to upgrade durable goods (sources of the services they sell) or extend their lifespan.

Though it reflects a blurring of the traditional analytical 'product and service' categories, PSS also questions (scrambles) our analytical categories in the field of innovation (whether or not related to sustainable development): its nature, its actors, its appropriation regime and its evaluation systems. In a PSS, therefore, innovation in products can come out of innovation in complementary services (this is well known in

---

<sup>10</sup> An illustration is provided in the area of rental and leasing photocopiers.

mature sectors, such as the automotive industry). Innovation takes systemic, architectural form. It concerns not only products as such, but also their consumption or use modes. It also raises appropriation issues, given the multiplicity of stakeholders (and in particular the role of the user). It requires innovations in our innovation and performance measurement apparatus, in order to reflect - beyond industrial and technical performance - environmental and social performance (Hyytinen et al., 2015).

## Conclusion

Insofar as it is through their material dimension that economic activities damage the environment, the alleged immateriality of services is often seen as a guarantee of their natural sustainability. Unlike goods for which the production process swallows up exhaustible natural resources and harms the environment, services, by dint of their evanescent nature (long since emphasized by the founders of classical economics) are supposed to have a smaller environmental footprint.

In this work we have sought, firstly, to refute this myth of the immateriality of services. Even though a service outcome may be (or seem) immaterial, we must not forget the many materiality sources that the service conceals: materiality of the service medium, the production factors deployed and the production/consumption spaces, as well as materiality relating to interactivity (which is integral to the previous two vectors of materiality).

Moreover, the materiality/immateriality of a service is not an objective, intrinsic, technical characteristic. It depends, firstly, on the output convention adopted - that is, the scope agreed upon for definition of the service, whether this is its topographical delimitation or its time horizon. Massive underestimation of service materiality often results from the exclusion (as often practiced by official statistics conventions) of certain components (such as travel) from the scope of a service. The materiality of the service is similarly underestimated when it is limited to direct materiality, excluding indirect ('grey') materiality, which is 'incorporated' to buildings, furnishings, intermediate goods and technical systems in particular, as well as to intermediary services mobilized in the course of the service transaction. This service materiality also depends on the materialization/dematerialization strategies being implemented by service organizations.

Thus, while the service is not intrinsically intangible, innovation strategies can be implemented that will make it more or less material/immaterial. In this chapter, we have only briefly touched on service materialization (industrialization) strategies in order to focus on dematerialization and greening strategies.

In their relationships to services, such dematerialization strategies can take two forms, each covering different sustainable innovation trajectories. The first of these internal dematerialization/greening approaches describes a set of innovation strategies entailing services dematerializing and greening themselves through actions designed to affect the vectors of materiality: service mediums, production/consumption spaces, and production factors. The second form, known as an external materialization/greening strategy, encompasses a set of innovation strategies which comprise the dematerializing/greening of goods (and of the whole

economy) through services and service innovation. The PSS concept occupies an important position in these dematerialization/greening strategies. It reflects (though sometimes ambiguously) various mechanisms: mechanical (passive) dematerialization via the simple association (juxtaposition) of goods and services; more complex dematerialization, based on a unified ontological conception of goods and services (everything is service) and on changing production and consumption patterns and ownership regimes, and dematerialization/greening through active KIBS intervention.

Overall, we can conclude that services are not by nature intangible and green, but that they are capable of dematerializing and greening themselves via the implementation of appropriate innovation strategies. This process of dematerialization and greening, supported by sustainable service innovation, must however be qualified by a number of remarks, some of which may be considered interesting avenues for a research agenda:

- In this work, we have focused on the dematerialization dynamics of services and of PSS. However, in contemporary economies, the two often go hand in hand with the contradictory dynamics of materialization. These are the two inseparable faces of Janus. Gallouj et al. (2015) describe the industrialization/servitization dialectic as one of the most powerful megatrends at work in contemporary economies. We might also ask to what extent these two contradictory processes lead to a zero sum game in terms of materiality and sustainability.
- Analyses of dematerialization must take into account what is called the rebound effect. Indeed, the success of eco-friendly solutions can induce increased production and consumption, thus reducing the overall benefit.
- The two remarks above refer to the fundamental question of measurement systems. Most of our analyses remain theoretical or qualitative. The dematerialization issue raises formidable measurement problems. Thus, the idea of PSS sustainability - that is, their less material- intensive nature (though considered acceptable in theory) is not validated by measurement. This is an important research issue.

# **XXV. International RESER Conference: Sustainable Development an Opportunity for Innovation in the Management Model of Public Organisations<sup>1</sup>**

*Martín-Segura, José Aureliano<sup>1</sup>; Navarro-Espigares, José Luis<sup>1</sup>; Pérez-López, César<sup>2</sup>; Maraver-Tarifa, Guillermo<sup>1</sup>*

<sup>1</sup>University of Granada, <sup>2</sup>Complutense University of Madrid

*The literature recognises the great influence that environmental spending has in implementing LA21. But some authors raise doubt about the real commitment of local government after the signature of the Aalborg Charter or when they declare their adherence to Local Agenda 21.*

*This is the main objective of this paper, to verify the authenticity of political commitment towards meeting the objectives of sustainable development by means of the budgetary support to these policies or specific actions in favour of environment. We also verify the impact of the political character of the local governments on their behaviours in this respect.*

*To accomplish this verification, we apply the Difference in Differences technique for the period 2002-2012 in the Spanish municipalities. Results obtained confirmed the initial hypothesis and show how those local governments that adhered to LA21 have had a better evolution in their environmental expenses.*

*This article introduces a new perspective for the LA21 analysis, based on the study of local budgets as evidence of the actual commitment to the sustainable development strategy promoted by LA21.*

<sup>1</sup> The paper has been carried out with the financial support of the research project: 014- ABEL-CM-2014A –Sustainable development as an innovation opportunity in management model of public organizations. Evaluation and promotion of citizen participation towards sustainability. Supported by a grant from Iceland, Liechtenstein and Norway through the EEA Financial Mechanism and operated by Universidad Complutense de Madrid. Call ABEL-CM-2014A of NILS Mobility Program for Science and Sustainability.

# **1. INTRODUCTION**

## **1.1. Local governments and environmental management (Local Agenda 21 and Aalborg Charter)**

In general, authors have identified an alternative, environmentally friendly, socially equitable, and sustainable development model with the term sustainability. This term is an ambivalent concept that raises two serious questions –first, the need to focus on political, social and economic issues, and, second, the need to define potential strategies to transform the current model. Regarding the management of collective proposals and problems related to legitimacy of governmental interventions, the sustainable development model boosts the value of participatory democracy against representative democracy, moving to the local level a large part of the role to the citizens. The Local Agenda 21 (LA21) meets these objectives and, therefore, is today one of the main instruments of management and intervention in favour of sustainable development.

The commitment, adopted at the Rio Summit in 1992, to promote sustainable development was reflected in four documents:

- The Declaration of Principles.
- WHO Framework, Convention on Climate Change.
- The Convention on Biodiversity.
- Agenda 21.

Agenda 21 consists of 4 sections developed into 40 chapters, in which the following issues are addressed: social and economic dimensions, conservation and management of resources for development, strengthening the role of major groups and means of implementation. The basis for action, objectives, activities and means of implementation for approval of the Local Agenda 21 are set out in the chapter 28 of the third section (Initiatives of local authorities in support of Agenda 21).

When it was adopted in 1992 at the Earth Summit, Agenda 21 was meant to be “a programme of action for sustainable development worldwide”. Furthermore, as stated in its introduction, it had the ambition of being “a comprehensive blueprint for action to be taken globally, from now into the twenty-first century”. The ambition was high, and so were the stated goals of the Agenda: to improve the living standards of those in need; to better manage and protect the ecosystem; and to bring about a more prosperous future for all.

Agenda 21 document is different from the other three documents mentioned because it is a plan of action. The implementation of the LA21 locally makes it possible to design intervention strategies for sustainability based on cooperation between governments and social partners. It is a strategic plan with the intention that the cities and municipalities assume their share of responsibility for the mobilisation of the citizenship in the effective management of the territory and the promotion of fair and long-lasting scenarios from the environmental, social, and economic points of view.

Since the Rio Conference, a timetable for implementation of Agenda 21 has been designed. That schedule included a consultative process at the beginning to encourage cooperation between local authorities at an international level. The first target stated that in 1996 local authorities of each country would have carried out the initial consultative process with their populations to agree on Agenda 21 at the local level.

In this process of intermediation between international organisations and local authorities, the International Council for Local Environmental Initiatives (ICLEI), which prompted the First European Conference on Sustainable Cities & Towns, held in the Danish city of Aalborg in 1994 at the request of the European Commission, has played a decisive role. At the Conference, the Aalborg Charter (Charter of European Cities and Municipalities for Sustainability) was adopted. The signature and adhesion to the Charter by local administrations is identified as the first step in the process of implementation of LA21.

The 'Aalborg Charter' (1994) is an urban environment sustainability initiative approved by the participants at the first European Conference on Sustainable Cities & Towns in Aalborg, Denmark. It is inspired by the Rio Earth Summit's Local Agenda 21 plan, and was developed to contribute to the European Union's Environmental Action Programme, 'Towards Sustainability'.

The Charter is based on the consensus of individuals, municipalities, NGOs, national and international organisations, and scientific bodies. There are three related parts to the Charter.

- Part 1 is a consensus declaration of European sustainable cities and towns towards sustainability.
- Part 2 relates to the creation of the European Sustainable Cities & Towns Campaign.
- Part 3 is declaration of intent that local governments will seek to engage in Local Agenda 21 processes.

The conference in Aalborg (1994) was followed by others, such as those held in Lisbon (1996), Turku (1998), Sofia (1998), Seville (1999) and The Hague (1999), in which the need was answered for strengthening participatory structures in the development of the A21 at regional level.

The XXI century started with Hannover (Germany) 2000, Aalborg (Denmark) 2004, Seville (Spain) 2007, Dunkerque (France) 2010, and Geneva (Switzerland) 2013. Gathering over 1000 participants from local governments and a variety of other actors across Europe, the European Conference on Sustainable Cities & Towns remains the largest European event for local sustainability. All conferences have been co-organised by ICLEI together with the respective host cities, and a Conference Preparatory Committee.

At the Third European Conference on Sustainable Cities held in the German city of Hannover in 2000, the need to standardise and regulate the different initiatives developed and give administrative support was raised. In this sense, the presentation of an initiative of systematic monitoring by defining specific standards or sustainability indicators was one of the major contributions of this conference. The final agreement stressed the need to establish and develop regional networks that enable greater

cooperation, exchange of experiences and dissemination of good practices, while ensuring greater economic and technical coverage of the various governments. Regarding this last point, the European institutions are encouraged to approve subsidies and grants under the Structural Funds scheme, subject to the existence of a sustainable development plan.

In the late nineties, 650 regional and local authorities from 32 European countries had achieved a commitment to local sustainability by joining the Aalborg Charter. In 2010 the number of local authorities that had signed the Aalborg Charter amounted to 2838.

Ten years after the release of the Aalborg Charter, the participants of the 4<sup>th</sup> European Conference on Sustainable Cities & Towns in Aalborg, Denmark 2004 (Aalborg+10) adopted the Aalborg Commitments - a list of 50 qualitative objectives organised into 10 themes:

1. Governance
2. Local management towards sustainability
3. Natural common goods
4. Responsible consumption and lifestyle choices
5. Planning and design
6. Better mobility, less traffic
7. Local action for health
8. Vibrant and sustainable local economy
9. Social equity and justice
10. Local to global

Local stories about the achievements in these 10 themes can be retrieved from the *sustainablecities* webpage at <http://www.sustainablecities.eu/local-stories/actionforhealth/>.

The move from Charter to Commitments signified a new, more structured and ambitious approach. To be signed by the political representative, the document requires the signatory to comply with time-bound milestones. Each local government is asked to produce a baseline review within a year of signature, conduct a participatory target-setting process and arrive at a set of individual local targets addressing all 10 themes within two years, as well as committing to regular monitoring reviews.

Agenda 21 recognises nine major groups of civil society, and stipulates the need for new forms of participation at all levels to enable a broad-based engagement of all economic and social sectors in making sustainable development happen. The Major Groups are Business and Industry, Children and Youth, Farmers, Indigenous Peoples, Local Authorities, NGOs, Scientific and Technological Community, Women and

Workers and Trade Unions. In this work, we will focus our interest on Local Authorities.

As in 1994 with the organisation in June 2004 of the last European Conference on Sustainable Towns (Aalborg + 10), the city of Aalborg has again become the capital of the local movement for sustainability. The Conference has assessed the existence of a large, active and aggressive local movement in favour of a more sustainable model of development, as well as the significant increase in the number of cities and municipalities that adhered to the Aalborg Charter. However, the success achieved over the past ten years has been devalued because it was found that adherence to the Charter of Aalborg sometimes has not meant more than just institutional declaration of good intentions, without anything definite or any action plan implemented (Brunet Estarellas et al., 2005). This last idea inspires the present work, in which the correspondence between the adherence to LA21 by local governments and the economic and budgetary support to sustainable projects will be verified.

In Spain, the Sustainable Development Strategy was introduced by the Government in June 2000, and included the commitment to promote a new model of integration and balancing of economic, social development and environmental protection in the long term. However, there has been a lot of criticism from certain political parties concerning the general nature of the document, the lack of budgetary measures necessary for momentum and a framework of broad and representative social participation and the absence of goals, commitments, priorities and specific deadlines. Given the discontent with the Spanish Sustainable Development Strategy, some regional governments have drafted their plans or strategies for sustainable development. In short, in Spain 'LA21 has become the symbol that presumes to include everything that is done at the local level to convert the overall design of sustainability into operational reality' (Font & Subirats, 2000).

## **1.2. Environmental Management and Innovation**

Most scholars and policymakers now recognise that economic development cannot be explained solely by levels of investment, by education, by culture, by policies, or by type of government. There is, instead, a growing consensus that economic development is primarily a function of institutions that help societies to reap potential gains from interactions among independent actors (Hoff & Stiglitz, 2001).

While social scientists agree that institutions are crucial determinants of outcomes across a variety of societal domains, perspectives differ as to when to anticipate institutional innovation and how to predict the performance of particular institutions over time. Analysis of institutions is especially important in circumstances characterised by instability rather than continuity: both the direction and the consolidation of change reflect the characteristics of institutions and their relationships to various stakeholders (Doner, Richard F., 2010).

Faced with the institutionalisation of a hierarchical model of intervention and conventional planning, from top to bottom, with the launch of the LA21 an attempt has been made to encourage new participatory processes based on the formulation of strate-

gies from the bottom up, with a large and active citizen involvement. This alternative causes the administration, rather than controlling the process, to have as main objectives those of facilitating it, encouraging the participation of different social, political and economic actors, shifting the protagonism to the public in addressing issues and solving problems by means of the consensus. This means that public participation and leadership of local government become the more characteristic signs of the process.

The transition from a conventional model of governance to another multi-level and relational one increases the capacity of local actors to intervene, share responsibilities in defining objectives, and specify solutions, while broadening the exchange of knowledge and strengthening the possibilities for cooperation.

However, the implementation of the principle of subsidiarity requires prior redefinition of roles, both by public administration and the economic and social agents. One of the essential elements of LA21 as a factor of institutional change is the need to consult citizens, businesses, the various institutions and social partners during its implementation (Foh Lee, K., 2001).

From the institutional point of view, the desire of local authorities to take centre stage can be an incentive for these governments to explore ways of gaining legitimacy and demonstrate their ability to solve collective problems geographically localised. Institutional theory emphasises the relationship between organisations and the environment and the diffusion of innovations explained by institutional mechanisms.

Institutional pressures faced by organisations to which they have to respond have been analysed through institutional theory. It is an approach that does not focus on efficiency as the sole purpose of organisations, but pays more attention to the relations established by the organisations with the various stakeholders from whom they need backing and social support to survive, i.e. legitimacy. According to this approach, legitimacy is established as a main objective of the organisations, to explain certain of their behaviours. The pressures exerted by these stakeholders are felt to a greater extent in public organisations, since they face highly institutionalised environments and rely on public opinion to gain legitimacy and resources (Dobbin et al., 1993). In such institutional settings, legitimacy, not efficiency, is critical for the ability to secure vital resources.

The response of Spanish local councils to changes in their institutional context by implementing a sustainable practice like the Local Agenda 21 has been studied by Rocio Llamas-Sanchez, Victor Garcia-Morales, & Inmaculada Martin-Tapia (2013). The analysis carried out by these authors reveals some institutional factors that explain the process of institutional change, the outcomes of LA21, and the differences between local councils. From that institutional point of view, they consider LA21 to be an effective instrument for improving both the sustainability of towns and the management of local councils.

The thrust of Local Agenda 21 has been to promote public involvement in negotiating programmes for sustainability, and it is here that many local governments have grasped the opportunity for institutional innovation and community outreach (Mason, 2012). LA 21 could be the grass-root catalyst for serious institutional innovation at the local level (Koutrakou, 2004).

The plan assumes that local well-being does not depend fundamentally on “development factors” (of supply) that exist in a given area; it looks instead at the possibility of favouring and reinforcing capacities for economic, technological, social, and institutional innovation that emerge from the complex local interactions between supply and demand factors. This idea supports the argument of “systemic vulnerability” in the sense that various types of crises precede and stimulate innovation and institutional changes.

The strict version of this systemic vulnerability argument is that the creation or evolution of efficient institutions only occurs when political leaders confront popular discontent and external threats but lack resources to address these problems (Doner, Richard F., Bryan, Ritchie, & Slater., 2005). Under these conditions, institutional innovation helps to generate required resources. In the Spanish context we found a similar consensus. Institutional context offers opportunities to develop innovative behaviours. Innovation can be an alternative in the fighting of organisations against the contextual pressures (Llamas Sánchez, Rocío, 2005).

In a first stage the diffusion of innovations reflects the need to solve a problem, but in the next stage, organisations adopt innovations because of the threat of losing legitimacy and losing the support of stakeholders. As the number of organisations that adopt an innovation becomes greater, the value attributed to it increases. So, organisations that have not adopted that innovation appear as illegitimate to stakeholders.

The *ecologically sustainable development* strategy in Australia has been evaluated by Curran (2015) through the prism of ecological modernisation. This author regards Australia's ecologically sustainable development trajectory as a ‘meta policy’. Ecological modernisation proposes two key interrelated strategies for achieving sustainable development: the modernisation of production and its practices and the modernisation of the political sector and its institutions. Curran’s work focuses on the latter, particularly on the political commitment to ecologically sustainable development at the political elite level. In considering key moments in Australia's political modernisation story, the article finds that, despite important developments and innovations, the ecologically sustainable development and ecological modernisation experiment in Australia has had limited success in significantly and permanently shifting the government business relations of sustainability in ways that would respect the spirit and goals of ecologically sustainable development. This can in part be explained by the limited capacity of a reform process such as ecological modernisation to shift the political dynamics of environment–development relationship.

Nevertheless, Australia’s institutional change has also been examined by some authors from a different point of view (Macintosh, 2015). This article questions the effectiveness of *Ecologically Sustainable Development*, asking whether it has had a material impact on Australia's environmental institutions. The argument made is that, while ecologically sustainable development has had some success at the margins, its overall impact has been limited. The institutions necessary to ensure that policy makers impose and abide by a binding strong sustainability constraint based on the maintenance of natural capital have not been created. This work recognises that there have been advances in environmental protection since the early 1990s but, by and large, these have been a product of the same types of political and contextual factors that drove policy prior to the adoption of ecologically sustainable development. The score may have changed, but the rules have remained the same.

### 1.3. Background

Most works studying the development of LA21 in different geographical environments focus their interest on the analysis of the implementation strategies of the Agenda at the local level. Sustainability as defined by the Brundtland Commission is a composite and thus ambitious policy target. It comprises environmental, economic, social, and institutional criteria with equal importance. Because of this complexity, the first step of a Local Agenda 21 process should be to develop a vision of a sustainable society attached to indicators that help to measure progress, distance to target, and failures of plans or their implementations (Valentin & Spangenberg, 2000). For instance, Adolfsson (2002) studied four small- to medium-sized municipalities in the southeast of Sweden. The study shows that the LA21 processes have instigated many new ideas, brought fields together and introduced new subjects into the municipal world. It also confirms that there are signs of an extended dialogue and of public influence, especially within fields where citizens are directly involved. LA21 does not seem to have great influence on which natural resources are dealt with, but does on how they are dealt with. New stakeholders within and outside the municipal organisation have been identified through the LA21 processes, and more comprehensive ways of solving problems and a positive climate for testing new ideas have been created. In these respects LA21 has been and will be a significant support to the development of appropriate natural resource management at the local level.

In recent years we have found other works in a similar vein [(Foh Lee, K., 2001), (Robert Rutherford, Robert A. Blackburn, & Laura J. Spence, 2000), (Eckerberg & Forsberg, 1998)]. A realistic counterpoint to the official monitoring and assessment procedures of national governments and international bodies has been offered by Lafferty & Eckerberg (2013). These authors highlighted the problems of assessment and policy evaluation and clearly set out the policy stages necessary for more effective realisation of Local Agenda 21 objectives.

Another widely explored perspective for the LA21 analysis is focused on the measurement of sustainable development outcomes anticipated by the Agenda [(Poveda & Lipsett, 2011), (Thomas, 2010)]. Thomas pointed out that the literature-based review demonstrates the richness of this engagement and that while there is enough information about the range of engagement, there is little evidence to indicate the effectiveness of these policies. The assessment process implies the existence of tools, instruments, processes, and methodologies to measure performance in a consistent manner with respect to pre-established standards, guidelines, factors, or other criteria. Sustainability assessment practitioners have developed an increasing variety of tools. That paper discusses a range of fundamental approaches, as well as specific and integrated strategies for sustainability assessment, as the foundation of a new rating system being developed for large industrial projects. In this line of research we also found several recent papers [(Devuyst, 1999), (Haapio & Viitaniemi, 2008), (Lawrence, 1997), (Nijkamp & Pepping, 1998), (Papadopoulos & Giama, 2009), (Cole & Valdebenito, 2013)].

Hess and Winner (2007) summarised some case studies and recommended local government action in favour of environmental sustainability. In their opinion there are many opportunities for financially constrained cities to assist the development of 'just sustainability' projects with minimal financial commitments. They can do so by rechanneling the purchasing decisions of public agencies, building partnerships with community organisations and developing the small business sector.

The study "Sustainable Development in the 21st century" (2012) offers a detailed review of progress in implementation of Agenda 21 from an international perspective. It reveals how various chapters of Agenda 21 have progressed at different paces. Success in Agenda 21 has been highly variable. Despite being a comprehensive plan to deliver sustainable development, implementation has not always been systemic. For example, Agenda 21 has stimulated a much stronger notion of participation in decision making. This affirmation of the important role of non-governmental actors has infiltrated all levels of government, international law and international governance. Although Agenda 21 has acquired considerable coverage among nation states, its implementation remains far from universal or effective. Progress has been uneven, and despite some elements of good practice most Agenda 21 outcomes have still not been achieved. Nevertheless, regarding our main interest in this work, Local Agenda 21 has been one of the most extensive follow-up programmes to United Nations Conference on Environment and Development (UNCED) and is widely cited as an unprecedented success in linking global goals to local action. Many local authorities around the world have adopted some kind of policy or undertaken activities for sustainable development, either as a main priority or as a crosscutting issue. Progress so far does not mean that the work is over, but rather that there is potential to build further on the success. Multi-level governance is needed, as well as increased integration between local authorities and multi-stakeholders in their communities. (Stakeholder Forum for a Sustainable Future, 2012).

Regarding the assessment of the degree of implementation of LA21 in Spain, several recently published studies provide a complete picture of the situation [(Font & Subirats, 2000), (Hernández Aja, Agustín, 2003), (Echebarria, Barrutia, & Aguado, 2004), (Moralejo, Legarreta, & Miguel, 2007), (Hidalgo, 2008), (Martínez & Rosende, 2011), (Observatorio de la Sostenibilidad, 2014), (Jiménez Herrero, Luis M., 2008)].

Regarding the environmental expenditure, we would like to highlight the relevance of the work by Aguado and Echevarria (2004) in which, by simple correspondence analysis, they analyse the situation that relates to the Spanish regions (Autonomous Communities, AACC) concerning budgetary expenditure intended for various environmental items. To do this, they perform an AACC typology using as criteria the per capita spending by type of environmental activity in each region. The ultimate purpose of this research is to examine the relationship of the use of public funds with the implementation of Local Agenda 21. The information analysed at the level of each region, was obtained from a survey sent to different Environment Departments of the CCAA and an analysis of the reports published by these Departments regarding the AL21. Their hypothesis tries to demonstrate the great influence that environmental spending has in implementing LA21.

This work has some points in common with ours, since it uses the perspective of environmental expenditure to assess the degree of implementation of LA21 in the various Spanish regions. In fact this work raises some doubts about the coherence between the political commitment to the Charter of Aalborg and Towns Campaign and

European Cities for Sustainable Development and the actual implementation of local strategies for sustainable development economic support.

However, there are two main differences from ours. On the one hand, there are differences in the basic unit of analysis. The work of Aguado and Echevarria analysed the CCAA behaviour, while in this research municipalities have been utilised as the analysis unit. On the other hand, their statistical methodology was based on the *correspondence analysis*, while this paper uses the impact assessment by the technique known as *Difference in Differences* (DID). We consider the comparison between the results that we obtained from the fixed effect panel data differentiated by CCAA and the groups of CCAA finally proposed by these two researchers, after applying the correlation analysis by budget items and environmental actions, to be of interest for further investigations.

#### **1.4. Evaluation of public policies by DiD**

The process of developing public policies can be broken down into three phases or stages:

- The formulation (ex-ante analysis, taking action as a reference). It is based on a diagnosis and a problem definition, so as to generate and analyse alternative solutions; thus we can select what we consider to be the most appropriate ones.
- The implementation, which should correspond to the implementation and control of the above formulation by taking operational decisions and concrete actions to affect the original public issue. In practice, the implementation typically deviates from the initial formulation for various reasons (design problems, political games, inadequate resources, etc.).
- Evaluation (ex-post study) allows us to measure the results and impacts achieved, describe the process developed, explain its determinants and constraints, and rate their degree of effectiveness. It is the basis for deciding whether to follow a policy evaluated, with or without modifications, or if instead we should proceed to its completion or replacement.

One of the first questions we should ask ourselves before examining the effect of any public policy is why we should assess it. Often policy makers focus on measuring inputs and immediate outputs of programs, rather than assessing whether the programs have achieved their objectives. Thus, the policy based on evidence comes to the forefront, of which the impact assessments is a very important part (Gertler, Martinez, Premand, Rawlings, & Vermeersch, 2011).

The analysis of the effectiveness of public policies is to test whether a concrete policy or action program has been capable of producing the desired effects or not. It should be based on data and opinions about what actually happened. This involves making sure that those effects have been produced, and that the policy has been its sole cause, ruling out other possible impacts of intervening variables.

These evaluations address three types of questions (Morra Imas & Rist, 2009):

- Descriptive questions: what is happening?
- Normative questions: comparing what is happening with what should happen.
- Questions about cause and effect: test results to determine the difference generated by the intervention carried out.

On the last question, it is what impact evaluations deal with, since they analyse changes in the results attributable to the program.

Quantitative methods emphasise the quantification and favour the use of experimentation in the impact assessment. Such experimentation seeks to establish causal links between the program and its effects. It relies on the methodological paradigm developed for the natural sciences, and tries to verify stable cause-effect relationships between certain actions and their presumed consequences.

The use of quantitative methods leads to the concept of counterfactual. That is what any chosen method should estimate, and that tells us what would have been the outcome for participants in the program if they had not participated in it. Therefore, in practice it requires finding a comparison group so as to estimate what would have happened to participants without the program.

Conducting a social experiment requires building a counterfactual condition that considers what would have happened if the intervention had not occurred. This design requires randomly creating two groups among the possible recipients of the evaluated activities, which ensures the statistical equivalence. In these two groups just one difference is introduced— the assessed program that is applied in one (experimental group, instance, or treatment) and not in the other (control group or untreated). Then it proceeds to make initial and final measurements in both groups on the topic of interest, to identify their different evolutions, whose only cause is linked to the policy developed in the case-only group (Cardozo Brum, 2013).

Thus, the econometric methodology used in modern evaluation of public policies can be summarised as follows: first, the causal relationship object of study is explicitly formulated. Then desired effects are estimated by using econometric methods on available data. Finally, the results are causally interpreted, so as to discover the implications for public policy (Durán, 2004).

There are different quantitative impact assessment methods such as random assignment, randomised promotion, and regression discontinuity design, which estimate the counterfactual through explicit allocation rules of the program that the evaluator knows and understands. But there are other methods, such as difference-in-differences (DID) and pairing, that provide additional tools that can be applied when the program assignment rules are less clear or when the application of any of the above three methods is not feasible. Specifically, the DID method estimates the counterfactual change in the result for the treatment group by calculating the change in the result for the comparison group, which allows taking into account any constant difference in the time between the two groups (Gertler et al., 2011).

In more detail, what it is being applied is the double difference. The first difference is calculated taking into account the results before and after of the experimental group, that is, considering the constant factors in time for the same group. But to observe the variable factors over time we should measure the change before and after the results in the control group that was exposed to the same conditions. This is the sec-

ond difference. Thus, the DID method would combine the two false counterfactuals (before and after comparisons and comparisons between experimental-control groups) in order to generate a better estimate of the counterfactual. This method does not require rules for the allocation of individuals in the treatment group, but requires that the control group could represent a change in the results that the treatment group have experienced in the absence of the program.

In other words, the identification of the effect of a program/policy could be intuitively treated in two ways:

1) Compare participants (“treated”) and non-participants (“untreated”) (in cross-section): simple “differences estimator” (OLS)

This methodology presents the problem of unobserved differences between treated and untreated that are correlated with outcomes

2) Compare outcome of individuals who participate, before and after “treatment” (in panel data set):

The problem in this case is due to the omitted time-trends (e.g. business cycles)

In order to solve the previous problems, the solution comes from the technique known as Differences-in-Differences Estimator (DID) (time-constant differences, and time-trends differences between treatment and control groups)

The use of this method is subject to one condition, to have a panel data, where entities (e.g. individuals or states) are observed at two or more points in time.

$$\hat{\beta}_1^{diffs-in-diffs} = (\bar{Y}^{treat,after} - \bar{Y}^{treat,before}) - (\bar{Y}^{control,after} - \bar{Y}^{control,before})$$

Fig. 1: Graphic illustration of the Differences-in-Differences Estimator (DID)

## **1.5. Objectives**

The main objective of this work is to measure the differences, in terms of environmental spending, between Spanish municipalities that adhered to the LA21 and those that have not.

The idea is to link environmental expenditure with the political commitment of local governments to achieve the goals set by the LA21. As we have stated above, there have been several studies that have questioned the authenticity of political commitment towards meeting the objectives of sustainable development, by local governments that have adhered to the Local Agenda 21.

With this approach we are ignoring the issue of efficiency in spending. However, in Spain most of the projects considered examples of good practice (Federación Española de Municipios y Provincias-FEMP & Observatorio de la Sostenibilidad en España-OSE, 2013) are linked to relevant initial investments. This circumstance makes it reasonable to link the political commitment to the variable "environmental expenditure".

The specific objectives are the following:

- Comparison of the behaviour of municipalities in the control group and the experimental group
- Influence of political orientation of local governments
- Influence of the population
- Influence of the overall volume of budgetary funds

## **1.6. Research questions**

- Do the municipalities that adhered to the LA21 devote a larger share of their budgets to environmental expenditures?
- Is adhering to the LA21 a determining factor when it comes to devoting more of their budget to environmental expenditure, despite the economic crisis and budgetary constraints imposed on the municipalities from the central government?
- Are the influence of the political character of local governments, the number of inhabitants, and the volume of the overall budget on environmental expenditure statistically significant?

## **1.7. Differential contribution of the work**

The differential contributions of this work are specified in the following aspects:

- The dependent variable is the environmental expenditure, understood from the perspective of the functional classification of municipal budgets
- Approach linked to the process of innovation in the management of local governments
- Implementation of DiD methodology for measuring the impact of public policies
- Use of municipal entities as the unit of analysis

## **1.8. Sequence of other sections of the article**

The following section describes the methodology used in the work, including hypotheses tested. The temporal and geographical scopes of the work, the data sources, and the treatment of these data for the selection of the final sample are all explained. Then, in the results section we will present the results, differentiating the descriptive analysis and the analysis by econometric models (DiD). We will close the work with a conclusions section, where the results referring to the hypotheses posed in the methodology section are discussed. Work constraints and major implications for local politics are also included in that section. Finally, we also discuss further research lines in the future to complement this study.

# **2. METHODOLOGY**

## **2.1. Hypothesis**

- The municipalities that adhere to the Local Agenda 21 devote more budgetary resources to expenditure functions related to the environment.
- The municipalities with local government political tendencies towards the left devote more budgetary resources to expenditure functions related to the environment, or reduce these resources the least, even in times of crisis.

## 2.2. Temporal and geographical scope

Regarding the temporal scope, the period 2002-2012 is covered. The geographic scope covers 100% of the national territory.

## 2.3. Data source and processing. Description of variables (experimental and control)

The analytical work of this article is based on a database of our own construction, in which we have combined the data from the final budgets for 2002, 2010, 2012 and 2013 and the initial budget for 2014, the population of each municipality for the years studied, the results of the municipal elections (1999-2011) and the ideology (L / R) of the political party that won the most votes in the municipal elections.

Regarding the budget, data have been obtained from the website of the Ministry of Finance and Public Administration (<http://serviciosweb.meh.es/apps/EntidadesLocales/>). It is important to note that there was a change in the accounting rules of local governments that generate a difference of content in programs of environmental expenditure between 2002 and 2010. Since 2010, the accounting methodology has been homogeneous.

In accordance with the Order of September 20, 1989, by which the structure of the budgets of local authorities is regulated, we have identified two spending sub-functions for the year 2002:

### 4.4 COMMUNITY WELFARE.

*It includes all costs relating to activities and services aimed at improving the quality of life in general.*

*It will be charged with costs derivatives maintenance, upkeep and operation of the services of treatment, supply and distribution of water; collection, disposal or treatment of waste; street cleaning; office of consumer information; protecting and improving the environment; cemeteries and burial services; slaughterhouses; markets; fairs and exhibitions, etc.*

*The sub-functions typified include:*

*4.4.1 Treatment, supply and distribution of water.*

*4.4.2 Waste collection and street cleaning.*

For this work, the variable environmental expenditure in 2002 is the sum of the costs incurred by the municipalities in the sub-functions 441 and 442.

In view of the results obtained, the content of these two sub-functions are not comparable to the costs included in the 17<sup>th</sup> policy "Environment". This policy is present in budgets subsequent to 2010 (Order EHA / 3565/2008, of December 3, in which the structure of the budgets of local authorities is approved). The 17<sup>th</sup> policy includes four programs:

170. General administration of the environment.

171. Parks and gardens.

172. Protecting and improving the environment.

179. Other activities related to the environment.

Nevertheless, because the programs do not indicate the specific content of the expenses included in each program, to simplify the analysis, we used aggregate spending in the 17<sup>th</sup> policy as variable of analysis from 2010.

Therefore, the concept of environmental expenditure is taken from the functional classification of municipal budgets by reference to the sum of the sub-functions 441 and 442 for 2002 and policy no.17 in 2012.

Data related to electoral consultations in recent legislatures have been obtained for Consultation Election Results of the Ministry of Interior for 1999, 2003, 2007 and 2011 (<http://www.infoelectoral.interior.es/min/areaDescarga.html?method=inicio>).

In total, a database with 11,857 records corresponding to those of local authorities that are in the budget database of the years 2002 to 2014 has been designed. From this whole, a sample of 1273 municipalities has been selected. To achieve this sample, we applied the following exclusion criteria on the whole of those of local authorities:

- Municipalities without environmental expenditure in 2002
- Municipalities without environmental expenditure in 2012
- Local government entities without associated population (Other municipalities: Councils, Commonwealths, Counties, etc.)

Of these 1273 municipalities that collected environmental cost in their budgets, the experimental group is composed of 161 Spanish municipalities that in 2002 had adhered to the AL21<sup>2</sup>. That is, after applying the exclusion criteria, 1273 municipalities, of which 143 belong to the experimental group (LA21) and the remaining 1,130 to the control group, were included in our study sample.

Table 1 provides information on the coverage of the sample with respect to the whole, in terms of number of municipalities, population and territorial coverage.

<sup>2</sup> Data obtained from the study of Hernández Aja, A. (2003). According to this study 409 municipalities were adhered to the Aalborg Charter in 2002. 189 municipalities adhered to the Aalborg Charter confirmed their commitment in a survey. 143 of them appear in our database with environmental costs in their budgets.

|                     | No. Municipalities | Population 2002 | Population 2012 | No. Regions |
|---------------------|--------------------|-----------------|-----------------|-------------|
| Experimental Group  | 143                | 15,111,812      | 16,469,325      | 14          |
| Control Group       | 1,130              | 16,819,579      | 19,700,568      | 18          |
| Total Sample        | 1,273              | 31,931,391      | 36,169,893      |             |
| Total Population    | 11,857             | 39,588,411      | 47,113,180      | 19          |
| Sample / Population | 10.74%             | 80.66%          | 76.77%          | 73.68%      |

Table 1: Coverage of the sample

The coverage of the municipalities included in the sample exceeds 73% in terms of territorial coverage and 76% in terms of population. The population included in the experimental group represents 38% and 35% of the national population in 2002 and 2012 respectively.

The variables included in the models are the following:

- Environmental expenditure (final budget)
- Total budget expenditure (final budget)
- Population
- Local governments policy trend

For the treatment of data and application of statistical techniques, software packages, SPSS (Statistical Package for Social Sciences), SAS (Statistical Analysis Software) and Eviews 8 have been used.

## 2.4. Difference in differences

Difference in Differences treatment effects (DID) have been widely used when the evaluation of a given intervention entails the collection of panel data or repeated cross sections. DID integrates the advances of the fixed effects estimators with the causal inference analysis, when unobserved events or characteristics confound the interpretations (Angrist, J.D. and Pischke, J., 2009).

Despite the existence of other plausible methods based on the availability of observational data for quasi-experimental causal inference -i.e. matching methods, instrumental variable, regression discontinuity-, DID estimations offer an alternative reaching the unconfoundedness by controlling for unobserved characteristics and combining them with observed or complementary information. Additionally, the DID is a flexible form of causal inference, because it can be combined with some other procedures, such as the Kernel Propensity Score and the quintile regression (Villa, 2012).

For econometric assess, the impact of the Local Agenda 21 (LA21 onwards) on spending the next base regression is used:

$$\text{Environmental Expenditure} = a_0 + a_1G + a_2T + a_3G*T$$

G is the dummy variable that distinguishes the group (treatment or control).

T is the dummy variable defining the baseline and the endline.

G \* T is the interaction between the dummy variables G and T; its estimated coefficient is the value  $\beta_1$ , statistical of difference in difference, which is that which assesses the impact of LA21 spending on sustainability.

The final budget of the two years of comparison, population, and political character of the municipalities of the sample have also been included as independent variables, along with the dummy variables referred to above, in the estimates.

To make the estimates, two data panels were built. One was by provinces and the other by Autonomous Communities. In this paper only the results of the panel CCAA were included. The calculation procedure used was fixed effects. Thus, in addition to estimating and evaluating the impact of LA21, comparisons between provinces and between regions could also be made.

### 3. RESULTS

#### 3.1. Descriptive results

For the descriptive analysis of trends in the variables studied, we offer a somewhat longer time perspective covering the period 2002-2014.

**Population:** the Spanish population experienced a large increase in the first decade of the 21st Century, going from 39.7 million in 2002 to 47.1 million in 2012. From 2012 to 2014 the resident population was reduced as a result of the economic situation, which has led to the return of immigrant populations to their countries of origin and the departure of Spaniards to other countries.

Fig. 2: Spanish population trend

**Municipal budgets:** The evolution of local budgets also shows a similar profile to the population in its evolution. After a strong growth in the period 2002-2010 with a maximum value of 81 billion euros, the subsequent recession did not slow down until 2014. The reduction of local budgets from 2010 is a key contextual element for understanding the reductions of environmental spending during the economic recession in Spain.

Fig. 3: Local governments' budget trend

**Environmental expenditure:** In the analysis of this variable, we must not forget the break in the series in 2010, as a result of a new accounting regulation that amended spending programs intended to concentrate the environmental expenditure. The two existing items in the 2002 budget were very general headings, in which concepts

such as sanitation, water supply and distribution, or waste collection and street cleaning were included, which have subsequently come to be integrated into normal community services, and since 2010 have been considered expenditure on environmental conservation.

Fig. 4: Environmental expenditure trend

The observable decline between 2002 and 2010 is due to the change in the budgetary rules, but the subsequent decline and final stabilisation in 2014 are associated with the reduction experienced by the total municipal budget.

**Relationship between environmental expenditure and the total budget:** Regardless of the methodological change in 2010, from this year the percentage of environmental spending remains relatively stable at around 2.5% of the total municipal budget.

Fig. 5: Environmental expenses over total budget

The environmental expenditure is concentrated in the 1273 municipalities included in the selected sample. This percentage in the municipalities of the sample that adhered to the LA21 is significantly higher, reaching 3.79% in 2012.

**Political tendency of municipal governments:** Given the large number of political parties that participated in the last four municipal elections, 1391 parties, a great difficulty in knowing the political affiliation of each of them arose. To simplify the analysis, we chose the ten political parties that have obtained the most votes in a greater number of municipalities. These ten parties, because of coalitions between political parties produced during the period 2003-2011, have been reduced to 7 (CiU, EAJ-PNV/EA, ESQUERRA-AM, IU, PAR, PP, PSOE).

Comparing the percentage of the total environmental budget expenditure in the experimental and control group, there are higher percentages for the LA21 group and the right-wing political trend in both time periods 2002 and 2012.

|                 | a                    | b                  | c                     | d                     | a/c           | b/d          |                |

| <b>LA21</b>     | <b>1.486.438.753</b> | <b>705.181.204</b> | <b>13.252.182.228</b> | <b>18.624.814.870</b> | <b>11,22%</b> | <b>3,79%</b> | <b>-66,24%</b> |
| -               | 402.608.627          | 155.521.066        | 4.226.207.366         | 5.754.219.046         | 9,53%         | 2,70%        |                |
| Right           | 940.859.295          | 478.380.005        | 7.327.268.475         | 10.548.047.693        | 12,84%        | 4,54%        | -64,68%        |
| Left            | 142.970.832          | 71.280.132         | 1.698.706.387         | 2.322.548.131         | 8,42%         | 3,07%        | -63,54%        |

Table 2: Environmental expenditure trend according to political character of local governments

However, the variation (decrease) between 2002 and 2012 is less for the municipalities included in the group of LA21, and within this group, for municipalities with left-wing local governments.

## 3.2. Results of statistical models

The results of the estimates were verified by statistical software packages mentioned in the methodology section. All estimates have undergone the appropriate tests to verify that the required assumptions thereof (normality of residuals, heteroskedasticity, multicollinearity, no correlation of disturbances) are met, as well as the various criteria that inform on the predictive capacity of the models.

Description of the variables used:

- Dependent variable: SUBF 441\_442\_02-12 (environmental expenditure budgets 2002-2012).
- (G) Dummy Group experimentation / Control: A21\_RU2002
- (T) Dummy compared years: T
- (GT) Dummy interaction: GT
- POBLACIÓN\_0212, TOTLIQUID\_0212, and SIGNO\_9911, correspond respectively to population, final budgets, and political character for the municipalities included in the sample.

| Estimates of Fixed Effects <sup>a</sup> |                 |               |          |         |      |                         |                 |

a. Dependent Variable: Environmental Expenses Sub-function 441-442( 2002-12).

b. This parameter is set to zero because it is redundant.

Table 3: Fixed Effects Model 2002-12 CCAA

It is noted that this is a very good estimate, with very low p-value in almost all the variables, which indicate very favourable statistical significance individually and jointly.

The coefficient of the interaction between the dummy variables of the model (GxT) is very significant and negative. The negative sign is due to the descending trend of local government's budgets and to the values of the temporal dummy (base year 0 and 1 year comparison). At any rate, the negative sign is indicating that belonging to the LA21 has been important to increase, or decrease less, the environmental spending during the period 2002-2012.

The coefficient of the variable referred to the budget liquidation also has a negative sign. This indicates that these budgets have declined, but its influence is significant in spending on sustainability.

The population was also significant, although positive, which would indicate that the population has a positive influence on the sustainability expenditure trend (in this case negative), but its influence is not the most important factor.

Finally, the political character of the left-wing municipalities (value 0) was a significant variable, like those of the other two trends (right and center), but with the highest coefficient value (negative). This fact indicates that it is the variable that exerts a great-

er influence on the overall increase (or lesser decline) in budgetary allocations for sustainability.

Among the regions with significant and positive coefficient results, Navarra, Basque Country, Cataluña and Baleares stand out. The municipalities of these autonomous communities that adhered to the LA21 are those that have the greatest influence on the results of the general model.

The above results are also confirmed for comparisons between the budgets for 2002-2013, and 2002-2014.

## **4. CONCLUSIONS**

The hypothesis that belonging to the LA21 has had an important statistically significant effect on local spending on environmental measures is confirmed. The population, the total budgetary expenditure and the leftist politics of the municipalities have exerted a significant influence on the evolution of environmental expenditure. In those municipalities governed by left-wing parties, actions dedicated to sustainability have been maintained or they have not declined as much as in the municipalities governed by right-wing parties.

Despite the verification of our hypotheses tested statistically, some methodological limitations of this study should be noted, although in our opinion, in no case did these limitations question the validity of the results:

- The change in accounting methodology of local authorities that causes a break in the time series of environmental spending. However, we consider that, since this circumstance affects all municipalities, it does not invalidate or limit the power of DiD analysis when assessing the impact of adhesion to the LA21 on the environmental municipal spending.
- The model of sustainable development promoted by the LA21 includes three objectives: economic, social, and environmental. In this paper we have addressed only the analysis of the environmental dimension.
- No official statistics are available regarding the political parties to which mayors who governed the Spanish municipalities in the years 2002-2012 belonged. To calculate the political tendency of municipal governments, we have used the statistics resulting from the elections of 1999-2003-2007 and 2011. The party that won the highest number of votes has been regarded as the political character of each electoral period.

As for the policy implications, it should be noted that maintaining budgetary allocations for environmental expenditure in a period of economic crisis and budgetary constraints imply a high commitment to the objectives of Agenda 21 in terms of promoting a model of sustainable development. Our work shows that in the municipalities adhering to the LA21 this effort has been even greater. However, we must not forget that the environmental commitment has also meant an additional way for re-

covery of the role and legitimacy of local governments for stakeholders. In this sense, it is expected that the economic recovery begun in 2014 by the Spanish economy will accentuate the effect of the innovation process in managing local governments and that this will be reflected in a higher intensity of the items of environmental expenditure in the coming years.

In this paper we have presented the results of the comparison in the period 2002-2012. The first line of progress in this investigation will be marked by the extension of the temporal scope thereof, incorporating two additional comparisons from 2002 to 2013 and from 2002 to 2014. Although we have some information, we have preferred not to include these periods in this study for two reasons— first, because there is no information of Navarre and Basque Country in the data used for the years 2013 and 2014; second, because the information of 2014 is exclusively in reference to the initial budget, not to the final budget.

Nevertheless, preliminary results indicate that, despite the limitations discussed, the results of the estimation reaffirm what we said before, even giving more weight to the sample selected and to the methodology applied. However, this extended time period will be conducted when definitive budget data for the years 2013 and 2014 are available.

The second line of advance in this work focuses on the distinction between urban and rural municipalities. In this case, an overall estimate has been made with all municipalities of the sample. However, in order to refine the policy implications of the results, it would be interesting to know whether the results are homogeneous for both groups of municipalities, urban and rural. This segmentation of the sample would also allow the comparison between our results and those obtained in other studies.

Finally, we end up by emphasising the verification of the assumptions made and the appropriateness of the DiD method to confirm them. Thus, we see that the political commitment expressed by the Spanish municipalities by signing the Aalborg Charter and adhesion to the LA21 is supported with greater intensity in fiscal effort and increased resources for environmental programs.

# **Creating and Capturing Value for Different Types of Services**

## **- A Contingency Approach**

### **Abstract**

Services can be differentiated by their basic value propositions. In this paper, we discern five archetypes of services—logistics services, facility services, entertainment, network-access services, and analytics services—that differ fundamentally across technologies and institutions in terms of their value propositions. These service archetypes also differ substantially in terms of how customer value is created and captured. Value-creation essentials, including critical capacities and competencies, are indicated for each service archetype. Value-capture essentials, including isolating mechanisms, are also highlighted. In addition, we develop a diagnostic framework through which service providers may check whether their value propositions and resource configurations are aligned. If misalignments are uncovered, the framework provides suggestions for how service providers can achieve strategic fit.

**Key words:** Service archetypes, value-creation essentials, value-capture essentials

## Introduction

To an increasing degree are services dominating developed economies and successful strategies for service providers are therefore in still higher demand. However, services are manifold and require different strategies and there exists no one-size-fits-all strategy for service providers (see, for example, OECD, 2005). Hence, a key contention in this paper is that services differ fundamentally across technologies and institutions in terms of how customer value is created and captured by the service provider. This assertion links up to a very general and contentious question in strategy research, namely: Is it possible for strategy scholars to provide managers – including those operating in the service sector - with practical prescriptions as to how their firms should create and capture value, and thereby achieve a sustainable competitive advantage (SCA)? Not surprisingly, the strategy literature gives contradicting answers to this question. One short and vigilant answer is *no*, which reflects the view that success formula are multifarious and based on highly idiosyncratic resources (Rumelt, 1984; Peteraf, 1993) and, to some extent, random, as they can be contingent on luck rather than managerial discretion (Denrell, 2004; Ma, 2002; Svensson and Wood, 2005; Salganik, Dodds, and Watts, 2006).<sup>2</sup> Therefore, proponents of this view suggest that instead of engaging in the futile task of attempting to uncover specific success recipes, strategy scholars should concentrate on developing general and generic schemes for achieving competitive advantage, such as the value-chain template (Porter, 1985), the VRIO framework (Barney, 1997), and the business model canvas checklist (Osterwalder and Pigneur,

---

<sup>2</sup> Refer also to the recent *Steve Jobs was not a genius but just lucky* arguments promoted in the business press, e.g., Goldberg (2012) and Moltz (2012).

2010). Those strategy scholars who have nevertheless ventured into a search for company-specific recipes of success through empirical observations of high-performing companies (e.g., Bullen and Rockart, 1981; Peters and Waterman, 1982; Porter, 1990; Kim and Mauborgne, 2005) have been criticized for their retrospective, uncontrolled, and unfalsifiable methodologies, as well as the lack of *sustainable* success or simple survival of the observed companies, which becomes evident with hindsight.

In an attempt to reconcile these two contradictory views, the strategy and marketing versions of the contingency approach (Govindarajan, 1988; Katsikeas et al., 2006; Zeithaml et al., 1988) aim to prescribe optimal strategies given a certain set of difficult-to-control factors, known as “contingencies,” within or outside the firm. The contingency approach assumes that it is possible to provide managers with guidance as to the best strategic responses to observed contingencies. However, even though the contingency approach can prescribe an optimal course of managerial action with regard to SCA, the prescription may only apply for a few firms facing similar contingencies. In other words, such a management prescription may not be generalizable. In the extreme, the strategy prescription may only apply to a single firm, in which case the contingency approach takes on the characteristics of business consultancy. Furthermore, the extent to which the contingency approach can deliver generally applicable management prescriptions depends on the nature of the contingencies. If the contingencies are many and equivocal, such that every situation is unique, the scope for generalization is limited. Conversely, if the contingencies are few and distinctive, the space for generalization is larger. Therefore, if we can identify contingencies that are few, distinctive, and of relevance to the service providers that are the focal point of this paper, we can move one big step closer to our aim of defining value-creation and value-capture essentials for service providers.

The paper proceeds in the next section with a discussion of and a search for a set of contingencies that can serve as the right basis for value-creation and value-capture prescriptions. We argue that service archetypes based on value propositions are suitable for this purpose. In the third section, we derive and explain five service archetypes that are differentiated in terms of their value propositions. In the fourth and fifth sections, we outline the essential mechanisms for value creation and value capture, respectively, and we show how these mechanisms differ among the archetypes. We then suggest a diagnostic framework for the SCA prospects of service providers. In the final section, we offer a concluding discussion.

### **Identifying Contingencies Relevant to Strategies of Service Providers**

According to the contingency approach,<sup>3</sup> no one strategy can be considered optimal for all businesses, regardless of their infrastructure and environmental contexts. The contingency approach suggests that the relation between strategy and performance tends to be conditional, and that no universal set of strategic choices is suitable for all situations and circumstances. As

---

<sup>3</sup> We prefer to use “contingency *approach*” rather than “contingency *theory*.” A theory is a set of assumptions, propositions, or accepted facts that attempts to provide an explanation of cause-and-effect (causal) relationships among a group of observed phenomena (BusinessDictionary.com). One requirement of theory is an ability to test the validity of the assumptions by showing that contradictory assumptions do not disprove the theory (Popper, 1963). If contradictory results are obtained in a contingency framework, the contingency response would either be that the situation is unique or that important dimensions affecting the situation were not tested. Thus, showing that contradictory assumptions disprove the theory is difficult at best. Nevertheless, we view the contingency approach as a useful tool for empirical research.

such, contingency research begins by specifying contingency variables, such as technologies (Thompson, 1967; Woodward, 1958), product characteristics (Stabell and Fjeldstad, 1998), industries (Johnson and Friesen, 1995), customer characteristics (Hunt, 1972), or competitors (Porter, 1980; McGee and Thomas, 1986), in order to categorize internal and external settings so that corporate strategies and organizational structures can be developed based on an analysis of the contingent variables. Strategy only translates into superior performance when contingent variables and strategy are properly matched (Katsikeas *et al.*, 2006). Empirical inquiries adopting a contingency approach usually include three types of variables: contingency variables, managerial-response variables, and performance variables (Zeithaml *et al.*, 1988). The performance variables depend on the first two types of variables—independently and in interaction (i.e., a “fit” measure). As they originate from organizational theory (Woodward, 1958), managerial-response variables have typically revolved around organizational design (Lawrence and Lorsch, 1967; Thompson, 1967) and structure (Mintzberg, 1979; Perrow, 1967). However, as the contingency approach diffused into the realms of marketing (Zeithaml *et al.*, 1988) and strategy (Govindarajan, 1988) other, non-organizational response variables have emerged, such as marketing-mix standardization versus adaptation (Katsikeas *et al.*, 2006) and differentiation versus a low-cost focus (Porter, 1980).

Our identification of a relevant set of contingencies is guided by the resource-based view (RBV, Barney, 1991; Rumelt, 1984). The RBV aims to identify the antecedents of SCA, and to spell out value-creation and value-capture mechanisms. The RBV (including the VRIO framework) is formulated as a generic template. As such, it does not adopt a contingency approach. However, the RBV is useful for our purpose as it lists a number of supply-side factors—resources and capabilities with certain characteristics—that arguably lead to SCA. As we are adopting a

contingency approach, we wish to differentiate these supply-side factors along a set of contingencies. One may view these supply-side factors as managerial responses<sup>4</sup> to contingencies. As we have supply-side factors on the managerial-response side of this “equation,” it seems logical to have demand-side factors as contingencies on the other side in order to avoid “double counting” and tautological reasoning. This logic limits our search for relevant contingencies, including characteristics of service products, customers, and demand needs, to the demand side. For all three dimensions, we examine characteristics across industries.

*Product characteristics:* The service-management literature suggests several ways to differentiate the product characteristics of services.<sup>5</sup> In a general study of service attributes, Contractor et al. (2003) distinguish between knowledge-intensive and capital-intensive service products. Driver and Johnston (2001) distinguish service products on the basis of whether they require interpersonal or non-interpersonal interactions. Berthon *et al.* (1999) differentiate service outputs in terms of the extent of their space manifestations, Ball *et al.*, (2008) distinguish between more and less information-intensive services. One widely used product distinction in the international-business literature focuses on “hard” and “soft” services (Brouthers and Brouthers, 2003; Ekeledo and Sivakumar, 1998; Erramilli, 1990). While the hard/soft distinction is highly

---

<sup>4</sup> According to the RBV, the warranted managerial response consists of spotting and acquiring valuable (in an *ex post* sense; see Schmidt and Keil, 2013) resources in the strategic factor market (Barney, 1986), and transforming those resources into firm-specific capabilities that are valuable and inimitable (Barney, 1991).

<sup>5</sup> For an overview of various distinctions of services and service firms, see Carneiro, da Rocha, and da Silva (2008).

relevant when studying the foreign-operation modes of service firms,<sup>6</sup> it may be less pertinent for predicting general strategies of service firms.

In one way or another, these product distinctions are indisputably relevant for service providers. However, it is remarkable that they all take a simplistic, dichotomous form. In our introduction, we highlighted a need for few, distinctive contingencies, but two contingencies seems to be below the requisite threshold. Even more compromising for the relevance of this category of contingencies is the fact that none of the mentioned product characteristics are particularly distinct, which suggests that the dichotomies are somewhat arbitrarily defined. For example, the distinction between “hard” and “soft” services is far from clear. Furthermore, product characteristics do not seem to be defined solely by demand-side factors—they tend to imply supply-side factors as well (e.g., factor inputs in the distinction between knowledge- and capital-intensive services). This is not the case with the other two sets of contingencies: customer characteristics and characteristics of service needs.

*Customer characteristics:* The marketing literature covers a wealth of ways in which customers can be characterized and categorized. For example, customers can be categorized based on lifestyle characteristics (e.g., Plummer, 1974; Kucukemiroglu, 1999). Although this categorization is popular and clearly of practical relevance, it is not well-defined as a general concept. As the various lifestyles are rather indistinct, they do not constitute an operational set of

---

<sup>6</sup> As an example, export is excluded as a mode of internationalization for firms offering “soft” services. These firms are confined to using the contractual and investment modes of operation (Erramilli, 1991; Erramilli and D’Souza, 1995; Erramilli and Rao, 1993).

contingencies. Another, conceptually well-established way to differentiate customers is in terms of their purchasing power. For example, bottom-of-the-pyramid (BoP; also known as “base-of-the-pyramid”) thinking, which reconciles aspirations to alleviate poverty and interests in exploiting a burgeoning market, has been highly influential in terms of guiding western firms in their approaches to customers in developing countries (Prahalad, 2004; London and Hart, 2004). In the BoP context, customers are characterized by an extremely low purchasing power of a few dollars per day. The low purchasing power of a large group of people constitutes a contingency factor to which firms respond by assigning their customers to various segments, and by adapting their products and marketing to the needs of each segment. Similarly, the above-mentioned dichotomies of standardization versus adaptation (Katsikeas et al., 2006) and differentiation versus a cost-leadership focus (Porter, 1980; Murray, 1988) may be viewed as responses to customer characteristics (together with other contingencies, such as product characteristics and technology). For virtually all product categories, some customers (not necessarily the poorest) are focused on low prices, content, and standardized products, while others are willing to pay premium prices for customized and/or highly differentiated products. There is little doubt that customers’ price orientations or their focus on product attributes other than price are also relevant contingencies for service providers, even though the bottom-of-the-pyramid view focuses on the basic needs of poor customers, which may pertain more to physical products—food, clothing, and shelter—than to services. Porter’s (1980) generic strategies of cost leadership and differentiation<sup>7</sup> are also relevant for service providers as responses to customer

---

<sup>7</sup> The generic competitive strategies double from two to four when another dimension—the scope of the targeted customer segments—is included. Firms can either target a few, narrow segments or many, industry-wide segments (Porter, 1980).

contingencies. Still, the dichotomous nature of the contingencies limits the extent to which the SCA analysis can be nuanced, which encourages us to continue our search.

*Characteristics of service needs:* Our search continues through Thompson's (1967) contingency approach to organizational design. Thompson viewed the design of organizations as contingent on three basic technologies—*long-linked*, *intensive*, and *mediating*—and their associated interdependencies. The first technology accommodates manufacturing firms, while the second serves advisory organizations, such as medical clinics and lawyer firms, and the third relates to organizations (e.g., banks, brokers, and insurance companies) that create value by connecting people with shared interests (e.g., lenders and borrowers).

Based on these basic technologies, Stabell and Fjeldstad (1998) formulate three “value-creation logics”—one of which was Porter's (1985) “value chain.” The other two—the “value shop” and the “value network”—applied to service providers rather than manufacturing firms. The thrust of Stabell and Fjeldstad's (1998) study was that basic technologies and the associated value-creation logics had implications not only for organizational design but also for SCA strategies in general. However, the two strategy scholars did not question the nature of Thompson's (1967) technologies. Thompson's basic technologies were primarily defined by their interdependencies (i.e., *pooled*, *sequential*, and *reciprocal*), which clearly had implications for the optimal design of organizations. Hence, the focal “fit” was between technological interdependencies (the contingency variables) and the organizational structure (the managerial response variables). Whereas the three types of interdependencies appear reasonably distinct and well defined, the same cannot be said about Thompson's basic technologies. Thompson did not define his basic technologies by their substance, objects, or artifacts. In fact, the technologies are better described by the customer needs to which they cater. Hence, Stabell and Fjeldstad's (1998) value shop and

value network are good representations of services provided by professional-service firms and network-access firms, respectively, but the two value-creation logics fail to encompass *all* types of service needs. For example, basic service needs, such as transportation, entertainment, and repair and maintenance, are not accommodated. Nevertheless, we suggest that it is possible to define a complete set of distinct service needs, and that these needs may serve as relevant contingencies for the formulation of SCA strategies. In the next section, we suggest such a typology of basic service needs.

### **Basic Service Needs as Contingencies**

Our guiding, deductive principle for deriving basic service needs is that they should be *universal*, i.e. the service needs should apply regardless of technological and institutional changes over time. Consider, for example, the universal character of the advisory and analytical services of a medical clinic. Medical doctors have offered their analytic (clinical) services throughout history based on the same value proposition: the identification (diagnosis) and resolution (treatment) of clients' (patients') problems (diseases). The value proposition remains the same although the services medical doctors provide have improved tremendously thanks to scientific and technological progress, and public regulation. The same liberation from technology and institutions should apply for the other service archetypes as well.

The guiding principle of universality leads us to identify five service archetypes that differ distinctively in terms of the customer needs they cover. These five service archetypes are: (1)

logistics services, (2) facility services, (3) entertainment, (4) network-access, and (5) analytics services. The five types are summarized in Table 1.<sup>8</sup>

--- Insert Table 1 about here ---

The five services types resonate well with the standard classifications of the service sector, although our focus is on the private (and not public) service sector. In the following brief outline of the five basic services we list a number of prominent providers – which, notwithstanding their prominence, may be diversified into other basic service needs.

*Logistics services* focus on the safe and timely transportation, storage and containment of cargo, data, money, or people.<sup>9</sup> If we look beyond the technological landscape, the common value proposition made to the customer is moving “something” from A to B (as defined by the customer). Prominent providers of logistics services include such firms as FedEx, Lufthansa, DB, Maersk Line, Shurgard Self Storage, Aldi GmbH, EMC<sup>2</sup>, Vodafone, and PayPal.

---

<sup>8</sup> The value proposition of goods production is included in Table 1 as a reference point. As with services, goods production could presumably be divided into distinctively different types based on value propositions. However, as our focus is on service firms, we have lumped goods production into one, very general value proposition.

<sup>9</sup> With “containment of people,” we are referring to imprisonment or penitentiary “services.”

*Facility services* center on fulfilling customers' physical needs for food, accommodation, exercise, hygiene, and safety, as well as their repair and maintenance needs related to their property and belongings. Prominent facility-service firms include Johnson & Johnson, the ISS Group, Hertz, the InterContinental Hotel Group, G4S, Securitas AB, McDonald's, and 7-Eleven Inc.

The next basic service type, *entertainment*, revolves around experiences that are stimulating and/or relaxing for the customers. Well-known providers of entertainment services include Cirque du Soleil, the Walt Disney Company, News Corp., Thomson-Reuters, Warner Music Inc., Manchester United, Betsson AB, and Rovio Entertainment Ltd.

*Network-access* services focus on offering customers access to a network of people or companies with common social and/or economic interests. As such, this is the basic value proposition of the financial sector (e.g., banks, pension funds, mortgage institutions, insurance companies, leasing and factoring companies), as well as of recruitment and dating bureaus, travel agencies, and various brokerage firms (e.g., commodity and ship brokers). Major providers of network services include HSBC, Banco Santander, NASDAQ OMX Group Inc., Allianz, Carlson Wagonlit Travels, Hamptons International, Sotheby's, eBay, Alibaba, Facebook, Twitter, and LinkedIn.

The fifth and final basic type is *analytics services*. This value proposition is about identifying, specifying, and solving client problems. Analytics services are basically the equivalent of "professional services" offered by, for example, law firms, accounting firms, consultants, and architects. Examples of prominent firms that offer analytics services are McKinsey, Tata

Consultancy Services, the WPP Group, DDB, Goldman-Sachs Private Equity Group, and DNV (Veritas).

The five basic service needs make up a *typology* (different from a *taxonomy*), as we have derived the service types on a deductive and conceptual basis (Bailey, 1994) rather than an empirical basis (e.g., through a cluster analysis of observable and measurable characteristics). There is no intrinsic ordering to the five service archetypes, such that the categories are to be considered as nominal, rather than ordinal or interval, scales. The latter two types of scales would have a clear ordering determined, by example, by the extent to which the categories assumed certain attributes (such as a continuum from hard to soft services).

It is worth noting that different service types can be found in one and the same service industry. Take the retail industry as an example. In this industry, logistics services, facility services, and entertainment services are offered by, respectively, factory outlets, convenience stores, and luxury goods boutiques. Conversely, a service archetype, such as logistics, is not confined to one service industry or sector (e.g., “transportation”). Rather, it can be found in a range of industries, including the telecommunications industry (in the form of data transmission), the banking industry (money transfer), and the IT industry (cloud services).

In the next two sections we discuss the essential sources of SCA for each of the five basic service types. The discussion falls in two parts inasmuch as SCA usually is seen as a duality of value creation and value capturing, see, for example, C. Bowman and V. Ambrosini (2000). We start with the definition, discussion, and exemplification of value-creating essentials.

## **Value-creation Essentials**

We define value-creating essentials as those mechanisms that are imperative for a firm's enhancement of customer satisfaction and through which the value-creating firm earns an economic rent when competition is limited.

The primary value-creation essentials of *logistics services* are scale and scope advantages. Logistics is a matter of capacity utilization. For example, a fleet of trucks should be used efficiently and not left idle, scheduled to load and unload for customers dispersed over a wide area, or driving around half empty. The same applies for a fleet of vessels, although an important difference between land and sea freight is that opportunities for enlarging vessel size are only restricted by port and channel dimensions. Consider, for example, the introduction of the new "Triple E" class container ships, which carry more than 18,000 TEU (twenty-foot equivalent unit) containers. The name Triple E is derived from the class's three design principles: economy of scale, energy efficient, and environmentally improved. The depth (48 feet) and width (194 feet) of these new, giant vessels imply that only deep-water ports with tall cranes with a wide reach are able to service them. On the other hand, the Triple E ships offer unprecedented economies of scale in terms of materials, manning and, not least, fuel consumption.

The value-creation essentials of *facility services* are about human resource management (HRM)—the recruitment, training, motivation, and retention of personnel. Motivated employees are easier to retain, and low staff turnover means cost savings on recruitment and training, which is a critical competitive factor for labor-intensive services for which attrition rates are often high. Hence, for some facility-service companies that rely on low-skilled labor (such as cleaning companies) attrition rates are well above 100%. Through a long and dedicated HRM effort the multinational facility-services provider, ISS, has managed to increase the average employment period of its low-skilled staff (of several hundred thousands) from six to nine months (Pedersen

and Petersen, 2012, and personal communication) through a long and dedicated HRM effort. Such an achievement has a substantial positive effect on the bottom line. The multinational fast-food restaurant chain, McDonald's, serves as another good example of the essentiality of HRM in the value-creation process. The sustained success of the company is usually ascribed its strong brand, but it is worth noting that McDonald's is often second to none in best-place-to-work rankings in many of the countries in which it operates. McDonald's ability to induce team spirit and associate professional pride with what might look like rather mundane or trivial jobs is remarkable.

The value-creation essentials of *entertainment* are also related to HRM, but they are applied to a much different clientele. In this regard, we highlight three essentials. The first is HRM's ability to spot and develop artistic and/or physical talents among individuals. An entertainment provider must employ individuals with unique artistic, sporting, or creative talents. However, a classic problem among these service providers is that the employed "stars" are usually perfectly aware of their market value and will appropriate that value to its full extent. It is therefore preferable to spot and develop talents among potential stars rather than compete with other entertainment firms to hire well-known stars. Hence, abilities related to talent spotting and talent development serve as an important source of competitive advantage. For example, some professional soccer clubs, such as Ajax Amsterdam and FC Barcelona, are recognized for their youth-development programs. Another example from the sports sphere is Oakland Athletics' successful use in the early 00s of analytical and evidence-based methods, "sabermetrics", to spot undervalued players (Lewis, 2003). Despite having the third-lowest team payroll in the Major League Baseball (MLB) in 2002 general manager Billy Beane's rigorous statistical approach challenging conventional baseball wisdom brought Oakland A's to the playoffs this and the following year.

The second essential is HRM's ability to create a work environment in which the employees' creative abilities come into play. One famous example in this regard is Pixar Animation Studios in San Francisco, which has used computer-animated imagery technology to produce a string of artistically and commercially successful movies, including the *Toy Story* and *Cars* films. Throughout the 1990s and 2000s, Pixar gradually developed the "Pixar Braintrust"—the studio's primary creative-development process in which all directors, writers, and lead storyboard artists at the studio look over each other's projects on a regular basis and provide candid "notes" (the industry term for constructive criticism) on those projects. The Pixar Braintrust operates under a philosophy of a "filmmaker-driven studio" in which creative individuals help each other move their films through a process somewhat like peer review, as opposed to the traditional Hollywood approach of an "executive-driven studio" in which directors are micromanaged through "mandatory notes" from development executives who rank higher than producers (<http://en.wikipedia.org/wiki/Pixar>, accessed October 30, 2014).

The third essential relates to the visionary capabilities of the managers (rather than HRM capabilities), especially the service provider's ability to anticipate or even create new trends and fads. John Lasseter, co-founder of Pixar and an executive producer, possesses such a capability, as did the Beatles' music producer, George Martin, in contrast to Decca's Mike Smith who turned down the Beatles, stating that "guitar groups are on the way out" and "the Beatles have no future in show business" (The Beatles, 2000). Another example, found in the gourmet restaurant business, is René Redzepi, the chef and co-founder of NOMA, which is currently considered to be the best restaurant in the world. NOMA (the name is an abbreviation of "Nordic food" in Scandinavian languages) foresaw and co-created a new trend of using local (Nordic) ingredients in untraditional combinations.

With regards to *network-access services*, we suggest the presence of two value-creation essentials. The first essential is buyer/supplier screening and segmentation capabilities. A provider of network-access services needs screening capabilities to avoid adverse selections that might compromise the value of the network access (Akerlof, 1970; Cawley and Philipson, 1999). For example, the online market places eBay and Alibaba both enforce strict regulations regarding sellers and buyers who do not live up to the auction sites' rules and ethical codes. Without systematic exclusion of such participants, the honest users would soon find other, more trustworthy intermediaries. In online sales, the elimination of uncertainty is an imperative competitive factor. The second essential is the capacity to ensure network externalities (Katz and Shapiro, 1985; Shapiro and Varian, 1999). Network externalities are usually described as economies of scale generated on the demand side—the value of the service (the network access) for each customer increases as the number of other customers using the service (the network) rises. *Ceteris paribus*, a large, worldwide network is more valuable to the individual customer than a small, local network. eBay and Alibaba both hold near monopolies in their parts of the world simply because they have obtained more network externalities than other online auction sites. The social and professional networks of YouTube, Twitter, Facebook, and LinkedIn are also strong, uncontested market leaders in the western world within their individual domains—again as a result of network externalities.

The value-creation essentials of *analytics services* revolve around the possession and combination of domain and client knowledge. Competencies, rather than capacity, constitute the essential resources. The service provider must possess domain-relevant expert knowledge, analytical skills, and a thorough knowledge of clients' preferences and routines. Although they do businesses in different worlds, the providers of analytics services and entertainment have a

common need to identify and recruit the “best-in-class” candidates. For example, Indian Evalueserve, a provider of business and technology research, data analytics, and investment-research services to companies worldwide, recruits from among the best candidates from the best management and engineering schools in India and elsewhere. This means that, in the Indian context, it focuses on very small fraction of the total pool of potential candidates (<http://www.evalueserve.com/>, accessed October 31, 2014). In the global market, McKinsey & Company is typically regarded as the most prestigious (and most expensive) management-consulting firm, but contenders may still maintain a competitive advantage by possessing specialized, “niche” knowledge and by focusing on their deeper knowledge of local businesses.

The above outline suggests that the five basic service needs are quite distinct in terms of the service archetypes with which they are associated. In other words, there is very little, if any, overlap in the value-creation essentials of the various service archetypes. In the next section, we examine whether this is also the case with value-capture essentials.

### **Value-Capture Essentials**

The value-creation essentials constitute necessary *but not sufficient* conditions for a firm—in this case, a service provider—to achieve a sustainable competitive advantage. A *sustained* competitive advantage requires mechanisms that isolate (Rumelt, 1984) the firm’s value creation

against expropriation by competitors.<sup>10</sup> Hence, we define *value-capture essentials* as those mechanisms that help to limit the competition faced by the value-creating firm.

The value-capture essentials of *logistics services* take two forms. The first relates to the scale and scope advantages indicated as value-creation essentials. For example, a logistics service provider may prevent competitors from expanding in the market through investments in pre-emptive capacities (e.g., Ghemawat, 1984). The excess capacity deters rivalries from making similar capacity investments to the extent that such investments are deemed unprofitable. Maersk Line's investment in a new fleet of Triple E class container ships may be an example of such preemption. To the extent that Maersk Line was the first shipping company to invest in these highly cost-efficient container ships, it was likely to achieve first-mover advantages (Lieberman and Montgomery, 1988). The second value-capture essential is the obtaining of concessions. In particular, when a logistics service takes on the characteristics of a "natural monopoly," governments become prone to making that service concessional. Postal services, telecommunications, ferries, and air and rail transportation have traditionally been provided on a concessional basis, although the general trend towards market liberalization and deregulation is challenging these concessions.

The value-capture essentials of *facility services* are reputation and branding. As entry barriers are usually low in the facility-services industry, consumers face a high risk of being cheated by

---

<sup>10</sup> We are aware that the existence of "isolating mechanisms" against competition constitutes a necessary but *insufficient* condition for SCA. The created value may be expropriated by parties other than competitors, including customers, suppliers, governments, competitors, or the firm's own employees. Given our space limitations, we do not discuss isolating mechanisms in relation to these stakeholders in this paper.

incompetent entrants. However, reputation and branding can mitigate such risks. Branding eliminates consumers' perceived uncertainties in two ways. First, consumers associate the brand with their previous purchases of products from the same brand and make inferences of similar (high) quality standards. Second, consumers assume that a facility-service provider owning a valuable brand is unlikely to put that asset at risk. Therefore, they do not consider the potential for freeriding or they expect full compensation from the provider if the service fails to meet expectations. The previous example of McDonald's applies as an illustration of these mechanisms.

The example of Pixar Animation Studios is well-suited for illustrating the value-capture essentials of *entertainment* providers. Pixar (part of the Disney Company since 2006) protects its movies against imitation through copyrights. This is fairly straightforward. However, it is considerably more difficult to protect the company's most important strategic assets—the many creative people it employs. How does Pixar keep competitors from headhunting its employees? As the use of competition clauses is restricted by labor-market regulations, Pixar must rely on its organizational principles and team spirit (“the legacy of John Lasseter”) to retain its creative individuals. Moreover, to the extent that the talent of the individuals is embodied in the Pixar team, its value would be significantly lower when deployed by competitors. Hence, the other value-capture essential is the entertainment provider's ability to “contain” the talent of its employees in teams. Whereas Pixar Animation Studios seems to be an exemplar of a company (though now a Disney Company affiliate) that is in possession of both value-creation and value-capture essentials, general manager Billy Beane and his Oakland Athletics may do as an example of an entertainment provider that developed value-creation essentials through adoption of

sabermetrics but failed to capture this value in as much as other MLB managers were able to copy Beane's use of sabermetrics as an analytical tool for spotting undervalued baseball skills.

With regard to the value-capture essentials of providers of *network access*, we point to authorization and consumer switching costs. For example, the establishment of certain networks, such as insurance and banking networks, requires government authorization. Social-network firms, like Facebook and Twitter, do not need such authorization, but network externalities have given them near-monopoly positions in the western world. For these social-network firms, network externalities serve a dual function as essentials for value creation and essentials for value capture. The isolating properties that seem to characterize network externalities are amplified by considerable consumer switching costs.

Switching costs are also value-capture essentials for providers of *analytics services*, as bonding with clients is the isolating mechanism *sine qua non*. The bonding *can* be social, but equally or more important is bonding by developing a common body of knowledge and shared communication routines. Certification of the service (e.g., by medical doctors, lawyers, and accountants) is the other value-capture essential.

As with the value-creating essentials, these isolating mechanisms appear to be fairly specific to one of the five service needs. However, there is some overlap with regard to concessions, authorizations, and certifications. Furthermore, we have not mentioned continuous innovation (Weston, 2001) or inter-firm causal ambiguity (King, 2007) as safeguards against competitors' imitation. Nevertheless, one may argue that to varying degrees are innovation and causal ambiguity relevant as isolating mechanisms for all five service archetypes.

In this outline of value-capture essentials, we have not mentioned continuous innovation (e.g., Weston, 2001) or inter-firm causal ambiguity (e.g., King, 2007) as safeguards against competitors' imitation. Nevertheless, innovation and causal ambiguity are relevant as isolating mechanisms for all five service archetypes to varying degrees. Causal ambiguity and innovation are definitely essentials for providers of entertainment. One could also argue that causal ambiguity is an important ingredient in the HRM practices of facility-service providers and in analytics-service providers' efforts to bond with clients.

As with the value-creation essentials, these isolating mechanisms appear to be fairly specific to one of the five service archetypes. However, there is some overlap with regard to concessions, authorizations, and certifications.

Table 2 summarizes the essentials of value creation and value capture for the five service archetypes.

--- Insert Table 2 about here ---

### **A Diagnostic Framework for the SCA Prospects of Service Providers**

The above juxtaposition of five service archetypes with particular value-creation and value-capture essentials prescribes a certain strategic fit between the focal service demand (the value proposition) and the resources possessed by the service provider. A service provider should be able to use these insights to check whether it is realizing a strategic fit between the service provider's value propositions and its possessed resources. However, what if this check reveals a *lack of fit*? Should the service provider reconfigure its resources (i.e., change its capacities and

capabilities), redefine its value proposition(s), or both? If it takes both steps, the service provider will basically define a new business model.

In the previous two sections, we indicated the implications of strategic fit for service providers—the value essentials for various service archetypes. However, we cannot advise the service provider as to whether it should achieve this fit by redefining its value proposition(s), reconfiguring its resources, or both. We are limited to putting these different ways of achieving a strategic fit into a diagnostic framework for SCA prospects, which we present in Figure 1.

--- Insert Figure 1 about here ---

The two dimensions of the framework—a service provider’s value proposition(s) and its resource configuration—echo a contingency approach, as the value proposition(s) captures the contingency (contingencies) along which a service provider configures its resources. In other words, service providers can make value propositions in relation to one or more of the five universal service demands, which can be viewed as constituting stable and unchangeable “environments.”

In summary, the diagnosis should establish whether a service provider is realizing a strategic fit between its current value proposition(s) and its resource configuration—the capacities and capabilities deployed by the service provider.

Let us consider an example that illustrates how a strategic-fit diagnosis may proceed. A retail bank offers three basic value propositions to its customers. First, it provides access to a wide (although not world-wide) network of lenders and borrowers on behalf of which the bank clears liquidity surpluses and deficits. Second, the bank offers logistics services—it facilitates the transfer of money from its customers to their designated recipients. Third, the bank offers advice (analytics services) to its clients regarding the best investments and loans. It also provides clients with an overview of their finances and disposable income. However, the bank is now experiencing a new situation: networking companies, such as Google and Alibaba, are extending their service offerings into banking by offering payment and loan services to private (household) customers. Due to their larger, worldwide networks and concomitant superior network externalities, the social network companies are able to outcompete the bank on these services. In response, the bank redefines its value propositions, putting more emphasis on its advising and analytics services. In order to do so, the bank cuts down on the number of staff dealing with payment services (and retains only its Internet-based self-services) and on the number of staff handling loans to households. At the same time, the bank expands the number of financial analysts in order to upgrade the advisory services offered to corporate clients and to private investors with substantial assets. Hence, in simultaneous actions, the bank reconfigures its resources (hiring and laying off staff members) and redefines its value propositions. In effect, the bank develops a new business model (see the lower-right quadrant in Figure 1), which implies a transformation from a retail bank to an investment bank.

Take a local discount supermarket as another example. The supermarket offers its customers low-priced groceries. The owner of the supermarket has managed to hold operating costs in check by maintaining a limited product assortment and minimum inventories (occasionally

resulting in empty shelves), and by providing himself and his employed family members with only modest pay. One day, the Aldi retail chain announces it will soon open a discount outlet next door. Through its scale and scope advantages, Aldi will assume cost leadership relative to the existing, local supermarket, and the local owner realizes that his supermarket will be outcompeted in terms of cost-efficient logistics. He also realizes that in order to survive, he has to switch from offering basic logistics services—making groceries available to customers in the cheapest possible way—to offering facility services and, if possible, entertainment. As a consequence, the owner of the local supermarket takes several steps. First, he renovates the store’s interior to look inviting and intimate (in contrast to Aldi’s austere interior). Second, he introduces a range of local, mainly organic food specialties and invites the producers themselves to present them to the customers using a shop-in-shop concept. Third, he educates himself and his family employees in delivering personalized, warm, and knowledgeable customer service. In other words, the local supermarket transforms from offering basic logistics services to facilitating and entertaining the customers while they handle their daily grocery shopping. In Porter’s (1980) vocabulary, the supermarket replaces its cost-leadership strategy with a focused differentiation strategy. The transformation also echoes the “wheel of retailing” model (e.g., Hollander, 1960), which describes an evolutionary development of retailers from low-margin businesses targeting cost-focused customers to high-margin enterprises appealing to more quality- and luxury-oriented customer segments. The supermarket example serves as another illustration of a redefinition of the value proposition combined with a reconfiguration of resources.

We can easily change the two examples to illustrate situations in which the service provider only redefines its value propositions or reconfigures its resources (respectively fitting the upper right and lower left quadrants in Figure 1). For example, the retail bank may decide to completely shut

down its money-transfer services and continue its usual activities in relation to savings, loans, and advisory services. Similarly, the local supermarket owner may choose to stick to the present value proposition and reconfigure the resources (e.g., by narrowing the product range even further) with the aim of matching Aldi's logistics in terms of cost efficiency.

Our diagnostic framework does not necessarily imply changes. Companies that observe competitors with apparently perfect strategic fit (the upper left quadrant in Figure 1) and want to emulate that fit can use the framework as a reality check or as a benchmarking tool.

## **Conclusions**

In this paper, we have promoted the basic view that services are more than just the opposite of manufacturing. In reality, service providers may differ fundamentally in terms of the basic needs they are fulfilling and in terms of the resources (capacities and capabilities) they must possess in order to fulfil those needs in a profitable way. If we only differentiate services on the basis of their dissimilarity with manufacturers (i.e., by the service characteristics of intangibility, heterogeneity, perishability, and simultaneity between production and consumption), we risk missing strategically important factors. Moreover, a reliance on conventional industry classifications of services—such as banking, retailing, and facility management—carries a serious risk that strategic imperatives will be overlooked. Extant discussions of servitization (see, e.g., Kastalli, van Looy, and Neely, 2013, and Suarez, Cusumano, and Kahl, 2013), as a turnaround strategy for many manufacturing firms therefore appear to be rather simplistic, as the service component is usually viewed as merely a matter of (more) repair and maintenance. Other

service logics—especially those related to logistics, network-access, and analytics services—deserve careful consideration as key elements of a firm’s servitization strategy.

We have highlighted the essentials of value creation and value capture as important components in the formulation and development of business models. For the practice-oriented company manager, the understanding and development of a competitive business model is a *sine qua non*. The situation is different for the researcher, for whom business models are—and should be—unique for each company. If the business model is not unique, it is unlikely to be competitive. As such, it is difficult to generalize and theorize about (successful) business models, as they tend to be idiosyncratic and firm specific. Moreover, business models are difficult to grasp because they embrace all aspects of a firm’s business operations. From this perspective, some broad and universal categories of service offerings may constitute general starting points for understanding and developing business models. As such, they may appear to be useful strategic-analysis tools for researchers as well as practitioners. In addition, the business-model concept tends to be technology oriented with a special focus on digital-technology business opportunities. Much of this focus has historical origins, such as the dot.com wave. In this paper, we have tried to avoid this “technological myopia” by categorizing services on the basis of universal characteristics that apply across institutions and technologies.

While the formulation of broad, universal categories of service offerings is appealing, we are also aware that such a categorization suffers from some ontological as well as methodological weaknesses. In ontological terms, it is difficult, if not impossible, to establish that there are only five archetypes of service offerings. The reader may question whether these categories fulfil the scientific typology ideals of exhaustiveness and mutually exclusivity. If this is not the case, the ability of the service categories to explain and predict corporate strategies is weakened.

However, our service categorization seems useful given the lack of tools for strategic analysis that has thus far characterized services research. The methodological weakness of our categorization has to do with the fact that service providers often make value propositions related to more than one service category. This complicates the use of industry statistics to make inferences between firms' value propositions and their behavioral or structural patterns (e.g., international growth, governance structures), and suggests that the unit of analysis is not the individual firm but rather the firm's current or potential value propositions.

Table 1: Basic service types

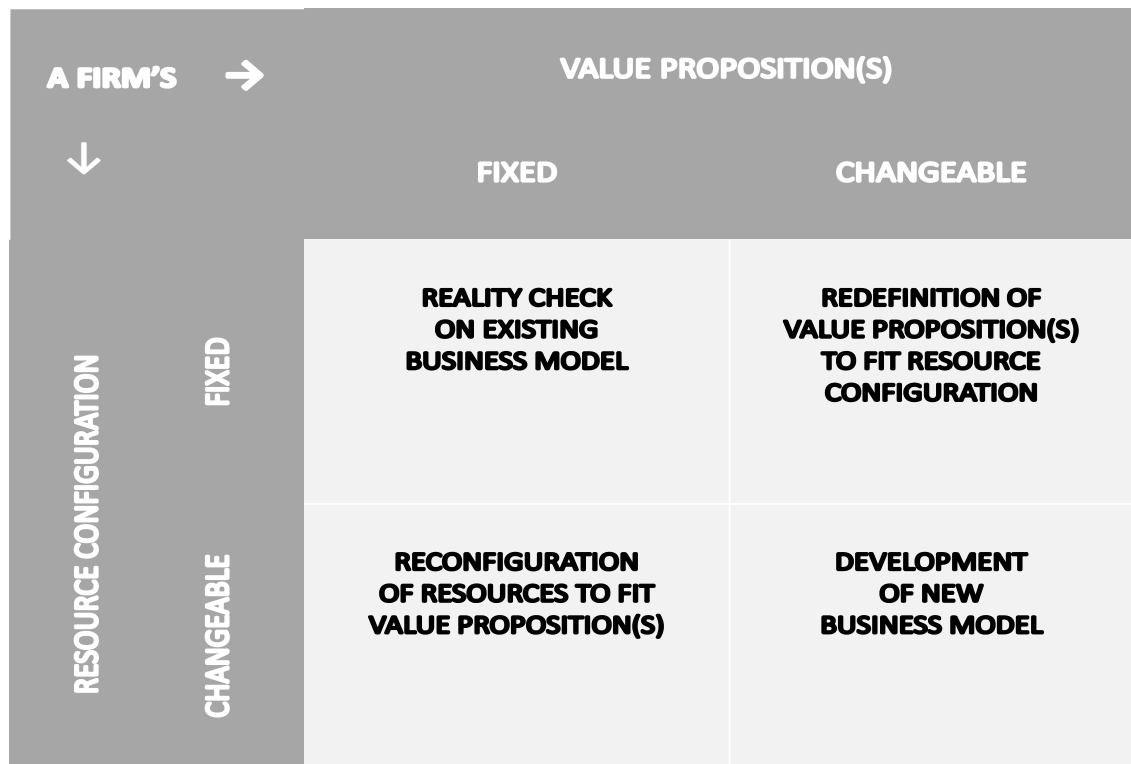

| SERVICE TYPE       | BASIC SERVICE NEED / VALUE PROPOSITION  | EXAMPLES OF PROMINENT PROVIDERS   |
|--------------------|---|---|
| LOGISTICS SERVICES | Safe and timely transport or storage of goods, equipment, data, money and persons     | FedEx, Lufthansa, DB, Maersk Line, Shurgard Self Storage, EMC <sup>2</sup> , Aldi, Vodafone, PayPal |
| FACILITY SERVICES  | Safeguarding, maintaining and facilitating the use of goods and properties            | Johnson & Johnson, Hertz, the InterContinental Hotel Group, G4S, Securitas, McDonald's, 7-Eleven    |
| ENTERTAINMENT      | Giving the client experiences that are exciting, stimulating and/or relaxing          | The Walt Disney Company, FC Barcelona, News Corp, Warner Music, Betsson, Rovio Entertainment        |
| NETWORK ACCESS     | Giving access to networks of individuals & firms sharing economic or social interests | HSBC, NASDAQ OMX, Allianz, Carlson Wagonlit Travels, Hamptons Int'l, eBay, Facebook, LinkedIn       |
| ANALYTICS SERVICES | Identifying clients' needs or problems and giving advice to their fulfilment/solution | McKinsey, the WPP Group, DDB, Goldman-Sachs Private Equity Group, DNV (Veritas)                     |

Table 2: Value-creation and value-capture essentials for different service types

| SERVICE TYPE       | VALUE-CREATING ESSENTIALS   | VALUE-CAPTURING ESSENTIALS                        |
|--------------------|---|---|
| LOGISTICS SERVICES | Scale and scope advantages  | Concessions and preemptive scale & scope capacity |
| FACILITY SERVICES  | Ability to upgrade and professionalize human resources                          | Reputation and branding                           |
| ENTERTAINMENT      | Ability to spot and develop artistic and/or physical talent at individuals      | Copyrights and team-embodied talent               |
| NETWORK ACCESS     | Buyer/supplier screening & segmentation capabilities plus network externalities | Authorization and consumer switching costs        |
| ANALYTICS SERVICES | Possession and combination of domain and client knowledge                       | Certification and bonding with clients            |

Figure 1: A diagnostic framework

# Emotion measurement services for knowledge workers

Maiju Vuolle<sup>1</sup>, Henna Salenius<sup>1</sup>, Johanna Lintinen<sup>1</sup>, Julia Mäkinen<sup>2</sup>

<sup>1</sup>Tampere University of Technology, <sup>2</sup>Intopalo Oy

*In order to understand and manage how emotions affect knowledge work, organizations need proper tools to become aware of emotions. Measuring emotions is an approach to consider. In this paper, three different emotion measurement services are tested: daily experience survey, electrodermal activity ring and self-tracking of emotions. The paper provides new insights and user experiences of emotion measurement services and their applicability in daily knowledge work. Managerial guidelines are drawn up for planning and executing emotion measurement in an organization for two purposes – supporting self-development and assessing company pulse.*

## 1. Introduction

Employees' moods and emotions have been recognized as important assets in organizations as they influence various outcomes, such as satisfaction, creativity, motivation and overall job performance (Brief & Weiss, 2002; Barsale & Gibson, 2007; Totterdell & Niven, 2014). The role of emotions in organizational life started gaining growing interest in the 1990's (e.g. Fisher and Ashkanasy, 2000). Hochschild's (1983) seminal work 'The Managed Heart' opened the path for researching emotions in organizational settings and the impetus for popular interest was given by Daniel Goleman's (1995) book 'Emotional Intelligence'. The book has made an impact on managers and employees worldwide, and the ability to use emotional information to guide thinking and behavior has become a valued skill ever since.

Specific topics in current emotion research in organization and management science include state and trait affect and mood, discrete emotions, the affective circumplex, affective events theory, emotional intelligence, emotional labor, emotional contagion, emotions and leadership, and building a healthy emotional climate (Ashkanasy & Humphrey, 2011; Barsade & Gibson, 2007). Service literature has been interested especially in studying emotions in the contexts of service experience, customer behavior during service failure and recovery as well as emotional labor and coping of service workers (Grandey et al., 2004 Schoefer & Diamantopoulos, 2008; Groth & Grandey, 2012; Strizhakova et al., 2012). There is, however, a need for more research at individual (within person) level and also taking context more into account (Gooty et al., 2009; Ashkanasy & Humphrey, 2011).

In order to make good use of emotions in workplaces, they need to be better understood and identified. One practical way for doing so is to start measuring emotions. There is a research stream that is interested in measuring emotions and their behav-

ioral outcomes at work (Payne, R., 2001; Gray & Watson, 2007; Mauss & Robinson, 2009; Scherer, 2005; Warr et al., 2014). The measurement approaches are varied, including, for example, general job satisfaction and emotion related surveys and self-reporting tools, experience sampling methods, diaries as well as physiological measures (Barsade & Gibson, 2007). Technological development has provided new practical tools and measurement services (such as wearables and mobile applications) for employees and managers that are relatively cheap and easy to take into use, but their applicability still remain uncertain.

The purpose of this paper is to find out how emotions can be measured in knowledge work context and evaluate the applicability of three different technology-based emotion measurement services. With the analysis of user feedback, the paper sheds light on what kind of role different emotion measurement services could play in knowledge worker's personal well-being and furthermore productivity. The focus of the study is on daily work experiences including momentary moods and discrete emotions. Moods and emotions are seen as important signals that affect, and at their best, benefit knowledge work performance. The paper provides new insights and user experiences of emotion measurement services and their use in knowledge work. Further, managerial guidelines are drawn up for planning and executing emotion measurement services in an organization.

## **2. Measuring emotions in knowledge work context**

### **2.1. Emotions as important assets of knowledge work performance**

Knowledge work productivity and performance development are stated to be the most critical management challenges of the 21<sup>st</sup> century (Drucker, 1999; Davenport, 2008). Work performance can be seen as a multidimensional concept, including task performance, contextual performance (or organizational citizenship behavior, OCB) and counterproductive work behavior (CWB) (see, e.g., Koopmans et al., 2013). Creative performance is also one important approach in knowledge work context as knowledge workers are expected to engage in continuous innovation and learning (e.g., Drucker, 1999). Despite all efforts and methods used by the organizations and managers, knowledge work performance results from "the constant interplay of perceptions, emotions and motivations triggered by workday events" (Amabile & Kramer, 2007). Therefore, emotions play crucial role when developing performance and they should be included in performance development projects and performance assessments.

Employees' moods and emotions can influence a variety of critical performance-related outcomes including judgements, creative problem solving, motivation, helping behaviors, risk taking, general performance, negotiations, relationships as well as counterproductive and withdrawal behavior (Brief & Weiss, 2002; Barsade & Gibson, 2007; Totterdell & Niven, 2014). Emotions can be classified into positive and negative emotions and usually it is assumed that positive emotions lead to positive behaviour and all negative emotions need to be eliminated. However, the links between

emotions and performance are more complex - various studies have shown also the differences between the activation level of emotions, the benefits of negative emotions as well as the drawbacks of positive emotions (e.g., Warr, et al., 2014; Spector & Fox, 2010; Lindebaum & Jordan, 2014; George & Zhou 2007, George & Zhou, 2002). In order to better understand emotions in workplace, the concepts of emotions and mood are discussed in this chapter.

Emotion is a wide concept that is difficult to define. There exists a broad diversity of different definitions of an emotion - for example, Kleinginna & Kleinginna (1981) discovered more than 100 definitions over 30 years ago. Although emotions are an inseparable and crucial part of human life, the specification of the concept is problematic. It has been challenging to reach consensus among scientists (Scherer, 2005). Some definitions emphasize how emotions are build up with different components such as physiological response, appraisal and expression of emotion (Totterdell & Niven, 2014). According to Gooty et al. (2010), definitions range from neurophysiological components to physiological changes, to reactions to events and from feelings in a certain way to mood states.

Emotions can be defined by component processes. According to Scherer (2005), emotions as component process models are reasonably common today and the component process model definition is gaining increasing acceptance. The component process model by Scherer (2005) describes emotions as following five components (1) Cognitive component (appraisal) (2) Neurophysiological component (bodily symptoms) (3) Motivational component (action tendencies) (4) Motor expression component (facial and vocal expression) (5) Subjective feeling component (emotional experience).

Emotions are thus driven by appraisals of the stimulus events and manifested by different expressions. As Scherer (2005) explains, "this seems rather obvious as we do not generally get emotional about things or people we do not care about." A similar component view is presented by Hochschild (1990): emotion is an awareness of four components (elements) that are typically experienced simultaneously (at the same time). These elements include (1) appraisals of a situation (2) changes in bodily sensations (3) the free or inhibited display of expressive gestures (4) a cultural label applied to specific constellations of the first three elements. Also according to Totterdell & Niven (2014), emotions are comprised of several components. A discrete emotion consists of components such as phenomenological "feeling", physiological activation, action tendency, cognitive appraisal and external expression.

When it comes to explaining structure of emotion, scholars are typically separated into two groups: those who prefer to use models such as the circumplex model and those who place emotions into separate categories. (Totterdell & Niven, 2014) In the circumplex model, emotions and moods are identified by two dimensions: valence and arousal. The horizontal axis represents thus the positive or negative valence of an emotion. This means, whether an emotions feels good or bad ie. pleasant or unpleasant. The vertical axis describes the amount of arousal of an emotion, in other words how energetic or active one feels. (Yik et al., 2011) For example calmness is high in pleasure, but low in activation (Totterdell & Niven, 2014).

The other way to model the structure of emotion is to classify emotions into discrete categories. These categories contain only "irreducible basic emotions from which more complex emotions are derived". (Totterdell & Niven, 2014) According to Ekman

& Cordaro (2011), “there is evidence for universality in the following seven emotions”: anger, fear, surprise, sadness, disgust, contempt and happiness.

Emotions are a very complex phenomenon. According to de Sousa (2014), emotions alter in several dimensions, for example in intensity, expression and object-directedness. Emotions are multidimensional, not just inner states or processes, but shaped in interactions, understandings and valuations (Sieben & Wettergren, 2010). What makes emotions more complex is that they are context-specific. How an individual reacts to a particular event may depend on the context: alone at home versus in a group or at work. (Zerbe et al., 2008) Also individuals vary in terms of how they experience emotions, as people evaluate events differently (Totterdell & Niven, 2014).

Emotions and moods are closely connected (Cropanzano et al., 2003). The most essential distinction between emotions and moods is diffuseness — “Emotions are always about something or someone” (Cropanzano et al., 2003), whereas moods lack this kind of an object or defining event (Forgas, 2011; Scherer, 2005; Cropanzano et al., 2003). Thus, there seems to be consensus in the scientific community that emotions are caused by specific events. (Totterdell & Niven, 2014; Scherer, 2005; Ekman & Cordaro, 2011; Nyklíček et al., 2010; Cropanzano et al., 2003). Often this event is evaluated as significant, as we don’t usually “get emotional about things or people do not care about” (Scherer, 2005).

Other distinctive factors of emotions and moods are intensity and duration. Moods are low in intensity (Scherer, 2005; Forgas, 2011) and relatively long in duration (Totterdell & Niven, 2014; Forgas, 2011), lasting from hours to days (Scherer, 2005). Moods are more typically more enduring than emotions (Forgas, 2013; Scherer, 2005). However, Cropanzano et al. (2003) state that emotions can be long in duration as well – people have a tendency to keep those “emotional states active by rumination”. To sum up, emotions can be distinguished from moods in three ways: they are shorter in duration, more intense and always directed to a specific object (Totterdell & Niven, 2014).

## **2.2. Approaches to measure emotions in workplace**

We assume that emotions have not yet been sufficiently taken into account when organizations try to figure out the state of well-being and performance at work. There are several inquiries concerning the well-being and performance, but much more emphasis should be laid on the emotional life of the employees. Emotional data can at its best be a proactive indicator in well-being. When emotional activity from certain periods of time is seen in real time, it can help to recognize the need for recovery (before burnout). For example, the follow-up of sick leaves is reactive rather than proactive, as it measures the consequences of burdening periods of work. There is a need for more real-time measuring of emotional well-being and performance than just the yearly well-being or performance enquiries. For example, companies have been questioning the conventional backward-looking assessments and applying quarterly or per-projects “performance snapshots” and weekly check-ins instead (see e.g. Buckingham & Goodall, 2015).

There are various different methods for measuring emotions in workplaces, for example, general job satisfaction and emotion related surveys and self-reporting tools, experience sampling methods, diaries as well as psychophysical measures (e.g., EEG signals, skin conductance, heart rate) (see Barsade & Gibson, 2007; Payne, 2001; Mauss & Robinson, 2009; Scherer, 2005). These measures include different emotion components and measures different emotional responses, including, subjective experience, physiological response (autonomic nervous system and central nervous system) or behavior (Mauss & Robinson, 2009). Moods and feeling are also included in subjective well-being surveys, such as job satisfaction, stress or work engagement (see, e.g., Salanova et al., 2014). These surveys, however, usually measure feelings in long duration, not short or medium term moods and discrete emotions which are in focus in this study. Emotional intelligence measures, on the other hand, assess personality or ability (Conte, 2005), not moods and emotions as such.

A widely used solution to measure emotions is different kinds of self-reporting tools, such as surveys. Measurement can, for example, emphasize positive and negative affect (or activation to be precise), with the PANAS Scales (Watson et al., 1988; Thompson, 2007) or take more dimensional model, such as circumplex model, into account using a 12-Point Affect Circumplex (12-PAC) scales (Yik et al., 2011). Scales to measure emotion at the workplace include Job-Related Affective Well-Being Scale (JAWS) and Multi-Affect Indicator (Warr et al., 2014). These previously mentioned surveys include both context free (i.e., “I was happy”, “I felt tense”) and job-related scales (“My job made me feel anxious”).

Psychophysical methods to measure emotions aim to capture the activation in the body’s autonomic nervous system (ANS). Emotions arouse activity in ANS which can be seen in increases in, for example, skin conductance response (electrodermal activity), blood pressure, heart rate and heart rate variation. The higher and more intense the emotional arousal is, the higher is the activation in the autonomic nervous system as well. (Totterdell & Niven, 2014) Previously electrodermal activity has been used mostly in laboratory setting, now these new tools (such as wearable technology) have made it possible to conduct measurements in real life context for a longer time period. However useful these measurement tools are, they do not cover all aspects of emotional life. As emotional responding can be measured in various ways and different measures complement each other, Mauss & Robinson (2009) suggest that experiential, physiological, and behavioral measures are all relevant to understanding emotion.

Emotional data of the employees have many potential possibilities of utilization: supporting individual’s abilities to perform and recover from stressing periods. One can also learn to utilize and manage some discrete emotions (e.g. anger, frustration) in a better and more sustainable way. Measuring emotions can at its best bring awareness to issues that would otherwise be hidden. For example, measuring skin conductance reveals the emotional activity – be it positive or negative. This can shed light into how emotionally burdening period one has had at work, perhaps even unconsciously. Understanding this, one can make the corrective actions to support recovery.

### 3. Empirical examination

#### 3.1. Research methods and data collection

Three emotion measurement services were tested by knowledge workers in real life work contexts. These services provided new ways to collect data of daily work and acted as personal development tools for workers at the same time. The usefulness of these services was tested through piloting services in small groups. The selected services approached emotion measurement with quite different approaches; web-based 'human intelligence' service was used for reporting daily subjective emotional experiences at work, wearable technology ring measured electrodermal activity during workday and mobile self-tracking service was utilized for identifying discrete emotions and their intensity. By utilizing various types of measurement approaches that consist of different emotional components, it is possible to gain more comprehensive view on employee's emotions. Feedback was gathered after each research period using interviews, diary reports or a questionnaire. Table 1 summarizes the measurement approaches and data collection methods.

*Table 1. Measurement approaches and data collection methods*

| <i>Measurement approach</i>           | <i>Type and component of emotion</i>  | <i>Research period</i>  | <i>Participants for pilot tests and feedback</i>                                |
|---------------------------------------|---|---|---|
| Daily experience survey               | Subjective emotional experience: valence and activation   | Twice a day during the first intensive week<br>Once a week for 11 weeks<br>Once a day during the second intensive weeks | 22 responded survey in one company<br><br>10 interviews for collecting feedback |
| Electrodermal activity during working | Emotional intensity - Arousal, activity   | Five days   | 8 participants, daily reports   |
| Identifying and labeling emotions     | Subjective emotional experience: Amount and intensity of discrete positive and negative emotion | Five days   | 8 participants, a questionnaire after research period                           |

The daily experience survey was carried out in a small knowledge intensive organization. The daily experiences were monitored within different periods of time. There were a two-week's intensive measurement period when the respondents answered

first two times a day and then once a day during second intensive week. Emotional data was also collected as continuous monitoring once a week between the intensive weeks. The survey included five questions or statements. Two emotion measures included activation and valence. The knowledge workers were asked to rate their daily experience on scale 1 to 100 as follows: “What is your energy level? (ranging from unactivated to activated)” and “How are you feeling? (ranging from unpleasant to pleasant)”. The other statements were measuring progress, workload and overall job performance. The web-based ‘human intelligence’ service (Celkee Insights) was used for collecting the data. E-mail reminder was automatically sent every week with the link to the service. After every statement it was possible to add some notes, e.g., own thoughts or development ideas. These open questions could be answered anonymously or published to everyone, to be discussed with other colleagues. After filling the form, it was possible to access the personal data and company level curves that were based on averages. Before the measurement periods the employees also took part for two lectures by professionals. Lectures concerned topics such as importance and consequences of emotions at work and short introductions to measurement services.

The second measurement service was wearable technology, a Moodmetric ring that measures the electrodermal activity (EDA). By this it is possible to monitor the emotional arousal or activation, that is, intensity of emotions (not valence, i.e. positive or negative). The ring transfers the EDA data from the ring’s memory to a smartphone application by Bluetooth. From the application it is possible to see the individual mood level (low-high activation, ranging from 0 to 100), relaxed minutes of the day and visualization of the emotional intensity and its variation during a day. The beta-version of the ring and its application was tested in everyday use by eight knowledge workers.

The third measurement service was an application to track discrete emotions and their intensity using a smartphone. The service, called Emotion Tracker, includes eight broad categories of positive and negative emotions: positive and negative activity, positive and negative thoughts, silent positivity, caring of others, negative passivity and uncontrollable bad feeling. Approximately 160 discrete emotions are included under these categories from which a user can browse and select his/her current emotions. Users can also track their current emotions by using a search tool. After labeling emotion(s), users can indicate the intensity of that emotion and make short notes. It is also possible to specify the object or cause of emotion, such as, relationship, family, work, sex, traffic, money or health. As a result, the application creates individual emotion cards including a table of identified emotions and their intensity. In addition, user can see daily, weekly or monthly summary report of top six emotions. Nine knowledge workers were recruited for pilot testing the Emotion Tracker service for one work week. Eight of them returned the questionnaire for providing feedback and user experiences of the service.

According to Scherer (2005), emotions consist of components such as cognitive, neurophysiological, motivational, motor expression and subjective feeling components. With the many measuring tools it is possible to measure different components. The Moodmetric ring monitors the electrodermal activity, thus making it possible to measure the neurophysiological component of emotion (i.e., autonomic nervous system). These emotions can also be unconscious to users. Emotion Tracker and daily experience survey both measures the subject feeling component of emotion. However, the type of emotion measured differs. In survey, only current mood or affect is

measured in terms of valence and activation whereas discrete positive and negative emotions are measured with Emotion Tracker. Through using different methods to measure emotions it is possible to gain a more comprehensive view on emotions.

When it comes to measuring and studying human behavior, it is dispensable to reason about whether the study might suffer from ethical difficulties. However, the data and findings reported in this study do not concern individual's emotions and their relation to knowledge worker's emotional wellbeing. Instead, the study focuses on user experiences that are related to applying different methods for measuring emotions in knowledge work context. Therefore, we see no specific need for discussing ethical concerns in this study.

### **3.2. Results - User experiences of emotion measures at work**

#### ***User experiences of daily experience survey***

The daily experience survey - named as IPOS sensor - was carried out among knowledge workers in one small company. Feedback on user experience was collected by interviewing 10 persons. Only two out of ten interviewees completed the survey regularly, three did not respond at all, and the rest five people completed the survey irregularly. Causes for low completion rate were diverse. Some of the respondents were not motivated due to no actions had been taken or discussions on future plans had been made after the IPOS Sensor was introduced. Some felt that they had more important work to do or answering was simply too much work. Technical problems such as losing email notification in the mailbox or challenges with the link or tool itself were reported as well. For new personnel the idea of collecting daily experiences with IPOS sensor was obscure, and they thought it did not concern them. It was seen good to have a possibility to add comments when people feel they have something to share. However, most of the interviewees did not enter comments as they already used instant messaging channel where comments are better acknowledged. It was also found that there was no need to be able to follow results daily or weekly but everybody was interested in seeing a snapshot of the results regularly (e.g., monthly) and have reflection on how we are doing, and why. None felt that only seeing and comparing results affect their working habits at this point.

As the case company is small, interviewees felt they can discuss face-to-face or in chat if they have any problems and questions and therefore, there was no need for anonymous feedback channel. For future reference and when company is getting bigger, all the respondents agreed that if the purpose of the survey is clear and the results have future impact, it would be important and interesting to collect data on the daily experiences in the company level. However, the tool for collecting the data should be simple application with only a few straightforward questions. Smaller scale and questions with faces were suggested. The application should be fast and easy to use and always available in mobile and laptop or even in iPad stand. A text message reminder instead of an e-mail would probably increase the completion rate and results could be shared and discussed regularly. The application could be integrated to the instant messaging tool that the company is using. Also other methods were suggested, such as automatic sensor collecting feedback (face movement), daily scrum like chat sessions or diary based system to reflect own day.

Overall, the user experience of IPOS Sensor can be categorized in four points. Firstly, the purpose for collecting data should be defined and communicated to the personnel well before starting the survey. To be more specific, the personnel should be informed how the results are followed and handled, and what kind of actions will be done based on the results. Secondly, data should be collected only when needed or periodically. Based on the survey respondents seemed to answer more regularly during the short intensive weeks than during the time between when data was collected once a week. Therefore, to achieve high response rate, company could do intensive weeks, for example, four times a year instead of continuous once-a-week. Thirdly, the survey should be planned in such a way that the results can be utilized. Fourthly, the results should be communicated regularly and made sure that the intended actions will get done.

### ***User experiences of electrodermal activity (EDA) ring***

Respondents wore the EDA ring during five workdays, typically from 8-9am to 4-5 pm. Some respondents wore the ring all day long. Three themes emerged from the analysis of the user experience data: technical issues, linkability to other applications or devices and self-awareness.

Technical issues concerned the ring's usability in daily life such as water resistance, size, and accuracy of measuring. Linkability to other applications or devices was seen beneficiary by the users due to the desire for more comprehensive understanding of the origins of the feelings. Being able to connect the emotional data, for instance with calendar events or other wearable technology, was seen as a complementary and value-adding feature. It seems that wearable technology is considered interesting, but too much to wear is too much to ask.

The test users agreed that the ring measures their emotional intensity quite accordingly and helped improving self-awareness on their emotions and behavior. However, the usefulness of emotional data remained unrecognized. The results may indicate that the link between emotional wellbeing and work performance has not been seen yet by the users. Alternatively, the user's emotional intelligence and emotion-regulation processes may be so well developed and self-evident that no external data is needed.

*"I do think it tells something about my emotion changes. But I have not found any good use cases for these data." (Male, approx. 35 yrs.)*

*"It was interesting to see the results. I could find a correlation with an emotion and a rise in the number. That being said, the information did not provide me any extra value. I knew what I felt and why without looking at the app." (Male, approx. 40 yrs.)*

*"I experienced several small self-analytical moments when using the ring, which helped to gain new or strengthen existing insights of myself and my reactions. For instance, I am more introvert than I've thought, work is sometimes more relaxing than being at home, I feel strongly emotional about interesting and exciting work. Equally, I feel strongly emotional about repulsive projects, in particular if I get a feeling that the project will exhaust me to my extreme limits." (Male, approx. 35 yrs.)*

*"Sure! It is interesting to see how feelings and emotional states fluctuate during the day and week. Reading articles alone at work is usually a peaceful moment, which*

*makes the MoodMetric number drop to 15-20. However if the article is very interesting, then the number can rise quite high. I still don't understand why the emotional load in the mornings is so high." (Female, 25 yrs.)*

Some users were surprised about their own emotional reactions, because they had expected the emotional responses to be something else. One has to understand that the ring only measures the amount of arousal (emotional activation): the meter reading can be the same if a person is in a peaceful meditative state or negatively numb. Also according to the circumplex model, an individual can be high in arousal both in negative or positive way, for example, overjoyed or angry. As the ring only measures one dimension (arousal), it cannot tell the difference between these situations. Thus, it should be made possible in the application to mark whether the peaks in emotional activation are caused by positive or negative events. Be the situation positive or negative, it is important to recover from situations that are high in activation. Enduring and long-lasting positive activation can be a burden for well-being as well.

Evidently long term benefits or disadvantages were not reflected, because the five-day test period was relatively short. However, it would be interesting to find out whether the perceived benefits would alter if the user collected data from a longer period of time. It can be assumed, that a five-day test week may not help the user to evaluate how a certain work week is related to other weeks during the year.

### ***User experiences of mobile emotion self-tracking service***

The user experiences of tracking emotions were collected using a questionnaire including eight statements related to the impacts of labeling and tracking emotions at work and four questions related to opinions on the use of emotion measures in workplaces. The 5-point scale for the statements ranged from strongly agree to strongly disagree. There were also one open-ended question for other comments and feedback.

Half of the respondents said that tracking emotions was easy. Two respondents reported tracking to be difficult and two were neutral. The vast majority (63 %) did not agree or disagree that tracking emotions in daily work is useful. The usefulness of tracking was supported by two respondents and disagreed by one. The potential usefulness of emotion tracking may not yet be realized due to the short test period. Users also reported inconvenience that manifested in extra work and effort and some even forgot to track any emotions during working. Although the usefulness of tracking emotions was not clear, half of the respondents reported that they had learnt to identify and understand their emotions better during the test week. Two respondents said that no learning had occurred and two could not tell. Learning to identify and label own emotions might take more time.

Somewhat more than half of the respondents reported that through tracking emotions, they had become interested in finding out about their discrete emotions and how to utilize these emotions. Three respondents reported that no specific interest in finding out about specific emotions and their use had occurred. No significant learning effects of the ability to exploit emotions to benefit working were reported. One respondent reported that she/he had learnt to take advantage of discrete emotions at work after the test week. Half of the respondents did not have an opinion and two reported that no learning had occurred. However, somewhat more than half of the

respondents would recommend tracking emotions for knowledge workers. The majority of the respondents (88 %) were of the opinion that, if emotions are measured at work it should always happen on a voluntary basis. Most of the respondents (88 %) were positive towards company offering emotion measurements as a service. More than half (63 %) of the respondents said they would continue emotion tracking also after the test week. The researchers will contact the respondents for follow up.

According to the respondents, measuring emotions and utilizing the data in working life should primarily be based on personal development and self-management purposes (7 out of 8 responses). Reasons for team-level (4 out of 8 responses) and company-level (5 out of 8 responses) measuring were seen as well. It was noted that measuring discrete emotions would be useful as part of knowledge worker's every day working life or periodically conducted. Some respondents reported that measuring emotions should be available and exploitable through occupational health service. One respondent envisaged that measuring could be applied in communities, conflicts, problem-solving and innovations. However, this notion was not further elaborated.

Most of the open comments concerned the usability of the application. Especially the user interface was considered too slow and some automated mechanisms were requested. It appears that users expected the application to be more automated and intuitive. Despite the technical challenges, tracking emotions was considered insightful. Getting a bigger, but also a more detailed, picture on one's emotional life was seen useful. By reporting emotions one could distance herself and make more rational conclusions. On the other hand, tracking emotional data on a daily basis would diminish the risk of overestimating one's emotions. It was seen that in general only the most intensive emotions are the ones that are best recalled. It is possible that this affects interpretations one makes of her life. Furthermore, it might have an impact on one's attitudes and beliefs, and that way personal choices and behavior. However, it was also critically reflected whether users tend to only report on strong emotions.

The question of whom the emotional data should be collected for seems to be relevant. The comments indicate that traditionally different reports have been collected for the use of upper management. However, reporting on emotions is considered personal and the information should be kept private. The benefit of reporting would be realized if people want voluntarily to learn about their emotional information and develop emotional intelligence. Therefore reporting on emotional data is probably best suitable for self-management purposes.

### **3.2.1. Summary of the results**

Strengths and challenges of each emotion measurement service are summarized in Table 2 and discussed below. At their best, all of the services offered a way to gain insights into emotions at work. Measures could be also used at the same time to complement each other in order to get more comprehensive view on emotions. Every approach drew also some criticism from which developmental actions can be conducted.

Table 2. Summary of the emotion measurement services.

| <i>Emotion measurement service</i> | <i>Focus</i>                   | <i>Strengths and opportunities</i>  | <i>Challenges and weaknesses</i>   |
|------------------------------------|--------------------------------|---|--|
| Daily experience survey            | Mood (pleasure and activation) | Easy, familiar and inexpensive tool   | Problems with the survey tool itself, no clear motivation to respond, subjective data    |
| Electrodermal activity ring        | Arousal, activation            | Automatic data collection, objective data, also unconscious emotional reactions | Technical issues, usability in daily life, integration to other devices and applications |
| Tracking emotions                  | Discrete emotions              | Easy and relatively cheap, can awake interest in emotions                       | Subjective data, no clear idea of the usefulness at work, effort to label emotions       |

Different types of surveys are a typical way to collect data of one's emotions. In this experiment, daily experience survey (IPOS sensor) was used to find out the overall mood of the employees. Surveys are generally an easy and inexpensive tool. However, to have motivation to fill in the form regularly, employees need to have a clear reason why it matters to take the time. In our experiment this wasn't the case and there were only few committed respondents during the weekly surveys. There were also some technical issues with the survey tool. In the future, the tool should be easy to use with only few well-chosen questions and the results should be reflected regularly.

The electrodermal activity ring provides objective data of one's emotional intensity (arousal). No subjective reflection is needed to collect the data, as the ring monitors activity automatically. Thus in principle, it is not hard to get accurate data of emotions. Still, there were some issues with everyday usability and with the meaning of measuring emotions or the benefits of this measurement. Compared with other measurement services here, the ring is also a bit more expensive. The most significant advantage of the ring relates to the instant and continuous feedback it provides. The user is able to monitor the results constantly and reflect how different situations affect results.

Putting negative emotions into words is one of the best ways to manage negative emotions (Lieberman et al., 2007) and it has been proved that affect labeling yields many benefits for well-being (Pennerbaker, 1997). In our experiment, employees learned to label their emotions with a mobile application. The experiences of this measurement varied again: although many of the employees were not particularly sure how to benefit from the information of the application, half of the respondents reported that they had learnt to identify and understand their emotions better. Getting a bigger, but also a more detailed, picture on one's emotional life was seen useful. Mobile app is also a relatively affordable solution to improve emotional awareness. The vast majority (88%) felt that emotion measures could be provided as services for employees. In this way, the work community could encourage its members to im-

prove emotional skills with measurement tools and provide some training to support getting insights and making use of the data. It is recommended that the employees could themselves plan and choose how to improve emotional skills.

#### **4. Discussion - In the search of an ideal emotion measure for work?**

Based on the user experiences of emotion measurement services, managerial guidelines for designing and deploying these type of services were identified. Our experiment revealed that when planning emotion measurement in the workplace, at least five issues should be considered: 1) a goal and a purpose for the measurement, 2) the frequency of the measurement, 3) data ownership and ethical concerns, 4) ease of use and 5) employees' motivation towards measuring emotions.

##### ***Goal and purpose – Self-development or company pulse?***

In order to be useful and motivating, the clear goal and purpose for measuring emotions at work should be specified. Through testing three measurement services, it was noted that they could be useful for two purposes: to provide information on company level pulse and to support individual self-development. Company level assessment can be useful when identifying baseline and changes during development projects. Emotion measures could also complement other well-being and performance measures. When utilizing measurement at company level, the results should be communicated effectively to employees and shared reflection is needed after the measurement period: what has been learnt and what is going to be done according to the results.

Company level measurement can be divided into teams and departments but comparability of the results might be problematic. It is important to note that, for example, personality affects how intensively emotions are experienced, so it has to be considered how well emotional data of different individuals can be compared. Also emotions influence behavior in different ways: some people get extra motivation from setbacks, as other people may give up. It is essential to learn what are the own tendencies to react to emotions caused by different events.

Therefore, the emotion measurement services at work could be useful especially when provided as tools for individual to support their daily work and well-being. Employee chooses the best tool for their situation and plans what is the appropriate length of the interval and a personal goal. The measurement is done independently based on a personal need, for example, when experiencing a tough period at work, employee can measure stress levels, amount of relaxed time and see how well he/she is recovering from highly intensive moments daily or during the weekend. It is important to have enough also calming periods at work to be able to perform well in the long run. Thus, time for self-reflection is needed. To support this, there could be some self-education materials available.

##### ***Frequency and length***

The suitable length and frequency of the measurement period varies between the measurement method and the purpose of measurement. To gain deep understanding and insights, the measurement period should be long enough. However, long period takes time from other important task and more motivation is needed. Filling forms and tracking emotions at work may not be suitable for everyday use in the long run, as reporting takes some time. It is also understandable that employees don't feel comfortable reflecting on emotions every day at work. Based on the user experiences, measuring emotions could be useful on a periodic basis. For example, daily experience survey could be done four times a year in one week intervals. At the same time, wearables, emotion tracking services or diaries could be provided to those employees who are willing to have deeper insight on their emotions and they could continue their measurement from one week to four weeks or longer.

A one week's period of measurement does not necessarily offer best possible insights into employee's emotional life, provide learning or encourage making changes in working habits. If one desires to deeply understand the emotional state, one should collect data from a longer period with different working conditions: e.g. meeting tight deadlines, being a bit bored or having a day off. This is a bit problematic, as this long-time data collection should be as effortless as possible, but in our experiment the employees didn't find the proposed services very high in usability.

Employees can better get a more holistic view of the results of the measurement when the data is collected within a longer time than a day or week. Employees should also have access to measurement tools, when they are facing an intensive and enduring time at work to reflect their stress and coping in these situations.

### ***Data ownership and ethical concerns***

Management should also state, how the data will be handled after and make statements on the data privacy. It should be made clear, to whom the emotional data belongs and somehow balance the private and public data. When measuring emotions of a group, it should be secured that individuals cannot be connected to data sets. Currently the way in which Moodmetric and Emotion Tracker save data is completely manageable by the user. Thus, organizations should agree with common practices how to interpret the emotional data: is the data only for personal use, or to be discussed with own manager or team or an occupational health member. It is also possible to share data within the whole organization. Because there are many ways to share and interpret data, it should be clear for the employee who can see their own emotional data, before they take part in such experiments. This is especially important when trying to avoid situations where an employee recognizes afterwards that their emotional data and private comments have been shared to others without purpose to do so. We propose that the employee should have the right of decision in these situations, as the emotional data can be seen very personal. Additionally, it is understandable that not every employee is willing to think about emotions at work, so participation in measurement periods should always be voluntary.

### ***Ease of use***

It has to be considered what kind of service or tool is required to meet the goal of the measurement. The tool should be easy to use and integration to the other applica-

tions, such as calendar and instant messaging tool, or wearables should be possible. It would also be useful to utilize some contextual data, for example, location information. Sometimes automatic tools such as the Moodmetric are preferred, as they are more user-friendly: one need just to wear the ring, no effort is needed to collect the data.

### ***Motivation towards measuring emotions***

As it takes time and motivation to commit to daily measurements, employees and their motivation should be taken into account. It should be made possible that employee has the time to fill in the forms and reflect on the results. Communicating why measurements are carried out and what benefits are to expect should be clear to everyone, as it can bring meaning and motivation to commit to regular measuring. After the measurement there should be a thorough debriefing about what have been learnt, what is going to be done based on to the results and how the employees felt the experiment. It would also be useful to offer information and training concerning emotions' effect on well-being and performance at work and provide other methods, for example mindfulness, to develop employees' emotional skills.

## **5. Conclusions**

In this paper, we have examined various approaches to measure emotions at work. Three emotion measurement services were tested in practice and user experiences were gathered. Managerial guidelines for deploying emotion measurement services were also discussed. Two different purposes for measurement were identified; providing emotion measurement services as self-management tools for employees and conducting company level measurements to gather company pulse.

We assume that recovering from intensive work (whether positive or negative) does not always meet the hopes and expectations of the employee or the employer. Due to individual differences and circumstances, it is challenging to estimate the endurance of recovery. Measurement tools such as Moodmetric ring can give unique and novel possibilities to monitor one's own well-being and performance in real time. By monitoring stress-levels, one could arrange job tasks so that they are in accordance with the emotional wellbeing. For example, when in good moods it's a better idea to commit to more creative tasks, whereas when the mood is negative doing systematic or analytical tasks that require accuracy would be recommendable (Klep et al. 2011; Forgas et al., 2009).

Getting results and feedback immediately can be highly motivating. We also believe that employees will take a more active role in enhancing well-being and performance at work, when it is possible to see, for example, physiological reactions in real time. As compared to typically once-a-year held job satisfaction surveys, emotion measurement services could help employees to take more proactive actions to their personal well-being. Being conscious and accepting the daily fluctuations and emotions and adjusting daily work (to these movements) can be a way to improve well-being and productivity at work.

## Future research

By using different methods to measure emotions, it is possible to gain a more comprehensive view on emotions. According to the user experiences from our experiments, it would be possible to develop a broader application to measure the different components of emotions. The application could integrate data from multiple sources, for example objective electrodermal activity data (emotional arousal) and subjective evaluations about the discrete emotions: what emotion is in question, intensity and object or cause. An interesting addition to the application would be a diary possibility and contextual data: to integrate data from calendar application and locations to see, whether the daily events and experienced emotions correlate. Another way would be the possibility to mark the emotional activity peaks, whether they have been experienced positive or negative or what has been the cause. Also some reflection possibilities could be added to find out the behavioral component: for example, if one felt frustrated at work, the reason could not concentrate well enough.

Although this paper focused on practical usefulness of emotion measures at work, these new measures can be used as research tools as well. With a more comprehensive and user-friendly service it would be interesting to carry out some new experiments with more users and also see if emotion measures could be used as interventions to improve daily work. The link between emotions and perceived performance could also be better studied with more users.

## **Empirical Analysis on Service Sector**

### **Growth in Hinterlands of China**

*Liu Yi*

National Academy of Social Strategy, Chinese Academy of Social Sciences

*In the reality of China's service sector development, many cities have taken advantage of their proximity to large cities while others suffered spatial exploitation of large cities. Despite the pivotal role of the hinterlands in theories of the development of the urban hierarchy, there has been little literatures related to the effect of service agglomeration of metropolitan on service sector growth in the hinterlands, especially in developing countries. By reviewing the relevant studies in the New Economic Geography, this paper has created an empirical framework to examine the effect of central cities on the development of service sector in hinterlands, and examined how proximity to different hierarchy cities affects the service sector and sub-sectors growth of hinterlands by using the spatial econometric model on the data of cities at or above prefecture level in China's three city clusters. Results indicate that when taking the distribution of different hierarchy cities into account, service sector growth in hinterlands is more dependent on the geographic proximity to higher hierarchy cities than the market potential caused by the near metro cities.*

## **1. Introduction**

Over the past thirty years, the wealthiest OECD economies have experienced rapid de-industrialization and more than three-quarters of employment in many OECD countries is now in services, while industrial sectors, on average, account for less than one-fifth. And for China, one of the greatest economic challenges it facing in recent 10 years has been the adaptation to a service-based economy. Service sector is now contributing more than 48.2% of GDP (Figure 1), and for some metropolises like Beijing, Shanghai and Guangzhou, the ratio is over 50%. Service sector is tipped to replace the manufacturing industry and become the strongest driver of many Chinese cities.

Figure 1: China's Ratio of service sector added-value to GDP(1995-2014)

There's many controversies on whether China should aim to build mega cities or follow a more balanced approach of regional development in the process of the-new-type-urbanization. In reviewing the development of service sector, we are able to identify many cities that took advantage of their proximity to regional centers in developing service sector. These instances include Ma'anshan's rapid development of leisure and entertainment services with its proximity to the central city of Nanjing and the case of real estate boom in peripheral counties of Beijing. However, there are also instances where large cities deprived neighboring cities of service sector opportunities. For instance, as they grow larger and more competitive, private firms based in Jiangsu and Zhejiang provinces began to relocate their headquarters, regional head offices and R&D functions to downtown Shanghai. Hong Kong and Guangzhou absorbed most high-end purchasing power in lower-hierarchy cities of the Pearl River Delta region. Beijing's attraction of cultural and tech resources has resulted in a poverty rim around the capital<sup>1</sup>. Judging by China's reality, service sector has either prospered or perished all because of its proximity to a central city. However, conventional wisdom believes that service industry is characterized by concurrent production and consumption and that many service activities cannot be traded. As a result, geographical factor has long been excluded from academic research on service sector, so we are left with very limited understanding on the interaction between central city and hinterland regarding service sector development. Furthermore, compared with world-class urban clusters<sup>2</sup>, China's primary cities of top three urban clusters

<sup>1</sup> Ding Jun, et al.: *Capital-rim Poverty Belt: 25 National-level Poverty-stricken Counties around Beijing*, 21<sup>st</sup> Century Economic Report, September 13, 2009.

<sup>2</sup> According to Yu Hongsheng (2010), measured by city primacy ratio, New York accounts for

are less influential but urban diseases have already occurred at this stage. Take Shanghai for instance, its economic primacy ratio kept on the decrease between 1994 and 2014 with primacy ratios of value added of service sector on the significant decline after a short increase in 2005 (Figure 2).

Figure 2: Shanghai's Primacy ratio of service sector added-value (2000-2014)

This paper focuses on the roles the regional center cities of different hierarchies play on the service sector growth of hinterlands, especially the effects of discrete distance penalty Metros play on their hinterlands. By reviewing the literatures of New Economic Geography, this paper has created an empirical analysis framework to examine the influence of a regional center cities on the service sector of hinterlands by using data above prefecture level for the China's three biggest urban clusters, i.e. Yangtze River Delta, Pearl River Delta and Around Bohai region.

## 2. The distance effects of urban hierarchy and service sector growth: literature review

### 2.1 Center-hinterland relationship of the service sector

Since Christaller published Central Places of South Germany in 1933, central geography theory has demonstrated very strong explanatory power till this

---

more than 22% of the US economy while Tokyo represents over 24% of Japan's economy.

day. According to the theory, under the assumption of desirable land surface and economic man, the space of activities has a remarkable feature of geographical centralism with central places servicing as nodes that provide all kinds of goods and services to residents in the hinterlands and defined by coverage of its service sector. Theory of new economic geography has introduced increasing return to scale into analysis and explained agglomeration using input-output correlation and accumulation of real wage effect. In a city system constructed under this theory, a small city only provides less competitive basic products, leaving more important goods and services to cities at higher levels. Hierarchical structure of cities is still highly consistent with central geography theory (Fujita and Thisse, 1996). But in order to follow the simplified assumption of iceberg cost, new economic geography only includes the movement of goods into the scope of analysis yet neglected the movement of people in the region. The model is created entirely based on the two-department (agriculture and industry) assumption and almost excluded service sector from consideration. With growing IT penetration, globalization and service outsourcing (Sassen, 2000), relocation of business production and activities gave rise to spatial reconstruction of cities. In parallel to the decline of manufacturing functions, high-end production services like accounting, legal affairs, advertising and consulting business are growing rapidly in central places (Castells, 1996). As production venues of high-end services, cities offer a vastly extended scope of products and geographical coverage. Their function as central places under city hierarchical system are increasingly replaced by intricately intertwined city networks featuring regionality, functionality and hierarchy. Center-hinterland relationship is giving way to a network of service-based cooperative relationship and service delivery cannot take place without frequent movement of people. In response to changes taking place in city system and the relationship among hierarchies with regard to the development and agglomeration of service sector, it is imperative to reevaluate the emergence of central places and their interactions from the perspective of urban service network.

Although Sassen's (2002) global city model well reflects changes in the spatial model, he focused only on networks linked by inter-regional production services and paid no attention to intra-regional spatial layout and center-hinterland interaction. Among existing studies, spatial spillover is considered to contribute to regional convergence (Rey and Montouri, 1999). For instance, Ertur et al. (2006) discovered a strong spatial spillover effect in the convergence of 138 regions of Europe between 1980 and 1995. Fingleton and Lopez-Bazo (2006) noted in their comment on spatial effect of growth that a region's growth rate is not only subject to the initial conditions of capital and human resources but conditions of neighboring regions. Negligence of inter-regional spatial dependence and heterogeneity will result in a series of wrong assumptions (Abreu et al., 2005). Despite fruitful results of overseas studies

on spatial spillover, existing literature studies on the spatial effect of China's regional economic growth are limited, particularly data of prefecture-level cities and studies on growth pattern and interactions of industries in the same category between cities of different regions and types. Using provincial-level data, Ying (2003) estimated China's output growth between 1978 and 1998 and found a negative inter-regional spatial self-correlation, explaining it as an effect of regional polarization in China's economic growth. Using China's inter-provincial GDP data, Jeon (2007) tested Nicholas Kaldor's hypothesis and found a weak relation of inter-regional dependence. Using vector self-regression model, Groenewold et al. (2007) conducted dynamic simulation for the effect on other regions when one region is under external impact using a three-region framework. Madariaga and Poncet (2007) discovered significant spatial dependence and rapid convergence between cities with respect to per capita GDP. On the contrary, using spatial econometric method, Lin et al. (2006) observed a tendency of dispersion in China's inter-provincial economic growth. Obviously, almost all existing studies are conducted based on provincial data and given that China's provincial administrative boundary usually will not overlap with economic boundary, it is improper to conduct this type of research based on the unit of provinces (Herrmann-Pillath et al., 2002). As a rare paper correlating geography with service sector, Lu Ming et al. (2012) studied the effect of distance between regional large cities on the labor productivity of service sector yet neglected the heterogeneity of service sector and the complexity of regional city system. Their simplified configuration of geographical factor failed to reveal the effect of distance on service productivity. Hence, with different types of cities, empirical study on growth path and spatial effect of service sector and its sub-sectors can increase data quantity and proximity of samples and reduce sample heterogeneity, which is of great significance to enriching currently very limited empirical analysis literature studies on the spatial effect of regional growth and arrive at convincing conclusions.

## **2.2 Death of distance or tyranny of distance: the role of geographic factor in the development of service sector**

Compared with manufacturing, service sector relies more on face-to-face communication. Under the traditional considerations, services cannot be transported over a long distance and thus does not comply with iceberg cost hypothesis. Below threshold distance, there is little difference in the cost of transportation; above threshold distance, marginal cost of transportation is infinitely high, and that is why that distance rarely entered the horizon of research on the service sector. In addition, improvement of information technology and transportation has led to flat service organizations like e-commerce, online media, online office and online meeting. Many scholars

believe that geographical factors such as distance and location are no longer problems in service production and delivery (especially between cities of high hierarchy), i.e. death of distance (Harvey, 1990; O'Brien, 1992).

However, more and more studies discovered that for quite a few service firms, technology did not eliminate their location-based decision-making and information technology supplemented but did not replace face-to-face communication (Glaeser and Kohlhase, 2004); as development of many service sectors relies on information externality, face-to-face communication became more frequent (McCann, 2007). Partridge *et al.* (2008a)'s empirical study indicates that between 1950 and 2000, geographical cost to remote hinterland cities in the United States kept increasing despite improvement of information and communication. Considering that services *per se* are studied as a special form of final product rather than a participant of production process, the effect of geographical factor on service sector seems very limited. Different from traditional services, producer services that offer professional knowledge and creativity can benefit from an extended scope of service provision. For productive service firms, technology may neutralize distance factor as a barrier but in reality, more service industries have taken on new features of agglomeration under the backdrop of economic globalization (Swyngedouw, 1997). Improvement of IT and commuting conditions did not eliminate the effect of distance but resulted in a mixture of agglomeration and dispersion in different ways than before (Sassen, 2000). It needs to be noted that regarding how the rapid growth and agglomeration of central places affect service industry of other regions and particularly remote regions, both theories of central place and new economic geography offered no final conclusions.

On the whole, geographical factor can promote industrial growth in many ways (Jovanović, 2003; Puga, 2010) such as proximity to input products and markets (King *et al.*, 2003; Rosenthal and Strange, 2003; Andersson and Hellerstedt, 2009), proximity to skilled workforce (Glaeser *et al.*, 1995; Simon, 1998, Simon and Nardinelli, 2002) and absorption of positive knowledge spillover from firms of supply side and demand side (Crescenzi, 2005; Ketelhohn, 2006; Maine *et al.*, 2010). Knowledge spillover from an industry is referred to as MAR (Marshall-Arrow-Romer) externality<sup>3</sup> and knowledge

---

<sup>3</sup> For the industrial promotion effect of MAR externality (localization agglomeration), existing studies are far from reaching an agreement. Partridge *et al.* (2008) found a negative correlation between initial employment of manufacturing, retail sales and services of US counties and the growth of above-mentioned industries in the 1990s. Feser *et al.* (2008) found in their empirical study on counties of Appalachian Mountain that existence of industrial agglomeration cannot accelerate industry growth; Duranton *et al.* (2010) reached similar conclusions through an empirical analysis on France. Glaeser *et al.* (1992) and Partridge and Rickman (1999)'s study found more evidence to support Jacobian externality. Maine *et al.* (2010) believe that in addition to absorbing the knowledge spillover of local firms in the same industry, firms are more likely to receive knowledge spillover from adjacent research institutions, universities, suppliers and clients. Knowledge spillover promotes industrial development through enhancement of corporate human

spillover from between diverse industries of large cities is referred to as Jacobian externality. Above factors are all embodied as driving effect of metropolis (North 1955; Glaeser and Khan 2004; Rosenthal and Strange 2001). Besides, infrastructure, technology and industrial superiority of metropolis will also generate a spillover effect on hinterlands, affecting the latter's service sector growth and job structure (Duranton and Puga, 2001). Crowding out effect of metropolis such as exorbitant land cost and pollution will lead to a spillover effect of central place on hinterlands (Glaeser, 1997). As research deepens, people began to realize that though most knowledge spillover relies on face-to-face communication in a limited region (Crescenzi, 2005), economies of agglomeration are not confined inside the boundary as shown by previous research. Meanwhile, economies of agglomeration become thinner while crossing over the boundary. The greater distance from central places, the less hinterland can benefit from economies of agglomeration and spatial spillover. This lead to tyranny or penalty of distance (Hanson, 1998) and the degree of impact decays with the increase of distance.

Scope of economies of agglomeration varies with different attribution of externality. Some studies believe that knowledge spillover thins rapidly through face-to-face communication but labor pool and investment sharing can extend to remote hinterlands (Rosenthal and Strange, 2001; 2003). According to the study of Rosenthal and Strange (2005), knowledge spillover can influence productivity 50 to 100 miles away. Effect of market potential will not dissipate until beyond 800 miles. Even for small central places, their agglomeration spillover effect and labor market dispersion effect arising from commuting extends beyond 180 kilometers (Partridge, Bollman, Olfert and Alasia, 2007). Considering that economies of agglomeration may vary with different hierarchical status of a city, the thinning process and effect on city system and hinterland can be non-continuous (Eaton and Eckstein, 1997; Brühlhart and Koenig, 2006). Furthermore, smooth and successive changes caused by market potential in New Economic Geography theory have ignored the discrete changes caused by the distribution of different hierarchy cities, which will lead to an incomplete measure of agglomeration spillovers on service sector growth of hinterlands(refer to Figure 3). Hence, service growth and employment will be subject to the market potential of central places and adjacent cities of other hierarchies.

---

capital or indirect increase of corporate productivity (Rauch, 1993).

Figure 3: Discrete distance penalty vs. market potential

Theory of new economic geography notes that due to self-reinforcement, once occurred, agglomeration will rapidly develop and maintain a stable condition with the elapse of time (Krugman, 1991). Rapid growth of metropolis will extract products, services and human capital from hinterlands, causing a negative spillover of growth, i.e. shadow effect (Tallman *et al.*, 2004; Rosenthal and Strange, 2003; Dobkins and Ioannides, 2001). Some studies suggest that shadow effect exists and is heterogeneous with magnitude partially subject to a region's development stage. In the initial stage of industrialization when central places come into being, shadow effect is weak; in the second stage of hinterland's population expansion and supply of agricultural produce to central places, central places and hinterland develop in tandem (Fujita *et al.*, 1999); in the process of industrialization and urbanization, shadow effect strengthens, uneven regional growth solidifies and shadow effect intensifies<sup>4</sup>. Net effect of proximity to metropolis depends on whether growth spillover effect or agglomeration shadow effect is in a dominant position. Liu *et al.* (2011)'s empirical study on China suggests that high-hierarchy cities will have a positive net effect on the growth of peripheral regions, which is consistent with the study of Partridge *et al.* (2007, 2008b)'s study on the United States. In addition, studies based on high-tech services suggest that distance has a heterogeneous effect (Arauzo-Carod and Viladecans-Marsal, 2009; Anselin *et al.*, 2000). However, judging by existing studies, although hinterland is important in explaining the development of urban system given that it supplies natural resources to central places, receives the influence of central places and may even become central places

<sup>4</sup> Refer to the empirical analysis of Tervo (2011) on regional structure evolution of Finland before and after the World War II.

itself, and many literature studies examined hinterland from the perspective of empirical pattern of urban system<sup>5</sup>, both central place geography theory and new economic geography theory paid little attention to the effect of service agglomeration of metropolitan on service sector growth in the hinterlands, especially in developing countries.

## 2.3 Summary

To sum up, for service sector, near to higher-tiered cities means not only the types of services hinterlands can get, but also the cost of achieving these services. Hence, service growth and employment of hinterlands will not only be subject to the market potential of central places and adjacent cities, but also subject to the distance to higher-tiered cities. The following parts attempt to conduct an empirical analysis on the role of distance in the growth of service sector of cities at or above prefecture level in the period 2002-2012<sup>6</sup>, offering policy implications on reducing regional gaps of service sector and the development of regional and urban service sector. Different from previous studies, this paper is committed to discussions on the magnitude and mechanism of interaction between central places and hinterland in such respects as intra-industry agglomeration, urban economy, spillover of human capital<sup>7</sup> and neighboring industries and purchasing power spillover using two types of sample of metropolises and hinterlands. Existing studies indicate that the institutional barrier of trade has important value in explaining China's regional economic growth and some literature studies have proven the existence of inter-provincial frontier effect (Poncent 2003; Amiti and Javorcik 2008) while frontier effect is partly driven by local protectionism and spatial exploitation<sup>8</sup>. Hence, we have included institutional variables including trade openness and local protectionism into the model for consideration.

---

<sup>5</sup> There are quite a few studies on hinterlands regarding empirical patterns such as city hierarchy. Refer to Gabaix, 1999; Eeckhout, 2004; Duranton, 2007.

<sup>6</sup> According to the *Planning*, considering that Anhui city directly receives industrial relocation and direct influence of Yangtze River Delta region, we included Hefei, Wuhu, Ma'anshan and Tongling cities into scope of analysis.

<sup>7</sup> A city's absorption power or the region's ability to convert knowledge spillover into growth is subject to the level of human capital (Rodriguez-Pose, 1999).

<sup>8</sup> As for the effect of local protectionism on trade, please refer to Bai *et al.* (2004) and Lu and Tao(2009) *et al.*

### 3. Empirical analysis

#### 3.1 Baseline Model

In order to incorporate factors affecting economies of agglomeration mentioned in neoclassical and new economic geography theory (Ottaviano and Pinelli 2006; Tabuchi and Thisse, 2006), we chose to follow the analysis framework of Roback (1982). According to the above analysis and assumption, the development level of service sector is subject to the effects of population density, local income, human capital level and tyranny of distance (distance to the higher-tiered cities). Our baseline model is as follows:

$$Y_{it} = \alpha_0 + \alpha_1 X_{it} + \alpha_2 DA_i + \tau_{it}$$

Where, DA reflects potential accessibility to higher-level service resources in high-hierarchy cities. Dependent variables describe service sector employment; service sector value added; service sector employment agglomeration and service sector value added agglomeration. For

independent variables,  $X$  is city  $i$ 's attribute vector, which includes trade openness<sup>9</sup>, urban density, resident income level and human capital level<sup>10</sup>,

and  $\tau$  is a residual error. Level of human capital is described by the ordinary high school population which reflects the local absorption of knowledge spillover. DA refers to the additional distance to the nearest higher hierarchy city, that is, the additional distance from the nearest metro city to the nearest higher hierarchy cities (km).

Different from previous studies, this paper has made the following special treatment to the selection and estimation of explained variables and explanatory variables:

First, it has overcome the defect of studying highly heterogeneous services as a whole<sup>11</sup>. According to definition of Browning and Singelmann (1975), service

---

<sup>9</sup> Due to unavailability of inter-city trade data, inspired by Fujita *et al.* (1995), port denotes the level of convenience of import and export in a region, so here, we use whether a city has a port to denote trade openness.

<sup>10</sup> In estimating growth using value added of service sector, we may also add the variable of initial per capita output level.

<sup>11</sup> Browning and Singelmann (1975) divided services into four categories by function: producer services, including banking, trust and other financial services, insurance, real estate, engineering and construction services, accounting and publishing, legal services and other types of commercial services; distributive services, including transportation, warehousing, communication, wholesale, retail (excluding catering retail); social services, including hospitals, education, welfare and religious groups, nonprofit organizations, postal services, government and other social services;

sector is divided into producer services, distributive services, personal services and social services for the research on their respective growth patterns. Given the regional attributes of China's culture and health sectors, this paper conducts a separate study on culture, sports and entertainment sectors.

Second, considering different development drivers, cities in three urban clusters are divided into two sub-sample groups of metropolises and hinterlands. If placed under the same sample group, the heterogeneity of service growth in hinterlands and metropolises is likely to be concealed and due to different levels of development, growth rates of service sector between metropolises and hinterlands are incomparable.

Third, in order to prove the existence of access penalty and its reinforcement attribute, this paper considers the impact of urban hierarchy system and interactions between cities, dividing distance variables into distance to neighboring central cities and incremental distance. In order to accurately measure incremental distance, this paper divided all cities of the three urban clusters at or above prefecture level into four hierarchies<sup>12</sup> in relation to population<sup>13</sup>, administrative level and economic vibrancy: the first hierarchy refers to national large city, i.e. Shanghai; the second hierarchy refers to regional large cities, i.e. Hangzhou and Nanjing, which are both provincial capitals and centers of an economic region; the third hierarchy refers to provincial capitals, which include provincial capitals Hefei and Ningbo as secondary provincial cities in addition to the above-mentioned two hierarchies; and the fourth hierarchy includes all prefecture-level cities.

## 3.2 Data

The sources of data analyzed in this research are from China City Statistical Yearbook 2001-2013, compiled by the State Statistical Bureau of China. Using panel data of cities at or above prefecture level from 2002 to 2012, this paper conducts an empirical analysis on factors affecting service sector employment and add-value in cities of the 3 biggest Chinese city clusters. In order to control sample heteroskedasticity, this paper adopted GLS regression method of panel data. According to Hausman test result, this paper estimated the samples using fixed effect model.

personal services, including household services, hostel and lodgment, catering, repair services, laundry, hairdressing, etc.

<sup>12</sup> See Wei Shouhua *et al.* (2012): *City Hierarchy and Service Sector Development – based on Share-Deviation Analysis Method*, *Industrial Economic Research*, 4<sup>th</sup> Issue of 2010, page 32 to 39.

<sup>13</sup> Based on standard of urban population.

### 3.3 Factors affecting service sector growth in hinterlands: panel data analysis

Appendix table 1 is the result of GLS estimation of panel data for hinterland cities of the three urban clusters. According to the result of fitting, with the exception of personal service agglomeration, the equation demonstrates strong explanatory power for changes in the employment and value added of other services. Generally speaking, improvement in transportation and information technology did not eliminate the effect of distance on service sector growth in three urban clusters of China. Distance from cities of higher hierarchy<sup>14</sup> will give rise to marginal penalty of distance on growth of local service sector; the causal effect of high-hierarchy cities on service sector of hinterlands not only exists but demonstrates strong heterogeneity as well.

As the top hierarchy metropolises in the region, Beijing, Tianjin, Shanghai, Shenzhen and Guangzhou has a centric driving effect on the value added and employment growth of all the service sectors of hinterland cities. The greater additional distance to them, the slower service sector grows, i.e. tyranny of distance does exist. As we can see from appendix table 1, second-hierarchy cities also have a major driving effect on the growth of value added and employment of some service sectors, especially the producer services and distributive services. The above conclusions are different from the result of empirical study of Partridge *et al.* (2008a)<sup>15</sup> on urban population growth of the United States and similar to the result of study by Duranton and Puga (2001) and Desmet and Rossi-Hansberg (2007) on the effect of high-hierarchy cities<sup>16</sup>.

As for the growth of service sector employment, nearest metropolis do not show any significant influence on service development in hinterlands (Appendix table 2), and there is also no significant correlation between population and income level of nearest metro and service sector employment growth, which did not verify the existence of market potential effects. The nearest metropolis has a driving effect on the growth of service sector value added, but proximity to the nearest metro cities has a certain restrictive effect on the growth of local social service sector. Greater distance from nearest metropolis also means highly probability for the growth of employment in service sector and the culture, sports and entertainment services agglomeration. Considering that service sector of regional center cities are

---

<sup>14</sup> Here it refers to the first-hierarchy and second-hierarchy cities.

<sup>15</sup> Partridge(2008a)'s study on hinterland cities of the US indicates that proximity to higher hierarchies of cities in an urban system is a major driver of population growth in hinterland cities.

<sup>16</sup> Duranton and Puga(2001) and Desmet and Rossi-Hansberg (2007) *et al.* believe that technology innovation will increase the value of agglomeration economies of a certain type and thus increase the benefits from proximity to the highest-hierarchy city.

still in the stage of agglomeration, proximity to them will exert a shadow effect on the service sector employment of neighboring cities. Comparing to the distance effects of high-hierarchy cities, market potential effects have a relative low impacts on the development of service sector growth of hinterland cities, and the larger the metropolis is, the stronger such spatial exploitation becomes.

On the whole, central agglomeration effect is more important to producer services and distributive services, which provide intermediate rather than final products. Compared with other cities, cities of the highest hierarchy have the most significant effect of dispersion on neighboring regions and the most of growth momentum for producer services and distributive services in hinterland cities. Growth of less tradable personal services is traditionally considered to be subject to the effect of local factors. Paul Krugman noted in his *Geography and Trade* (2000) that “(to the effect) in the second half of the 20<sup>th</sup> century, a considerable number of US workforce were employed in service sector rather than manufacturing. Many of these services are untradeable and have the same geographical distribution with population employed in the manufacturing of goods – regional Gini coefficient of fast food stores, day care centers and divorce lawyers must be very close to zero.” Though the empirical result indicates that employment growth of personal is not influenced by geographic factors, but social and creative services is still subject to the integrated effect of spatial spillover of higher-tiered cities. For social services that have the nature of public goods, proximity to public infrastructure of nearest metropolis will result in the loss of clients and thus restrains development of local social services. For cultural services that Chinese cities are enthusiastic to develop, hinterland cities close to the first hierarchy cities have a natural advantage of talent, market and knowledge spillover but second-hierarchy will not have a significant spillover effect. As for the third-hierarchy cities, near to them will even have a shadow effect on the development of creative service employment in hinterlands (appendix table 2).

In addition to distance, service sector of hinterland cities in the three urban clusters is subject to the impact of some other factors. Different from conclusions of Murphy *et al.* (1989) and Ades and Glaeser (1995) on industrial development and population agglomeration, industrialization and urbanization failed to promote value added and employment of service sector as a whole. Service growth of hinterland cities is mainly correlated with geographical distribution of purchasing power, i.e. household income level, and urban density do not has a significant effect on service sector employment. Initial scale is in positive correlation with service sector employment, which suggests that service sector agglomeration is a source for the increase of value added and job creation of local services. This conclusion supports relevant assessment of Desmet and Fafchamps (2005) and Fallah *et al.* (2012). Similar to the conclusions of Brühlhart and Sbergami (2009),

Henderson (2003, 2005) and Fujita and Thisse (2002), initial industrial scale can self-reinforce and promote growth and localization economies have a significant positive effect on the job growth of service sectors. That is to say, for job growth of service sector, proximity to large cities with input factor and client resources is more important than the market potential. Factors of trade openness such as access to port will promote the growth of value added and employment in service sector. Despite unclear causal relationship<sup>17</sup>, human capital inventory can significantly promote the value added and job growth in service sector as a whole. However, availability of human resources and absorption of technology spillover are not embodied in the growth of the producer, distributive, personal and social service sectors. Different from the study of Sridhar (2010) on India, accumulation of human capital cannot effectively promote the growth of service sector in hinterland cities and currently all service sectors are yet to enter the stage of technology and human capital driven growth.

### **3.4 Neighbour factors affecting service sector growth: spatial regression models**

Given the likely presence of spatial dependence, spatial panel regression models were run for testing. In order to reflect the spatial influence of cities of the same hierarchy, we have included the average distance variable of nearest two neighboring prefecture-level cities into the equation. In these spatial regression models, neighbouring cities are defined using geographical proximity as measured and weighted by the travel distance. Appendix table 3 and table 4 shows a clear pattern of positive spatial autocorrelation among cities.

On the whole, there's no difference with respect to distance to the higher-tiered cities factor between non-spatial and spatial regression models. Similar to the conclusion of Sridhar (2010), penalty of distance has a significant effect on the growth of service sector and sub-sectors in hinterlands of three urban clusters. The more distance from higher-hierarchy cities, the slower service sector grows. Different from the growth pattern of non-spatial models, the sources and impact direction of spatial spillover effect are relatively heterogeneous of higher-hierarchy cities, and the nearest metro cities have a significant effect of negative spatial spillover on the growth of service sector and sub-sectors in hinterlands, which indicates that the third hierarchy metropolises of China's three city clusters have a strong absorption power of resources from the hinterlands.

---

<sup>17</sup> For a human capital intensive industry, it is possible that the abundance of local service jobs resulted in the relative abundance of human capital inventory.

Regarding the spatial spillover effect of neighboring cities at the same level, lower-hierarchy cities have not played a supportive role to the growth of service sector in hinterlands. Service sector value added and producer service employment has a significant effect of agglomeration, and neighboring cities have played their role as labor pool for service sector, especially personal and social service employment. As for service agglomeration, however, competition effect of growth is at play, i.e. proximity to cities of the same hierarchy with significant income level has a siphoning effect on the development of local service sector. Neighboring cities with great scale of population will benefit the development and agglomeration of local social services.

Different from the results of non-spatial models, population density is also a major driver of service sector development in hinterlands, especially for value added. Human capital level has a strong positive effect on the development of service sector and sub-sectors, which indicates that knowledge spillover and absorbing capability are crucial to the service sector growth in hinterlands.

#### **4. Conclusions and policy implications**

Location of a city in the city hierarchy system is vital to the development of service sector. Exclusion of distance factor in the research on service sector will result in the negligence of an important dimension in service sector and cause deviations in the result of study. Result of this paper indicates that continuous improvement in transportation infrastructure and information technology did not flatten the development of service sector in the biggest three China's urban clusters, and on the contrary, highlights the value of central place agglomeration. Access and proximity to higher-tiered cities especially the first hierarchy cities brings about conveniences arising from economies of agglomeration and are more outstanding in the promotion of service sector growth in hinterland cities, compared with market potential factors described in NEG.

Empirical study on the three Chinese urban clusters suggests that the penalty of distance on the growth of service sector in hinterland cities not only exists but is a major factor of influence. Service sector agglomeration in regional central cities is currently in continuous enhancement and affects service sector growth of hinterland cities in the form of regional competition and shadow effect. So hinterland cities may benefit from mutual growth by improving transportation with first and second hierarchy cities and proactively matching service demand from them. Third-hierarchy cities affect neighboring hinterland cities mainly in the form of supply spillover and currently, hinterland

cities can only passively receive the effect and proactively undertake consumption spillover.

Empirical results of this paper support the analysis of Fujita and Mori (1997), Fujita et al. (1999) and Chen et al. (2010) on center-peripheral model but having taken city hierarchy system into account, relationship between center and hinterland becomes more complicated, becoming a dynamic system featuring the coexistence of centric drive and spatial exploitation and interaction between support and competition. In addition, this paper also suggests that service sub-sectors are indeed highly heterogeneous, although study on service sector as a whole may reflect general patterns of its development, it may also conceal special factors of influence for specific industries and may even arrive at totally opposite results.

This study helps deepen our understanding on the tendencies of new-type-urbanization and growth patterns of service sector. In recent years, there have been heated debates on the “diseases of big cities” in China, which aroused reflections among academia and decision-makers on unilateral city circle and uneven development arising from it. In fact, both the NEG theory and our empirical results indicate that debates are meaningless on whether mega-cities or small and medium-sized cities are more desirable in new-type-urbanization. Agglomeration is a self-reinforcing existence and the strength of market derives from economies of scale rather than government planning and plays a decisive role in the formation of city system linked by service sector. The world has to become pointed before it becomes flat. Whether spatial spillover or shadow effect takes hold depends on the development stage of a city. Policy-enabled creation of multi-core network development pattern to achieve regional growth convergence is not only damaging to the spatial spillover of mega cities but will cause serious efficiency loss and impede the development of regional service sector as well. In order to promote the development of regional service sector, mega cities as primary cities of urban clusters should not only expand in space but focus on the upgrade of urban functions, develop productive and distributive services, avoid regional protectionism in service resource allocation. Hinterland cities should offset the tyranny of distance by improving transportation infrastructure connecting with mega cities and proactively match the spillover of services including recreation and health services from regional central cities for balanced development of service sector based on reasonable division of labor.

# **XXV. International RESER Conference: Host country impact of services FDI: the case of Visegrad countries**

*Zoltán Gál, Magdolna Sass*

Centre for Economic and Regional Studies, Hungarian Academy of Sciences

*This paper contains the main results from a work-in-progress research on the impact of three selected services sector FDI on various host country characteristics in the case of the four Visegrad countries. FDI in three service sectors: financial services, ICT-related services and business services are analysed, which differ in terms of their predominant horizontal or vertical nature. We found both the employment effect and export effect being significant only in the case of the predominantly vertical business services FDI. Furthermore, we analysed the impact of financial FDI on the economy, which we found significant for GFCF with considerable country differences especially after the crisis.*

## **1. Introduction**

Services sectors have been important “hosts” to inward foreign direct investments (FDI) in former transition economies and among them in Hungary. In the nineties their main aim was to supply the domestic market of the host country with various services, which were unavailable or less developed in the pre-transition era. Thus their main motivation was market-seeking and they can be characterised as horizontal FDI. Starting from around the beginning of the years 2000, more and more FDI projects arrived to Hungary, the main aim of which was to build up export capacities in certain service sectors relying mainly on the abundantly available mid- to high-skilled local labour with relatively low wages – thus the efficiency-seeking motive has become increasingly important for services foreign investors and vertical FDI projects mushroomed. While the host country impact of manufacturing FDI is analysed extensively in various areas, the number of studies dealing with services FDI is much less numerous, especially in fields such as exports or employment and especially in former transition economies.

The main aim of the research is to analyse the impact of FDI on growth, export and employment in selected service sectors of the host country. Three service sectors: financial services, ICT-related services and business services were analysed in the case of Hungary. The three service sectors were selected, because i) they are important host sectors to FDI in Hungary; ii) they differ to a great extent in terms of their export-intensity (export/sales) ratios: business services being highly export-oriented, financial services sell their products mainly on the domestic market, while ICT-related services can be positioned in-between the other two sectors. Furthermore they can be classified as predominantly horizontal (financial), confluent horizontal and vertical (ICT-related) and predominantly vertical (business services).

## 2. Background: theory and literature

FDI is of outstanding importance for the CEE countries and among them Hungary. FDI inflows have increased in the CEE in the past 20 to 25 years to become the most common type of capital flows. FDI inflows into CEE economies has been a vital factor in the first stage of privatisation, and FDI became the predominant type of incoming capital investment in the first stage of the economic transition. (See among others Holland et al., 2000 or Kalotay, 2010.) This process not only was to facilitate the restructuring and transformation of centrally planned economies but also the privatization process, i.e. the increase of the share of private ownership at the expense of state-ownership. In services, the banking and insurance sector and later other business services became the primary targets of strategic foreign investors, resulting in significant inflows of FDI in these sectors, connected mainly to the privatisation of state-owned banks and insurance companies in the financial sector and to mainly greenfield projects in the other services sectors. Similarly to global processes foreign investors' entry has been geographically/regionally concentrated, and the main investors have come from traditional/strong economic and trading partner countries (from mainly eurozone countries) of the host countries.

The impact of FDI on the host economy is widely analysed. In theory, companies with foreign participation may affect positively the economic performance of the host country. (Blomström, Kokko, 1997) Their role is of special importance in the case of an economy in transition. According among others to Lankes, Venables (1996) FDI has often been viewed as a potential catalyst for the economic transition. It can accelerate economic development and transition from a planned to the market economy. It may increase the production base in a country, which lacks capital and new investments. FDI may increase productivity; it can raise the level of competitiveness. It can transfer technology and know-how and spread managerial and marketing skills by transactions with domestic firms. It contributes to the restructuring of existing enterprises. It may help the development of markets, relevant behaviour of economic agents, a market based business culture and market institutions. However, these positive impacts do not occur automatically. Companies with foreign participation may form a separate island in the economy, having very limited contacts with local enterprises. They may conserve the technological backwardness of the host country by transferring low value-added activities. They may make the host country overspecialised on a few products thus exposing it to an exceeding extent to the business cycles of the world economy. They may cause political problems as well. The responsibility of the economic policy of the government lays in trying to divert the balance towards the positive impacts of FDI. Blomström and Kokko (1997) identified channels for the FDI spillovers, as backward linkages, forward linkages, training of employees and demonstration and competition effects. Venables and Barba Navaretti (2004) distinguish between the impact on the host countries of vertical and horizontal FDI.

Empirical evidence is inconclusive regarding the positive impact of FDI on the host economy. In many cases, empirical analysis could not show a positive and/or significant relationship between FDI and economic growth. For example in the case of studies analysing data for a group of countries, no evidence of a positive impact of FDI on growth is found by de Mello (1999), Crankovic and Levin (2000) or Lipsey (2000)). On the other hand, Borensztein, de Gregorio and Lee (1998) showed, that

the impact of FDI can be positive on economic growth, depending on the level of human capital and on the absorbing capacity in the host economy. If the quality of human capital reaches a threshold level, FDI can significantly increase the rate of economic growth. Hermes and Lensink (2000) presented similar results. They emphasized that not only the level of human capital, but also that of the financial markets must reach a certain threshold level. Greenaway and Görg (2001) over-viewed over 30 empirical surveys on potential positive growth effects of FDI in various countries. One main conclusion of their paper was that positive and negative impacts usually simultaneously affect host economies. The interference of the two may eliminate measurable positive impacts. Majcen et al (2003) drew similar conclusion after an analysis of spillover effects in transition economies. Campos and Kinoshita (2002) found that FDI affected economic growth positively and significantly in the period between 1990 and 1998 in transition economies. Gorodnichenko et al. (2013) showed using firm-level data, that the various channels of FDI spillovers differ in their significance, as well as sectors, FDI source and characteristics of the business environment, education of workers etc. affect the impact of FDI on the host economy. Iwasaki and Tokunaga (2014) prepared a meta-analysis of studies analysing the macroeconomic impacts of FDI in transition economies and found that the effect size and statistical significance of the estimates depend on study conditions: especially the estimation period, data type, estimator, and type of FDI are important factors that affect the heterogeneity of the results. Their main conclusion is that further rigorous research is needed to identify the true effect.

The impact of services FDI on former transition economies is relatively rarely analysed. Generally, Aykut and Sayek (2007) show that the sector composition of FDI has an effect on its growth impact. Eschenbach and Hoekman (2005) found that reforms in services policies result in a higher inflow of FDI into these sectors and thus positively affect the post-1990 economic performance of transition economies. Riedl (2010) found similar results, though she assumed that services FDI is almost exclusively market-seeking. Gorodnichenko et al. (2013) showed that services firms benefit more from FDI. The impact of business services FDI on the local economy, emphasizing the vertical nature of it, was presented by Sass (2011), showing that spillovers are scarce because backward and forward linkages with indigenous firms remain limited. Hardy et al. (2011) compare the local impact of horizontal and vertical business services in the Czech Republic, Hungary and Slovakia. They show the differences in local impact, stating among others that the most salient static impacts of these investments are on the labour market, where horizontal investments provide fewer, but more skilled jobs than vertical investments. Gál (2004) analysed financial services FDI in Hungary from that point of view.

Overall, there are numerous studies analysing the impact of FDI on the host economy, but regarding the nature of that impact, the evidence is inconclusive. On the other hand, there are only a few studies on the impact of services FDI on the host economy, especially for former transition economies.

### **3. Methodology**

Measurement and data problems are especially widespread in services, and in certain services sub-sectors. (See e.g. Sass and Fifekova, 2011 for business services in post-transition economies.) FDI and export data are especially affected (see e.g.

Pindyuk, 2008 or Francois et al., 2009). The main aim of this section is to analyse the impact of FDI on growth, export and employment in selected service sectors of the host country. Three service sectors: financial services, ICT-related services and business services were analysed in the case of Hungary and the other three Visegrad countries. The three service sectors were selected, because they are important host sectors to FDI. In 2012, business services represented 32.3 % of total inward FDI stock, financial services: 6.2% and ICT-related services 0.4% in Hungary. (Chart 1) These are important host sectors in other CEE countries as well, especially for the other three Visegrad countries: the Czech Republic, Poland and Slovakia. (Sass, Fifekova, 2011)

Chart 1 FDI stock in selected service sub-sectors in Hungary, 2008 and 2012, million euros

Source: Hungarian National Bank, <http://www.mnb.hu/Statisztika/statisztikai-adatok-informaciok/adatok-idosorok/vii-kulkereskedelem/kozvetlentoke-befektetesek/bpm5-modszertan-szerinti-adatok-2013-ig-archiv>

Furthermore, they differ to a great extent in terms of their export-intensity (export/sales) ratios: business services being highly export-oriented, financial services sell their products mainly on the domestic market, while ICT-related services can be positioned in-between the other two sectors. Connected to this, the three selected service industries are different in terms of their horizontal or vertical nature: financial services are predominantly horizontal, offering the same services as in the other home and host countries of the investing multinational (bank or insurance company). At the same time, ICT-related services are confluent horizontal and vertical, where not only the same services are offered, but there is another type of motive and project: where activities are located in the host economy in order to minimise costs and the output is “fed back” into the activity of the multinational company and thus (intra-company) export is occurring. Furthermore, the third selected service industry, business services is predominantly vertical. As a “benchmark”, we also added data on an

important manufacturing sector, playing a significant role in all Visegrad FDI stock and economy: machinery.

As for the methodology, we rely on the analysis of a panel dataset containing time series data for the period 1990/95-2013 on FDI inflows, stock, FDI share on GFCF, sectoral FDI, export and import, employment and various composite indicators proxying the level of development of the analysed services sectors. Using SPSS, we examined how FDI in a given sector impacts upon employment, exports and the other variables. Basically we have chosen two options in the framework of multivariate regression analysis run by SPSS for detecting the sectoral effects of FDI. Both the selected explanatory variables and dependent variables have a sector-related nature. FDI impact can be measured on exports or employment within the selected sectors as OECD database for Visegrad countries with fine data granularity available for analysis. Export and employment in this case are dependent variables. Another option when the sector-specific variables are explanatory variables (eg. FDI inflows into the financial sector), while the dependent variable is selected from macro economic data (e.g. GDP growth rate). The second case is a much stronger argument, which presupposes that FDI has a direct impact on growth, not just on the sector itself, but also has implications for the whole economy. First we examined the FDI effects on the financial, ICT, other business services, and selected manufacturing sectors, then we tested the hypothesis whether financial sector FDI has a much more significant effects on the whole economy. The analysis is performed in three distinct periods (transition: 1994-1999, boom: 2001-2007, crisis: 2008-2011). We expected that on the basis of the theory, that both vertical and horizontal services FDI sectors increase employment and while vertical increases exports, horizontal decreases it.

## 4. Results

As it was described in the methodology section, we have carried out various calculations on a database containing data for the four Visegrad countries: the Czech Republic, Hungary, Poland and Slovakia. The results of our calculations can be found in Table 1.

*Table 1 Impact of FDI on employment and export in different sectors in the Visegrad countries between 2001-2011*

| Dependent variables             | Sectoral employment within the total employment |                        | Dependent variables             | Export as % of GDP |                        |
|---------------------------------|---|------------------------|---------------------------------|--------------------|------------------------|
| Explanatory variables           | p-values  | Regression coefficient | Explanatory variables           | p-values           | Regression coefficient |
| Financial sector FDI , % of GDP | .919  | -.035                  | Financial sector FDI , % of GDP | .994               | -.002                  |
| ICT sector FDI FDI , % of GDP   | .321  | -.351                  | ICT sector FDI FDI , % of GDP   | .087               | -.579                  |

|                                      |      |      |                                      |      |      |
|--------------------------------------|------|------|--------------------------------------|------|------|
| Business services FDI FDI , % of GDP | .284 | .351 | Business services FDI FDI , % of GDP | .034 | .645 |
| Machinery FDI FDI , % of GDP         | .686 | .134 | Machinery FDI FDI , % of GDP         | .227 | .471 |

Employment: OECD:

Labour/Labour Force Statistics/Annual labour force statistics/Employment by activities and status

The analysis tried to assess the magnitude and significance of the impact of FDI in the three selected services sectors and for comparative reasons the one selected manufacturing sector. In the case of employment we cannot find extremely low p-value, which means the FDI inflows do not exert significant influence on the employment growth of the particular sectors. The employment effects of FDI were the lowest in the financial and the automotive manufacturing sectors. The increase of employment in the machinery sector has a low correlation coefficient with sectoral FDI as a percentage of the GDP, which means that due to the huge import generated by local car manufacturing and other assembly plants resulted in a kind of crowding out effect in the labor market as well. This has a direct impact on the domestic supply chain manufacturers which decreased the labour force also in the related industrial sectors (e.g. metal production).

At the same, in the case of the financial sector not only the lack of significance of the correlation between the financial sector FDI stock as a percentage of GDP and employment is the case but the regression coefficient is negative indicating the decrease in financial sector labour force. This is the direct consequence of the general consolidation, technological upgrading and to a large extent the direct result of the crisis affecting heavily the employment of financial sector in the Visegrad countries, and within this group in particular in Hungary.

The relatively the largest p values (although above the 10% threshold) were found in the case of the business services and ICT services. However in the case of business services there is a positive impact on employment growth while negative regression coefficient in the ICT means that FDI increase leads to a decrease in the employment. Although this can be tested by the Granger's causality test in the future, but this negative coefficient is probably the consequence of the less labour intensive character of this particular sector. In the Visegrad countries the expansion of business services is apparent, the number of projects and employment increased substantially in recent years (see e.g. Hardy et al., 2011). Thus we can conclude here that vertical type FDI in services led to an increase in employment, while the horizontal and confluent types there is no such effect detected.

If we move to the examination of the impact of the sectoral FDI on the relative export intensity of the particular sectors we can find much lower p-values indicating the largest significance of FDI in business services (0.034) and in ICT services (0.087). Business services are proved to be the largest export-oriented sector (with the largest correlation coefficient: 0.645) not only in comparison with all the other sectors in question but also with the ICT sector which has a negative coefficient. This means confluent horizontal and vertical FDI in the ICT sector still follow the market demand led strategy (domestic market oriented) and not necessarily leads to export in the ICT

sector, rather, it generates imports. Similar is the case with the predominantly horizontal financial services. On the other hand, the mainly vertical type business services FDI generates exports. These findings are in line with what was expected on the basis of theory, however, for the confluent case a higher positive export impact was expected.

Table 2 *Impact of financial sector FDI on macro-economic performance between 2008-2011*

| Dependent variables | GDP growth rate |                        | GFCF     |                        |

| Hungary             | .544            | -.280                  | .083     | -.695                  |

**Explanatory variable:** Share of Financial FDI

Sources: as in Table 1

If we take a closer look at the crisis period the previously mentioned country stability effects can be also applied to Czech Republic and Slovakia where the banking sector did not lose its financing ability even during the crisis. This is verified by positive and significant impacts of financial FDI both on the GNI per capita and GFCF. In the rest of the Visegrad countries financial FDI lost its significant explanatory effects.

Besides labour market and foreign trade impacts we analyzed the macro-economic impact of the financial FDI (as explanatory variables) choosing GDP growth rate, GNI per capita and gross fixed capital formation (GFCF) as dependent variables. (Table 2) Data were available for the period between 2001 and 2011 so we were able to distinguish between the economic boom (2001-2007) and the crisis (2008-2011) periods. Annex tables contain the results of the various calculations. To sum these up, on the Visegrad level we cannot find significant impact of financial FDI on the GDP growth and GNI per capita. We argue that the direct effect of the financial sector on economic growth and development cannot be detected during the period between 2001 and 2008. However, the impact of financial FDI on gross fixed capital formation is not only significant (0.002) but FDI has a positive impact on GFCF. (This is due to the direct financing effect of the banking sector). We can also measure this impact at the level of individual countries. We found positive and significant correlation in the cases of the Czech Republic and Slovakia where the banking sector has the strongest financing effect). In the case of Poland this correlation is non-significant while in Hungary significant and negative. This latter case means that financial FDI in Hungary did not finance the real economy but rather the household consumption. The second concern is that the allocation of foreign capital has been changing during the pre-crisis period as less foreign capital is directed to the private sector (through FDIs, loans) but more inflows are channelled via the public sector (through government bonds, EU funds), which can undermine the potential impact of financial FDI on growth and investments.

## 5. Conclusion

This paper contains the results of an ongoing research, where we tried to assess the impact of three selected services sector FDI on the local economy in the area of employment and exports in this case of the four Visegrad countries. We have selected three service sectors, which represent a relatively high share of the overall FDI stock on one hand and which are different in terms of being predominantly horizontal (financial services), vertical (business services) or confluent (IT-services) nature. Our preliminary findings are more or less in line with what could be expected on the basis of the theories in terms of the impact of these services FDI on exports: FDI in the sector with predominantly vertical projects, business services has a positive impact on exports, the sector with predominantly horizontal projects, financial services had no effect, while contrary to the findings, the confluent sector, IT-services we could not find a positive impact, which indicates that even in that sector, FDI projects are mainly horizontal and are attracted mainly by the domestic market of the analysed countries. In terms of the employment effect, surprisingly, it is only FDI in the sector with mainly vertical projects, business services, which had a positive impact on employment, while in the horizontal sectors no such effect was traced. This is contrary to the findings of other research.

The second part of the research tried to assess the impact of financial services FDI on the Visegrad countries as a group and at the individual country level. The two main areas analysed were GDP growth and gross fixed capital formation. Here we assumed that financial services FDI has a much stronger impact on the economy as a whole compared to other industries and sectors, via the impact of the financial sector on the economy. We found a positive impact of financial FDI on GFCF in the country group, but individual countries differ to a great extent.

Further research will address the directions of causality and it will include the extension of the variables in order to find more clear explanations about how vertical and horizontal services FDI impacts upon the host economies and overall, what the impact of services FDI can be on host economies.

## **D2: Collaboration, networking and innovation**

*Chair: Lars Fuglsang*

# Towards a Multi-level Framework of Collaborative Innovation in Tourism

Olga Høegh-Guldberg<sup>1</sup>, Lars Fuglsang<sup>2</sup>

<sup>1</sup>Lillehammer University College, <sup>2</sup>Roskilde University

*Tourism companies share resources and need to collaborate in order to develop and innovate. However, in the literature on tourism innovation, many different types of collaboration can be found, and it is unclear what role they play for innovation. In the growing research field, scholars use such terms as 'tourism network', 'destination', or 'innovation system' or combine some of them. The purpose of this paper is to describe and compare six different perspectives on collaboration and discuss their role for innovation in tourism. The review also discusses the type of mind-set that underpin the different types of collaboration ranging from the more personalized firm-to-firm collaboration to more generalized forms of collaboration with stakeholders within an institutionalized environment.*

## 1. Introduction

Research on innovation in services progresses rapidly as innovation is considered necessary for doing business in constantly changing environments. However, innovation in services has gained importance in research only during the last few decades, and the topic seems underexplored compared to all the attention drawn to how innovation takes place in manufacturing. Innovation can be defined as the realization of new services in an organizational context or the market. There are various ways to understand and analyze innovation, with the main trajectory shifting from Schumpeter Mark I focusing on the role of individual entrepreneurship for economic development (Schumpeter 1934), to Schumpeter Mark II, focusing on the role of R&D for economic development and wealth creation (Schumpeter 1947) towards a broader concept of Schumpeter Mark III (after Schumpeter), where innovation is seen as an interactive process (Lundvall 1988) as well as a 'strategic response to change-processes in the market and society' for sustainable growth and survival of organizations (Sundbo and Fuglsang 2002, 1). As the perspective of innovation as an interactional process becomes more accepted, it raises scholarly awareness of the importance of collaborative innovation, which is the main concept in this paper. While today there is a very large body of literature on collaborative innovation, we still need good ways to integrate these approaches into a conceptual framework of collaboration to understand how innovation takes place in a business and societal context. This paper will contribute to creating such an integrative framework based on the existing literature.

The remainder of the paper is structured as follows. First, the review method used to elaborate an integrated framework is described. Next, some key aspects and definitions of collaborative innovation are explained. Following this, five perspectives on collaborative innovation are discussed with the sixth approach being further de-

veloped. Finally, the six perspectives are integrated into a multilevel framework of collaborative innovation and the contribution of the paper is discussed.

## **2. Comparing Strategies for Research on Collaborative Innovation**

The widening perspective of innovation theory follows a more general shift in organizational theory of the 1960th, when the emphasis is moved from “controlling internal activities to managing external constraints” (Whetten 1981, 1). Richness and variety of research in the ‘new’ paradigm allowed reviewing and creating classifications. Five decades later the debate does not seem to fade away but to attract more interest in the research world. The inter-organizational paradigm, studying a set of inter-connected actors rather than isolated elements, seems to enter a number of disciplines “such as economics, sociology, anthropology, psychology, and political science as well as in organizational behavior, organization theory, and strategic management “ (Smith, Carroll et al. 1995, 9).

Going beyond organizational boundaries allows learning the experience of others. Yet, an increased level of interactions within a field may also cause what DiMaggio and Powell (1983) named isomorphic change. Therefore, quite early research came to recognize the dilemmas of inter-organizational relations and institutional influences (Meyer and Rowan 1977, DiMaggio and Powell 1983), i.e. that collaboration may lead to innovation but also adaption to and engagement in a societal context.

As “recent research (on innovation in tourism) is now reaching a level which is comparable with studies in other economic sectors” (Hjalager 2010, 1), scholars operate with such terms as ‘tourism network’, (Håkansson and Snehota 2006), ‘destination’ (Pearce 2013), or ‘innovation system’ (Mattsson, Sundbo et al. 2005), etc.. Yet, there is a need for an integrative framework that helps us understand the dilemmas, arenas and levels of collaboration. Therefore, the main contribution of this conceptual article is to create such an integrative framework by reviewing recent research literature on collaborative innovation in tourism and as a result, building a multi-level framework that give greater attention to the varied aspects and ambitions in collaborative innovation.

The paper compares six generic strategies for research on collaborative innovation that are relevant to tourism research. The paper is inspired by a similar attempt by Pearce (2013) to distinguish conceptual frameworks of destinations based on exemplary papers. The generic strategies are compared with regards to the main characteristics inherent to each of them. Not all of the six approaches have been used extensively in research about tourism, but where they have, some examples will be given. If possible, the study goes back to a foundational work that describes the main characteristics of the approach. In cases where no foundational work can be identified, a review of a wider spectrum of articles is made in order to point out the main characteristics (cf. Pearce 2013).

This form of review is chosen in order to clarify varied positions in the literature that involves a collaborative approach that are often not clearly distinguished. Furthermore, more specifically, the paper also seeks to discuss how an emerging per-

spective on collaborative innovation in tourism based on a notion of institutional innovation (Hjalager 2002, 2010) can be framed, what it adds to research on collaborative innovation in tourism, and how it can be developed.

The paper provides analysis of each approach by theoretically deducing the main characteristics which are then systematized in a table. The table includes conceptualization of each approach, types of studies predominantly used in research literature, as well as how collaborative innovation is possible in each approach. While the comparison of research strategies is meant to contribute to a better understanding of varied forms of research in studying collaborative innovation in tourism, it also helps us to understand the particularities of an institutional approach to collaborative innovation.

This is a broad, expert-based review where the analyzed literature was gathered by means of snowballing method. The process of picking up the sixth particular collaborative approaches was facilitated by discussions with colleagues making interpretations of the identified literature thematic. Once approaches and exemplary papers were identified, the sample of articles for the review was widened by means of Google scholar search with the key words 'collaborative' plus 'innovation' plus 'tourism' (where possible), picking the most relevant articles published in international journals for the research purposes as well as published anthologies in international volumes. The method selection is caused by the large number of research articles on each approach, which otherwise would make it difficult to seize within the limits of the article in order to construct the unified framework.

### **3. Collaborative Innovation**

Collaborative innovation being seen as one of the ways to perform innovative activities can be defined as "bringing together public and private actors with relevant innovation assets, facilitating knowledge sharing and transformative learning, and building joint ownership to new innovative visions and practices" (Sørensen and Torfing 2012, 1). This definition is derived from studies of public innovation but may also be used for the private sector. The advantage of the definition is that it does not merely focus economic value but innovative visions and practices in a broader sense. The first part of the definition focuses on the interaction of agents involved in the innovation process. The combinations of such interactions will be further discussed in a more detail. The second part of the definition outlines multiple approaches to collaborative innovation such as learning, which is also a research interest in tourism, for instance captured by the notions of Learning Tourism Destination (Schianetz, Kavanagh et al. 2007, Liao, Chang et al. 2010), knowledge sharing (Matlay, Braun et al. 2006, Svetlik, Stavrou-Costea et al. 2007, Baggio and Cooper 2010), or building innovative vision (Bramwell and Lane 2000). These approaches are useful in identifying studies on collaboration without explicit use of the innovation as a term. Finally, the last part of joint management of the outcomes of innovation, the visions and practices, are left for further research.

Tourism as arena for collaborative innovation may be defined broadly as "all those firms, organizations and facilities which are intended to serve the specific needs and wants of tourists" in a given location (Mattsson, Sundbo et al. 2005, 358). These arenas are often characterized by a large number of SMEs (Hjalager 2010),

rather low professional qualification of employees (Rønningen, Lien et al. 2013), seasonal employment, destination development (Shih 2006), and specificity of tourism product and experience-oriented demand (Arnould and Price 1993). Collaborative innovation may be important for developing tourist products from a wholeness perspective, but tourists companies are often small with few resources for networking and large-scale cooperation (Fuglsang and Eide 2013).

Collaboration on innovation can be compared on different dimensions. The collaborative relationships can be formal or informal. Formal ties are usually intertwined with multiple informal connections between companies. The difference can be defined by “characteristics of contractual obligations and formal structures of control” (Smith, Carroll et al. 1995, 10). According to Ring and Van de Ven (1994) formal relations can outgrow formalities and develop into informal type. However, it might also happen the other way round by contracting informal cooperation where ‘behavioral norms’ would be of a great importance (Smith, Carroll et al. 1995).

In addition, cooperation can be local or distanced (global) (Asheim and Isaksen 2002, Bathelt, Malmberg et al. 2004). The difference then often is in ‘place-specific’ coupled with tacit knowledge opposite to ‘world-class’ coupled with codified knowledge. Collaborative innovation can focus exploitation versus exploration, i.e. experimenting with new solutions versus appropriating new inventions (Benner and Tushman 2003, Andriopoulos and Lewis 2009, Sørensen and Fuglsang 2014). Innovation processes are often seen as open because an organization “cannot innovate in isolation” (Dahlander and Gann 2010) but they may also be conflicted and based in mutual exploitation (Obstfeld 2005). There are also parameters characterizing collaboration itself such as network position, goal congruence etc. These characteristics as well as the type of cooperation are important in studying empirical phenomenon of collaborative innovation and will be further reflected in the integrated framework.

In the following section, five understandings of collaborative innovation will be further developed based on a review of the main characteristics of the approaches: dyadic relations, innovative communities, social networks, destinations and innovation systems. Further, the sixth approach of institutional environment is discussed as broader setting for collaborative innovation claiming the potential of sixth form of such cooperation.

### **3.1. Dyadic Relationships**

The concept of dyadic business relationships attributed to earlier works on interfirm collaboration, is a critical form of business relation beyond organizational boundaries. It is an extensive topic within management, marketing and organizational studies, especially within the so-called international marketing and purchasing group (IMP) in international marketing research. Since the discussion on dyadic business relationships takes place from around 1960 to 1990, the main sphere of research is manufacturing with the emphasis on buyer-seller relationships (Dwyer, Schurr et al. 1987), manufacturer-distributor relationships (Anderson and Weitz 1989, Anderson and Narus 1990), and broader exchange relations in marketing (Frazier 1983), interfirm adaptation (Hallen, Johanson et al. 1991), etc.

Looking into dyadic business relationships, Anderson, Håkansson et al. (1994) analyzed a number of studies within the approach providing its further conceptual

development. While not denying a wider environment of a firm, these scholars chose to concentrate on a 'focal firm' and 'focal relation'. They argue that "if business networks are to possess advantages beyond the sum of the involved dyadic relations, this must be due to considerations that take place within dyadic business relationships about their connectedness with other relationships" (Anderson, Håkansson et al. 1994: 1). Studying focal relationships "connected to several different relationships", scholars discuss their functions: firstly, by the essential elements of activities, actors and resources; secondly, by primary and secondary functions. The key difference between the two types of functions is whether positive and negative effect of relationship come from the interaction of firsthand focal firm relation with its partner, or from being (directly or indirectly) connected to other relationships. The outcomes of the two types of relationships may supplement each other. But this is where innovation is first looked upon as an outcome of a user-producer dyad: based on the premises of "interlinking of activities, creative leveraging of resource heterogeneity, and mutuality based on self-interest of actors" (Anderson, Håkansson et al. 1994, 3). Furthermore, innovation may also be an integrated outcome of innovative effects of several dyadic relationships. To which extent a focal firm can be influenced or develop such an outcome must then be dependent on actor's network context, i.e. a 'relevant' part of the network. The key difference between dyadic and network perspectives, scholars define as "the focus on relationship states (e.g., the state of cooperation in the relationship) in the dyadic relationship perspective versus the focus on activities in the network perspective" (Anderson, Håkansson et al. 1994, 7).

Even though later in his work Håkansson mostly operates with the term network, there is still an emphasis on studying network through the lenses of a focal firm perspective (Håkansson and Ford (2002), Håkansson and Snehota (1989), Håkansson and Waluszewski (2013)) with interaction seen as "not just a simple mechanism" but "a specific substance" affecting the involved companies, their activities and resources (Håkansson and Waluszewski 2013, 444). Scholars notice that "no one interaction, whether it is a sale, purchase, advice, delivery or payment can be understood without reference to the relationship of which it is a part" (Håkansson and Ford 2002, 134). The limitation in terms of narrowness of dyadic approach to marketing as well as dyad being interior to "interactions in networks of relationships" is similarly described by Gummesson (2004).

Research literature utilizing the concept of dyadic business relationships is preoccupied with conventional marketing and manufacturing dyads (Frazier 1983, Dwyer, Schurr et al. 1987, Anderson and Weitz 1989, Anderson and Narus 1990, Hallen, Johanson et al. 1991). Ontologically, such dyads are studied through exchange processes of ongoing business relationships characterized as potentially 'long-term' (Anderson and Weitz 1989), 'working' (Anderson and Narus 1990) relationships. Scholarly work to a higher or lower degree involves literature reviews (Frazier 1983, Dwyer, Schurr et al. 1987, Hallen, Johanson et al. 1991, Anderson, Håkansson et al. 1994) that allow developing models (Anderson and Narus 1990, Hallen, Johanson et al. 1991) and frameworks (Frazier 1983, Dwyer, Schurr et al. 1987, Anderson and Weitz 1989) of such exchange relationships. It is likely to be explained by the attempt of developing success factors of "lasting exchange relationships" in business markets that are often developed in business markets (Hallen, Johanson et al. 1991, 29). Some of the studies also provide quantitative evidence in support of the hypotheses underlying the models and frameworks (Anderson and Weitz 1989, Anderson and Narus 1990, Hallen, Johanson et al. 1991). Reputation, trust, commitment, common goals and dependence are found to be among key char-

acteristics of long-lasting dyadic interfirm relationships. Innovation, in neither narrow nor wide interpretation, is not discussed in the early studies of the approach; unless potentially seen through early concepts of value-adding functions, value-chain or value-adding partnership.

Summarizing main characteristics of the approach that are common across research literature, dyadic business relationships is long-lasting cooperation of two companies built on trust and driven by self-interest of each company in a dyad. Being important as pioneering approach to inter-organizational relations, it can be found fragmented in a sense of leaving behind all the complexity of business relationships beyond dyadic boundaries.

Since the maturity of tourism research and particularly innovation in tourism has only been gained over the last two decades, scientific work utilizing the approach of dyadic business relationships in tourism is modest (Sautter and Leisen 1999). Empirical studies, however, often provides evidence of dyadic ties being essential for long lasting and informal tourism collaboration.

### **3.2. Communities-of-practice**

The community of practice approaches to networking and inter-organizational collaboration are based on the community of practice literature (Newell, Robertson et al. 2009) stressing the connections between working, learning and innovating within a community of practitioners (Brown and Duguid 1991). Hence, innovation and learning emerge from practice rather than they are prior to practice. Communities-of-practice emerge spontaneously among the individuals sharing similar activities and/or interests across organizational units, or even across organizational boundaries.

Such communities are first of all seen as social learning systems (Wenger 1998, Wenger 2000) meaning that the learning occurs by a number of engaged individuals constructing solutions to common challenges, creating and communicating knowledge in practice. Therefore, ontologically communities-of-practice represent dynamic knowledge resources (Wenger 1998) or resources of adaptive learning processes (Tyre and Von Hippel 1997). Empirical insight is essential examining the concept as it allows to study the actual practices as well as to define the key features of the concept (Tyre and Von Hippel 1997, Swan, Scarbrough et al. 2002). Once such communities are discovered by an organization, a question of manageability and nurturing of knowledge creation and learning arise (Wenger 2000, Swan, Scarbrough et al. 2002). Though innovation is directly addressed in research on communities-of-practice (Brown and Duguid 1991), it is addressed in terms of rather incremental innovation, improvisation, adaptation and bricolage. While later research points at radical innovation frequently occurring at the interstices across communities (Swan, Scarbrough et al. 2002).

Earlier works on communities-of-practice are mostly preoccupied with studying managing technologies within an organization (Brown and Duguid 1991, Orr 1996, Tyre and Von Hippel 1997). However, the very characteristics of such communities as being fluid and interpenetrative (Brown and Duguid 1991) explains their potential for business relations across organizational boundaries. Besides, physical context of

such human interactions plays an important role and may enhance learning (Tyre and Von Hippel 1997).

Going beyond the community, developing working knowledge between organizations or across communities, may happen owing to 'boundary-spanners' (Newell, Robertson et al. 2009). According to Newell, Robertson et al. (2009) these are "highly connected people" utilizing connections both within the community they belong to and linking similar representatives engaged in the same social practice in other communities. They play entrepreneurial role, opening up relatively closed group of the community to novel information and in some cases to innovative activities.

A similar concept that might potentially add to the communities-of-practice is the innovative milieu approach that evolved around 1990. The core idea of collective learning processes and communal synergy makes it allied but at the same time enlarged, in terms of inter-organizational cooperation, approach. Innovative milieu is characterized by "collective learning process, fed by such social phenomena as intergenerational transfer of know-how, imitation of successful managerial practices and technological innovations, interpersonal face-to-face contacts, formal or informal cooperation between firms, tacit circulation of commercial, financial or technological information" (Camagni 1991, 1). In tourism context, Fuglsang and Eide (2012) discuss practice based approach that emphasizes "the integration of networks into pre-existing local social structures that facilitate learning and innovation" (13). Instead, their practice-based model conceptualized as a bandwagon metaphor contributes to ongoing discussion by explaining how the concept of experiences can be translated into network formation and innovation.

The main characteristics of the communities-of-practice common across research literature is their bottom-up formation based on joint learning by practicing common social task. Interweaving of working and learning produces community-specific tacit knowledge. These characteristics can turn out to be both an advantage and a limitation for a member of such community since concentrating on a particular social practice developing tacit knowledge may facilitate omission of codified knowledge transmitted over distances through broader information flows.

### **3.3. Social Network Approach**

Alternatively to studying networks emphasizing "the importance of shared practices and understanding amongst the members of the community" that are essential for shared learning, there is also more static quantitative approach focusing on structural configurations of network serving as "channels for the flow of knowledge" instead. (Newell, Robertson et al. 2009, 165, 166). Usually serving as a more formalized tool, social networks are studied as a type of spacious collaboration.

An approach of social network has been successfully utilized in tourism research. Evolution-wise, it takes its roots from a network theory build on a premises of nodes and ties. In Granovetter's well-known theory of the strength of weak ties (1973), he studied the connection of smaller interpersonal networks to larger structures. He argues that if there is a strong tie between the two individuals A and B, and B and C, then there is most likely at least a weak tie between A and C. Providing a qualitative description of strong and weak ties, Granovetter opens a potential for quantitative studies. Studying the importance of strong and weak ties, Granovetter

also introduces the concept of a “bridge” between A and B, i.e. “the only route along which information or influence can flow from any contact of A to any contact of B, and, consequently, from anyone connected indirectly to A to anyone connected indirectly to B” (1973, 1364). Granovetter’s focus on various kinds of ties points at the weakness of sociometric techniques: that is “there is almost never an attempt to directly retrace the exact interpersonal paths traversed by an innovation” (1973, 1366). The main message of Granovetter’s theory is that individuals are “closely bound up with larger-scale aspects of social structure” with weak ties providing opportunities for their integration into communities as well as serving as the channels for ideas, influences and information socially distant from such individuals (1973, 1377, 1370).

Borgatti and Halgin (2011) discussing network approach also refer to Burt’s structural holes theory (1992) as fundamental. Summarizing the theory: “ego networks—the cloud of nodes surrounding a given node, along with all the ties among them”, meaning that not the number of ties but the way they are organized might be decisive for receiving more nonredundant information, and as a result, the capability of performing better or being perceived as the source of new ideas (Borgatti and Halgin 2011, 113). In line with our interpretation, Borgatti and Halgin (2011) point at both theories aiming at sharing new ideas and information as the key feature of network formation: “the concept is the same and so are the consequences: more novel information” (1171). A ‘social’ constituent of a network naturally comes from a growing area of literature on social capital which in management describes network by creativity, performance, entrepreneurship, mobility, power, etc.

The analysis of literature on collaboration on the level of social network in tourism provides following results. The main categories which scholars operate with are network, including social network (Borgatti and Foster 2003), complex social network (Miguéns and Mendes 2008); tourism destination (Shih 2006, Baggio, Scott et al. 2010), clusters (Erkuş-Öztürk 2009) and diagonal clusters (Novelli, Schmitz et al. 2006). Ontologically, networks are seen as a set of actors/nodes denoting people, companies etc. connected by a set of ties/edges/relationships (Borgatti and Foster 2003, Novelli, Schmitz et al. 2006, Miguéns and Mendes 2008). While other scholars may describe network elements similar, they emphasize also other characteristics of a network such as complexity and adaptive features (Baggio, Scott et al. 2010) or seeing it in a wider setting of economic, cultural and social activities within destination (Shih 2006). Among works reviewed, case-study is the most common way of approaching data collection (Novelli, Schmitz et al. 2006, Shih 2006, Erkuş-Öztürk 2009, Baggio, Scott et al. 2010) besides conventional review of research literature (Borgatti and Foster 2003), statistical data (Miguéns and Mendes 2008). Social network analysis is prevalingly used as tool of analyzing network features quantitatively, while very few point at the necessity of qualitative analysis for a sound case description and, as a result, findings. Recent work by Hoarau, Wigger et al. (2014) can be one of the few examples combining quantitative and qualitative methods. No similar findings across reviewed articles could be found: some arrive to a low degree of collaboration detrimental for innovation (Baggio, Scott et al. 2010), while others draw their conclusion depending on the scale of network under investigation. Among others, Novelli, Schmitz et al. (2006) find positive impact of collaboration on improved quality, enhanced visibility, cross/marketing activities etc. Yet, in most (but one) of the reviewed articles innovation is seen as a benefit (Erkuş-Öztürk 2009) or outcome of networking: through learning (Borgatti and Halgin 2011), knowledge and information transfer (Miguéns and Mendes 2008, Baggio, Scott et al. 2010).

Similar to overall research claims on benefits of networks for innovation being manifold, research on tourism networks and innovation is said to be weakly integrated across research areas and deprived empirical prove of benefits. Van der Zee and Vanneste (2015) review distinguishes four major research areas within the studies on tourism networks: business networks, policy networks, 'co-opeting' networks, and network configuration; which require scholarly attention to diffusion across the areas as well as more empirical insight into the outcomes of networking.

Summarizing research finding, social networks are commonly understood as structural configuration of nodes and ties serving as channels through which learning, knowledge sharing can be transmitted. Statics and quantification in network approach is both theoretically beneficial in terms of visualization as it allows creating models and frameworks, but also limiting in terms of few dynamic qualitative descriptions (Ahuja, Soda et al. 2012, Sørensen and Fuglsang 2014). Though creating and sustaining networking activities for tourism companies is claimed to be favorable, it also implies costs that may demotivate some of them.

### **3.4. Destination**

There are a number of scholars both within economic and sociological disciplines that would discuss tourist destinations as the environment potentially rich for collaboration about innovation. Particularly this concept is widely used in tourism research, and it pulls together some of the features of both the communities of practice approach and the social network approach in a not very clear way. The streams of the research on destination include destination management and marketing, and destination development. Destinations are also studied from various perspectives: tourists, stakeholders, Destination Marketing Organizations (DMOs), and other public actors. The scope of research on destination is simply so broad that it won't allow to go in-depth but rather to refer to some of the generalizing works as well as to provide the directions useful for the purposes of the study.

Wide application caused ill-considered understanding of destination as 'the heart of tourism' (Leiper 2000). Thus, there have been a number of attempts to reach consensus on what a destination is. One of such attempts is made by Framke (2001), who describes a complexity of finding a unified meaning of destination, first of all, because of the controversy in understanding of destination's main attributes: physical boundaries, content, co-operation, and tourist behavior. He concludes that the destination is not only a static but also a dynamic phenomenon where "interaction, cooperation, networking and social practice are crucial activities describing a 'destination', it's content, it's relations and it's tourists" (Framke 2001, 2). This line of research is surely not exhausted nowadays. Haugland, Ness et al. (2011) develop an integrated multilevel perspective on destination underlining that research emphasizes only on some of the areas of destination development. They view a destination through prism of destination capabilities, intra- and inter-destination ties; emphasizing the importance of collaboration for the development of destinations, especially inter-destination bridge ties, that are important among others for imitation innovation. Among recent works integrating various destination perspective is also one by Pearce (2013), who reviews the concepts of industrial districts, clusters, networks, systems social constructs applied to destinations. The key features of these concepts allow to develop an integrative framework consisting of geographic dimension, mode of production and dynamic dimension. What all the concepts seem to share is inter-

dependencies and need for cooperation within a specific location, which is also seen as a source of innovation, particularly in local cluster approach. The latter approach has also been stressed by Nordin (2003): “the interdependence of attractions, services, transportation, information and promotion highlights the need for collaboration and it is evident that companies located in a destination have a lot to gain from being located in a close proximity” (17).

Collaborative innovation within a destination is a promising research area uniting few different streams. Firstly, the destination development stream of literature including development of both companies and destination itself with its “inherited business traditions, specific infrastructures, competences and skills and trade systems” (Hjalager 2010) proved the collaboration being important. Secondly, collaboration is important in destination marketing research (e.g. Buhalis (2000), Jensen and Korneliussen (2002), Mossberg (2007), also with innovation research angle Hjalager (2010), Nordin (2003). The marketing research confirms that tourists do not perceive one separate business or one separate attraction but rather a complex of attractions or conditions within a destination as they make up the experience or impression in a synergy (‘total experience’), thus representing “an integrated system in a limited geographic area” (Nordin 2003). And thirdly, an important stream of experience-based literature discussing sophisticated market demand challenging tourism companies has also echoed on collaborative innovation within the destination (Arnould and Price 1993, Sørensen 2004, Mossberg 2008, Eide and Fuglsang 2013).

Thus, a number of studies of destination share common understanding of networking within a particular geographical space directed to the construction of a tourist destination, i.e. filling the geographical space with meaning and experiences. The place-specific characteristic makes tourism companies share common vision and interests facilitating collaboration and specifically collaborative innovation.

### **3.5. Innovation Systems**

Among the first scholars using ‘national system of innovation’ (NSI) were Bengt-Åke Lundvall and Christopher Freeman in the late 80th- early 90th , then some major books on national innovation systems followed (Edquist 1997). Since then, works on innovation systems of different scale have multiplied significantly. Not being a theory on its own right, systems of innovation approach rests on such theories as interactive learning theories, evolutionary theories or innovation theory (Edquist 1997). There are concepts of national (Edquist and Lundvall 1993, Nelson 1993), regional (Cooke, Uranga et al. 1997, Doloreux 2002) and local innovation systems (Cassiolato and Lastres 2000, Mytelka 2000); also sectoral systems of innovation (Nelson and Rosenberg 1993, Malerba 2002) and technological systems (Carlsson and Stankiewicz 1991). Defining the approach, similar to Edquist (1997) examining systems of innovation, one must look into the components constituting it. Firstly, the concept is delimited by either geographical or sectoral/industrial dimension. Secondly, systems represent a set of institutions and their interactions defining innovative potential of the dimension they represent. Besides being an approach rather than a theory, Edquist (1997) distinguishes eight more common features of systems of innovation: innovation and learning at the center, holistic and interdisciplinary perspective, historical perspective, differences between systems and non-optimality, interdependence of system’s actors and non-linearity , variations in the concept of innovation, central role of institutions, and conceptual diffuseness (15-29).

NSI approach originates in examining the advances of national economic growth and appreciating the role of institutions and particularly state. It is based on comparative studies of national systems of innovation (Nelson 1993, Wong 1999), also regional innovation systems (Asheim and Coenen 2005) aiming at formulating policies stimulating growth and development. The knowledge generated during two and a half decades becomes subject of further theorization and conceptualization. For instance, Edquist (2004) discusses the potential of NSI to become more theory-like, which it is not due to the lack of “conceptual precision, clarity and a clear identification of independent and dependent variables and their relation to one another” (486). While Lundvall (2007) criticizes attempts to make the concept ‘more rigorous’ by identifying activities or functions influencing innovations. Carlsson, Jacobsson et al. (2002), discussing innovation systems, point at vagueness of the approach in terms of the level of analysis, system’s boundaries and particular hardships in studying performance of such a system.

Remarkably, there’ve been studies conducted examining and conceptualizing tourism through the lenses of innovation systems (Mattsson, Sundbo et al. 2005, Prats, Guia et al. 2008). As noted by Mattsson, Sundbo et al. (2005) innovation systems theory is developed in relation to technology-laden manufacturing sector, and should be distinguished from innovation in services which is “more social or organizational in nature” (358). Sundbo and Gallouj (2000) argue, for example, that innovation system in services are loosely coupled frameworks. Tether and Metcalfe (2004) argue that innovation systems in services evolve around a problem as a focal device. Studies of tourism industry based on the approach of innovation systems inherit ‘systemic’ component in the interactions within “the network of institutions in the public and private sectors” (Freeman 1987, 1), dynamic nature of which “requires continuous learning in order to adapt to challenges” (Soete, Verspagen et al. 2010, 18). Even though, the above-mentioned studies use different definitions of systems, they share common understanding of tourism companies being set in a wider environment especially important in terms of interactive purposes concealing resource and learning potential essential to predominant number of SMEs in tourism.

Thus, common understanding of systems of innovation approach in the research literature is that appreciating systemic features of innovation process it tends to analyze factors at the macro-level that owing to multiple interdependencies can support and facilitate innovation in and between companies at the micro level through various innovation policies. However, the limitations of the approach appear twofold (Soete, Verspagen et al. 2010): firstly, national innovation policy becomes limited as a consequence of globalization processes; secondly, the concept of classic innovation process based on R&D becomes limited as a result of the developments in modern communication technologies and internet information flow.

### **3.6. Institutional Environment**

Vast variety of research on collaborative innovation discusses inter-organizational relations both narrowly (dyadic business relations) and broadly (continental innovation system (Freeman 2002). However, the development of the approaches on collaborative innovation shares similar logic. That is institutional embeddedness, common understanding of the necessity of opening up and interacting with one’s environment in order to secure sustainable business development. This development trend was pointed at as early as by Granovetter (1973), who identified the

weakness of micro-level interactions not being related to macro-level interactions “in any convincing way” (1360). The contribution of the research that followed has covered the gap to a high degree, explaining the embeddedness defined as “to be anchored in a larger structure” (Johannisson, Ramírez-Pasillas et al. 2002, 297) and systemic character of interactions with one’s institutional environment. However, the appreciation of such environment in different concepts is not equally high: it grows with the growth of the scale of interactions from business dyad towards innovation system studying broader set of stakeholders influencing business and deeper integration into interactive processes. To support this argument, institutional economics applied to the approach of innovation systems have been introduced by Johnson and Lundvall (1992) where they discuss institutional set-ups in relation to national innovation system. However, one can still find a call for the necessity of further development of the concept of ‘embeddedness’ of economic activity of a local firm or local network (Johannisson, Ramírez-Pasillas et al. 2002).

We thus suggest another approach to collaborative innovation to be discussed in broader societal context which we call institutional environment. That is so because companies in general, and tourism companies in particular, face the necessity of collaborating beyond local networks with institutions and organizations in other areas of the environment, especially those affecting information flow, learning, and exploring. Types of environments can be conceptualized in different ways. They can be discussed scope-wise as micro-, meso- and macro-environment (Prats, Guia et al. 2008). Some scholars identify various dimensions crucial for innovative capacity of tourism companies, such as political, economic, technological, social and historical (Prats, Guia et al. 2008); while others go in-depth studying types of institutions influencing collaborative innovation in a particular dimension, similar to political dimension by Hall and Tribe (2003). Buhalis, Fletcher et al. (1995) discusses relationship of tourism industry and its environment economic-wise: considering interests of tourism enterprises, tourists, tour operators, host populations, and public sector and government. Other scholars emphasize the distinction between local versus global cooperation being crucial for collaborative capacity (see above, e.g. (Asheim and Isaksen 2002, Bathelt, Malmberg et al. 2004).

Thus, the approach looks upon collaboration of tourism companies as active members of society (rather than just proximity-based collaboration), where negotiations set or alter general course of economic action, settling conflicts and entering agreements. Theoretically, the development of the approach is based on institutional theory within organizational, or more specifically inter-organizational, field (Meyer and Rowan 1977, DiMaggio and Powell 1983, Oliver 1991). That is the stream of literature discussing how an organization adjusts to the rules and values existing in institutional environment in order to gain legitimacy or other benefits: studying types of isomorphic behavior, changes of organizational structure, strategic responses to institutional processes, etc. seeking “legitimacy, resources, stability, and enhanced survival prospects” (Meyer and Rowan 1977, 340). In the institutional setting laden with own routines and habits, organizations change causing at least incremental innovation. However, once organizational field has emerged, an interesting paradox of wide homogeneity among organizations arise (DiMaggio and Powell 1983). Meaning isomorphic behavior of any kind (coercive, mimetic, or normative) does not only lead to change but also to stabilization, posing a dilemma for research on innovation: whether institutional settings facilitate or also hamper collaborative innovation. This dilemma is discussed as ‘convergence’ by Borgatti and Foster (2003), who explains it by belonging to the same business environment with its stakeholders network.

Once institutional theory explained how institutional arrangements influence an organizational field, it offered limited explanation of how institutional arrangements are created, i.e. "limited theory of action" (Fligstein 1997, Maguire, Hardy et al. 2004). Projected on tourism research, that is how innovative behavior of tourism companies can be realized in broader societal context. Institutional entrepreneurship is a steam in the research literature that tends to cover the gap (Fligstein 1997, Maguire, Hardy et al. 2004, Svejenova, Mazza et al. 2007). It explains how social actors may influence and contribute to institutional arrangements. Institutionalization of an environment is a result of ongoing negotiations of different institutions and organizations that agree on a common course of actions. In tourism industry, examples of such course could be total experience within a tourism destination. That is intention of tourism companies, destination management organization, local municipality and local community and other interested organizations to fill the space with meaning, to tell the story, to link separate attractions and experiences together offering a package satisfying the criteria of a tourist's stay in a specific destination. Thus companies, collaborate adapting to the established common course changing their products and organizations, altering their strategies, innovating incrementally or radically and thus, at the same time contributing to current institutional settings.

Research finds evidence of companies differing in the ability to influence institutional settings (Fligstein 1997). While some companies have 'stronger' social skill, i.e. are able to undertake strategic action forming common identities within the field, while others have to adhere to it in order to stay legitimate and competitive. Whether an organization can sustain and further develop the common trend depends also on its ability to justify its actions. In its turn, the ability to justify is argued to be dependent on one's engagement into the environment: from simply being familiar, on to a planned action and further on to the regime of justification with "collective conventions of common good" (Thévenot 2001). Both components constituting good social skill as well as activities of institutional entrepreneurship may differ depending on the status of a particular organizational field, i.e. whether it is "forming, stable or in crisis" (Fligstein 1997, 398) defining the potential for institutional change. Thus, Maguire, Hardy et al. (2004) identifies three critical activities of institutional entrepreneurs in emerging fields: "the occupation of "subject positions" gaining legitimacy and bridging various stakeholders, "the theorization of new practices", and "institutionalization of these new practices" (657). Svejenova, Mazza et al. (2007) describes the qualities that facilitate abilities of strong institutional entrepreneurship through four 'mechanisms' of creativity, theorization, reputation and dissemination based on a longitudinal case-study of chef-owner of a Spanish restaurant.

Similar to institutional entrepreneurship aiming to explain the emergence of institutional arrangements, a collective action model of institutional innovation was developed by Hargrave and Van de Ven (2006). They discuss the action model among other three models of institutional change. Unlike design, adaptation or diffusion of institutional change, collective action model describes institutional change as a result of interactions of the field's actors through dialectics, namely conflict, power and politics (Hargrave and Van de Ven 2006).

Though institutional change has been discussed in research literature for about four decades (Meyer and Rowan 1977, Fennell 1980, DiMaggio and Powell 1983), examples of institutional innovation in tourism are not articulated enough. Among few examples of institutional innovation in tourism, are "new rules of the game" changing institutional course by Hjalager (2002, 466). Hjalager (2010) defines

‘institutional innovation’ as “new, embracing collaborative/organizational structure or legal framework that efficiently redirects or enhances the business in certain fields of tourism”(3). Such all-embracing change happens across sectors and may echo on more than one organizational field.

Sound theoretical basis described in this section, provides potential for further theoretical development of the approach of institutional environment to study collaborative innovation in tourism. Institutional environment is, thus, an action oriented approach where interactions are ‘built’ in broad societal context where adherence to institutionalized course legitimacy, resources and competitiveness of tourism companies.

## 4. Discussion

As discussed above, all approaches are characterized by specific features summarized in the table below. The table consists of three column: conceptualization, methodology and innovation. The conceptualization column summarizes fundamental features of the approaches. The methodology column describes the predominant methodology chosen in the reviewed articles: quantitative or qualitative. The last column to the right describes the way innovative collaboration is possible in studying inter-organizational relations using different approaches.

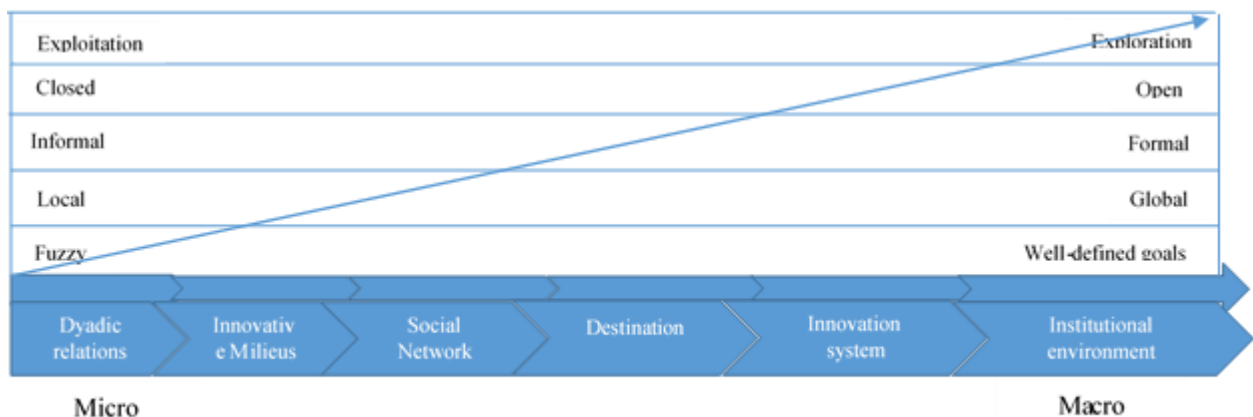

| Approaches                     | Conceptualization   | Methodology                  | Innovation   |
|--------------------------------|---|------------------------------|--|
| <b>Dyadic relationships</b>    | Long-lasting cooperation of two companies built on trust and driven by self-interest of each company in a dyad  | Quantitative and qualitative | Innovation can emerge from dyadic interactions of two companies through their close, historical interaction, and their self-interest |
| <b>Communities-of-practice</b> | Bottom-up formation based on joint learning by practicing common social task. Interweaving of working and learning produces community-specific tacit knowledge            | Qualitative                  | Innovation can emerge in practice-based communities centered around the learning and development of a specific practice              |
| <b>Social network approach</b> | Structural configuration of nodes and ties serving as channels connecting both localized and more distanced businesses  | Mainly quantitative          | Innovation activities are embedded in various types of networks that function as 'channels' of exploitation and exploration          |
| <b>Destination</b>             | Networking within a particular geographical space directed to the construction of a tourist destination, i.e. filling the geographical space with meaning and experiences | Mainly qualitative           | Innovation takes place in local geographical places where public and private actors collaborate to construct tourist destinations    |

|                                  |   |   |  |
|----------------------------------|---|---|--|
| <b>Innovation systems</b>        | It tends to analyze factors at the macro-level that can support and facilitate innovation in and between companies at the micro level through various innovation policies | Qualitative and quantitative (mainly descriptive) | Innovation activities in companies are supported by policy initiatives. Innovation systems in services may emerge as loosely coupled structures or around problem-areas that function as focal devices |
| <b>Institutional environment</b> | Interactions are 'built' in broad societal context where adherence to institutionalized course provides with legitimacy, resources and competitiveness                    | Theory-laden, often case-study-oriented           | Innovation takes place in a societal context and involves societal and political conflicts that companies can be progressively engaged in leading to a change of the institutionalized environment     |

*Table 1 Summary of the main findings of the reviewed literature on collaborative innovation*

Appreciating the development of the theory of inter-organizational relations towards openness and interactivity of the businesses with their institutional environments, among others led to formulating and developing concepts of business dyad, community of practice, network, destination, system of innovation, and institutional environment. Taking on holistic retrospective view and analyzing the logic and major outcome of such development especially in terms of collaborative innovation, we shall now introduce the integrated framework.

*Figure 1 Integrated framework of approaches to collaborative innovation*

By this figure, we frame the logic of the development of approaches to inter-organizational relations. The main contribution of such review is in systematizing approaches relative to micro-, macro-environment scale that tends to describe both the number of stakeholders involved, the depth of such relations, as well as the environment influencing collaborative innovation. In other words, different kinds of collaboration may imply different innovative potential. Thus, the fundamental part (bottom continuum line) of the figure starts with the dyadic relations describing collaboration between two companies that is usually long-lasting relationships built on trust. Such collaboration may sometimes result in incremental innovation. Similar to dyadic relations, 'bricolage' concept of innovation improving shared practices by a larger number of actors defines its second position in the figure. The next approach presented in the figure, is social network approach. It implies opportunities for both incremental innovation when taking part in localized networks as well as radical innovation resulting from collaboration with more distanced businesses. The approach of destination

follows social network approach because even though collaborative innovation here takes place in a specific geographical space, it usually includes quite vast areas with significant numbers of members including both private and public actors. Innovation systems approach is presented next as it is a systemic approach to facilitating collaborative innovation at the micro-level by macro-level policies implying involvement of a large number of institutions and organizations at different levels. Finally, the sixth approach of institutional environment, following innovation systems approach, implies the broadest potential for collaborative innovation described by institutional embeddedness of businesses with the potential of changing institutional arrangements.

This logic is also reflected in the width of the cells framing each approach on the bottom continuum line. That, in no circumstances, depreciates any of the approaches and their theoretical or empirical use. Quite opposite, in some cases studies built on fewer empirical units may become an important source of knowledge about the phenomenon of collaborative innovation. What we intend to do is to warn against hasty judgments as a consequence of casting aside institutional setting. In defense of such a 'sliced' study, Lundvall (2007) emphasize on importance of understanding "how the core of the innovation system is embedded in the wider set of institutions" that is "firms in interaction with other firms and with the knowledge infrastructure. (31, 14).

The framework does not exclude the opportunity of studying smaller collaborative unit through the lenses of the wider collaborative approach. That also applies to institutional environment approach. For instance, collaborative innovation in tourism dyad can be considered in the context of interactive processes within a destination. The boundaries between the approaches are, however, fuzzy. This must be explained by the heterogeneity of definitions found in research literature. This does not only apply to each following approach. As for instance, some may argue the approach of institutional environment being an extension of the innovation systems approach that is "an institutional conception, par excellence" (Nelson and Nelson 2002, 265). While we would reserve its right as a separate approach to collaborative innovation developed to reduce the limitations of other approaches (as mentioned above). It also applies to fuzziness when a collaborative unit of one approach is appropriated as case of the following. Here, an example could be fuzzy definition of destination, which some researches place it into the domain of a local innovation system (Flagestad, Hope et al. 2005).

The buildup part of the figure serves as directing in research on collaborative innovation, describing the growth of innovative potential through exploration, openness to both local and global knowledge and respective access to resources, purposefulness, as well as being a part of both formal and informal inter-firm collaboration. The main idea here is that the combination rather than one particular type of collaboration would be the most favorable for innovation (Sørensen and Fuglsang 2014). That is in practice, tourism companies may benefit from different kinds of collaboration. However, it is not always possible in regard to limited resources of tourism companies which are mainly small and medium enterprises.

As for the further research, it is important to find out how a local company or local network is embedded within wider institutional settings that are to a various degree supportive for innovative activities. Following Lundvall's (2007) reasoning: life-style entrepreneurs with moderate business skills, often in charge of small tourism companies, may need stimulation and training in order to facilitate development and

innovativeness of their companies; while sometimes a tourism company may develop at more rapid pace making changes in institutional course necessary. Therefore, it is important to know which institutions and how (which interactive processes) influence collaborative innovation of tourism companies with respective empirical examples.

Leaving tourism industry, it is also interesting to learn about the potential of the approach of institutional embeddedness in other areas, because “different sectors contribute differently to innovation processes” (Lundvall 2007, 14) including interactive innovation. Learning about what institutional set-up prove to be more favorable for a single company or industry (Hirsch 1975, Prats, Guia et al. 2008) can also provide an illustrative example for practitioners. As “fields only exist to the extent that they are institutionally defined” (DiMaggio and Powell 1983, 148) with the paramount importance of interactive processes between organizations and institutions within a particular organizational field.

# **XXV. International RESER Conference: Evaluation of design thinking for the creation of service innovations in developing countries**

*Silvia Gliem<sup>1</sup>, Astrid Boeger<sup>2</sup>, Harald Goegß, Christiane Hipp<sup>4</sup>*

<sup>1, 4</sup> Brandenburg University of Technology Cottbus-Senftenberg, <sup>2</sup>Deutsche Telekom Healthcare and Security Solutions GmbH, Berlin, <sup>3</sup> Launchlabs GmbH, Berlin

*The constantly growing services sector in developing countries has the potential to sustainably contribute to the people's well-being and foster overall development. This especially applies to educational and health care services whose demand and supply often do not fit due to non-existing or traditional, product based marketing instruments in use. In response to this misfit, we propose to employ design thinking methodology. Therefore, we conduct a case study demonstrating the creation of health care service innovations in Kenya using design thinking methodology. Our findings prove that design thinking methodology is promising but still struggles to convince compared to conventional business paradigms.*

## **1. Introduction**

Developing countries face several challenges when it comes to service innovation. In the so called “bottom of the pyramid” markets (BOP markets; Prahalad, 2012, 6) insufficient infrastructure causes a series of problems (Berger; Nakata, 2013). People live scattered in the whole country. Scarce road systems make it difficult to reach people face to face (cf., 1200). Missing electricity and telecommunication infrastructure aggravates the introduction of information and communication technologies (ICT) crucial for many service innovations (e.g. Barrett; Davidson; Prabhu; Vargo, 2015; Bygstad; Lanestedt, 2009; Miozzo; Soete, 2001). Future staff and future clients require a greater amount of training as a result of insufficient or missing means of acquiring, e.g. a television or a personal computer (Berger; Nakata, 2013, 1204). Furthermore, low levels of literacy and numeracy pose additional challenges for the roll out of service innovations (cf., 1200). Although not referring to service innovation in specific, Anderson and Markides (2007) put it precisely arguing that innovation in developing countries and their markets has its focus not on “finding customers than addressing issues of product affordability, acceptability, availability and awareness ” ( 88).

The inhibiting constraints for the innovation processes sketched before probably constitute the most urgent areas of innovation. In particular, infrastructure in terms of electricity and telecommunication is one big area where innovations can be seen as means of improving living conditions for many people. Berger and Nakata (2013) dealt with the subject of technology implementation for financial service innovation. They conducted a multiple case study analysis. Their findings indicate that, because of the specific conditions present, e.g. low income of potential customers and insufficient infrastructure, companies have to adapt their products and services, e.g. in

terms of pricing and paying infrastructure. These results also correspond with the findings of Anderson and Markides (2007, 83-84) that analysed several examples and demonstrated the need for companies to adapt to the exceptional conditions in BOP markets. Education and, although not mentioned before, health and social services also belong to the areas where innovation leads to improvement of people's welfare. At the same time these services rely on infrastructure and are more efficient when ICT is used. As in the case reported by Berger and Nakata (2013) technology implementation is only the first step. If people did not get into touch with technologies such as ICT before, issues in relation to literacy, culture, and technology acceptance have to be taken into consideration. Thus, fostering innovation activities in developing countries and BOP markets respectively demands an approach that is flexible enough to embrace the specific and manifold conditions that apply in developing countries.

In this paper we present the method of design thinking as an appropriate approach for this task. Design thinking is user-centred (Rhinow; Meinel, 2014, 245-246). It is an approach that divides out a problem before solving it. By this a problem is illuminated from different angles. This wide view is even intensified and complemented by including stakeholders in the design thinking process. If we consider, e.g., a service innovation settled in the field of telemedicine, there are several groups of people that "get in touch" with such an innovation. From all these groups of people a representative is included in the design thinking process and thereby bringing in important inputs. This might be particularly relevant stakeholders participating in the process are very different; especially in terms of their living environment. For instance, developing a telemedicine service for first world patients will not be suitable for patients in developing countries. Furthermore, the design thinking approach incorporates the conditions that apply to the innovation setting. We stressed before that these conditions in developing countries differ in comparison to the ones we experience in, e.g., in Europe.

The objective of this paper is to evaluate design thinking methodology as means of creating service innovations in developing countries. Thus the remainder of this paper is organized as follows: Section 2 describes the process of design thinking from a theoretical perspective. We then explain our research methodology in Section 3 and present a case study settled in the area of health services in Kenya in Section 4. The results of our case study analysis are presented in Section 5. Section 6 discusses lessons learned and draws on resulting research gaps. Our work is summarized in Section 7.

## **2. Learn how to innovate: the process of design thinking**

Defining design thinking requires comprehension of the term design itself. Today "to design something" does not only mean to give something tangible a shape or "to make things" (Kimbell, 2011, 290) respectively. Instead, the term design has experienced a twofold upgrade in relation to its meaning: First, design is not only affiliated with tangible products but with services as well. Second, the notion that something that is designed resulted from a "sudden breakthrough (...) [or] the lightning strike of genius" (Brown, 2008, 4) is broken up and demystified. Instead, design is revealed as a process incorporating not the one and only design method but a compilation of

methods for problem analysis and problem solving (Simon, 1969 cited by Kimbell, 2011, 290-291). Although this broadened view on design might meet with what we intuitively perceive as design thinking, the concept as such was first discussed by Rowe (1987). Although Rowe is considered to have a slightly different understanding of design thinking methodology than businesses understand it today due to his work as a professor for architecture and urban planning (Liedtka, 2014, 2). Design thinking as means of “(...) [addressing] the needs of people who will consume a product or service and the infrastructure that enables it” (Brown; Wyatt, 2010, 29) was brought up by IDEO, a consulting firm focusing on the development of innovations. Design thinking methodology experienced a boost in development when IDEO started receiving more requests aimed at the development of service innovations. This triggered a shift in how design thinking methodology was used and perceived. Today, design thinking methodology is not only a means of designing new products and services. Instead it is a method to design new experiences for customers (Brown; Wyatt, 2010, 29).

In the following, we provide a “look and feel” of design thinking methodology and take a closer look at the process itself. Therefore, let us consider a cooking recipe and the correspondent cooking process. The recipe tells you what you need for preparing a meal: ingredients, know-how or experience, and cooking equipment. The cooking process as such is linear, except for some iteration concerning the addition of some seasoning. Though, linear components of the process remain dominant. Switching perspectives from cooking to business, we admit that there are linear processes in business as well, e.g., production processes, also containing phases of iteration, e.g., quality management. However, when it comes to activities in businesses that inhabit some kind of developmental activities the predominance of linearity vanishes. Instead, non-linear components, such as iterations, loops, etc. outweigh the linear components. Such a non-linear nature coincides with the perception of design thinking methodology in research. Brown and Wyatt (2010, 30; also Brown, 2008, 4) pictured the process “as a system of overlapping spaces”. This in line with Ingle, who characterizes the process as being of an “adaptable [and] flowing nature” and “with no direct line from Point A to Point B” (2013, 4-5). Cross (2011) carried out several case studies and uncovered one of the fundamentals of design thinking methodology: he recognized that people employing design thinking were continuously changing their perspectives from the problem side to the solution side and vice versa.

Despite the unique nature of design thinking processes, there are elements every design thinking process consists of (see Figure 1). Brown (2008) and his colleagues (Brown; Wyatt) speak of three elements: 1) inspiration, 2) ideation, and 3) implementation. Ingle (2013, 3-4) elaborates on these elements in more detail and divides the elements of inspiration and implementation into two sub-elements (“understand” and “define” and “prototype” and “test” respectively). Meinel and Leifer (2011, xiv Fig. 1) identify five common phases of design thinking.

**Figure 1:** Elements of the design thinking process  
**Source:** Data adopted from Ingle, 2013, 3-15; Meinel; Leifer, 2012, xiv Fig. 1

Every design thinking process starts with briefing providing the basic parameters of the project such as available resources and time frame (Brown; Wyatt, 2010, 30). The next step is to gain a deeper understanding of the problem at hand (Ingle, 2013, 5). Therefore, you have to determine who you address with a solution. This means not only to give the target group a name but to collect data about diverse parameters that draw a precise picture of the members of this group. This helps to get an idea of how the problem is perceived by the target group and its needs and desires (Brown, 2008, 2; Ingle, 2013, 6). Especially, when the solution is a service there are more stakeholders that have to be considered, e.g. people who deliver the service. They as well are affected by the problem at hand. Their perspective on the problem has to be explored too. If not a solution might be developed for the target group but fails to be delivered because the correspondent providers where not considered in the process. Exploring the stakeholder's different perceptions of a problem can result in the realization that different groups of people perceive the problem differently (Thienen; Meinel; Nicolai, 2014, 99). For the data collection diverse sources and methods can be used. In order to design an experience, the observation of the experiences of the stakeholders presents an appropriate starting point (Brown; Wyatt, 2010, 30). The better your data, the better your comprehension of the problem will be and the easier it will be to specify the problem in-depth (Ingle, 2013, 6).

Therefore, the before gathered data and the information about the problem from the different perspectives of the stakeholders have to be joined together. As a result a "stable problem view" is achieved (Thienen; Meinel; Nicolai, 2014, 99) which is required if possible solutions shall suit all stakeholder's needs. Furthermore, the consolidation of the different point of views enhances re-evaluation of the problem itself (cf., 101) and fosters a more detailed definition of the problem. Dedicating time and effort for the definition of the problem can reveal aspects that have not been considered before. They could have been the cause why the problem is still unsolved or former solutions did not work (cf., 100).

With the well-defined problem at hands, there begins the phase of ideation. Using creativity techniques, e.g. brainstorming, the participants of the design thinking process think up solutions for the problem (Ingle, 2013, 7). Every creativity technique has its peculiarities and demands specific things when coming to realization (Brown; Wyatt, 2010, 31). Apart from those specialties, Ingle (2013, 8-9) emphasizes rules to get the best out of ideation sessions. She states that before every ideation session its goals should already be communicated to the participants. By this, their minds already start to chew the problem over. Then, when the ideation session takes place participants already might have in mind solutions for the problem. Different stakeholders are involved in ideation sessions. Outside of the design thinking process these stakeholders differ in terms of background, education, position in the company or institution. It has to be made clear that during ideation sessions there is no hierarchy. Instead there is freedom to speak and the etiquette of listening when someone presents his or her ideas. Furthermore, a moderator is needed to ensure that the sessions keep focused on the defined problem and participants do not get stuck on a single issue. Besides, a moderator should actively engage in the time management and keep an eye on the group's energy and pause or finish sessions adequately. A proper documentation of the results is obligatory. Ingle (2013, 9) even suggests to document results redundantly.

The implementation phase contains prototyping and testing activities. Especially, when there resulted a bunch of ideas from the ideation phase, probably not every idea will be prototyped and tested. Therefore, the results of the ideation phase have to be sorted. To do so, researchers propose different approaches. Ingle (2013, 10) suggests evaluating the ideas from a business perspective and to differentiate them into different categories ranging from feasible and realistic to dreams of the future. Subsequently, feasible ideas should be re-evaluated in regard to the available resources and the extent of contribution to the solution of the problem (Ingle, 2013, 10). If there no ideas that fulfil the conditions of feasibility and affordability, and show a great promise in relation to the solution of the problem, you have to go back to the ideation phase and make up more ideas (Ingle, 2013, 11). Prototypes can be simple (Brown, 2008, 2) but at the same time should embrace what is essential for the solution (Ingle, 2013, 11). In other words, the prototype should serve you when tested (Brown, 2008, 2). Starting with the prototype of the ideas that needs least resources supports the starting of the prototyping process. By this, the motivation of the team is likely to keep stable and enhance a productive environment for this phase (Ingle, 2013, 11).

In the following test phase prototypes will be evaluated. Therefore, representatives of the different stakeholders that are using the solution or are affected by it should be recruited for testing (Ingle, 2013, 13). Documentation of the test results is essential and realized by different means, e.g., written reports, videos, audio recordings, images (cf.). Afterwards, the documented data is analysed. Common concerns, reactions, e.g., expressed by means of body language, or suggestions of the different stakeholders are aligned to clusters. Each cluster represents an important topic for the further development of the solution and has to be considered carefully (Ingle, 2013, 14). When each prototype was tested, an analysis and comparison of the test results reveals weaknesses as well as strengths of each prototype. Weaknesses and strengths have to be evaluated on basis of their importance for the solution. There may be major and minor weaknesses and major and minor strengths. Furthermore, it has to be considered that test results are a composition of the feedback of stakeholders that are affected by the solution in different degrees. This means a weakness

reported from a stakeholder affected in a high degree should be top priority (cf.). In the end, best alternatives are selected for further development. If none of the prototyped alternatives worked out well it should be investigated what went wrong. By this the team knows to which phase they have to go back and start again.

### 3. Methodology

A qualitative approach using a case study with a single-case design is employed to prove our research propositions. We decide for a single-case design because of several reasons. First and being most important, the data available did not allow for a multiple-case design. Furthermore and in line with Yin (2003), we argue that the single-case design is justified because of the representative and revelatory nature of the case (41-42). Although the application of design thinking methodology is not yet that common in business, it still has earned its position in the group of innovation methodologies (see Section 2). The idea of applying design thinking methodology to BOP markets is not new. In conclusion, we consider the case presented in Section 4 to be representative. Still, as the diffusion of design thinking methodology is not yet finished, conducting a case study which was carried out in a BOP market may uncover new knowledge about the application of design thinking methodology in such settings. Therefore, we regard the case as of being of a revelatory nature too. In the style of Eisenhardt (1989), we conduct our case study with the following steps.

*Defining a research question.* We want to prove our proposition that design thinking is a promising/sound method for the development of service innovations in developing countries. In doing so, we want to uncover the potential of design thinking methodology as a means to develop innovations customized to market conditions, customer and stakeholder needs. Thus, we define our first research question as follows:

*RQ 1: "How is design thinking methodology contributing to the development of service innovations in developing countries?"*

Design thinking is a demanding approach in terms of openness, patience, enduring motivation, and thoroughness required from the participants of the process (see Section 2). Additionally, every design thinking process is conducted in specific and unique circumstances. As a result, the course of events and the outcomes of the process are highly non-predictable. Hence, insights from a case study may provide lessons learned helping to improve design thinking processes in the future and derive implications for practitioners. Accordingly, our second research question is:

*RQ 2: "Which are the lessons learned to improve future design thinking processes in developing countries?"*

*Case selection.* This paper's objective is to demonstrate that design thinking methodology is an appropriate means for creating service innovations in developing countries. Therefore, we chose to present a case settled in the country of Kenya which is, according to the latest World Economics Situation and Prospects report (2015, 140) a developing country. The project described in our case study aimed at the development of a service that helps reducing child and maternal mortality in Kenya.

*Data sources and data collection.* Data was retrieved from different sources and in different forms. Above all, two of the authors of this paper were involved in the project

described by the case study. They were on-site and participated actively in the process taking the roles as a member of the Telekom team and a coach guiding and directing the process. They provided data by inputting their direct and participant observations. Moreover, they provided documentation in various forms such as presentations and photos. Data about Kenya and the issue of child and maternal mortality was retrieved from governmental sources of the country of Kenya and from the inter-governmental organization of the United Nations and its subsidiaries like the World Health Organization.

*Case analysis.* In order to analyse our case and find answers to our proposed research questions, we decided to adopt the approach employed by Berger and Nakata (2013). They conducted a case study dealing with the implementation of financial innovations based on ICTs. Using the Socio-Technical View, Berger and Nakata (2013, 1201) assessed which circumstances of ICT implementation facilitated or aggravated the implementation of financial innovations. In doing so, they depict which conditions and circumstances surrounding the innovation process have to be considered during the innovation process to achieve the highest possible fit between innovation and market. As a result, they defined eight research propositions grouped into socio-human conditions, governmental-regulatory conditions, and market conditions (cf., 1204-1208; see Table 1).

| <b>Socio-human conditions</b>   |  |
|---|--|
| 1) ICTs for financial service innovations in BOP markets are more effectively implemented when customer limitations such as low literacy, lack of identification, and technology unfamiliarity are addressed.   | 1) Health care service innovations in BOP markets developed by using design thinking methodology, exhibit a good market fit because customer limitations such as low literacy, lack of identification, and technology unfamiliarity are addressed.   |
| 2) ICTs for financial service innovations in BOP markets are more effectively implemented when support agent limitations such as technology and business development uncertainty are addressed.   | 2) Health care service innovations in BOP markets developed by using design thinking methodology exhibit a good market fit because support agent limitations such as technology and business development uncertainty are addressed.  |
| 3) ICTs for financial service innovations in BOP markets are more effectively implemented when staff accepts the technology and are trained to support its use by customers and agents.   | 3) Health care service innovations in BOP markets developed by using design thinking methodology, exhibit a good market fit because community health worker's technology acceptance and the need for training to support technology use by customers and agents is addressed.                  |
| 4) ICTs for financial service innovations in BOP markets are more effectively implemented when staff monitor and adjust the technology after introduction.  | 4) Health care service innovations in BOP markets developed by using design thinking methodology, exhibit a good market fit because health care staff monitor and adjust service offers and technology after introduction.   |
| <b>Governmental-regulatory conditions</b>   |  |
| 5) ICTs for financial service innovations in BOP markets are more effectively implemented when the governmental-regulatory environment is understood, opportunities for technologies exploited, and government relations cultivated to support their use. | 5) Health care service innovations in BOP markets developed by using design thinking methodology, exhibit a good market fit because the governmental-regulatory environment is understood, opportunities for technologies exploited, and government relations cultivated to support their use. |
| 6) ICTs for financial service innovations in BOP markets are more effectively implemented when governments install, or allow banks to   | 6) Health care service innovations in BOP markets developed by using design thinking methodology, exhibit a good market fit because  |

|  |  |
|--|--|
| install, sound EFT switches and provide facilitative regulations around usage.   | governments install, or allow providers to install sound ICT-infrastructure and provide facilitative regulations around usage.   |
| <b>Market conditions</b>   |  |
| 7) ICTs for financial service innovations in BOP markets are more effectively implemented when market conditions such as an underdeveloped financial sector and low financial literacy are addressed through educational programs. | 7) Health care service innovations in BOP markets developed by using design thinking methodology, exhibit a good market fit because market conditions such as an underdeveloped health care sector and low levels of health education and health literacy are addressed. |

**Table 1: Research propositions by Berger and Nakata (2013) and derived evaluation criteria**

**Source:** Data adopted from Berger and Nakata, 2013, 1204-1208

Originally, the Socio-Technical View was used to assess the fit of technology to technology users, technology purpose, and setting of technology use (Berger; Nakata, 2013, 1201). This pattern of thought matches the user-centered paradigm embraced by design thinking methodology. Therefore, we want to join the Socio-Technical View with design thinking using the research propositions set up by Berger and Nakata and transform them into criteria to evaluate the fit of design thinking to the setting of developing countries.

The research propositions created by Berger and Nakata have to be adapted to the present case study. First, our case study deals with child and maternal mortality rates and possible service solutions aiming at the reduction of these rates. As a result, we altered this key aspect in the research propositions from ICT and financial service innovations to health care service innovations. This included integrating stakeholders involved in health care, e.g., community health workers. Second, there is one solution in our case study where ICT plays only a minor role. Consequently, we put into focus not the technology needed to realize a solution but the solution itself. Finally, we do not want to limit our analysis to the outcome of the innovation process. As our aim is to evaluate design thinking methodology when applied for the development of service innovations in developing countries, the method has to be included in the research propositions. The adjusted research propositions constitute the basis for our case study analysis and the evaluation framework we need to prove our research questions.

## 4. Learn how to innovate: design thinking in Kenya

The case is settled in Kenya, Africa. Kenya is one of the Sub-Saharan African countries where child and maternal mortality rates are still high. Reduction of child and maternal mortality rates are one of the Millennium Goals of the United Nations Development Program to be reached in 2015 (Millennium Development Goals (MDG) Acceleration Framework, 2014, 19-20). Therefore, Kenyan Government brought several activities underway to reach these goals, e.g. medical service bundles including, above others, immunization for pregnant women and children under five (Ministry of

Devolution and Planning Kenya (MDPK), 2014, 17). Results of these activities are mixed but encouraging. Since 1990 the infant mortality rate reduced from 60 out of 1,000 to 52 out of 1,000 children in 2011 and aimed to be down by 22 in 2015 (MDPK, 2014, 17). Under five-mortality rate dropped from 91 out of 1,000 in 1990 to 74 out of 1,000 children in 2011 and is desired to diminish to 32 (MDPK, 2014, 17). The maternal mortality ratio decreased from 590 out of 100,000 in 1990 to 488 out of 100,000 mothers in 2009. This ratio is not satisfactory. The aim for 2015 is to reduce this ratio to 147 out of 100,000 mothers (MDPK, 2014, 18-19). The outlined situation in Kenya is a result of several conditions that are symptomatic for developing countries (see Section 1). To provide comprehensive maternal and child care there is not enough personnel. Furthermore, the personnel lack proper training to assist women in prenatal and postnatal stages. People have poor access to health facilities or lack the financial resources to do so. In fact, insufficient financial resources contribute to poor health of mother and child. This is especially severe when financial resources are too little to satisfy nutritious requirements. Sometimes mothers-to-be simply do not know which medical treatments they need in preparation for the birth of their child and are unaware of its benefits. Even if there is awareness of the use of pre- and postnatal care families are unwilling to embrace it (MDPK, 2014, 17, 20).

Seeking an opportunity to enter the African market, the German telecommunications and ICT provider Deutsche Telekom AG took the two Millennium Goals as a starting point to set up an initiative, the Telekom Challenge, aiming at the development of a solution that tackle the problems of child and maternal mortality in Kenya.

As a first step and required for the design thinking process is an appropriate team. Via means of the before mentioned initiative, Deutsche Telekom AG called on to every employee within worldwide Telekom companies to apply for this project. In the end, ten employees were selected and assembled a team. Additionally, there were two coaches from Launchlabs, a consultant agency who specializes in intrapreneurship and innovation processes (Launchlabs, 2015) and four people from the Group Transformational Change. The employees from Deutsche Telekom AG came from Monte Negro, Serbia, Hungary, and Germany. Apart from their cultural diversity, team members owned different professional skills such as engineering, strategic management, marketing, and software programming. Although combining different cultural backgrounds, working cultures, and competencies, at this point of the process no other stakeholders were involved.

For the whole project two times two weeks were scheduled on-site in Kenya. In the following, we want to provide insights from the different phases of the design thinking process presenting the course of events, goals and results of each phase.

Understand. First, the team had to gain a deeper understanding of the question "Which solutions can be developed by Deutsche Telekom to reduce child and maternal mortality in Kenya?". Therefore, team members and coaches were briefed and provided with information material by Deutsche Telekom in advance of their stay in Kenya. Second, the team had to gain the same understanding of this question. Using the method of reframing, a method fostering people to view an issue from different perspectives and catalyse new stimuli for developing problem solutions (Kolko, 2010, 22), the original question was split up resulting in five new questions (Deutsche Telekom AG, 2013, 12):

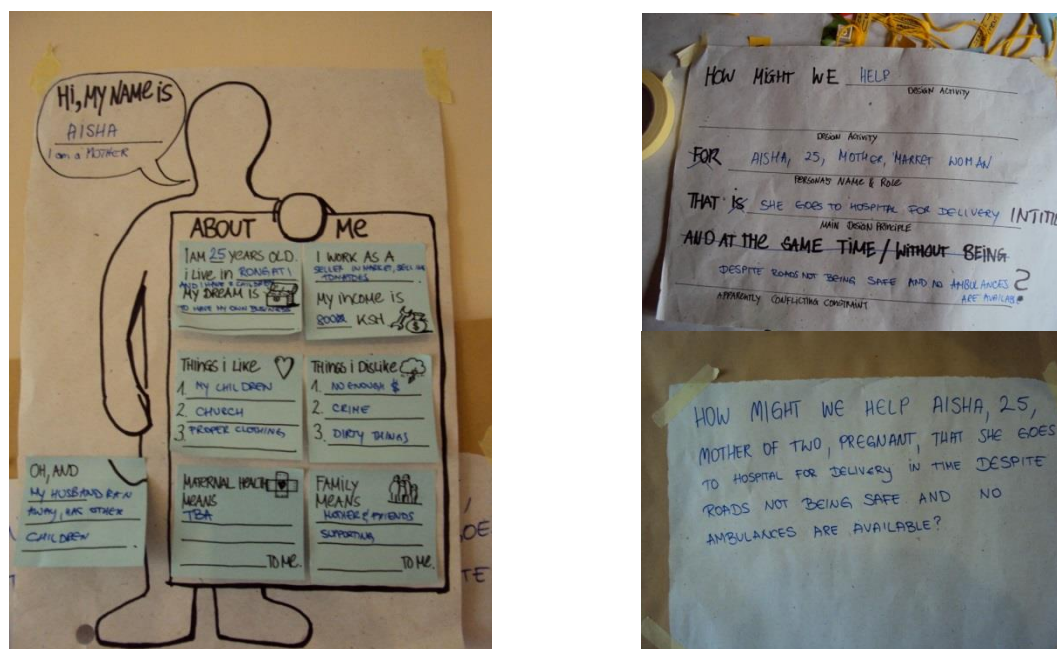

- How to decrease the mortality rate of pregnant women?
- How to improve the education of pregnant women?
- How to improve the awareness about the health situation?

- How to increase the income of CHWs?
- How to achieve consistent patient data to improve treatment and drive women's behaviour?

**Observe.** The five questions that resulted from the former phase were used as a basis for the observe-phase. In order to achieve a 360-degree-perspective on the topic of child and maternal mortality in Kenya, the team split up into smaller groups and conducted research on-site. Data was collected through talks with NGOs and other health care stakeholders such as mothers and mothers-to-be, entrepreneurs of the health care market, or hospital representatives. These talks included visiting the environment of stakeholders, e.g., homes and hospitals. Thereby, the team learned about living and working conditions of mothers and mothers-to-be as well as people in the maternal health care-process chain.

**Define.** In order to consolidate the gained information from the former phase and connect it with the original problem, teams were split up again. Then, two fractions separately reworked the questions from the understand-phase. Rephrasing via means of cloze texts helped rendering the questions more precisely. This in turn, enabled the team to uncover the problems implied by the questions and direct subsequent efforts for developing a solution more focused. An example of these activities can be seen in Figure 2.

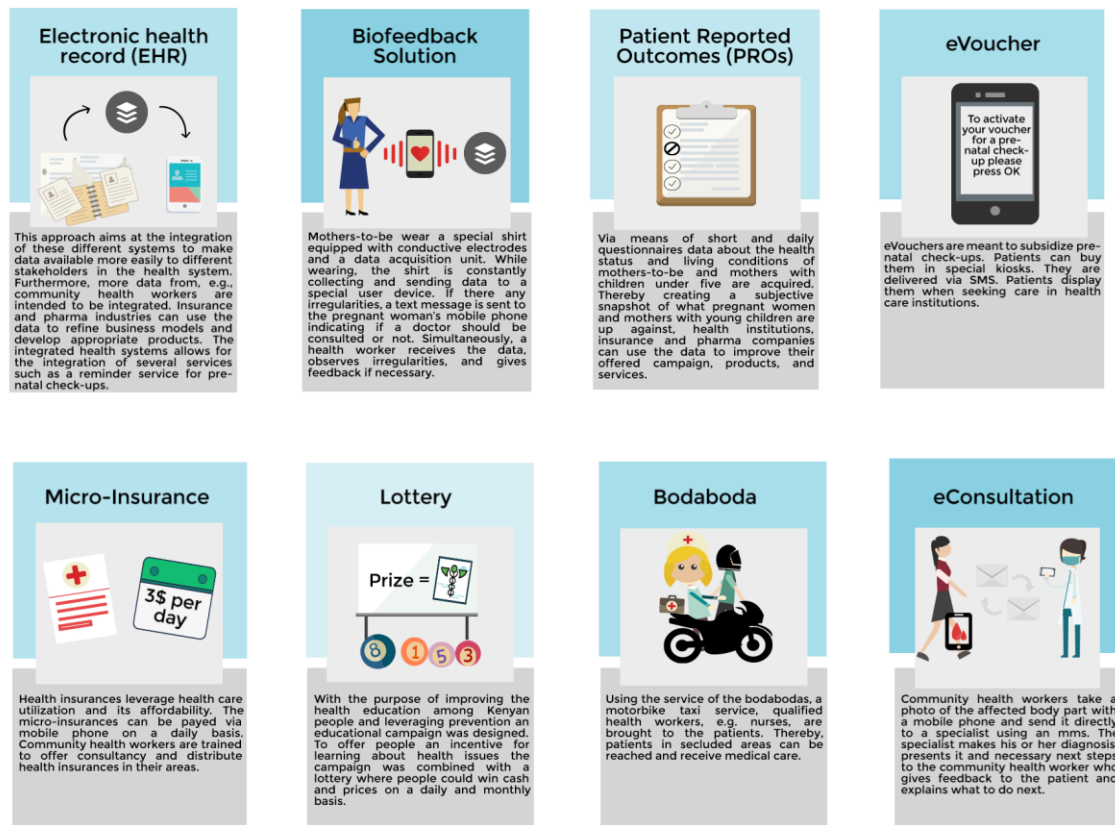

**Figure 2:** Reframing using templates  
**Source:** Launchlabs, 2013

**Ideate.** In a matter of hours and deploying different modes of brainstorming, a creativity technique to make up ideas, eight ideas were developed. Subsequently, the team was split up again into groups of two that worked separately on the further development of the ideas. By this, all eight ideas experienced further consideration and the variety of the made up solution could be secured. It has to be mentioned, that not

all of these eight ideas were developed exclusively by the team. Instead, there were influences from the outside that brought in a single artefact or process idea that now could benefit from the design thinking methodology as such and be advanced. A brief description of the eight ideas is presented in Figure 3 (Deutsche Telekom AG, 2013, 13).

## Solutions

powered by  
**Piktochart**  
make information beautiful

**Figure 3:** Solutions resulting from the ideate-phase  
**Source:** Deutsche Telekom AG, 2013, 13

*Prototype.* Every idea was prototyped using posters, post-its, Lego bricks, and other cheap and easy to use materials. Such a prototype demonstrating the fundamental functionality of the micro-insurance is presented in Figure 4.

**Figure 4:** Micro-insurance prototype  
**Source:** Launchlabs, 2013

*Test.* After setup of the first generation of prototypes, stakeholders were invited. During co-creating sessions the prototypes were presented and discussed together with stakeholders. In order to refine the solutions the next generation of prototypes was setup together with stakeholders.

Most of the time was spent on the observe-phase. Other phases were passed in a matter of hours. In sum, there were four iterations. Thereby, the solutions eVoucher, lottery, and micro-insurance were not further developed. The electronic health record was the solution favoured by Deutsche Telekom. In the end, none of the solutions was further developed by Deutsche Telekom.

## 5. Results

In Section 3, we defined eight criteria for evaluating design thinking methodology as promising for the development of service innovations in developing countries. Now we will prove if these criteria are satisfied. Thus, we will discuss the criteria in groups beginning with the criteria displaying the socio-human conditions.

During the observe-phase the team retrieved exhaustive information about the different health care stakeholders in Kenya. Being on-site, the team collected data during several days up to a week. A combination of action research and desk research was

employed to gain a 360-degree-perspective on the topic of child and maternal mortality.

*Problems/ Issues:* Apart the means of information retrieval mentioned in Section 4, the team also wished to experience face to face against what young mothers and mothers-to-be are up to. To ensure the safety of their people, Telekom provided an obligatory safety-training and set up strict safety regulations which forbid this kind of experience and limited mobility in Kenya. Without the intention to dismiss these safety concerns, one could argue that these limits cause bias in information aggregation and aggravate or, in worst case, prohibit getting a 360-degree-perspective on the problem.

Being from a big and known German telecommunications company smoothed the way for personal interviews with stakeholders. At the same time it created expectations that could not be met. For instance, entrepreneurs waited for financial sponsorships to advance their ideas. However, innovative product or service solutions at the end of their development phase were denied to enter the design thinking process because of the danger that they were developed not as a response to concrete demands and therefore not being user-centred. Furthermore, acting as representatives of such a known company created uncertainty within the team. There were discussions about interview strategies as well as the dress-code (jeans vs. suit).

Governmental institutions form another group of stakeholders. They are also included in the research activities conducted during the observe-phase. In our case study they brought in the lottery and eVouchers to foster further development of these ideas. During co-creating sessions governmental representatives gave feedback to prototyped ideas. By this, valuable information supplemented the data from the observe-phase and the transfer of tacit knowledge was stimulated.

*Problem/ Issues:* Again, representing a well-known company caused uncertainty for the team. As demonstrated in Figure 4, prototypes were made with post-its and LEGO. Presenting these childish appearing prototypes caused discussions between team and coaches. Telekom employees who probably stood one's ground several times during their professional life were insecure if they will be taken serious when showcasing the prototypes to governmental representatives. Coaches were asked to smooth discussions in order to keep motivation up for ongoing iterations.

Before being on-site, the Telekom team as well as the design thinking coaches received a reader provided by Deutsche Telekom. The reader contained information about the country of Kenya, the Kenyan health care system, data about child and maternal health issues, and information about the Kenyan telecommunications and health care market. Naturally, the information was selected and brought together to sketch business opportunities for Deutsche Telekom. This means, before the design thinking process started the team learned about the innovation setting and the market conditions. This information was complemented with the research conducted during the observe-phase.

*Problem/ Issues:* Contrary to the expectations of the whole team regarding business development, innovation activities, and telecommunications infrastructure, Kenya surprised by possessing a vivid start-up scene with people eager to create new solutions. In terms of telecommunication Kenya demonstrated having better network coverage than Germany. Furthermore, owning a mobile phone is self-evident.

*General problems/ issues:* The observe-phase aims at perceiving a 360-degree-perspective on a problem. An important issue in this phase of the design thinking process is to draw a final stroke. One possible way to do this is introducing time frames. Still, deciding for an adequate time frame needs gut instinct and experienced coaches.

Some team members showed difficulties leaving their usual work sphere and breaking loose from their perceived roles in their home companies. As demonstrated before, this resulted in doubts and discussions about the way things are done using design thinking methodology. Especially, when stakeholders are involved that represent important potential business partners, design thinking methodology was questioned.

## **6. Lessons Learned, Research Gaps, Limitations**

Although the design thinking process resulted in promising ideas for reducing child and maternal mortality in Kenya, none of the solutions was realized and implemented. Deutsche Telekom abandoned the idea of entering the Kenyan market after the project. The authors are not aware of when or if Deutsche Telekom reconsiders this decision at present. Apart from strategic concerns this act of retreat reveals that design thinking does not end when prototypes are tested and adjudged to be ready for market launch. Instead, design thinking has to be integrated into everyday corporate culture so that the before mentioned role conflicts can be avoided. This does not necessarily mean that future employees change their keyboards for post-its but it encourages thinking beyond traditional structures such as business units.

There is need for actions when it comes to avoid conflicts originating in the way things are done with design thinking. Leaders of a project teams and design thinking coaches have to prepare people thoroughly to leave these doubts aside. This could be achieved by an introduction to the design thinking methodology. In doing so, people have more time to break loose from their conventional everyday business practices. Furthermore, instead of being thrown in at the deep end, learning about a method may be the best way for team members to eliminate doubts. Simply put, measures of converging the project team's expectations of the look and feel of design thinking methodology to the actual design thinking experience present a research gaps. Furthermore, we propose that the issue of documentation shall be an area of future research. Given the fact, that many design thinking case studies in literature focus on the problem solutions developed by design thinking methodology rather on the design thinking process itself, details about the process of design thinking are valuable.

## **7. Conclusion**

In our article we responded to a research implication brought up by Berger and Nakata (2013, 1209-1210). They proposed exploring further the conditions that characterize BOP markets and find ways to respond to these conditions. Design thinking methodology is one way of response. It includes the conditions sketched in the di-

mensions of the Socio-Technical View before thinking up innovations. This means the information gathered throughout a design thinking process stimulate creating raw patterns that support seeing things from a different perspective and by this, seeing things from the eye of stakeholders.

## **D3: Services, regional and local development**

*Chair: William Beyers*

# Dynamics of Trade in Services: Exports, Imports and Local Demand in Washington State and the U.S.: 1963-2007

*William B. Beyers*

University of Washington

*This paper documents changes in export shares (to the rest of the U.S. and on foreign trade account), import shares (from the rest of the U.S. and on foreign trade account), and Washington state production shares over the 1963-2007 time period for service industries. The paper utilizes the unique history of Washington state i/o models (eight survey-based models spanning the 1963 – 2007 time periods) along with data from the benchmark U.S. i/o models to develop the metrics described above. While there is a significant literature on export trade in services, including producer services, this literature has tended to be cross-sectional rather than longitudinal, and it has not focused on local and external sales relationships simultaneously. There has been much less focus given to the issue of services imports. The data base to be utilized in this paper allows a simultaneous focus on purchases (local plus imports) and sales (local plus exports).*

## 1. Introduction

This paper begins with a discussion of early concepts regarding trade services. The characteristics of this trade are then reviewed from multiple perspectives, including the role of trade in services revealed using various statistical sources and a review of surveys of trade in services. The paper then turns to selected data from input-output models that document the growing importance of the demand for and trade in services.

Greenfield (1966) pioneered a vision for what we now accept as producer services—activities whose primary clients are businesses and governments, as opposed to households. The classic view of services as being perishable, being consumed in the moment of their supply, was challenged in Greenfield’s work, opening up the notion that services could be consumed (traded) other than at the time of their production. Greenfield conceptualized “semi-durable” and “durable” services, extending concepts introduced by Kuznets as a part of his pioneering work on national accounts. Since Greenfield’s work the modes by which the outputs of services can be traded are very different. Information and communications technologies were much less developed 50 years ago; the advent of networked computers to store information combined with telecommunications technologies now allow interactions in modes not even imagined in 1966. Entire categories of service industries that are accepted as routine today--such as provision of cloud computing services or investment services guided by modern portfolio theory--did not exist when Greenfield conducted his research. Text, data, and graphic files were certainly created at that time, but their storage and transmission (over media such as the internet) has subsequently helped to facilitate the growth and development of

services trade. We can anticipate future changes in producer services supply and demand in ways that are unpredictable at the time of this writing.

Trade is defined as a sale between a buyer and a seller, and from a geographical perspective we can classify where this trade takes place. The simplest dichotomy is between trade that takes place between clients and suppliers locally or in close geographic proximity, and nonlocal trade that takes place over some greater distance. Such interregional trade, however defined, can be defined in a local-nonlocal dichotomy, or within a multiregional framework with many regions of supply and demand.

Unlike trade in goods, which has been tracked through customs and international trade regulations, and reported in great detail (such as through the World Institute for Strategic Economic Research), trade in services has not been the subject of government statistical programs in most countries. Output or sales of services has been measured through series such as the Economic Census in the United States, but the geography of these sales is undocumented. National programs for the measurement of trade between industries are reported in input-output models, but these are typically one-region as opposed to interregional models, and are rarely explicitly international models. Data on the geography of trade in services have come from two broad sources: ad-hoc surveys, and regional input-output models that have an export measure of sales. One of the highest priority topics for the expansion of official statistics from national and international government agencies is the development of robust statistics on trade in services. Given the dominance of services employment and output in the global economy, this is a major oversight in measurement programs that needs to be remedied. The reasons include the need for basic documentation of the structure of regional and national economies, and the role or value that this type of data has for economic development programs.

It is useful to look back on how the notion of trade in services was treated in early literature on the regional economic base. The classic economic base model divides economies into two markets: export and local. Before direct measures of regional trade were undertaken, authors classified industries as exogenous or localized, but struggled with this dichotomy recognizing that some industries were “mixed.” A paper by Polzin is an example of how services trade was treated in this early literature: “Trade and service activities constitute the bulk of the mixed industries and the planner/analyst has little to lose by ignoring them in the construction of the exogenous sector” (Polzin 1973, 231). The statistical basis for this statement is not explained and it was not until surveys of the markets of service industries were conducted in the mid-1980’s that it became evident that this conclusion was erroneous.

Pioneering spatial models of service industries—such as central place theory—were built around services trade, but trade of a localized nature. The hierarchical structure of these models were linked to variations in the spatial thresholds for successful entry of sellers of particular services, services largely consumed by households. The growing size of markets for services not primarily destined for household consumption—sparked changing perspectives on trade in services. This paper turns to a review of these developments in measures of trade in services, with an emphasis on research focused on trade in producer services.

## 2. The unfolding of perspectives on services trade

In a discussion of types of services, Daniels noted that geographic markets are likely to be very different across them. Discussing markets for a greengrocer versus a consultant providing advice on the purchase of telecommunications facilities he wrote: "It is conceivable...that the specialist consultant has a market which extends throughout a country, either because no other organization is able to provide the service or because there is insufficient demand to justify the existence of more than one such firm (Daniels, 1982, 31)." Daniels wrestled with location principles guiding the greengrocer, and the producer services firm, noting that central-place model location principles were less likely to apply to location choices of producer service specialists. Without mentioning the geography of trade explicitly, Daniels implied the potential for trade, especially in the face of the development of information technologies.

In 1985 Daniels extended the argument just made, with some of the first estimates of the magnitude of trade in services: "During the last decade trade in services has become one of the most rapidly growing and changing sections of international trade. It has been estimated that services now account for one third of world trade amounting to a massive \$550,000 million in 1980. About 20 per cent of the world total is accounted for by the USA, with France and Britain in second and third place respectively (9.4 percent and 9.2 per cent of world trade in invisibles). Until recently most of the services crossing international boundaries were ancillary to, or in support of, the trade of goods (such as the financial services which permit trade in goods, transportation or consulting services). Now services are traded in their own right: advertising, market research and management consulting, telecommunications services, computer services, specialized financial services in banking and insurance and business services. The spread of multinational enterprises has encouraged the growth of international trade in services, even though some of the transactions will be between the constituent parts of the same enterprise. Unfortunately there is a shortage of reliable statistics on international trade in services; it remains difficult to measure and analyze trade volumes, patterns and composition." (Daniels 1985, 35-36).

Ochel and Wegner focused on trade in services in Europe and explored the transformation of markets in the context of the 'new economy': "The internationalization of markets is facilitated by the growing tradability of services. Advances in communications technology and in information storage and processing have made it possible to produce services in one place and to consume them somewhere else and to produce services at one point in time and to consume them at a later date. Any service product that can be reduced to electronically coded pieces of information can theoretically be delivered to any point in the world with great reliability, at relatively little cost, and with no time-lag. Of course, there are many difficulties in implementing such an information system." (Ochel and Wegner 1987, 62). Their argument seems to ignore types of services where face-to-face communications is important in delivering the service.

Improvements in technology were also important such that: "Trade in producer services is also growing because the cost of 'transporting' services is falling over time. The long-term rise of trade in goods is in part due to innovations in transportation technology:

navigation; shipbuilding; railways; trucking; etc. Improvements in communications technology (telephone, fax, television, courier services, etc.) have had a similar impact on trade in services. To this must be added improvements in the transportation of persons, lowering travel costs for “labor embodied” services. From this follows increasing interregional specialization with respect to services, bringing into play questions of comparative advantage, where services come to play an increasingly critical role in the definition of the economic base of regions.” (Bailly et al. 1992, 25). This was later confirmed in a survey of producer service firms that identified increased use of digital modes of delivering services, but no reduction in the need for face-to-face meetings with clients. Bailly et al. also examined the channels of interregional trade in services, distinguishing between direct service trade, intra-firm trade in services, intra-firm service trade by primary sector and manufacturing firms, trade in services as a result of trade in goods, links with factor flows, labor-embodied services, and service flows versus factor flows. They argued that intra-firm flows are important and can be tracked using survey methods and that survey data on inter-firm trade in services underestimates total trade flows.

Daniels returned to the issue of trade in producer services, observing that: “In order for services to become prominent actors in the world economy they must possess attributes that enable them to be exchanged across geographic space (Daniels 1993, 25).” He noted that some services are not tradable, and presented a taxonomy for service firm internationalization with regard to service multinational enterprises, international trade and foreign direct investment in services, the global system of cities, and the internationalization of services and the restructuring of cities. He also speculated about the desirability of service-dominated economies, the inevitability of the globalization of services, the unfulfilled potential of telecommunications, and whether IT advances will impact interaction: “Innovations in the applications of information and telecommunications technology are therefore set to continue. They are worth noting because their ultimate effect, threatened for years but yet to be manifested, may be to replace a global service economy dependent upon intensive transactional flows (people, information, electronic messages etc.) between a small number of large, highly centralized control-points with a more dispersed telecommunications-dependent network of transactions. Flows of human capital will be far less significant though still necessary for the conduct of high-level negotiations and information exchange.” (Daniels 1993, 175-176). He went on to speculate about the role of telework, and the possibility of business cycles in advanced services.

Another evaluation of the means of exporting services was offered by Rief et al.: “There are different ways of selling services across borders. Direct selling is by no means the primary method for residents of one country to provide services to residents of another.”... “*International Consulting*. International consulting, also termed transient service exports, occurs when a US businessperson renders a service to a foreign client on a short-term basis.”... “*Direct Exporting*” Because the value of some services is embedded in the tangible products associated with these services, the export of a service sometimes can be shipped much like a manufactured good. Examples of this type of service export include books, pharmaceuticals and software.” ... “*Telematic Trading*. Telematic trade is another means of exporting a service and one which involves the transfer of knowledge and information abroad via telecommunications.” ... “*Royalties and Licensing Agreements*. According to the Bureau of Economic Analysis, royalties and licensing fees consist of receipts and payments for the use of patented techniques, processes, formulas, and other intangible property rights used in

goods production, as well as copyrights, trademarks, franchises, rights to broadcast live events, and other intangible rights.”... “*Franchising*. A franchise is a business arrangement in which an established business gives an independent party (the franchisee) the rights to use its brand names or trademarks, and transfers knowledge which is essential to running the business.” “*Providing services to foreign visitors*. This export can be simply defined as a service performed and completed in the United States and sold directly to a foreigner which in the United States (Rief et.al., 1997, 5).”

A recent assessment by the EU of the delivery of business services speaks to some of the issues surrounding the expansion of trade in services, including producer services. Four pathways to internationalization are identified and these could also be interpreted as pathways for interregional trade in a huge internal market such as within the United States. These pathways are:

Mode 1: *cross-border supply*, which occurs when suppliers of services in one country supply services to consumers in another country without either supplier or consumer moving into the territory of the other.

Mode 2: *consumption abroad*, which refers to the process by which a consumer resident in one country moves to another country to obtain a service.

Mode 3: *commercial presence* occurs when enterprises in an economy supply services internationally through the activities of foreign affiliates.

Mode 4: presence of natural persons describes the process by which an individual moves to the consumer’s country to provide a service, whether on his or her own behalf or on behalf of his or her employer.” (European Commission, 2014).

There are no data included in this EU report to illustrate the relative importance of these pathways.

### **3. Broader Arguments Regarding Trade in Services**

The emphasis in the preceding section of this entry has been on the growing role of interregional trade in services, but it is important to recognize that local demands for producer and other services remain important. This can be measured using a two region model inspired by interregional input-output models of trade in all economic activities, with explicit producer service trade modules linked to intraregional and interregional demand (Beyers 1990). Figure 1 illustrates this two region system; in each region there is a block of local final demand (personal consumption expenditures, investment, and government), and a block of local income which is linked to the local production system (producer services, and the transformative, distributive, retail, not-for-profit and mainly consumer services sectors). Exports and imports are shown for all sectors in this fully enclosed system and it was argued that, on the basis of

these connections, if demands rose or fell in one region this would lead to inter-regional consequences across all elements of the multiregional system.

Figure 1 A two-region system of trade

Using data for Bureau of Economic Analysis (BEA) economic areas in the United States, Beyers used the system illustrated in Fig. 1 to estimate producer services trade using location quotients. He concluded that: "The growth of producer services employment in a given region should be seen to be a function of the growth of producer services exports and exports of other key industrial sectors. These changing export demands in turn lead to local direct requirements for producer services and other inputs, and they directly create local income. These direct requirements lead to a chain of indirect effects, which have associated with them additional demands for producer services and other sectors, that also create additional income. Expenditures of locally created income leads through the consumption and government expenditure process to additional indirect and induced effects, including local final demands for producer services." .. "In regions with a strongly expanding export base, this set of linkages appears to have led to strong growth in producer services, and the opposite has been the case in regions with a declining or slowing growing export base." ... "Over time, the importance of these interregional connectivities may be increasing in the producer services as businesses are able to extend market areas through the use of advanced information processing and telecommunications technologies" (Beyers 1990, 167).

Returning to trade in services in 2007, Daniels reminded us of the traditional argument for service production and consumption to be co-located because of the ‘non-tradable’ nature of many services. However, he argued that this restricted view has been modified by the advent of information and communications technologies (ICT), including the associated increases in service sector productivity. These forces have led to services globalization with four dimensions: flows, networks, frameworks, and brands and trademarks. Daniels offers a portrait of trade in these dimensions benchmarked against the year 2000; the system of flows is similar to Figure 1, but reports estimates of inter- and intra-regional flow (Daniels 2007). This rich diagram documents strong intra-region and export trade in Europe, the Americas, and Asia & Oceania. Implicitly, imports are captured in the system of trade flows documented in Figure 2.

The size of the boxes in this diagram are proportional to total exports across the four regions, divided into intraregional and interregional trade. The high intra-regional percentages for Europe reflect the large number of relatively small countries with large European markets. The export shares for each regional block add to 100%.

Daniels mentions a number of indicators of these dimensions associated with this pattern of trade, such as the availability of infrastructure and institutions allowing the four modes of supply identified above to operate for trade and foreign direct investment (FDI) (for example, growth in services share of FDI and structural change within OECD countries in the composition of services FDI, especially the strong growth in the share of business services and transportation & communication services, and decreases in the share of trade, financial intermediation, and other services (subject to strong cyclicity)). Another indicator is a new international division of labor allowing integration of production systems across national boundaries (such as the offshoring of telephone based support systems to places such as India by US or European service firms), particularly by multinational corporations (MNC’s) that threatens services job creation in the US or Europe.

Figure 2 Daniels model of global trade in services

#### 4. Producer Services trade – survey research

Beginning in the 1980's there was a burst of survey research on the markets of producer service businesses. It is fair to say that this stream of research was stimulated by the lack of industry detail in official statistics and in regional input-output models that presented data for producer services in a highly aggregate manner, as well as by the recognition of the rapid growth of producer services employment and output. It is worth noting that there has not been a comparable body of research undertaken since the turn of the century, so it is not clear whether and how the conclusions of this earlier research may be altered by current data that show continuing increases in the magnitude of trade in producer services.

Beyers and Alvine reported on a large scale survey of the markets of 2,200 producer service establishments in the Puget Sound region of Washington State that found half of them had sales of at least ten percent outside the local area (Beyers and Alvine 1985). Of the establishments that met this criterion the average percentage of external sales was 55%, with the overall level of export markets about 35% when merged with the localized establishments. There was no correlation between firm size and export market percentage although a large cohort of establishments that had experienced growth in their export percentage also expected an expansion of export share in the near future. Major variations in export propensities were reported by industry, with accounting having a low export market percentage while other industries such as research & development reported a very strong export market percentage.

The channels of trade in producer services, including (1) direct service exports, (2) intrafirm service exports by producer services firms, and (3) intrafirm service exports by manufacturing firms were surveyed by Coffey and Polèse. They reported that: "With the language may have acted as a barrier to exports, as well as transport costs, professional licensing requirements, and work permits. They argued that given these barriers, producer-service firms would be tempted to establish local offices to penetrate outside markets. (Coffey and Polèse 1987, 600-601).

A survey of Vancouver BC producer service firms measured their markets by sector served (primarily sales to other service industries), as well as their geographic reach (Ley and Hutton, 1987). The study found 51.4% of firms had greater than 75% of their sales in the Vancouver area, 20.4% had at least 25% of sales elsewhere in British Columbia, 20.9% had at least 10% sales elsewhere in Canada, and 13.3% had sales of at least 10% elsewhere in the world (percentages do not add to 100% because of the way in which this survey was phrased). The respondents also thought that Vancouver would be a major source of growth (68%), along with the rest of British Columbia (20%). This contrasts with later research that showed a sample of firms anticipating much more growth in markets outside Vancouver (Davis and Hutton, 1991). That paper also explored the idea that producer services were becoming increasingly tradable. This draws from Davis's work on an input-output model of the Vancouver regional economy from the mid-1980's that showed strong exports of business services from the Vancouver area (44.7% local markets, 44.2% to other B.C., 7.2% to other Canada, 1.5% to the U.S and 2.4% to the rest of the world). A related study in 1990 reported higher levels of exports from the Vancouver region for engineering, management consulting and computer services businesses, while advertising was estimated to have strong local markets. This survey also asked firms about expected changes in markets, finding that they expected a larger share of exports: exactly what the Beyers and Alvine study reported in 1985.

Further corroboration was provided by surveys of the export markets of producer service firms in Edmonton, Alberta which showed an average of 36% in service exports - very similar to Beyers and Alvine's documentation of trade in producer services in the Puget Sound region (Michalak and Fairbairn, 1988). Michalak and Fairbairn concluded, first, that a peripheral city such as Edmonton did not have strong producer services links to the Canadian economic core (Toronto/Montreal), implying a weak role for the core-periphery model in explaining markets for producer services. Second, their data suggested that the Alberta region was developing independently of the Canadian economic core. Third, they found that services exports were to places unrelated to their size. Fourth, they found markets links with

services and government and, finally, that a successful regional economy depended upon an adequate supply of producer services as inputs to the production process in ways that made their clients/users competitive.

A study centered on Chicago by Esparza and Kremnec found that manufacturing was not the dominant market of producer services except for advertising firms. The linkages of the firms were mapped, revealing a two-tier system. The first tier involved interaction among world class cities, and argued that gateway cities dominated interaction in the contemporary global urban system. The second tier was found to be within the U.S. system of cities, resembling a hierarchical structure, with distance mitigating interaction over long distances (Esparza and Kremnec 1994, 44).

In the late-1990s it was recognized that trade in producer services would likely be influenced by considerations such as the adaptive behavior of firms (Beyers and Lindahl 1997a). Using survey data focusing on changes in services sold, changes in client types, and changes in export markets, Beyers and Lindahl tested the Ansoff model of adaptive behavior, with the results clearly indicating that producer service firms engaged in adaptive behavior had higher growth in sales than those that were not adaptive.

The behavior of producer services located in rural areas, rather than the city regions, was also a potential source of variation in local versus non-local transactions. Based on an analysis of a national sample of producer service firms in rural counties in the US, Beyers and Lindahl (1997b) found that 43% of the firms were strongly engaged in selling their services in nonlocal markets, with most being niche market players. These firms were categorized as Lone Eagles (proprietors) or High Fliers (strongly exporting firms with employees). Quality of life, cost concerns, and proximity to the location of the firm's headquarters were primary location considerations, along with other personal factors. Those working for export-oriented firms often traveled to meet with their clients and generated higher revenues per worker compared to locally oriented firms.

Finally, the results from eight surveys of producer services markets, some of which are referenced in this entry, were usefully summarized by Illeris. He reported that local markets varied from about 32% to 71% of sales, with an average of 49%. Put another way, the Illeris compilation indicates that just over 50% of producer service markets were non-local or export (Illeris 1990, 146).

## **5. Services Trade—Evidence from Input-Output Models**

Useful insights on the scale and geography of trade in services are available from studies and reports that rely on a mix of primary and secondary data. An alternative source of data on the use of and trade in services is data from input-output models. In the United States these models are estimated annually for the national economy, and every five years at a more detailed industry level in “benchmark” tables. These models document the value of purchases of producer services by industries, as well as households, governments, investors, and on export accounts.

Anne Carter reported on the increasing importance of producer services in a landmark analysis of structural change in the American economy utilizing U.S. input-output models. Advertising was the fastest growing portion of the business service sector in the time periods analyzed (1939 to 1947, and 1947 to 1958) and, citing Greenfield's work, Carter wrestled with the reasons for this growth. While there were "costs of coordinating a growing volume of specialized transactions", externalization (the shift of provision of services internally in a sector to their external procurement) is also important: "Only part of the growth of the service sectors represents actual increases in the total volume of services performed. The rest is the transfer of service functions from firms and establishments primarily engaged in manufacturing and other product-oriented activities to specialized service sectors." (Carter 1970, 65). The data on this trend were sketchy, but she noted increasing contracting out for research and development services, for banks to increasingly "perform record-keeping and information-storage functions that were formerly in the province of bookkeeping departments of customer establishments. Similarly, insurance companies assumed an increasing proportion of risks formerly taken by the insured companies themselves. Some of these services, such as workmen's compensation, are mandatory. Specialized record-keeping and computer services have been growing rapidly. Such business services range from very sophisticated data retrieval schemes to assisting small businesses in coping with tax regulations. To a greater and greater extent exploratory and trouble-shooting research on engineering and business problems have been delegated to consulting organizations. Advertising work is more centralized in specialized agencies. Complex equipment, including cars and trucks, is beginning to be rented more frequently than being bought outright." (Carter 1970, 65, 68).

## **5.1 *Purchases and imports***

Apart from the national level, input-output models at the level of a region can also provide data on the demand for and trade in producer services. In practice such models are rarely based on survey data, and are generally derived by adjusting national input-output models inter-industry structure to produce regional multipliers, rather than a full transactions table with estimates of imports and exports. However, a set of eight models stretching from 1963 through 2007 are available for Washington State, that can be used to estimate spatial aspects of trade in services. When combined with data from the U.S. national input-output models, it is possible to compile very useful portraits of changing levels of services purchases. Table 1 summarizes these data for the greatest level of detail available over the history of the Washington input-output models. In some cases the U.S. data have a smaller value than data from the Washington models; in these cases it was assumed that the Washington data were the appropriate estimate, and that imports from the rest of the United States were zero.

The data in Table 1 indicate a significant increase in the share of total purchases accounted for by services over the history of the Washington input-output models. Regional services purchases increased from approximately 9% in the 1960's to approximately 18% in recent years, while nationally service purchases have increased from 15% to 26% of total inputs (It should be noted that these percentages are as a share of total purchases, which include purchases of labor income and other value-added payments, and purchases of goods.) Let us turn to histories of purchases for the lines of service industries captured in Table 1.

Washington State

|                | 1963  | 1967  | 1972   | 1982   | 1987   | 1997   | 2002   | 2007   |
|----------------|-------|-------|--------|--------|--------|--------|--------|--------|
| Transport      | 1.45% | 1.37% | 1.47%  | 1.54%  | 1.14%  | 1.20%  | 1.19%  | 1.62%  |
| Utilities      | 1.64% | 1.54% | 2.06%  | 2.93%  | 2.57%  | 2.36%  | 1.41%  | 0.76%  |
| Trade          | 1.89% | 1.30% | 1.83%  | 2.06%  | 2.74%  | 2.32%  | 2.45%  | 3.40%  |
| Producer       | 3.00% | 3.13% | 3.12%  | 3.51%  | 3.90%  | 9.56%  | 9.98%  | 9.20%  |
| Other Services | 1.62% | 1.36% | 4.17%  | 4.77%  | 3.72%  | 3.30%  | 2.62%  | 2.22%  |
| Tota           | 9.59% | 8.69% | 12.66% | 14.81% | 14.07% | 18.73% | 17.66% | 17.20% |

United States

|                   | 1963  | 1967  | 1972  | 1982  | 1987  | 1997  | 2002  | 2007  |
|-------------------|-------|-------|-------|-------|-------|-------|-------|-------|
| Transport         | 2.1%  | 2.1%  | 2.1%  | 2.3%  | 2.0%  | 2.0%  | 2.0%  | 2.1%  |
| Utilities         | 1.5%  | 1.4%  | 1.5%  | 3.2%  | 1.8%  | 1.1%  | 1.1%  | 1.1%  |
| Trade             | 2.8%  | 2.8%  | 3.0%  | 2.5%  | 3.0%  | 2.8%  | 2.5%  | 2.5%  |
| Producer Services | 6.5%  | 7.1%  | 7.6%  | 10.6% | 10.9% | 14.5% | 16.6% | 17.5% |
| Other Services    | 1.8%  | 2.0%  | 2.1%  | 2.7%  | 2.5%  | 3.7%  | 3.8%  | 2.9%  |
| Total             | 14.7% | 15.4% | 16.3% | 21.2% | 20.2% | 24.1% | 26.1% | 26.2% |

Table 1 Services Intermediate Purchase Estimates, Washington State and United States(% of Total Purchases)

Figure 3 shows a clear upward trend in the economy-wide purchase of producer services as a share of output in the United States. It also shows Washington State purchases as a share of output over time, along with the difference between national purchases and Washington regional purchases (these are interpreted here as the implicit imported share of producer services to Washington businesses). These estimates are approximate, since the industry mix in Washington differs from the U.S., and patterns of purchase within particular industries may differ between Washington State and the same industry elsewhere in the United States.

Figure 3 is derived from the history of the Washington and U.S. input-output models and shows the percentage of total purchases accounted for by producer services from 1963 to 2007. (The author has estimated values for some of these years, as detail was not sought in the surveys for these purchases). The large increase in the 1987 to 1997 time period is undoubtedly related to the shift from the Standard Industrial (SIC) system to the North American Industry Classification System (NAICS), in which some activities were reclassified from industries such as manufacturing to producer services. One example of this type of reclassification is headquarters activity, that was classified as “administrative & auxiliary” employment in each broad class of industry (such as manufacturing or construction) in the SIC system, but transferred to “management of companies” in the NAICS system. The WA regional requirement is the sum of values reported in Figure 3 for FIRE and Business Services.

Figure 3 Producer Services Intermediate Purchases

An increase in the share of production costs accounted for by producer services over time is clearly evident in Figure 3, split in this figure between Washington State production as measured in the Washington input-output models, and between imports from the rest of the United States, implied by U.S. input-output models. Estimates of the share of imports suggest that they have diminished somewhat over the time period included in these figures, suggesting that Washington producers have supplied a somewhat larger share of total demand for producer services over time.

Figure 4 presents estimates of regional purchases and imports of transportation services. Unlike the data for producer services, that indicates a rise in regional supply and imports over time, the data for transportation services indicates stability in the overall demand for these services and in the geography of their supply.

Figure 4 Transportation Services Regional Purchases and Imports

Figure 5 reports a clear trend towards larger regional purchases of trade services over the history of the Washington input-output models, and a corresponding fall in imports. Unfortunately, some of the early Washington input-output models did not distinguish between retail and wholesale trade, so it is not possible to identify which industry was the source of regional growth in purchases.

Figure 5 Wholesale and Retail Trade Regional Purchases and Imports

Figure 6 reports estimates of regional purchases of other services, and imports from the rest of the United States. Clearly, imports are modest, but appear to have risen since 1987. The rise and then fall in regional purchases is not easy to explain, but this category is dominated by types of services that likely have stronger final demands than intermediate demands (such as health care).

Figure 6 Other Services – Washington and Imports

## 5.2 Sales and Exports

The Washington input-output models also allow estimates of exports as a share of total sales, over time. These have been calculated from the series of Washington input-output models (Fig. 6). Shares of sales by service industries in Washington State in Figure 6 are divided into three broad categories: sales made within Washington State on intermediate account, sales made to Washington households, investors, and state and local governments (C.I.G), and sales made on export account. The data in Table 6 document a remarkably stable sales distribution for services on intermediate account (in the range of 25% to 30%). In contrast, sales to regional final demand contract over the history of the Washington input-output models (from about 62% of total output to about 40% of total output), while exports rise from about 10% to about 30% of total output.

Figure 6 Sales Distribution of Washington Service Industries

While the history of Washington input-output models has gaps regarding sectoral detail for exports, overall exports as a share of total output in services can be reported. Figure 7 reports this detail. The export of services rose from about 10% in 1963 to 31% of total services output in 2007. Clearly, the growth in sales to the rest of the United States was the largest source of growth, but foreign exports also exhibit growth, while sales to the federal government have been stable.

Figure 7 Overall Service Export Market Shares

The composition of exports is documented in Table 8, which documents significant structural change in export sales. Clearly, the early dominance of exports of transportation services has been replaced by strong exports of producer services. Trade and transportation service exports are linked to the export of goods, such as agricultural or forest products, and while still significant in absolute magnitude, their relative importance has been overshadowed by the strong growth of exports of producer services. It should be noted that Figure 8 (and figures 9 and 10) do not report data for 1972 and 1982 because the Washington input-output models for those years did not disaggregate trade in services consistent with the categories in Figure 8.

Figure 8 Share of Total Exports by Sector

Figure 9 reports the pattern of sales on intermediate account to Washington businesses by all service industries. This figure reports less dramatic structural change in markets than reported in Figure 8. Transportation and trade margins remain important, in relation to the purchase of commodities used in the production process. Utilities output is dominated by electricity in the Washington economy, and the reduction in the share of output associated with this sector is no doubt related to the contraction of the aluminum industry that was a major consumer of electricity in the 1960's, and has almost disappeared from the Washington economy by 2007. The increased share of sales of producer services mirrors data presented earlier that documented the growth in purchases of these services as a share of output over time.

Figure 9 Intermediate Sales by Sector

A final perspective on changing service markets is presented in Figure 10. This figure documents the share of services sales made to households, on investment account, and to state and local governments. This figure reports strong markets related to trade, reflecting the importance of trade margins (and transportation margins) associated with the distribution of goods through retailers. The growth of other services importance is no doubt related to the expansion of demand for health services, and other consumer services such as repair and entertainment. While producer services markets are primarily with business and government, Figure 10 does report an expansion of markets to households, investors, and state and local governments for producer services. Growth in sales of financial and real estate services to households, and of legal services to households, are examples of sales by producer services to these industrial markets. While modest in magnitude, telecommunications and utilities appear to have had relatively constant shares of markets to households, investors, and state & local governments.

Figure 10 Washington Service Industry Sales to Consumers, on Investment Account and to State and Local Governments

## 6. Concluding Comments

This paper has documented the dynamics of trade in services in the Washington state economy over half a century. Placed in the context of earlier work that has argued the growing importance of trade in services, the Washington data represent a unique regional data series providing hard evidence about the growing importance of trade in services. Washington state may differ somewhat from other states with regard to the service economy, but the data presented in this paper on services purchases document consistency between the Washington state input-output accounts and the U.S. national input-output accounts. It would be interesting to explore the possibility of analyzing historical European input-output data to determine if similar patterns of change in exports and imports in services are documented. The lack of hard statistical data on trade in services from government agencies such as the U.S. Bureau of Economic Analysis is a major omission in economic statistical data, given the domination of services output and employment in states and regions in countries such as the United States today.

*This paper aims to discuss the specificities of the role of services in the economic structuring and in the social liveliness and attractiveness of periurban areas. Drawing upon on the result of an empirical work developed in 5 different parishes of Lisbon Metropolitan area, which represent five categories of periurban spaces previously identified, it is analysed the role of services in these “in-between” territories and the way they are important in the spatial economic structuring of these areas and in the quality of life and well-being of their inhabitants and users. A tentative typology for framing the analysis of the role of services on periurban metropolitan spaces is suggested and some policy implications are pointed out.*

## 1. Introduction

The aim of this paper is to discuss the specificities of the role of services in the economic structuring and in the social liveliness and attractiveness of periurban areas, drawing on an empirical work developed at Lisbon Metropolitan Area (LMA).

Periurban areas present specific characteristics in terms of the competitive factors they develop to attract economic activities, users and residents, which make them special in terms of contemporary metropolitan contexts. Specific types of economic activities and specific branches within economic value chains (from logistics to agriculture, from proximity services to KIBS, from clean energy supply to specialized exported oriented businesses, from specific touristic branches to environmental protection services)

find their place in these areas, and services have a fundamental role on it. At the same time, the social restructuring of these areas, marked by increased territorial and social mobility(ies), and permanent identity challenging processes, is intimately marked by these service activities, that, on one hand, condition the attractiveness of residents and users, but on the other hand, are the result of these new social composition and the fruit of the re-composition of the needs of that population.

The role of services in these “in-between” territories and the way they are important in the spatial economic structuring of these areas and in the quality of life and well-being these areas provide are clearly understudied, and this paper’s objective is to problematize that issue, drawing on the result of an empirical work developed in five different parishes of Lisbon Metropolitan area, which represent five distinct categories of peri-urban spaces, previously identified.

Next section introduces the framework in which this paper was developed (the PERIURBAN research project), its main phases, and the methodology used in the part of the research that was mobilized for this article. In section 3, a discussion on the structuring and dynamics of periurban spaces is held, and the main characteristics of LMA periurban area (and of the 5 parishes studied) are presented. Section 4 provides a more focused discussion on the role of services in LMA periurban, and presents a tentative typology of services regarding the general analysis of periurban territories. A brief concluding note refers to the issue of policy implications, in terms of territorial planning policies.

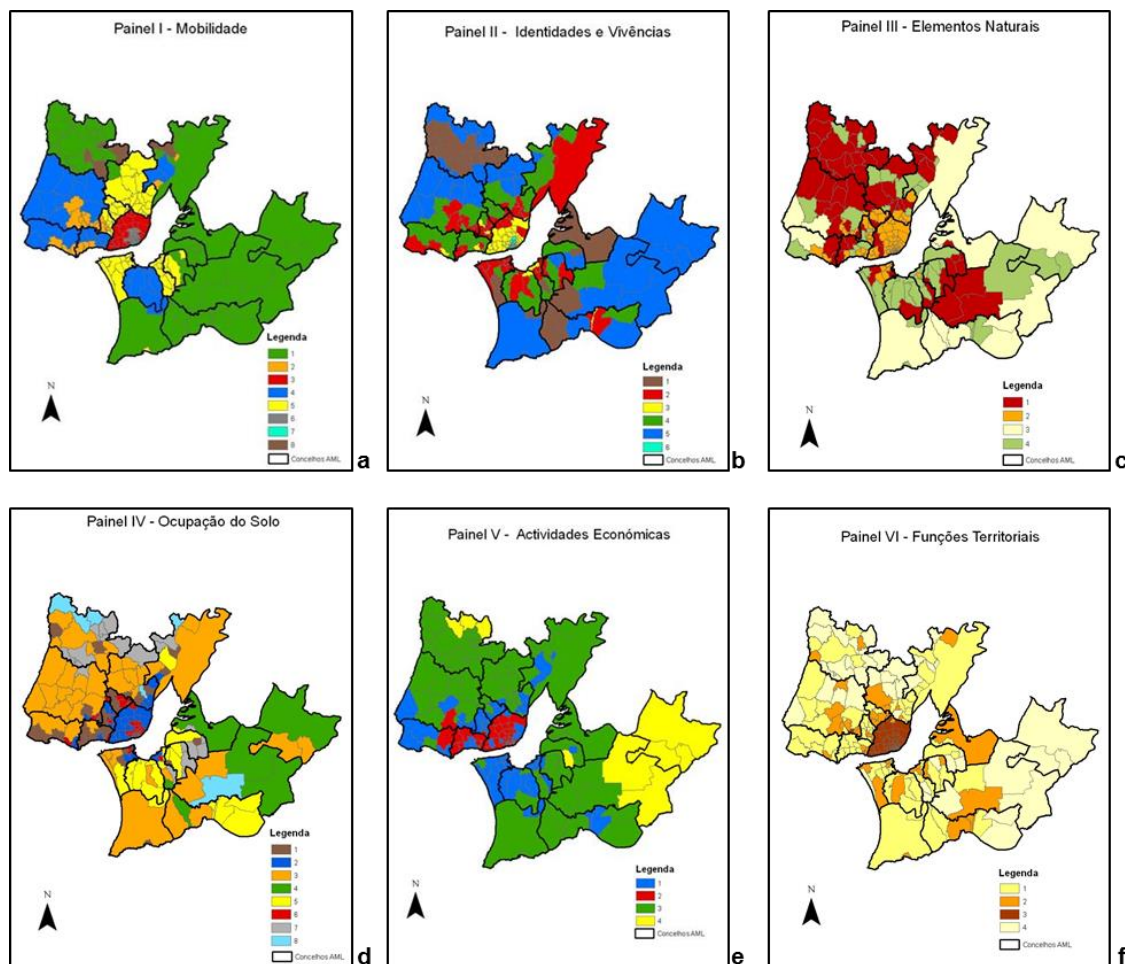

## **2. Context and methodology**

The paper is developed under the broader scope of a funded research project on the challenges that periurban areas of Lisbon Metropolitan Area face to achieve sustainability, the PERIURBAN project<sup>1</sup>). The main goal of this project, involving different Portuguese universities, crossing academic fields and integrating the knowledge of stakeholders from diverse institutional and territorial (local and regional) backgrounds, is to assess the potential of periurban areas to meet future challenges for sustainable development in a changing world. It aims to look in-depth into the periurban areas of Lisbon Metropolitan Area with their physical, environmental, social, economic and institutional characteristics, using a prospective approach.

<sup>1</sup> “Peri-urban areas facing sustainability challenges: scenario development in the Lisbon Metropolitan Area” [PTDC/AUR-AQI/117305/2010] funded by Portuguese Science and Technology Foundation (FCT).

In the first phase of the project a typology of periurban spaces in the Lisbon Metropolitan area has been identified, starting from a thorough diagnosis, at six different levels (Mobility; Identities and Experiences; Natural Elements; Territorial Functions and Topology; Occupation; Economic Activities), which made it possible to map, based on a cluster analysis, a set of different types of parishes in AML, among which we have defined 5 types of periurban territories (cf. Gonçalves et al, 2015, for details). Figure 1 shows the typology of periurban territories resulting for each of those 6 analytical levels, and figure 2 presents the final typology of periurban spaces which resulted from the integration of those 6 dimensions and clusters analysis.

Figure 1: Typologies of periurban territories in LMA, in each of the 6 analytical dimensions

Source: own elaboration (PERIURBAN project)

Five different types of periurban were identified (Figure 2), plus one category of more “pure” “urban” space, which was discarded of our analysis. Details on the characteristics of each of these 5 types of periurban spaces can be found in Gonçalves et al (2015).

Figure 2: Final typology of periurban territories in LMA

Source: own elaboration (PERIURBAN project)

In a second phase of the project, and drawing upon a more detailed analysis, based on quantitative and qualitative methodologies (including, but not limited to, interviews, the application of a survey and a discussion of visual material recollection on the territories concerned), we proceeded to an in-depth study of 5 parishes which were assumed as representative of each of these clusters (Nossa Sra. da Anunciada; Sarilhos Grandes; Poceirão; Vialonga and Agualva – cf Figure 3), considering the challenges to the sustainability of these territories within the timeframe given by the project, based on a characterization of the current situation and a discussion with local stakeholders on scenarios for its future development.

Figure 3: Selected parishes ("parishes-type", representative of each typology):

Source: own elaboration (PERIURBAN project)

This analysis was based on an in-depth evaluation carried out at five distinct levels, which constitute what we've called "the pentagon of sustainability": the "physical" system; the "ecological" system; the "social" system; the "economic" system; and the "institutional" system. For each one of these "systems" a methodology was developed in order to access the conditions for sustainability in that particular field, and specific analytical tools were put in practice.

In this paper, we focus specifically merely on part of the results obtained on this second phase of the project, namely, in just two of those five analytical dimensions: the "economic" and the "social".

Based on the information collected via interviews (with 50 selected stakeholders, e.g. local and regional administration, associations, businesses, schools, employment centers, firefighters), survey (applied to 600 individuals, with a stratified sample, in the 5 parishes) and visual recollection (observation with a photographic approach, involving 2 days of observation, 7 specific points at 3 times slots in each parish), and crossing these 3 methodological sources (also with the second-order information recollected statistical data, information from municipalities and parishes, planning documents, etc.), a discussion is made in order to stablish a profile of periurban services, and to inquire the way services condition and (re)produce the economic (re)structuring patterns and identity(ies) and quality of life in metropolitan peri-urban areas.

### **3. Periurban territories and metropolitan (re)structuring**

#### **3.1. In-between spaces: periurban between centres and the margins**

Periurban territories, particularly the metropolitan ones, can be seen as “in-between” spaces, mixing and making the transition between urban and rural economic forms of organization, as well as social and cultural practices, attitudes, values and identity construction aspects. This can be reflected on a variety of declinations in the production-consumption systems, in lifestyles, in identities and, generally, in all social, cultural and economic processes, which make these areas also interesting spaces of heterotopy and liminality.

The specificities of these spaces are clearly understudied and often are underestimated due to the visibility of the globalization processes and the competitive processes between agglomerations (e.g, amongst metropolises, or among these and smaller towns) to attract residents, users, tourist or economic activities. But the specific competitive advantages of these periurban areas should be examined more thoroughly, as they are important in the contemporary intra-metropolitan (re)structuring processes as well as in the potential these areas can provide in the external affirmations of those territories, at economic, social, cultural or ecological levels, for instance.

The changing pattern of population occupation, settlement characteristics, economic activities or social practices observed in these areas, can be observed both in what relates to economic activities as socio-cultural and identities construction (beside physical, ecological, and morphological dimensions, or other that are not the specific concern of this article).

Considering economic activities, periurban territories are characterized by complementary relations between urban and rural systems. This links result from the flow of products, information and people as from the connections between sectors related to agriculture, manufacturing, and services (Pradoto, 2012). This is expressed in a complexification and mixing of the traditional accounting “sectors” which increases a “smoke screen” on the economic structure of these spaces, where various kinds of services are clearly underestimated: ‘The flow of goods, people, capital, and economic sectors overlap at both household and wider levels creates reciprocal linkages between agriculture, manufacturing, and service as part of the urbanization’ (Tacoli, 1998).

Pradoto, (2012) argues that there are three main processes modelling the transformation of rural-urban economy, including: (i) the relocation of manufacturing and service industries in peripheral areas of the city due to lower rent prices that, in turn, attracts people to leave the city and reside in periurban areas; (ii) the declining of local employment, forcing young people to migrate out and engage in non-farm work; and (iii) the demand of middle class for a better quality of life by residing in a green environment in the peripheral zones.

Periurban is influenced by both rural and urban dynamics. The influence of a metropolitan area is expressed by continuing investments in peripheral areas that offer sources of labour and land. The presence of industries, services, logistics and distribution platforms, SEZ (Special economic zones) enterprises, housing, big store chains etc. constitutes physical manifestations of this realm. Plus, and in parallel, the coexistence of a rural – agriculture matrix establishes a hybrid territory where distinct activities occur like the one related to agro-industrial, distribution but also to food subsistence and pluriactivity, etc. This complex set of conditions defines distinct degrees of specialization/diversity of the economic tissue. The analysis conducted during the first phase of this project, acknowledges this economic diversity, including the issues of the specialization and diversification of economic activities (creating a clearly fragmented economic mosaic), the special presence of agriculture and related business and industry, and the attractiveness to new activities and real state development (cf Ferreiro et al, 2015 for details).

But these “in-betweenness” can also be seen regarding identities and lifestyles, which are intimately interrelated to territorial recomposition processes. Considering peri-urban spaces as 'in transition' and strongly marked by social and territorial recomposition, a 'flows-based' approach was adopted in order to address the 'processes of rapid economic, sociological, institutional, and environmental change' that occur in these territories (Marshall et al, 2009). Understanding inherent social dynamics in LAM, led us to the identification of trends/characteristics through the use of static and dynamic indicators. This approach made possible the distinction between urban centre and peri-urban territory, but also the identification of types of peri-urban spaces with diverse social character. Considering peri-urban as an interface of social/territorial metamorphosis, imminently 'fragmented', and composed of changing communities with distinct identities, it was necessary to translate the fragmented territorial and social mosaic (as it's inner 'movement') in a geographic image of attributes and trends. Portuguese Census (2001 and 2011) information and other quantitative data sources enabled the characterization in social terms (cf. Ferreiro and all, 2015) considering several dimensions: population growth and composition; residential mobility and social diversity; family types; types of housing; territorial reconfiguration; spatial inequalities; community relations).

This process allowed us to understand better the processes and interdependences that may express what can be called of 'peri-urban' (Berger, 2004), giving us some preliminary hints on how to disentangle this relation between territorial restructuring, identity and community relations on those transitional spaces (cf Ferreiro et al, 2015 on this).

The social restructuring of these areas, marked by increased territorial and social mobility(ies), demographic and sociocultural change, and permanent identity challenging processes, is intimately marked by the service activities, that, on one hand, condition the attractiveness of residents and users (as amenities which are increasingly required by larger segments of population), but on the other hand, are the result of these new social composition and the fruit of the re-composition of the needs of those populations.

### **3.2 . The periurban in LMA: growing attractiveness in a metropolitan restructuring context**

The attractiveness of the periurban areas is stated in the specificity that these can offer between an "urban" territory in progressive expansion and a "rural" in transformation and reconfiguration. This is particularly visible and complex in metropolitan areas, such as the one studied. In situ urbanization dynamics coexist with the "oil-stain" expansion of the urbanization process, in a framework in which the dynamics of mobility and accessibility have a key role in the expansion of economic activities for the urban peripheries, which were progressively structuring the territorial occupation. This expansion, clearly visible throughout the 20th century in Lisbon Metropolitan area, both in the North as in the South banks of Tagus River, along the main road and rail routes (and, in recent years around new axes, as the one defined by the Vasco da Gama bridge), marked the demographic expansion to the peripheries, successively in a 1st, 2nd and 3rd crowns around the centre. This entailed the relocation of support services to all these populations, and a dynamic economic activity of proximity (small commerce and support services to families, in areas such as food and restauration, aesthetics, health, leisure, car equipment and repair, as well as small business support services - accounting, informatics etc.), which was gradually spreading across the territory, in addition to activities associated with construction and building activity and with residential equipment cluster (household equipment, furniture, gardening, ...). The centres of the residential agglomerations and small settlements, some more traditional, other more modern, were thus progressively consolidating its economic role as providers of services to nearby surrounding, of variable dimension (i.e., with a diversity of hinterlands).

On the other hand, along the same routes, the offer of more "heavy" economic activity, be it industrial oriented, or be it (mostly) in the field of the

activities related to logistics, distribution, storage or wholesale, exploring the benefits of accessibility, and the cheaper costs of land and labour, was structuring according to the specific competitive advantages of each territory (from the existence of natural resources, as in the case of extractive industries, to the locative centrality with regard to export channels, or the ease of obtaining manpower available, for example). This process gets a supplementary impulse with the economic dynamics related to contemporary globalisation processes, having these spaces often a capacity of global hyper-connectivity that is result from the combination of exogenous and endogenous competitive factors that can be mobilized in the face of its metropolitan location and the resulting advantages of scale and connectivity (see for example the case of "Auto-Europa", the country's largest exporter, or others). New centres were developing in such a process, for instance technological and industrial parks, logistics poles, spaces for energy infrastructures, or shopping malls of relative large dimension, polarizing a more specialized trade, throughout the metropolitan area, these days. The existence of physical space transforms easily these periurban areas in a "platform" for strategic regional investment (when not even national or transnational), functioning as a pool for new specialized activities, infrastructure and housing, what ends up reflected in land price pressure and, often, in real estate speculation, which may be more or less articulated with the local or regional planning logics.

In parallel, activities focused on the direct exploitation of more traditional territorial resources (in particular farming and agro-industrial activity, and also fishing), as well as the exploitation of the touristic resources (in particular those associated with seasonal and weekend spend and secondary residences), but also, increasingly, to leisure and to the use of protected and preserved areas) were adapting to this profile of transformation, co-existing and competing with it, and providing services more or less specialized (albeit often seasonal) to a floating population that uses regularly these areas. In the case of agricultural activity, which is striking in the occupation of the soil in much of this periurban territory, the progressive co-existence with other activities and the pressure of the real estate market have led not only to a loss of land for other activities, but also, in cases where the component "rural" is still as dominant, to an increase of the plural-activity of farmers, to the abandonment of land, or to the recourse to subsistence farming familiar. These are phenomena that develop in parallel, conversely, to the intensification of more focused and intensive-production specialized activity and to the conjunction with the agro-industry, clearly market-oriented, as well as in more punctual exploration of new production and distribution mechanisms and market niches (organic farming, short circuits, etc.).

The fragmented economic mosaic that characterizes Lisbon's metropolitan periurban fabric is therefore defined in a constant tension between diversification and specialization, in each concrete space, in which the various competitive factors gain shape and provide opportunities for the location (sometimes temporary, others more definitive) of various activities, in

conjunction (more or less achieved, depending on the specific cases) with the more traditional activities and occupations of those same spaces.

Considering the five parish-type we analysed, this pattern is clearly noteworthy, as much as some of these typical activities of the current peri-urban fabric (the big shopping centre, the industrial and logistic pole, the technological pole) can be sometimes outside of the physical border of these parishes (though on a substantial physical, affective and symbolic proximity).

Therefore, generally coexist in these spaces, on the one hand, highly specialized activities, with very large hinterlands (which can be of large size, such as beer in Vialonga, cement in N<sup>a</sup> Sra da Anunciada or some wine production in Poceirão; but also of smaller dimension, as the highly internationalized flower industry of Sarilhos Grandes, or even informal – and illegal – fishery activity in the same parish), and on the other hand, a very diverse range of activities, essentially services, which can be more or less specialized (provided for residents of and/or businesses), or small-scale commercial activity and logistics, with highly variable hinterlands (mostly in the cases of N<sup>a</sup> Sra da Anunciada and Agualva).

This proximity economic fabric, striking in all the parishes, in some cases is more concentrated around the main urban areas and major roads (Sarilhos Grandes, Poceirão, and even Vialonga), but in other cases is more decentralized and is based on a multiple polarization within the parish (mainly in N<sup>a</sup> Sra da Anunciada and Agualva).

Some particularities mark, apart from this, the profile of each of the territories analysed, which we will present briefly in the next section.

### **3.3. The five “parishes-type”: five examples of an evolving peri-urban socioeconomic structure**

#### **a) Agualva**

Economic activities in the parish of Agualva are essentially related to the small local commerce and services associated with the high population density and the housing market, which can be considered the predominant. There are also some industrial poles with a certain dimension, such as the one at Colaride, where the presence of a pharmaceutical industry small cluster stands out. The factors of attractiveness of the parish are related to its location near the metropolitan employment centres (Lisbon) and exporting flows, the rail and road access (IC19/A16/Sintra railway line), the low value of the soil, the availability of space and the human capital represented by a volume of population of 80 thousand inhabitants.

Yet, there are problems related to the commuting flows associated with job polarization in the city of Lisbon, since the cost of journeys to other parishes of the municipality of Sintra is higher than the cost of travelling to the capital. The parish is thus a dorm-territory where there have been progressive processes of urban decay, combated using public investment programs for requalification (e.g., POLIS-Cacém), trying to induce a new push in the housing market and in private investment. The construction of a range of more consistent competitive advantages to attract activities with higher hinterlands is particularly important in the face of competition from several other territories in the surrounding parishes, both in the municipality of Sintra as in Oeiras (including Taguspark science and technology pole, nearby).

#### b) Vialonga

Vialonga presents some diversification in its economic fabric, with the co-existence of economic activities related to logistics and distribution, industry, hypermarkets and a lively housing market, to which are associated the local proximity commerce, the provision of services, or the social economy. In logistics and distribution stands out the presence of companies like DHL, in industry, Central de Cervejas (largest employer of the parish), as well as the catalyser presence, in the neighbouring parish, of the MARL (Lisbon region supply Market), with very significant effects on local economic activity; in the housing market, the presence of companies related to the construction of recent residential neighbourhoods that have streamlined the local trade and services. The existence of social housing neighbourhoods and socio-economic difficulties led also to an important presence of the social economy sector.

The factors of attractiveness of the parish are related to its location (near the A1, A8, CREL highways), the proximity to the supply centres in the area of large distribution and wholesale, the advantageous soil value, the presence of important complementary commercial relations (e.g. MARL with distribution and logistics companies), as well as the existence of human resources with some level of qualifications (lower rate of unemployment in the municipality of Vila Franca de Xira). The area has also endogenous resources that give interesting competitive advantages, such as high-value soils, in ecological terms, in the area of "várzea de Vialonga" (currently existing conflicts between the occupation for new companies and their protection and utilization for agricultural production), geological resources (quarrying) and energy assets (solar and wind). The parish counter-cyclically increased its economic dynamism between the first half of 2011 and 2014, slowing down from that time for reasons of national economic crisis. The current development constraints relate mainly to the conjunction between residential and business and to the conflict between the occupations of areas of high ecological value for new investments. Al-

so in the housing market, the foreclosures for inability to pay loans are driving to a certain retraction.

### c) Nossa Senhora da Anunciada

Nossa Senhora da Anunciada is a parish which has part of its territory inserted in the city of Setúbal and the other corresponds to a rural area under the jurisdiction of the natural park of Serra da Arrábida, being also marked by an extensive riverfront and seafront. This allows understanding well the parish in terms of the diversity of existing economic activities. The fact that of being located in the urban context, in a region capital (Setúbal city), boasts central functions expressed through the presence of district hospitals, court, social security, regional services, etc., which are important sources of employment, as well as enhance the polarization of some private economic activity, in the fields of trade and services, with supra-local hinterlands.

The economic fabric in the urban context of the parish is, nevertheless, mainly characterized, above all, by the importance of local trade, standing out the restaurants, bars and shops associated with local products (fish, wine, cheese, etc.) the nightlife establishments (bars, clubs) and the services (although some of them polarize a market which corresponds, at least, to the whole of the city, and not only to the parish). Industrial dynamism associated to natural resources (SECIL cements) or the presence of infrastructure (port of Setúbal) can be also immediately identified. In its rural area, the farms of rural tourism, small enterprises of production of wine, cheese and butter, and subsistence agriculture stand out. The presence of the sea, the fishing port and fishermen's cooperatives determine also an important part of the fishing activity in local economy (in conjunction with catering establishments) and the informal dynamics associated to these. Tourist activities associated with the natural and cultural heritage of the parish are also emerging, as expressed by the opening of some hotels, new rural farms touristic facilities, the development of maritime activity-tourism, or Arrábida's candidacy to world heritage. There is a local government effort to promote the regeneration of the riverfront, rehabilitating industrial zones and brownfield areas, and installing new equipment capable of regenerating the urban context and attract foreign visitors. The tourism associated with local activities and local heritage is seen as the main factor of economic attractiveness once there is no more room for allocation of space to industrial activities in the parish (due to legal and regulatory constraints of the natural park).

#### d) Poceirão

Poceirão is a markedly rural parish which corresponds to half of the municipality of Palmela. Agriculture, viticulture, cattle raising and the forestry sector, denoted by the production of cork, are the predominant economic activities of the parish, with some scale and degree of integration both at internal and external markets (e.g. wine). The attractiveness of this territory for those economic activities relates to its flat orography, fertile soils, water availability (largest aquifer of the Iberian Peninsula), the structure of land register, based on large property, the proximity to supply centres on LMA, and the existence of specialized labour and 'know-how' in those areas of activity.

The endogenous characteristics of its territory also determine its attractiveness in relation to major investments expected (but suspended), such as the Lisbon-Madrid high-speed railway link (TGV), the new Lisbon Airport (NAL) and the logistics platform supposed to be able to increase the hinterland of the ports of Lisbon, Setúbal and Sines. The direction of the economic development of the parish (more agricultural oriented, more related to logistics and transport activity, or a mix of the two) will be so dependent on the future and on the implementation of these (or other) intentions on the part of the Portuguese State. In addition to these activities, a profile of service activities and small commerce, relatively low specialized, marks the local activity, being especially implanted around the axis formed between the village of Poceirão and Lagameças.

#### e) Sarilhos Grandes

Sarilhos Grandes is a markedly rural parish, as the parish of Poceirão, but offers, though, several specific characteristics in respect to its territory which determine also differences with regard to the main economic activities and the attractiveness of the parish. The high degree of land consolidation and enclosure determines the presence of small businesses in the area of intensive agriculture, livestock and greenhouse floriculture. This last with some expression because of the concentration of farms in the parish and in the municipality (due to its particular climate) allow to create scale and to stabilize prices. The accessibility and the IC main road create also a potential for fast transportation to the airport which is important in the trade and export of flowers. Greenhouse production (of flowers, red fruits, etc.) is one of the factors which are most pointed to as a potential for economic development and internationalization of the parish. The accessibility (ease of access to Lisbon) and the low cost of soil

constitute factors of attractiveness; however the parish undergoes the constraints caused by lack of manpower (ageing population) and the small size of the property, preventing the installation of large companies and big investments. Due to the fact that the parish confine with the Tagus river estuary, other economic activities also emerge (often informally), related to the use of local resources (Clams, Eels, etc.) and their consumption, through specialized restaurants some of them polarizing markets with significant areas of influence. The cultural and natural heritage assets are, in fact, singled out as possible factors of development of the parish, regarding the tourism associated with local values.

Sarilhos Grandes is also considered a “passage” territory, being crossed by N10 road, along which proliferate the small industry, services, construction companies and small local businesses, mostly commercial. Employment is provided especially outside the parish. Local employment is predominantly empowered by some proximity services and by agricultural activity, which pays the minimum wage and refers largely to immigrant labour.

## **4. Services, sustainability, and periurban territories**

In this section, we look more specifically for services activities, taking in account the results obtained in our project while assessing social and economic sustainability of periurban territories, and aiming to understand the particular role played by the diverse service activities in this kind of spaces.

### **4.1. The dimensions to assess sustainability**

In order to achieve our project objective of accessing sustainability, both in economic and social terms, it was developed a framework which is based in a diversity of analytical dimensions, recurring to a multiplicity of indicators, which were then operationalized recurring to qualitative and quantitative data (using the diversity of sources above mentioned), in the framework of a continuous intense discussion among team members (see Costa et al, 2015a, for details).

In the case of the assessment of sustainability in economic terms, 4 main dimensions were considered: (i) the capability to polarize economic activity and attract residents, users and visitors; (ii) the consistency of the productive structure and the specialization basis; (iii) the wealth factors, related with living standards, consumption and well-being; and (iv) the expectations-related factors and attitudes towards uncertainty. Each of these dimensions was subdivided in several sub-dimensions which were operationalized in descriptors/indicators. Figure 4 presents the dimensions used for the economic sustainability. A list of all the indicators used is presented on annex A.

Figure 4: Assessment of “Economic Sustainability”: analytical model

Source: own elaboration (PERIURBAN Project)

Figure 5: Assessment of “Social Sustainability”: analytical model

Source: own elaboration (PERIURBAN Project)

In the case of the assessment of social sustainability, five main dimensions were taken into account: (i) the questions related to equity and to the access to services and facilities; (ii) the social cohesion issues; (iii) the question of social diversity and the ways it enhances and conditions social dynamics; (iv) the perceptions of wealth and quality of life; and (v) the issues related with identity and the sense of place. Each of these dimensions was also subdivided in several sub-dimensions which were operationalized in descriptors/indicators. Figure 5 presents the dimensions used in the assessment of social sustainability. A list of all the indicators used is presented on annex B.

Details on the operationalization of this assessment (on both dimensions) and on the results achieved can be consulted in Costa et al (2015a).

## **4.2. The structuring role of services: some examples**

Among the dimension used for the assessment of sustainability, several can be mobilized to understand the importance of services in the structuring and vitality of these periurban areas. The results of our analysis, drawing upon the results of each specific indicator (cf. Costa et al, 2015a), can give us some hints to recognize this role of services in LMA periurban territories.

Regarding the economic sustainability assessment, it can be seen, mostly, in two of the analytical dimensions considered. On one hand, services are fundamental for the capacity of attractiveness and polarization of these areas. Their role in territorial vitality is evident concerning the capability to play central roles, at different levels (with the most diverse hinterlands, both in private and public sectors), as well as, consequently, by the “amenities” these services generate in terms of attracting residents, tourists or other economic activities. The situation is naturally diverse, through the 5 parishes analysed, according to the central functions concerned, but Nossa Sra. Anunciada (clearly, in the centre of an autonomous town) and, at other level, the more (sub)urbanized ones (Aqualva and Vialonga) seem to stand out, for more specialized functions. On the other hand, services play a fundamental role in the structuring of the economic productive basis and in giving consistence to the productive systems. Concerning this issue, there are a multiplicity of mechanisms through which services can enhance the territorial vitality, including the incorporation of knowledge and economic value in the local productive systems, the supply of additional competitive factors for a particular territory, the part played by the existence of proximity services, or the way they can fuel the seizing of endogenous resources or particular institutional resources. Here, the results are more diffuse, concerning the different processes involved, and some services are in certain cases particularly important in the support to a specific productive specialization (e.g, agro-industrial activities on Poceirão and Sarilhos Grandes, tourism in NS Anunciada, logistics in Vialonga, etc.), and on the other cases important for its diversity in the structuring of “urban” ambience and economic urban life (e.g, Aqualva, or, particularly, N.S. Anunciada). Still in economic terms, services can be also seen as important in the other dimensions used to assess sustainability, more occasionally, for example, in support of wealth and welfare, through the informal economy (e.g Sarilhos Grandes case with the informal trade of clam or other banned shellfish).

Considering the assessment that was made in terms of social sustainability, the relevance of services can also be evidenced. Among the five dimensions which were used for the assessment of sustainability in this field, just some of them are particularly interesting to understand the importance of services, and thus we will centre mostly on those components: equity; well-being and quality of life; and identity and sense of place. In the case of equity, the relation with services is immediate. The existence and quality of provision of services in the diverse fields analysed (e.g, housing, education, health, security, mobility,...) is a fundamental aspect in the access that people have to these components of their lives (and of territorial development), be it based on public or private provision. The results reflect clearly the territorial density aspect, with lower scores in the less “urban” parishes (Poceirão and Sarilhos Grandes). Regarding the issue of well-being and quality of life, services are fundamental for the social satisfaction they provide in these fields. The perception of quality of life in the area of residence by the subjects takes this aspect clearly in account, and the existence of amenities provided by these services is clearly valued in the survey, though very diversely between parishes, accordingly to the diverse aspects which are much valorised, in the residential choices, in each space. Finally, what concerns to identity and sense of place, the importance of services is also indirectly expressed, particularly on the type of anchorage (relational, functional, spatial) that can be inferred from the survey’s results. The importance of functional related aspects, particularly (but also the relevance of other aspects, like the ones linked to nature, environment, or culture, where services can play a particular role), is a sign of the importance of the existence of a variety of services (very diverse from parish to parish, and, also and even mostly, within the territory of each parish) to the construction of identity(ies) and to the development of the sense of place. But even in the others dimensions used for the assessment of social sustainability the importance of services can be seen, more sporadically, such as in the case of the role of (cultural, sportive, political, environmental) associations to the empowerment of populations and enhancement of participation, which is an important feature for social cohesion, for instance.

### **4.3. A typology proposal for understanding services in metropolitan periurban territories**

With these examples in mind, and the notion that we are facing five very different parishes, that are representing five distinct typologies of periurban territories which will have, naturally, their specificities, we can try to extract some regularity and propose a typology which enables us to bring some systematization to this analysis. In effect, despite all this diversity and the natural particularities of each situation, there are some common factors which allow us to try to establish a grid for evidencing the importance (and specificity) of the different types of services in these territories and the challenges services have (and bring) to periurban territories.

Service activities (as well manufacture or agriculture, for instance) are irremediably an artificial and unsatisfying categorization for apprehending the complexity of the contemporary production-consumption chains, and the knowledge incorporation in

good-service continuums (cf. Ferrão, 1992), which incorporate progressively more intangible contents in material goods. Besides, the services label has proven to be a conceptual umbrella for many diverse and highly heterogeneous activities, which are very dissimilar in their economic characteristics (e.g. knowledge incorporation mechanisms, qualifications involved, productivity gains, growth rates) locational structures and geographical dynamics. As Glückler and Hammer (2011) point out, this diversity is usually studied in one of two different ways: or by micro approaches usually conducting case studies within selected service branches in order to reveal the particularities of these activities; or by macro approaches attempting to capture the diversity of services by classifying services into homogenous statistical categories of similar attributes. In spite of the multiple developments on the research and application on service taxonomies, scholars and policy makers still lack pragmatic tools to capture and monitor the importance of these activities on the development of local and regional economies. The profusion of service typologies, often based on idiosyncratic definitions and sometimes incomparable classifications of service sectors (both in academic world and in policy-making and statistic administrations) do not solve this problem. We will not contribute to that here, certainly. But we will try to contribute with a proposal that enable us, and other researchers, to deal with another layer of complexity in all these on-going discussions: the spatial differentiation within the urban-metropolitan spaces, namely considering the specificities of periurban territories.

Glückler and Hammer (2011), drawing upon several precedent debates, suggested what they called a multi-dimensional taxonomic framework meant to deliver a useful differentiation of service types in the economy (a “pragmatic service typology”), which have supported their (quantitative) empirical analysis in several German regions. They have based on three main divides that have been often used to distinguish the diverse types of services: (i) the demand orientation (consumer services vs business services); (ii) the knowledge-intensity (operational services vs knowledge-based services); and the technology intensity (checked by the degree of technology using). With this basis, they operationalized the use of the following 5 analytical categories:

- OCS – operational consumer services
- KICS - knowledge-intensive consumer services
- OBS - operational business services
- KIBS - knowledge-intensive business services
- TKIBS - technological KIBS

It is not our aim, in the scope of this work, to proceed to an extensive statistical approach to this issue as the one made by the authors, as we are well aware of all the problems with it, some of them identified by the own authors, and our purpose is distinct. Our specific interest is in the comprehension of intra metropolitan spatiality of these activities, and specifically, to understand their importance for periurban territories and for that it is essential a more qualitative approach, based on more detailed information.

In that sense, after the analysis developed in LMA and in the five parishes we have studied, we suggest to cross this typology with another 3 axis, which we found structuring for the intra-metropolitan geographical distribution of these activities (and their importance for the affirmation of the respective productive structure):

- a) Locally oriented / externally oriented (related with the demand internal or external to the metropolitan/urban space), dividing the locational aspects, particularly on business services.
- b) Degree of specialization (related to the hinterland of the respective central function), with spatial differential impacts both on knowledge-intensive and operational services, and both on consumer and business services, but selectively attracted by periurban territories.
- c) Collective / individual services (regardless of the public/private provision) (considering the weight of amenities, and particular the service provision of collective goods, with impact mostly on operational and knowledge intensive consumer services).

Not all of them are discriminant to other classifications (e.g, is not so relevant if the KIBS are private or public, for their territorial implementation), so after clearing up, the typology suggested is the one presented in figure 6, which presents also a schematic classification of the relative importance of each kind of services in urban, periurban and rural territories. ,

Figure 6: Typology of services and urban/periurban/rural territories

|          |   | Urban    | Periurban | Rural |
|----------|---|----------|-----------|-------|
| Ind OCS  | Individual operational consumer services                | +++      | ++        | +     |
| Col OCS  | Collective operational consumer services                | ++       | ++        | ++    |
| Ind KICS | Individual knowledge-intensive consumer services        | +++      | ++        |       |
| Col KICS | Collective knowledge-intensive consumer services        | +++      | ++        |       |
| L OBS    | Local-oriented operational business services            | +++      | +++       | ++    |
| E OBS    | External-oriented operational business services         | ++/(+++) | +++       |       |
| L KIBS   | Local-oriented knowledge-intensive business services    | +++      | ++/(+++)  | +     |
| E KIBS   | External-oriented knowledge-intensive business services | +++      | (+++)     |       |
| TKIBS    | Technological KIBS                                      | +++      | (+++)     |       |
| S OBS    | Specialized operational business services               | ++       | (+++)     | (++)  |
| S KIBS   | Specialized knowledge-intensive business services       | +++      | (+++)     | (+)   |

Legend: + to +++ represents intensity degree, readably in line; (+) represents eventually, in specific cases

Source: own elaboration

This tentative typology intends to be a contribution to the discussion. We are aware of the simplifications and limitations of this kind of exercise, but it aims to be a first step to the disentangling of the importance of the diverse kinds of services to the diverse components of metropolitan spaces, and particularly to the identification of the periurban specificities. Certainly other crossings could be presented on the figure 6 and several oversimplifications were made in this brief exercise. It can be further developed and tested in other contexts. For now, we just would like to highlight that this tensions between geographic concentration and dispersion, intra metropolitan space, must also be seen at the light of the specific preferences of particular parts of populations (and economic activities) for specific kinds of amenities, as well as, especially, at the light of specific territorial assets (e.g. tourist or cultural points of interest, natural resources,...), that will be, in each specific situation stronger than several other factors, in the development of certain activities or the provision of (more specialised or banal) services, as we've seen several examples in LMA, particularly when external markets are at stake.

## **5. Concluding note**

This paper aimed to discuss the role of services in the "in-between" territories that periurban metropolitan spaces are. They have a specific importance in the spatial economic structuring of these areas and in the quality of life and well-being these areas provide, and that was shown, drawing upon the results of an empirical work developed in five different parishes of Lisbon Metropolitan area, which represent themselves five distinct categories of periurban territories.

From this analysis it was possible to observe that these territories are able to explore some special advantages of locating between the centre and the margins, attracting residents and economic activity with those competitive assets, and contributing actively to the territorial restructuring of an area that is restructuring itself fastly at economic, demographic, social and cultural terms. We can assume the existence of a peri-urban socioeconomic specific situation, characterized by a diversification of activities and social practices, but also by a diversity of territorial dynamics, which appeals to different forms of intervention regarding nowadays and future challenges of metropolitan areas, including naturally the specific challenges of periurban areas. The typology of services which was suggested is a first contribute to the continuation of this discussion, extrapolating for other realities than LMA.

This should take seriously in terms of policy making and spatial planning, as well in the realm of regional development policies. On one hand periurban territory has specificities that should not be ignored not diluted amidst the challenges metropolitan territories are facing, on its whole, in contemporaneity; on the hand, there are different types of periurban, as shown by our research, which need to be revealed and assumed by policy makers and planners in their decisions. The perception of this diversity may be an important instrument to support a more coherent and realistic decision-making process regarding the enhancement of the sustainability of a territory whose evolutionary pathways are strongly conditioned by planning, governance mechanisms, and territorially management policies, as well as by general driving forces of change in-between local and global processes.

## **Abstract**

This paper examines the development of international financial centres (IFC) in Central and Eastern Europe (CEE). The study argues that the development of the financial services in CEE is characterized by external dependency, which is manifested in the form of hierarchical command and control functions over CEE financial subsidiaries within the West European IFC network. The paper quantitatively compares the factors of IFC functions of Budapest in comparison to those of Warsaw and Prague. It argues that despite the lack of market evidence showing signs of a regional-centre focus during the transition period, there are some signs of IFC formation. The paper assesses the uneven impact of the global economic crisis upon CEE financial centres and confirms that their development trajectories became more differentiated as a result of the crisis. The steady decline of Budapest during the second half of the 2000s was accompanied by the rise of Warsaw. Our analysis concluded that Budapest, despite its earlier endeavours, most likely lost the competition to become an international financial centre.

Key words: international financial centres, Central and Eastern Europe, post-socialist transformation, FDI, IFC functions, crisis

## **Introduction**

Global financial capital has played an important role in all transition economies. Foreign direct investment in the banking sector is closely connected to the transition process in Central and Eastern Europe (CEE) and has received considerable attention from both a theoretical and an empirical perspective. However, much less attention has been devoted to the major determinants of international financial centre (IFC) formation within the “de-nationalised dual banking system” of CEE (Gál, 2014).

During the last three decades the financial services industry has experienced major transformations in which the largest market players, institutions, and global hubs, namely IFCs, have gained importance. Although market activity is spreading to new corners of the world, a powerful process of centralization is reinforcing the traditional dominance of financial capitals, led by London and New York, and to a lesser extent by second and third tier international financial centres (Faulconbridge et al. 2007, Engelen and Grote 2009, Gál 2010). Despite the growing body of literature (Grote, 2008, Engelen, 2007; Grote, 2008, Wójcik, 2007, Engelen,

2007, Boschma and Ledder, 2010, Zademach and Musil, 2012) on the development of global financial centres, very little attention has been paid to the evolution of financial centres in peripheral or emerging regions (Poon et al. 2003, Kareman- van der Knaap, 2009, Zhao et al. 2013)

Despite the geographic dispersal of financial services, the increased importance of central coordination and control functions is the main characteristics of IFCs. A financial centre is defined as a large city with an agglomeration of the headquarters of the largest financial firms providing all banking and financial services, nationally or internationally (Porteous 1999, Cassis 2010). The term is used for strategic urban locations where the financial sector plays a dominant role in the local and/or global economy, as measured by the share of financial services in national income, GDP, or in total employment, and by the presence of foreign banks. Apparently, financial sector agglomeration reflects and reinforces 'real economy' concentrations, as firms tend to agglomerate similarly to other advanced producer service providers in order to achieve the location advantages of urbanization economies (Porteous, 1999). Financial centres can be classified, in terms of their geographic influence, as national, regional (international functions with macro-regional scope), and global centres (Zhao et al. 2004). A global centre is defined as a city with a strong presence of a wide variety of financial players (investors, brokers, securities firms, investment banks, etc.) with extensive international activities, while the domestic centre is dominated by firms with a domestic scope of operations.

These international financial centres, which are also referred to as global cities, have developed a dense network of linkages, and provide a full-spectrum of advanced producer services. Most of the major international financial centres are also world cities (Sassen, 2004, Taylor, 2004). These global centres have massive concentration of resources that allow them to maximize the benefits of information and connectivity, with other centres generating asymmetric power relations executed through their affiliates, which are the key mediators of their command and control functions. Key social and information-generating processes occurring in IFCs, such as face-to-face contact, are facilitated by a high degree of social proximity. IFCs are also a gateway for financial services for other lower tier centres. The emergence of IFCs depends on several factors, among which the most important are: (1) the size of the domestic economy, (2) the information hinterland, and (3) path dependence (Cassis 2011). Scale economies, together with the diversity of the financial sector, are a key factor explaining the formation of a financial centre. The concept of an information hinterland defines a geographical area for which the financial centre provides an ideal access point for the exploitation of valuable information flows. The path dependence approach refers to a historical incidence that would have long-run cumulative consequences in the evolution of financial centres (David, 1988). The development trajectories of the Central and Eastern European financial centres, as well as the impact of the economic crisis, are likely to differ from those of higher-rank international financial centres.

Central and Eastern European financial centres are neglected from this point of view, and Kareman's (2009) or Wójcik's (2007) studies on contemporary financial geographies of Eastern Europe do not provide a detailed overview of the development of financial centers, and do not consider the development of IFCs' functions in the region. Despite its re-integration processes into the global financial markets, little attention has been directed towards the development of financial centres in Central and Eastern Europe. This paper examines the financial centre function of Budapest in comparison to those of Warsaw and Prague, two other significant financial centres in the contemporary CEE region, and how they are integrated into the network of established European financial centres. As the development of the financial sector in

European emerging markets is largely dependent on foreign investments, explicit attention is directed to determine which CEE centres exhibit sufficient power to attract multinational financial service firms and develop certain international functions. The paper examines whether the concentration of command and control functions over CEE within the Western European IFC network make it possible to develop parallel IFC function in CEE capital cities.

The paper explores the international financial centre function of Budapest relative to Warsaw and Prague, assessing the preconditions (including the main indicators of banking & capital markets) for the creation of a regional centre. It presents the requirements for the formation of an IFC and discusses arguments about the ongoing competition among the CEE metropolises. The paper also raises the question of whether the CEECs need to develop their own regional financial centres, or whether they could instead rely on existing 'western' IFCs. This study also examines the impact of the recent global economic crisis on the future of Central and Eastern European financial centres. This raises the question of cross-border financial exposures and the related risks of financial contagion, as well as of asymmetric shifts in capital flows between West European and CEE financial centres during the crisis.

From the methodological point of view, both qualitative and quantitative data have been collected. Primary data is collected from national statistical offices, central banks, and private financial firms' reports (Raiffeisen CEE Banking Reports), as well as from the websites of international financial organizations (e.g. Bank of International Settlements, World Federation of Exchanges). We also used consultancy firms' reports. With regard to the development of the financial centre functions of Budapest, expert interviews were conducted with the stakeholders of the Hungarian banking sector and policy makers in 2007.

The paper is organised as follows: the first section summarises the impact of transformation on IFC formation. The second section examines the development of the international financial centre function of Budapest, as compared to Warsaw and Prague, assessing the preconditions for the creation of a regional centre transition using quantitative indicators. The third section assesses the impact of the global crisis on Central and Eastern European financial centres. Finally, in the concluding section, key findings are summarised.

## **Impact of transition on the formation of International Financial Centres**

Since the early 1990s CEE countries went through fundamental political, economic, and institutional transitions on the way from a centrally planned economic model to an open market economy. Structural adjustments were accompanied by the rapid internationalization and re-integration of CEE countries into the global economy, and later – by European integration and accession into the European Union.

Most of the literature studying the transition process has described the transformation and the (re)-integration of the region into the global capitalist system as a linear convergence with the advanced market economies, following the path of liberalization and privatization. However, there is considerable diversity among Central and Eastern European countries, due to their different legacies, varieties of implemented transformation models, and economic policies

(Sokol, 2001).<sup>2</sup> The crisis further strengthened these different developmental trends, resulting in diverging economies and regions within Central and Eastern Europe.

Concerning IFC formations there were three parallel processes, namely the *post-socialist transition*, *financialization*, and *world-city formation*, which not only accompanied but also influenced the conditions of the development of financial centers explored in this study.

*The post-socialist transition* was characterised by external pressure from the intertwined virtues of neoliberalism, foreign capital, and international institutions (e.g. IMF). The international situation in the context of which the change of regime was to take place in CEE was crucially shaped by two major currents of the twentieth century, namely, *globalisation* and (*neoliberal*) *economic paradigm change*. These developments not only contributed to the fall of the Soviet bloc, they also created rather strict economic conditions for post-communist countries about to reintegrate into the global market economy. In the course of this transition, CEE countries had to adjust to the *modus operandi* of a world economy fraught by shocks and uncertainties (debt crisis, money market and currency crises), driven by competition, which could sometimes be extremely disadvantageous. The forerunners of economic transition, like Hungary, were exceptionally vulnerable and had to act as an experimental ground for the dominant interests of foreign capital (Gazsó-Laki 2004). According to Gowan's (1995) view, the transition, and especially the 'shock therapy' approach, was designed to allow Western capital to conquer the Eastern European markets, to capture cheap production lines and create dependent West-East economic relations. As a result, the chief characteristics of this blend of "*outer directed capitalism*" or the 'dependent market economy' model (DME) included a relatively fast recovery from the transformation crisis but also a dominant role of foreign capital in the process of stabilisation. (Szelényi et al 2000).

Although there is no single indicator of international integration, the transition process is heavily influenced by dependence on foreign financial inflows, and generally by the high level of *financialization* (Myant and Drahokupil, 2012). Foreign Direct Investment (FDI) inflow into CEE economies has been a vital factor in the first stage of privatisation, and FDI became the predominant type of incoming capital investment in the first stage of the economic transition. The banking and insurance sectors were the primary targets of strategic foreign investors, resulting in significant inflows of FDI into these sectors, connected mainly to the privatisation of state-owned banks. The other forms of foreign capital inflows were also important in many countries of the CEE region. Indebted states (Hungary, Balticum) inherited or generated larger debts, and due to their 'fiscal alcoholism,' they remained dependent on foreign investors in public debt financing. Other forms of private flows, such as equity investment, increased as the local blue chip companies started to attract more foreign capital through revitalised local stock exchanges. The most important form of financialization was driven by an increase in domestic consumption credit.

---

<sup>2</sup> Martin (2001) puts the CEE transition into the context of the centre-periphery model and divides the regions by different subregions: 'super-periphery A' (ECE and Baltic states) have a more solid economic structure, legacy of modernization, and more experience with market and political democracy. In 'Super-periphery B' (former Soviet Union) countries, liberal-capitalist economic and political structures were relatively underdeveloped.

The *network of world cities* was another determining factor for the formation of IFCs in the 1990s. The rapid integration of economies through the structural effects of globalisation on production, financial transactions, and wealth creation have also stimulated the *formation of world cities* (Lo and Yeung 1998). This is also accompanied by an unprecedented concentration of new tertiary and quaternary activities, such as various forms of financial and advanced producer services (Bourdeu-Lapage and Huriot 2003, 2005). It is therefore not accidental that the Globalization and World City Network's approach ranked world cities on the basis of the concentration of advanced producer services (Taylor, 2004). The process of globalization, defined as increasing the cross-border integration of economic activities, is enhancing interlinkages and interdependencies among major cities located around the globe. The process of the formation of world cities impinges upon the transformation of the structural and functional role of these cities, focusing on the role of command and control activities (Sassen, 2004).

In this regard, pressures of globalization, particularly in the form of city competition for attracting investments and improving their position within international urban networks, have posed significant challenges for the transforming capital cities of CEE countries. The capital cities of the most dynamically reforming states of Poland, Hungary, and the Czech Republic were the most exposed to globalization and EU integration, and have been playing a leading role in their transforming economies.

The transformation and modernization of capital cities were characterised by two simultaneous processes. *First, metropolitan transformation* has led to important structural changes in Central and Eastern Europe, characterised by economic restructuring, and by the shift from industrial to service economy. *Second, the international integration* of the capitals of the Visegrád Group<sup>3</sup> into the global world-city networks has played a key role in the formation of IFCs. These cities started to internationalise their financial and business functions beginning in the early 1990s, while simultaneously searching for investors and a particular 'niche' in which to specialise in trans-national (European) and cross-border (regional) urban networks. Simultaneously, capital cities became gateway cities by attracting a significant number of western corporations, who placed their regional headquarters responsible for business operations in the entire CEE region there. The position of Budapest, Prague, and Warsaw was enhanced from the rank of cities of national significance to cities of European importance (Enyedi 1998, Csomós 2011).

Economic transition has been most beneficial for capital cities. It means that the overwhelming part of GDP is produced in the capital city-regions (in Hungary - 48%, in Slovakia - 60%). In the period 1995–2009, capital city-regions in CEE countries grew more rapidly than other regions and cities of the European Union (Gál-Lux 2014). In fact, after two decades of city transformations, there is considerable rivalry and competition among CEE cities for access to resources, investments, and networks, which could diminish the overall competitive strength and cohesiveness of an enlarged European Union. If we take a closer look at the financial functions of competing capital cities and examine them in the context of financial market transitions, we can clearly see the emergence of winners and losers.

## **Development of functions of national and international financial centres in Central and Eastern Europe – the rise and fall of Budapest**

---

<sup>3</sup> Czech Republic, Hungary, Poland, Slovakia.

### *Revival of financial centre functions during the transition period*

Transitions of the financial markets and changes in the urban fabric of national financial centres in CEE are seen as both path-dependent and path-shaping process, where history and the legacies of earlier modernization processes (catching-ups) in the region matter, but new trajectories are also possible (Sokol, 2001).

In the early 1990s, after 40 years of discontinuity during the communist period, Hungary's financial sector reintegrated into a global financial system that was shaped by powerful processes of globalization. A common characteristic of the spatial organization of the Hungarian banking system before and after the political transitions in the 1990s was an extremely high concentration of headquarters function in the capital city. This peculiarity could be explained by the mode of revival of the modern Hungarian banking system. A specificity of banking systems in transition economies is that financial markets did not emerge organically. With the separation of central banking and commercial banking functions in 1987, a two-tier system was established from above and was supervised by a central authority. At the same time financial resources were mainly concentrated in the capital cities as a legacy of the centrally managed state economy. Its main command and control functions were already strongly centralised in capital cities, like Budapest. In this sense, the new system practically reproduced the earlier Budapest-centred, over-centralised state-socialist mono-bank structure, even if more financial institutions were founded. Early privatisation dominated by foreign banks and EU regulations further reinforced these functions of financial centre.

As the centre of the national economy, Budapest is also the country's financial centre. International relations in the financial sector are administered via the capital city. All institutions and functions associated with these roles are located there. Budapest has the only stock exchange in the country. It concentrates the head offices of banks, insurance companies, specialised credit institutions, building societies, mortgage banks, and lease companies. The significance of the capital's special strategic geographical location in the national financial system also derives from the fact that important, so-called "critical information" (i.e. making bank strategies, central data provision, access to the giro-system) flows exclusively via the centre. Institutions for maintaining contact with other IFCs are also to be found there. The number of financial sector employees in Budapest is equal to 40 thousand, which is 56% of the total country's workforce in this sector (2013).

Financial centres located at the top of the urban hierarchy concentrate the greatest amounts of capital. This results in significant regional disparities (Porteous 1995, Leyshon-Thrift 1997). In the case of Hungary, this means that 94% of banking capital stock is concentrated in Budapest. Since banks available for privatisation were exclusively located in Budapest, as were greenfield banking investments, in effect 100% of foreign capital invested in the sector was concentrated in the city. The common feature of CEE transition economies is the scarcity of locally founded banks.

### *Role of the foreign capital in the formation of financial centres and asymmetric power relations*

Dependent market economies<sup>4</sup> of Central and Eastern Europe are heavy importers of capital, therefore the ratio of inward and outward FDI stock is much higher than in the EU-15, due to

---

<sup>4</sup> See: Nölke and Vliegenthart, 2009, Raviv, 2008.

the low level of capital exports from these countries (Nölke and Vliegthart, 2009). Foreign financial inflows and especially FDI have resulted in dramatic changes of ownership structures. In 1994, in the wake of the early transition crises, an overwhelming majority of the banks in post-communist countries were still state-owned. There was a double shift of ownership from the public to private sector and at the same time from domestic to foreign owners through privatisation. In contrast, in 2007 private foreign ownership already accounted for about 80% of banks' assets in the CEE region.<sup>5</sup> Hungarian financial markets, similarly to other CEE counterparts, remained rather bank-centered, and security markets played only a limited role. The only exception in the region is the revival of the Warsaw securities market since the mid-2000s (Mykhnenko, 2007, Wójcik, 2007).

At the beginning of the 1990s, the Hungarian banking system – similarly to its Eastern and Central European counterparts – faced the problem of reintegration into international markets, while also witnessing the swift spread of foreign capital, which was to play a leading role in accelerating modernisation and privatisation. Unlike in the Czech Republic, where voucher-based mass privatization was followed by a relatively belated recapitalization and foreignization of the banking sector, or in Poland, where not only a belated banking reform but also a gradual and well-regulated privatization made much more room for the state and privately owned domestic banks, the rapid “de-nationalisation” and foreignization of the Hungarian banking system was unique in the region in the beginning of the transition period.<sup>6</sup> It created a peculiar ownership structure, differing from the majority of developed countries as well, in which *the share of foreign-owned banks* reached around 75% by 2000 (Gál, 2005). Foreign financial inflows have resulted in dramatic changes of ownership structures throughout the region. In 1994, in the wake of the early transition crises, an overwhelming majority of financial intermediaries in the post-communist countries were still publicly owned. By contrast, in 2007, more than a decade later, private foreign ownership already accounted for about 80% of financial intermediaries' assets in the CEE region.<sup>7</sup>

Traditional “modernization theory” highlights the key role of foreign banks in institutional development, stability, and the increase of financial depth of the banking sectors, and emphasizes that FDI increased the host country's integration into the global economy (Wachtel 1997, Várhegyi 2002, Csaba 2011). If we try to place the CEE region in the comparative typologies of capitalism following Nölke and Vliegthart's (2009) argument, the primary source of investment in the CEE is foreign direct investment, not the stock market as in Liberal Market Economies (LME), or domestic credit as in Coordinated Market Economies (CME). Although FDI does play a role in the other capitalist models, the degree of external dependency is much more extreme in the CEE (Raviv, 2008). Foreign banks (understandably) followed commercial market-seeking principles, and even the governments of host countries were not active in gearing or “diverting” them through various regulations towards addressing

---

<sup>5</sup> These figures are especially striking when we compare them with the average level for the EU-25, where the share of foreign-owned banking assets in total is less than one quarter. In the Euro area this figure is equal to 15.5%. Even the average for non-OECD countries is 50% (Gál, 2014).

<sup>6</sup> This rapid privatization of the banking sector can be explained by bankruptcies and the regulation of the supervision of the banking sector as well as *bank and credit consolidation* with significant state participation (its cost was equal 14% of the GDP by 1999).

the development needs of their economies. “Rather, they were always aimed at redressing the declining profitability of financial institutions operating in the already financialised economies of Western Europe. As a result, foreign financiers emerged as a powerful rentier class in Central Europe able to extract rent incomes far in excess of their profits in the west” (Raviv, 2008. p.311).

DMEs are characterised by an unequal power relation between the home countries and the CEECs through parent-subsidiary networks of TNCs. ‘Dual banking system’ model, characterized by the dominance of foreign-owned commercial banks, became common in these economies (Alessandrini, and Zazzaro, 1999, Gál, 2005). Dual-economies literature argues that FDI generates typical core-periphery disparities between old and new Member States. That model, consisting of large foreign banks and small local/indigenous banks, displays strong dependence on foreign banks and their resources (external liabilities vs. local savings). Financial TNCs in the primary international financial centres have a massive concentration of resources that allow them to maximise the benefits of information and connectivity with other centres. Inter-linkages that are established between their subsidiaries and their parent bank generate asymmetric power relations executed through their affiliates (Kareman, 2008; Wójcik, 2007, Gál 2010). These power relations mediate strong command and control functions over CEE countries within the international financial centre network from which these investments are controlled. Asymmetric power relations also play a significant role in the international financial centre function of Budapest, Warsaw, and Prague, and provide certain unfavourable preconditions.

As Central and Eastern European countries are largely dependent on foreign investors in finance, explicit attention is directed at determining which CEE financial centres attract multinational financial firms, and Kareman (2008) examined from which international financial centres these investments are controlled. The banking sector in the CEE region is predominantly commanded from the financial hubs of the neighbouring ‘old’ EU Member States.<sup>8</sup>

### *Factors of the formation of Budapest’s IFC in comparison with its CEE counterparts*

This section quantitatively examines the development of international financial centre function of Budapest, as compared to Warsaw and Prague, assessing the preconditions for the creation of an IFC. It also tries to find market evidence showing some signs of IFC formation, with a particular regional focus in the three cities.

As we noted before, the capital cities of Central and Eastern Europe became major gateways for FDI investments, and headquarters of TNCs’ subsidiaries expansion towards new markets. Early GaWC<sup>9</sup> research (Beaversock et al., 1999) reflects the increasing economic significance of these capital cities in CEE, and as a consequence they became an agglomeration of advance business services. On the basis of the agglomeration of banking, accountancy, legal, and advertising services firms, capital cities of CEE have shown their visibility in the third level group of gamma world-cities, in line with other secondary European services centres (Hamburg,

---

<sup>8</sup> Vienna, Stockholm, and Athens, among others, became gateways to the East and hosted the headquarters of large investors in the CEE, Baltics, and Southeastern Europe, respectively. The largest concentration of parent-subsidiary connections forms bridgehead centres (Moscow, Warsaw, Budapest) in the CEE.

<sup>9</sup> Globalization and World City Network

Munich, Berlin, Cologne) (Csomós 2011). Prague, Warsaw, and Budapest were major centres in at least one category of high-order services. According to Taylor (2004), who examined the global network connectivity of banking firms, Warsaw ranked 9th in Europe, followed by Prague (17th) and Budapest (19th).<sup>10</sup>

Csomós (2011) compared these capital cities on the basis of their economic strength measured by GDP (PPS). In 2008, Warsaw, with 68Bn USD, ranked 85th (followed by Hamburg), Budapest with 53 Bn USD was 100th and Prague was the 106th. Functions of coordination and control can be measured by the number of corporate headquarters of domestic companies located in these capitals.<sup>11</sup> Multinational companies and banks prefer to hierarchically control local subsidiaries from the headquarters of their parent banks located in the IFCs outside the CEE region (Myant & Drahekoupil 2010). From the emerging international financial centre functions point of view, headquarters of locally based multinational companies matter more as they concentrate their own control functions in Central and Eastern European IFCs (Gál, 2014).<sup>12</sup>

The next section summarises the factors of IFC functions through analysis of the selected indicators in the three capital cities (Budapest, Prague, Warsaw). Various data, such as employment figures, presence of foreign banks, depth of financial sector, and the size of stock markets, illustrate the main factors of the development of international financial centre functions.

### *Employment in financial services*

Employment in the financial sector has the highest share (10.6%) in Warsaw, demonstrating the growing importance of financial centre functions (Table 1). The relative weight of its financial sector corresponds with the share of the leading global IFCs. Contrary to Warsaw, Budapest shows the lowest relative weight of this sector, which also demonstrates higher volatility and very slow growth during the entire transition period.

Table 1  
*Share of Financial sector in total employment of the capital cities (%)*

| % of total employment        | BUDAPEST |      |      | WARSAW |      |      | PRAGUE |      |      |
|------------------------------|----------|------|------|--------|------|------|--------|------|------|
|                              | 1995     | 2002 | 2013 | 1995   | 2001 | 2013 | 1995   | 2001 | 2013 |
| Financial Intermediation (K) | 3.5      | 3.8  | 4.3  | 6.0    | 7.8  | 10.6 | 3.2    | 4.9  | 6.3  |

<sup>10</sup> Warsaw was the 25th most connected IFC worldwide according to the banking network connectivity in 2003.

<sup>11</sup> According to the Forbes Global 2000 database, in 2010 the world's 135th largest HQ city in CEE is Budapest, with 26 Bn USD aggregate turnover of the companies located there. Budapest is followed by Warsaw, which is only ranked 227th, and Prague with 238th place (with 11 and 10Bn USD turnover respectively). It has to be noted that while both Hungary and the Czech Republic are represented by single capital cities with a very high geographical concentration of HQ function, Poland is represented by three additional cities (Plock, Gdansk, and Lublin).

<sup>12</sup> Budapest is a peculiar IFC in this sense, as it is the only centre that developed its own control functions due to the fact that the only Eastern European regionally based multinational bank (outside Russia and to some extent Slovenia), the OTP Bank, has its headquarters in Budapest.

The relative importance of the financial sector in the three cities is evaluated by calculating location quotients (LQ).<sup>13</sup> According to the domestic LQ, Warsaw's financial sector dominance within the Polish economy is clearly marked by its almost five-folds (4.4) share in comparison to the share of that sector in nationwide employment (Table 2). In the case of Budapest the same ratio (2.0) rather indicates a stagnation, while Prague managed to increase the importance of its financial sector within the domestic economy. The intercity LQ compares the weight of finance of each city with the average structure of all three capital cities. While Budapest's position negatively deviates from the average, Warsaw's share significantly exceeds it, demonstrating the successful adaptation of the Polish capital to the requirements of the global economy, and the common tendency towards metropolization marked by the increasing weight of its financial sector.

Table 2

### *Size of banking sector within the economy*

Banking assets of eight new Central and Eastern European Member States (who joined in 2004) was only a small fraction of the EU as a whole, 1.2% of the total EU-25 assets in 2005, and so only a small segment of the European banking market.<sup>14</sup> The Hungarian banking system was

<sup>13</sup> For the financial sector, the domestic LQ is the ratio of the share of that sector in the city employment to the share of that sector in the nationwide employment. It relates the city structure to the country structure, so identical city structures generate different domestic LQ values depending on the country structures. The intercity LQ is the ratio of the share of that sector in the city employment to the average share of that sector in the five capital cities. This LQ is independent of the country structures. It permits direct comparisons between the employment structures of the three cities.

<sup>14</sup> This was equal to the size of the Portuguese banking system or the assets of the Royal Bank of Scotland (in 2003), and almost three times smaller than the size of Deutsche Bank. The average bank size in this market was about 1.3 billion Euros.

the smallest of the three countries, only slightly more than one-third of the Polish banking system (50 billion Euros).

(Table 3). *Overview of banking sector developments, 2005-2013*

\*data for 2009.

Financial markets in the region remained rather bank-centred as a consequence of slowly developing capital markets (Mykhnenko 2007). The share of banks in the financial sector assets is still around 70%. The depth of banking, measured by assets per GDP, was the highest in the Czech Republic (101 and 135% respectively) and the lowest in Poland (62.4 and 86%). Hungary with its figures ranked in the middle (Table 3). As for the banking sector, when measured by operational efficiency and profit indicators the Hungarian banking system proved to be the most at the beginning and the least efficient at the end of our research period.

Operational efficiency of the banking sector has improved significantly in the region after a relatively short transition crisis. However, prior to the recent 2008 crisis, banking sectors in CEE had become a major target of credit-fuelled growth. Foreign banks played a significant role in the transmission of contagion to transition economies.

### *Presence of foreign banks*

The spatial concentration of foreign banks is an important indicator of the global integration of the financial center of the region. However, the clear indicator of a thriving international financial center is the increasing presence of private investment banks. As the economies recovered from the transition crisis and the EU expansion was completed, foreign investment banks such as Goldman Sachs, J. P. Morgan Chase, and Credit Suisse set up their offices in each of three analysed capitals. The presence of the 15 largest investment banks was examined in 2005 (Gál 2010). Despite the relatively low level of overall presence at that time, Warsaw proved to be the most attractive location, where seven investment banks had their representation, while only four such offices were opened in Budapest (Table 4). A relatively

large and crisis-resilient Polish economy attracted more investment banks than all their counterparts put together. In 2011 Goldman Sachs opened its Warsaw investment banking office, considering Warsaw as an important financial hub with huge development potential for the whole region (Hashimoto, 2015).

#### *Cross-border flows in the financial sector*

Cross border financial flows and their direction (inflows-outflows, capital import-export) are one of the major indicators of the international integration of IFCs.<sup>15</sup> During the first phase of transition, FDI was the most important source of cross-border capital flows in CEECs, although, with varied timing, mainly because of the different privatisation timetables in different countries in the pre-crisis era (Fig. 1). Data shows that Hungary lost its attractiveness even before the financial crisis. In terms of the stock of FDI in the sector, Poland stood out in 2007,

<sup>15</sup> Although the data available on country level, due to the dominant role of financial centres these flows are controlled and intermediated by financial institutions/subsidiaries located in the host IFCs.

with more than 20 billion Euros foreign investment demonstrating its greater potential to attract new strategic investments in the Polish financial sector. Changes in FDI flows during the crisis period were substantial. While there was a smaller fall of FDI in the Czech Republic and a larger one in Poland in 2009, FDI stock in financial services was mainly characterised by growth, while in Hungary this indicator slightly decreased during the crisis (Gál and Sass, 2013).

There are significant cross-border transactions channelled through the networks of the West European parent banks and their local subsidiaries. About 50-70% of corporate lending and 60% of interbank lending in 2009 was the subject of cross-border transactions, which not only has an implication for increasing international integration of CEE financial markets by strengthening connectivity to the European IFCs, but also, these links generated imbalances in the banking system during the time of the crisis, as the CEE remained largely reliant on cross-border lending. Hungary experienced higher cross-border lending, which is expected on the basis of economic fundamentals, and the fact that it had developed significant vulnerabilities in the pre-crisis period. This resulted in the largest drop in cross-border lending (unlike Poland, which almost managed to maintain its international position, and the Czech Republic, where demand for cross-border lending remained low). Cross-border bank flows demonstrate that Poland has leading position of attracting banking flows, while Hungary shows larger fluctuation in this sense (Table 5).

*Fig. 1*

*FDI stock in financial services, 2006-11 (million Euros)*

Source: National banks

Another parallel process, namely the rapid surge in outward foreign direct investment (OFDI) generated by the cross-border activities of locally-based multinational banks, made Hungarian companies prominent foreign investors in the wider Eastern European region. Financial capital export to Eastern and Central Europe is dominated by bank acquisitions of OTP, the largest bank of Hungary, and OTP become the only “indigenous” multinational bank in the region (by

2008, 40% of assets, 66% of branches, and the 38% of total loans of OTP bank were generated abroad)<sup>16</sup> (Gál, 2014).

### *Size of the capital markets*

Studies focused on global cities draw attention to the fact that the dominant feature of these leading cities is the considerable concentration of financial capital, not only in banking but also in stock markets. Data on total market capitalisation and the number of companies listed on stock exchanges, therefore, serves as an ideal index for measuring financial centre development. It has to be noted that stock exchanges in the CEE countries have taken a fairly short period of time to reach their recent potential. There are no large companies in the region with longer stock market experience and none of the institutional investors has long history of presence in the region. All CEE stock exchanges were launched as late as the early 1990s, after the change of the political and economic regime. Budapest Stock Exchange was founded in 1990. As the fast economic uplift in the countries of the Visegrad Group was substantially driven by FDI, the contribution of domestic companies to the GDP of the national economy remained rather small. As it is primarily domestic companies that are listed at the regional stock exchanges, it is not surprising that the value for domestic market capitalization is low (Csomós, 2011) (Table 6). The market capitalization of the new EU Member States accounted for only 2% of market capitalization of the EU in 2004. The aggregated size of the Warsaw (WSE), Prague (PSE) and Budapest (BSE) Stock Exchanges was equal to only 13% of capitalization of the Deutsche Börse at a time. Due to the relatively strong banking sector and the non-organic development of capital markets in the region, firms were allowed to seek affordable bank loans rather than to endeavour to attract investments through less mature stock exchanges. In addition, the propensity of households to raise funds in the capital market is still low.

<sup>16</sup> OTP Group currently operates in Bulgaria, Croatia, Romania, Serbia, Slovakia, Ukraine (CJSC OTP Bank), Russia, and Montenegro via its subsidiaries. Until 2004, 28% of Hungary's FDI export was generated in the banking sector.

Figure 2

Total market capitalisation in Million USD

Source: Edited by the author, World Federation of Exchanges, Annual Reports and Statistics,

Despite its slow start, the Warsaw stock exchange rapidly increased its capitalization from the early 2000s and attracted more companies for listing than did neighbouring stock exchanges (Budapest, Prague, Vienna). The effect of financial crisis was visible in both 2008 and 2011, although Warsaw seemed to recover faster than the other financial centres. The development of the stock market in Budapest, once a forerunner in the region, has been rather weak, with the current level of market capitalisation being comparable to the pre-EU accession period level, despite a steady increase of GDP (Figure 2). The number of companies listed in Warsaw in 2013 doubled since 2009 and reached 895, out of which 26 are foreign. This level is significantly higher than that of Vienna - 102 companies, 20 foreign; Prague (23 with 10 foreign) in Prague, and Budapest (50, none foreign) (Federation of European Securities Exchanges, 2015) (Table 6). By the mid-2000s, the Warsaw Stock Exchange, due to its larger

capitalisation, posed serious competition to the Budapest Stock Exchange. The Warsaw Stock Exchange became the leading stock exchange of the region, and that is why the Wiener Börse intends to compete with it by acquiring control over the smaller stock exchanges in the CEE region. The rearrangement of the ownership structure of these stock exchanges suggests that Vienna and Warsaw are strengthening their leadership roles in the CEE region, while the roles of Budapest and Prague are diminishing (Csomós 2011). As far as foreign listing is concerned, Budapest no longer seems to be a strong international capital market centre.<sup>18</sup>

### *Assesment of the function of Budapest international financial centre*

The stake of the ongoing race among metropolises in Eastern and Central Europe at the beginning of the 2000s was in part whether Budapest, with the relatively most developed financial markets at that time, could become a regional business and financial centre of Central and Eastern Europe (Enyedi 1992). Nevertheless, contradicting former optimistic expectations, Budapest has not yet become such a regional financial and business (gateway) centre, the envisaged “Singapore of Central Europe.”<sup>19</sup> Rather, as a result of the crisis and the recent unorthodox economic policy, Budapest seems to have exited from the regional competition of international financial centres located in the region (Szabadföldi 2001, Gál 2010). At the same time, the Hungarian capital did have the potential to acquire competitive advantages in certain areas of the financial sector in the early 2000s. Such advantages could stem from its central location, early economic reforms and its bridging role within the region. Budapest’s only peculiar role as an international financial centre is strengthened by the fact that due to its housing the OTP Bank’s headquarters, it is the only financial centre in the region which developed its own command and control functions over subsidiaries located abroad (Gál, 2010b). OTP’s expansion abroad since the beginning of the 2000s increased the connectivity of Budapest as a regional financial centre. However, the regional banking networks alone do not make a city an international financial centre – especially when capital markets are concerned.

In other respects, however, Budapest is not unique in comparison to other regional capitals (Prague, Warsaw), which are rapidly catching up – they had compatible, and even larger domestic markets. Another reason for this is the overlapping foreign ownership. Foreign banks established subsidiary banks with parallel networks controlled by managements of foreign parents rather than by selecting a single regional financial centre. Therefore there is little evidence of regionalisation in the banking markets of Central Europe.

However, already during the 2000s there were serious impediments to Budapest’s becoming an international financial centre. Its previous competitive advantage in the financial sector and capital-attracting potential gradually decreased due to the deteriorating macro-economic position of the country prior to the crisis. The competitive advantage of Budapest was also weakened by the organizational transformations of the BSE in 2004. This allowed the Wiener Börse, following a policy of expansion in the framework of takeovers, to acquire majority

---

<sup>18</sup> In 2011, Poland’s stock market ranked fourth in the amount of capital raised. At the WSE, 38 new companies were listed in 2011, and 25 of these were foreign ones.

<sup>19</sup> In the period of dynamic growth in Hungary the first Orban government had made attempts to develop Budapest as CEE regional business and financial centre. See: <http://www.bibca.net/en/home>

shares in the Hungarian and Czech stock exchanges. Budapest's position concerning its independent decision-making functions was adversely affected by the acquisition of the Vienna Stock Exchange.<sup>20</sup>

In Budapest, despite a suitable supply of highly qualified professionals, qualifications of the available workforce still fall short of international quality standards. In an interview, the CEO of a US-owned bank emphasised that in certain areas of finance (accounting, cost-management, marketing and sales), there are especially serious shortcomings in labour supply. Consequently, financial services providers tend to employ foreign managers.

In a 2007 interview with a banking analyst, the issue of functions of regional IFC was discussed. The interviewee argued that there was a genuine niche for creating a regional sub-centre in Budapest and for providing certain special back office services for the global financial firms. Although the capital city would remain primarily a national financial centre while extending its lower level international embeddedness in shared services and business process outsourcing. The question is whether these shared services locations attracting new types of FDI might help in repositioning weakening business and financial centre functions.<sup>21</sup>

Although earlier consultancy reports revealed strong international business presence (regional headquarters, advanced service providers, IT, accounting and HR) to be a necessary factor for developing international business and financial centre functions in Budapest, surveys also demonstrated the lack of leadership both within Budapest as well as in the CEE region (Szabadföldi, 2002, Gál 2010). The plan to compete against Warsaw and Prague as the regional business centre was introduced in 2001. This plan seemed to have correctly identified Budapest's comparative advantages vis-a-vis 'western' cities (e.g. Vienna), but it was short on explaining the vision for distinctive features of Budapest vis-a-vis Prague and Warsaw as financial centres. Nevertheless, it should be noted that the rise and fall of Budapest as a prominent regional financial centre could be explained to a large extent by the actions and successes achieved by other financial centres.

### *Possible role of financial & business services offshoring in IFC formation.*

The rapid surge of globalisation, opening up of formerly isolated regions such as Eastern Europe, Russia and China to global trade, has substantially boosted task trade and service related cross-border investments. Many Central and Eastern European countries invigorated by EU enlargement became important locations for offshored service centres. Building on the region's nearshoring advantages such as geographical-cultural proximity and on its multilingual graduate supply, CEE is likely to utilise more value added and quality-driven services investments. Relocation of service offshoring-related activities, such as outputs, value added, employment, foreign direct investments and exports in services have grown rapidly, particularly

---

20 Since the Wiener Börse has acquired control over the Budapest stock exchange, a series of debates arose between the Austrian management and the handful of domestic blue chip companies (OTP, MOL, Richter) in strategical issues, which hinders the development of a long-term strategic vision for the BSE.

21 EU accession, competitive infrastructure, low wages, and a strong education system were favourable preconditions that supported the growth of the first group of capital cities, such as Prague, Budapest, and Warsaw, in the first wave of the offshoring boom of the late 1990s (however, it is notable that advantages in rival capitals are similar and mostly based on low wage cost) (Gál-Sass, 2009, Gál, 2014).

after 2000, especially in the new EU member states (NMS) of the region (Czech Republic, Hungary, Poland and Slovakia though “latecomers” such as Romania and Bulgaria have also begun to act as host for this type of investment) (Gál-Sass, 2009). This section discusses the additional location factors selecting Central and Eastern European city-locations. The question is here whether these shared services locations attracting new types of FDI might help in repositioning weakening business and financial centre functions.

Offshoring can have benefits for the host market and generates changes within the service sector as a whole, and in particular has an impact on their locations and on the urban network. What is the most likely impact of services offshoring on the home economies? GDP growth of nations largely depends on service innovation. Offshoring is a major driver of shift towards services in FDI. This gains a particular importance in the CEE countries after their EU accession as it helped to mitigate the fear of TNCs’ outmigration in manufacturing and it substituted the decreasing share in manufacturing FDI by service investments. Offshoring enables the host countries to shift to higher value services (Sass, 2008, Micek et al. 2011).

Besides the general home market effect the process of selecting and opening new locations is similarly important as offshoring has a strong impact on the cities selected. As far as the geographical distribution of the investments in business services is concerned, there is a strong spatial concentration in all the analysed countries. Capital cities are the main hosts to business services companies, and sometimes secondary centres emerged (Cracow, Brno). It is understandable, that demand-led horizontal investments locate in the capital city where there is the highest demand for their services. For supply-driven vertical investments, the main attracting factor in capital cities is the large supply of suitable workers (Hardy et al 2011).

The metropolitan transformation accompanied by both the rapid deindustrialisation and expansion of services has resulted in the concentration of the high-level business and financial services into the capital cities (Lux, 2010). Simultaneously interactions and symbiotic competition emerged between the capital cities, as they have been competing for attracting investments. EU accession, competitive infrastructure costs and strong education system as favourable preconditions supported the first group of capital cities, such as Prague, Budapest and Warsaw in the first wave of the offshoring boom from the late 1990s (Gál, 2014) (see Figure 5). These cities were the most successful to reposition themselves during the early stages of transition by exploiting their comparative advantages on global market place. At the beginning costs (labour cost, real estate prices and facilities) were the most important driver in selecting these location mostly for routine offshoring activities. However, these capitals have relatively higher wages. Nevertheless, cost differential with Western Europe are still significant, making these cities still attractive for higher value added nearshore service activities.

The first wave of cities in the offshoring boom, including the first tier capital cities such as Warsaw, Prague and Budapest are saturating in terms of skilled labour and offices supply, to the point that raises the opportunity for the second tier cities to find alternative locations in the midsize provincial cities and to tap their unexploited talent pool has become an increasingly important operational consideration (see Fig. 5).

Figure 5

*Geographical and sectoral breakdown of the major services offshoring sites in Central and Eastern Europe, 2010*

*Legend:* BS=business services; FS= financial services; ITO= Information Technology Outsourcing; R&D=Research and development, Knowledge process outsourcing; One box is equal with one offshoring site.

*Source:* drawn by the author based on data of PAIiZ, Czehinvest and ITD-Hungary.

Poland, with the largest potential supply of skilled labour and the availability of untapped provincial locations has developed the most extensive network of offshoring locations. The spatial concentration is more pronounced in Hungary and Slovakia where the capital cities, which are the main locations of this type of investments, represent a higher share of the total population than in Poland and Czech Republic.

However, Hungary once a forerunner in the establishment of shared service centres opening its first location in 1999 has lost its leading position. Contrary to Poland, most of the projects have concentrated into the capital city of Budapest and governmental agency failed to channel most of new investments towards the midsize cities. While BPO investment has been selected by the Polish and Czech agencies as a priority, the Hungarian agency however received criticism concerning its marketing activity. As in other spheres of economic activity in Hungary Budapest dominates the BPO and ITO sectors. Hungary has no suitable office markets in its midsize cities. More Vendors maintain operations in both the capital city and secondary cities in Hungary. Budapest is leveraged for higher-value work, while lower level processing is accomplished in secondary locations that offer much lower costs and extremely lower attrition sites.

Contrary to IFC locations, shared services centres (SSC) are less embedded in their national and regional hinterlands, and these supply and efficiency-driven<sup>22</sup> vertical investments across national boundaries are seeking low-cost global locations within *transnational production systems*. The demand-led market seeking investments (such as financial FDI) were the most

<sup>22</sup> The demand-led horizontal investments are located in the capital city, where there is the highest demand for their services. For supply and efficiency driven vertical investments, the main attracting factor in capital cities is the large supply of suitable and relatively cheap skilled workers (Hardy et al 2011).

common throughout the beginning of the transition period in CEE (Hardy et al. 2011). Due to their low level of territorial embeddedness, SSCs' impact on their host location is rather limited. Consequently, SSC locations can not result in a natural evolution to an IFC, as it lacks the geographical concentration of indigenous and international financial firms and the exercise of command and control functions from their headquarters (*Bellon 1998, Pelly 2001*).

## **Impact of 2008 global economic crisis on CEE financial centres**

The transition of the financial sector in the CEE region has received considerable attention during the transition from both a theoretical and an empirical perspective (Bonin et al. 1998, Wachtel 1998, Claessens et al. 2001, Gál, 2004, Várhegyi 2002, Banai et al. 2010, Csaba 2011), but much less attention has been devoted to the post-transition period and the impact of the crisis, which has become the most serious challenge of transition models, and has indirectly affected the IFC conditions of the capital cities.

Concerning the transmission of the crisis in CEE, there are two distinct approaches in the transition literature. According to Myant and Drahokupil (2012), the financial crisis was an external shock to the CEE region and affected countries in different ways, where financial inflows and export flows were the transmission channels of the contagion. The other arguments emphasize that the crisis cannot simply be understood as an internal adjustment to an external shock (Bohle, 2010); rather, the global financial and economic crisis exposed the weaknesses of the post-socialist neo-liberal economic development model in CEE (EBRD Transition Report, 2009). Smith and Swain (2010) focus on the dependent models and uneven forms of transition to capitalism and the internationalization of the financial sector in CEE. They argue that this model of transition has contributed to systemic vulnerabilities exacerbated by the crisis in the CEE region.

In a few CEE countries, catching up in the first half of the 2000s was generally accompanied by macroeconomic stability (Czech Republic, Slovakia, and partially Poland), but certain countries (Hungary, Estonia, Latvia) of the region became increasingly vulnerable to external shocks due to unsustainable trajectories of credit-fuelled housing and consumption booms, high current-account deficits, and quickly rising external debt (a large proportion of it denominated in foreign currencies). Foreign currency indebtedness channelled through interlinkages occurring between West European parent banks and their local subsidiaries had an implication for the internal and external imbalance within the EU banking system (Gorzelać and Goh 2010). The impact of the crisis has been highly uneven within the European Union and has not only increased the gap between the core countries and the peripheries, but also resulted in growing diversity within CEE.<sup>23</sup> Poland has avoided recession by not having expanded huge debt and by benefiting from its large internal markets (Smith and Swain, 2010). The excessive burden of debt repayment resulted in severe decline both in investments and consumption. This was the case in some of the countries that experienced negative or zero growth in 2008 and 2009 (Latvia, Hungary, Romania).

---

<sup>23</sup> Hungary's external funding exposure was the highest (while the Czech Republic had the lowest), reaching one third of total liabilities in 2009.

In Hungary, foreign currency indebtedness had direct spillover effects on the national economy since 2009, when local debt crisis affected all indebted sectors (Gál, 2014). The impact of the financial crisis increased Hungary's dependence on external financing and also weakened the position of Budapest as an international financial centre. In Hungary and the Baltic states, funding availability and capital outflows led to a more severe decline in bank lending than the Eurozone average (measured by loans to the nonfinancial corporate sector).<sup>24</sup> The crisis has also altered the future growth prospects of these CEE countries; monetary and fiscal policies are on a tightening course for several years and there is little room for powerful countercyclical policy responses. External capital inflows suddenly and significantly stopped despite the relatively quick recovery in the region. For example, in Hungary, despite its recovery, the scale of investment and the financial intermediation sector remained much below its pre-crisis level.

The financial and economic crisis has had an impact on the international financial centre position of the capital cities studied. Various data on banking and capital markets (lending activity, market capitalisation) illustrates the fluctuation in the concentration of IFC functions. After the ambitious start of Budapest thanks to the seemingly successful gradual transition model, it is now losing the race with other CEE capitals to become the international financial centre in the CEE region.

The rapid decline of Prague as a financial centre in the late 1990s and Budapest in the second half of 2000s was accompanied by not only a less spectacular recovery, but also by the rise of *Warsaw*, especially after the 2008 financial crisis. Despite the fact that the recent financial crisis had a visible effect on Warsaw in 2008 and 2011, it recovered faster than other financial centres in the region. In this regard there are two effects in play – the country effect and the financial center effect. Poland was not only able to avoid the recession, but well-timed regulations managed to prevent the burst of the housing bubble. Foreign capital inflow was not significantly affected. Warsaw experienced a tremendous scale of public and private investments, and the large domestic market generated huge demand. Poland does not rely heavily on export (it accounted for only 40% of GDP, half of the percentage of the Czech Republic and Slovakia). The EU funds also contributed to the mitigation of the effects of the crisis (Berend, 2013).

Besides its crisis resilience, there are important factors that make *Warsaw* suitable for the functions of IFC with a strong regional focus. For instance, the high-standard of financial regulations in the Polish financial market in general, and the wise and active strategy that made the Warsaw Stock Exchange the largest player in the CEE region. This strategy is accompanied by active marketing, and by an active engagement in multilateral trading platform, which helped link the WSE with London (Wójcik 2007, Hashimoto 2015). Warsaw was the only city of the three that managed to attract many foreign investors and influential market players, even during the time of the crisis. With its global presence, the WSE successfully maintained its independence from Vienna, unlike its larger regional counterparts (Budapest, Prague).

---

<sup>24</sup> The current FDI literature (Claessens and van Horen 2012) focusing on the impact of foreign bank presence on credit creation and financial stability during the crisis confronts the once-dominant approach of “supporting effect” of foreign banks (Haas and Lelyveld 2009).

The financial and economic crisis have had a moderate impact on *Prague's* banking sector as the banking market was prudent, and the share of foreign currency loans, which proved to be the Central and Eastern European subprime, was insignificant. The Czech Republic experienced “reverse flows” because of the decrease in cross-border lending in spite of its strong economic fundamentals. However, the indirect effect of the crisis became clearly visible in declining demand, largest pressure on profit, efficiency and risk management. The strong presence of German and Austrian retail banks in the Czech Republic and the incorporation of the Prague Stock Exchange into the Wiener Börse was accompanied by an integration trend in the capital markets as well. However, the PSE did not recovered from the financial crisis, as the total market capitalisation in Prague was only a half of its 2007 value.

Similarly to Prague, the development of financial markets in *Budapest* has been rather weak, reflecting the deteriorating macroeconomic situation, which started long before the crisis and was characterised by the lack of strategic-minded long-term economic policies in Hungary. Starting in the late 1980s, Hungary was a pioneer country for transition success, but its badly designed and managed fiscal and monetary policies have served poorly in preparing it for the global economic crisis in 2008. Despite sustained rapid development continuing up to 2006, imbalances and negative trends have gained ground since the beginning of 2000s. Paradoxically, its financial integration, once the engine of transition and growth, became the source of relatively large accumulated private and public debt, and contributed to the crisis. Hungary's public debt, although below the EU average level, had increased rapidly, from 54% in 2000 to 80% of the GDP in 2010. The foreign currency indebtedness of the private sector resulted in the largest risk for macroeconomic imbalances.

Although the Hungarian ‘gradual’ transition model is characterized by some degree of stability, at the same time, foreign investment and takeovers seem to have strengthened the fundamentals in Budapest. However, the lack of consistent and long-term economic policies and the fiscal alcoholism of serving governments and weaknesses of regulations made the Hungarian financial markets unstable during the crisis, and further weakened Budapest's international financial centre position. The recent right-wing government's campaign against foreign-owned banks in Budapest presented big challenges to Budapest's ambition to become an international financial centre. On the one hand, foreign capital inflow has stabilised the Hungarian economy and even developed it to the highest level in the region by 2004. On the other hand, the the Hungarian banking system's over-reliance on foreign capital made the risks of high reverse capital flow evident during the recent financial crisis, demonstrating the dependency of Budapest on the West European IFCs (Mihaljek 2010).

The capital inflows to the financial sector have recovered somewhat since the outbreak of the crisis in 2008, and stock has increased substantially in the Czech Republic and Poland, while decreasing in Hungary. The seemingly successful stabilization programme in Hungary could not take advantage of counter-cyclical measures until recently, due to the huge burden of public and private indebtedness (the transfer of foreign currency debt to local currency that was decided upon in late 2014 could cost 8% of the GDP). The right-wing government launched a major re-nationalization program after 2010, primarily in the energy and banking sectors. It aims to increase the domestic/state share of the banking sector, which reached more than 50% by 2015 at the expense of purchased foreign owned subsidiaries. The Hungarian government heavily taxed foreign-owned banks in past years, and therefore the Hungarian financial market is considered less attractive for foreign financial players. The nationalist approach strongly

discourages the internationalisation of Budapest as a financial centre and as it looks now, it has left the competition to become the international financial centre of CEE region.

## **Conclusions**

The aim of the present study was to examine the development of international financial centre function of Budapest as compared to Warsaw and Prague during the transition period, assessing the preconditions for the creation of regional centres. Various data used, such as employment figures, presence of foreign banks, and size of the banking sector and capital markets, illustrate the signs of financial centre formation. However, despite the significant growth in financial sector employment, banking assets, stock market capitalization, and cross-border capital flows since the early 1990s, the size of the financial sector and the number of global players concentrating in these capital cities are still much smaller than their western counterparts.

The paper finds that despite the increasing integration of these capital cities to the network of the West European IFCs, the external dependency of these capitals, which appears in the form of hierarchical command and control functions by global IFCs, reinforces the high level of financial dependence of CEE. This prevents the development of fully-fledged financial centre functions. A key finding of our study is that despite these preconditions, carefully tailored economic policies combined with city branding strategy make it possible to develop certain IFC functions in each of the three capital cities, providing significant benefits through international economic integration and networks, as illustrated by Warsaw's example, or by the post-crisis development of Budapest as a counter-example.

The paper argues that the global crisis not only exposed the weaknesses of the post-socialist development model in certain CEE countries, but it has also had a significant impact on the future development of IFCs. Our analysis confirms that diversification is observable not only at the country level, but on the level of capital cities as well, as their development path also became more differentiated as a result of the crisis. Various data on banking and capital markets illustrates the fluctuation in the concentration of IFC functions. Despite there being little market evidence showing signs of a regional-centre focus there around the millennium, recently there are more signs of IFC formation, especially considering the current development of Warsaw. Budapest, once a forerunner in economic transition, lost its previous competitive advantage in the financial sector and declined due to the deteriorating macro-economic conditions and mismanaged economic policies long before the crisis. Budapest has not become a regional financial centre despite its favorable preconditions, which largely stemmed from the regional network of OTP Bank. The paper argues that regional banking networks alone do not make a city an international financial centre – especially when capital markets are concerned. However, in the case of Warsaw, its prudent and investor-friendly economic policy, high-standard of financial regulations, and active strategy in the capital markets, made the city the most important IFC in CEE. With its global presence, the Warsaw Stock Exchange not only maintained its independence from Vienna, but also became the largest exchange in the region.

The rise and fall of Budapest as a prominent regional financial centre can be explained not only by the badly managed fiscal and monetary policies prior to the global economic crisis, but also to a large extent by the competition and successes of the other financial centres. We argue that besides the lack of consistent economic policies and weaknesses of regulations that made the Hungarian financial markets vulnerable during the crisis, the recent nationalist approaches of the government (re-nationalization, levy on banking) have further weakened Budapest's international position. Our analysis concluded that Budapest, despite its earlier endeavours, has most likely lost the competition to become an international financial centre.

## Outward FDI in financial services: the case of Hungary

Magdolna Sass

Center for Economic and Regional Studies, Hungarian Academy of Sciences

*This work-in-progress document contains results of a research analysing outward FDI in financial services from Hungary between 2001 and 2014. We identified the main foreign investor companies, of which one is a Hungarian-controlled, majority foreign-owned bank and a local subsidiary of a German bank. The paper examines in detail the foreign investment activities of the leading investors and changes in it during the crisis. The methodology applied is detailed case studies of the main investor banks, based on semi-structured interviews with leading managers as well as other information collected from specialised newspapers and journals and the bank balance sheets. On the basis of these, Hungarian OFDI in financial services is analysed, regarding the main ownership advantages of investors, their motivations to invest, the entry mode chosen, the geographic locations of the investments, the strategy settings of the companies and the home country impact of outward FDI.*

### 1. Introduction

Outward foreign direct investments (OFDI) increased substantially from former transition economies after the start of the transition process. Hungary was among the frontrunners in OFDI in this country group, starting to invest abroad considerable amounts from the mid-nineties. (Kalotay, 2002; Antalóczy and Éltető, 2002) At the end of 2012, the stock of Hungarian OFDI amounted to more than 26.5 billion euros, which is the second largest behind Poland among the new member states of the European Union. In per capita terms, only Estonia and Slovenia have higher OFDI than Hungary in the same country group.

Hungarian OFDI is concentrated in a few sectors, partly in connection with the largest transactions connected to a few companies. (Sass, Kalotay, 2010) Thus it is highly concentrated in terms of the investing companies. According to the data of the Hungarian national bank, the outstanding sectors are mining, in manufacturing: oil, pharmaceuticals and electronics and in services: financial services, professional and other services (mainly business services). Thus the high concentration in terms of the investors is connected with the sectoral composition of OFDI. The leading sectors are: financial services (20% of total OFDI, with OTP Bank as the most important outward investor), mining and quarrying and manufacturing of refined petroleum products (18%, connected to the activities of MOL) and pharmaceutical industry (6%, mainly Richter). OFDI in financial services has represented a significant part of modern Hungarian OFDI (Gál, 2006; Antalóczy and Sass, 2008; Sass, Kalotay, 2010; Sass et al., 2011), though its absolute values had been relatively small: it surpassed

the half a billion euro stock only in 2000, but afterwards it grew dynamically to exceed a stock of 3 billion euros by the end of 2009. At the end of 2009, it represented 23.5 % of total Hungarian OFDI, being the leading services sector in terms of OFDI. By the end of 2012, the OFDI stock in financial services increased to more than 5 billion euros, a significant increase from previous year. (Direct comparison with developments before 2008 is not possible because of the change in methodology in sectoral data collection.)

Similarly to total OFDI, financial OFDI is highly concentrated in terms of the number of significant investors (Gál, 2010): according to our estimation, OTP represents the overwhelming majority of investments abroad in the sector, while a small share (an estimated 100-200 million euros) was taken up by MKB until 2014, thus 2012 data contained the foreign investment of this bank.<sup>1</sup> The third investor is also small, the formerly OTP-related OTP Garancia, operating in investment services may be responsible for the majority of OFDI in that sector, amounting to a stock of 26 million euros in 2009. OTP Garancia was acquired in 2008 from OTP by the French Groupama and thus this company inherited an office in Slovakia.

Table 1 Outward FDI (stock) in Financial activities, 1998-2009 (million euros)

|                            | 1998  | 1999  | 2000  | 2001  | 2002  | 2003   | 2004   | 2005   | 2006   | 2007   | 2008   | 2009   |

The relative importance of OFDI in financial services in Hungary has changed considerably over time compared to other new EU members, in which OFDI is significant. Financial services was the dominant sector compared to the Visegrad economies before the crisis (Sass and Radlo, 2011). However, this has changed considerably over the crisis years – as in all other countries in the region. (Table 3) In 2012, Hungary had the third highest share of financial services in overall outward FDI stock among the analysed countries

Table 3 Share of Financial intermediation in total OFDI stock, %, selected economies, 2008 and 2012

Note: data for 2011

In spite of the decline in relative significance of Hungary as an outward investor in financial services, the main investor, OTP Bank is still the only significant regionally-controlled player in that area together with the Polish PKO Bank. (Raiffeisen Research, 2015) Other banking players in the region are coming from Western European countries (and smaller projects appear from Russia). Thus increasing outward FDI from other countries of the CEE region in Table 3 may be mainly of indirect nature.

The paper is organised as follows. After presenting the theoretical framework, the main aim of the research and the methodology used are shown. The next section provides information about the two main foreign investor banks in Hungary. This is followed by the analysis of their outward investments in various areas (indirect versus direct investors, ownership advantages, strategy, motivation, entry modes, choice of location, impact of/on the home economy; and the impact of the crisis). The last section concludes.

## 2. Financial OFDI and multinational banks – theoretical framework

The emergence of multinational banks can be explained using the theory of multinational enterprises. Thus banks may have different motivations when expanding abroad. Due to the nature of bank activities and the relative fragmentation of markets (due to national regulations), the most important motivation can be to access new markets (especially in relation to developments in the domestic market), thus the market-seeking motive dominates. Furthermore, banks can improve their efficiency through lowering costs or increasing revenues, or through economies of scale and/or scope, thus the efficiency-seeking motive may also be relevant. Furthermore, banks can gain important strategic assets and can diversify risks through their foreign expansion, thus the strategic asset seeking motive may also be relevant.

This paper uses Dunning's extended OLI framework for analysing the process of the internationalisation in the financial services sector. According to the OLI-framework, the investors must own an ownership advantage, which is based on intangible assets in order to be able to move abroad. Ownership advantages enable the foreign bank to compete with local banks in spite of its "liability of foreignness". On the other hand, this intangible asset may be used by the bank by keeping it inside the organisation and not "putting it to market forces", i.e. not to sell it on the market (internalisation advantage). This type of advantage in banking is usually connected to information: for example, a cognitive imperfection (Dunning (1981) and stems from the importance of the flow of information between the bank and the client, which is made mainly through personal contacts. Thus banks may follow their (important) clients to foreign countries – or vice versa. In their most updated form (Dunning- & Lundan, 2008), ownership advantages can be divided into asset-based advantages (Oa) such as cutting-edge technologies, marketing prowess or powerful brand names, and transaction-based advantages (Ot) such as common governance of assets and interaction with other corporate networks. From this it can be deduced that transaction-based ownership advantages are indirectly shaped and influenced by the home-country business and regulatory environment and culture. Furthermore, the locations of the investment must possess some specific advantages in order to be able to attract these investments (locational advantages). Empirical research shows that location-specific advantages such as size, human capital and cultural distance, do provide an explication of the internationalization of financial firms. (Outreille, 2007)

Another theory of "stages internationalisation" is used to some extent, when describing the geographical spread of the investments. According to the stages approach, which is described in detail in the Uppsala model, companies go through different stages of internationalisation. The first stage is the ad hoc export, the second is systematic exporting through an independent foreign sales firm, in the third stage a foreign representative company (for sales) is established, and in the fourth stage, a foreign production unit (affiliate) is established. (Johansson, Wiedersheim-Paul, 1975; Johansson, Vahlne, 1977) In the stages approach, a determining role is played by the decision taking capacity of the management, which is determined by available information, knowledge and experience. The Uppsala model underlines the importance of continuous learning based on foreign experiences, and thus how the stages are built on each other. Moreover, the importance of psychic distance is emphasized, thus in international transactions cultural, language and other differences act as barriers to the flow of information and thus the decision taking capacity of the company. Parallel with the increase in foreign experiences of the company, this psychic distance decreases.

### **3. Research question and methodology**

The main aim of the present paper is to describe developments in Hungarian OFDI in financial services. On the basis of the analysis, we can relate the characteristics of Hungarian OFDI in the financial sector on one hand to the theories and empirical findings of multinational companies and banks and emerging multinational companies and banks. The main areas where the foreign expansion of Hungarian banks are analysed will be the following: direct versus indirect investors, ownership advantages, strategy, motivation, entry mode, choice of location, impact of/on the home economy and impact of the crisis.

The research is based on semi-structured, questionnaire-based interviews with leading managers of the two leading foreign investor banks in Hungary. Two interviews were conducted with the representatives of the two banks back in 2011 and another one with the representative of OTP Bank in 2015. The interviews were based on the same semi-structured questionnaire. Besides information from these interviews, data from the balance sheets of the companies and specialised journal and newspaper articles and texts of interviews with the CEO of OTP Bank were also used. This methodological approach can be justified by the extremely low number of important investors in financial services in Hungary, and thus the high concentration of investment in terms of investors. Furthermore, “qualitative research” could also be carried out using this method, which may supplement well and even correct results gained from quantitative analysis.

### **4. A short presentation of the two leading investors: OTP and MKB**

#### **4.1. OTP**

OTP Bank, is Hungary's leading commercial bank. The legal predecessor of OTP was established in 1949, which was a nation-wide state-owned bank specialised in retail banking. In 1990 it became a public company and non-banking activities were separated. At present, OTP is the determining financial institution in Hungary as far as retail banking is concerned; in retail deposits it commands a market share of around 32%. Its share in the mortgage loan market is also above 30%. It is a market leader also in consumption loans (over 10% share) and the other loans category (over 20%). (Molnár, Holló, 2011) It owns the highest number of ATMs and branches in Hungary. Its market share is estimated to reach 19.3% in Hungary, according to Raiffeisen Research (2015).

The privatisation process of OTP Bank was launched in 1995. It was privatised through the stock exchange, in three “tranches” (1995, 1997 and 1999). As a result of three public offerings along with the introduction of the bank's shares into the Budapest Stock Exchange the state's ownership in the bank decreased to a single voting preference (golden) share. Individual foreign shareholders were limited to 5 %, and domestic shareholders to 10 %. By the end of the decade, the bank's privatization had been completed and nearly all of OTP's shares had been placed on the Budapest exchange. In 2008, OTP sold one of its subsidiaries: the French Groupama S.A. acquired its insurance business line, OTP Garancia. At the same time, Groupama S.A. has acquired 8% of shares of OTP Group. Currently the bank is characterized by dispersed ownership of mostly private and institutional (financial) investors. In

March 2015, 60.06 % was in the hand of foreign investors. Above 5 % was held by Megdet, Timur and Ruslan Rahimkulov (8.88 %), the French Groupama (8.29 %) and the Hungarian petrol company, MOL (8,57 %) as well as the Lazard Group (5.1%). The state owned 5.03 % (until 2007: a golden share); through the Hungarian National Asset Management Inc. Employees of OTP held 1.24 %.<sup>2</sup> Thus while the majority of OTP's shares are held by foreigners, they are widely dispersed, with no controlling shareholder, and Hungarian shareholders are also numerous and none of the foreign or domestic shareholders own more than 10 per cent of the shares. Due to the regulations of the banks, none of the above 5% owners have more than 10% of the voting rights.

OTP started its "shopping spree" in the region after its privatisation was finished in 2001, when it acquired IRB in Slovakia. At present has foreign operations in Romania, Slovakia, Croatia, and Bulgaria (where its subsidiary, DSK Bank, has become market leader), in Russia, Serbia, Montenegro and Ukraine. In 2008, OTP sold its insurance company to the French Groupama, and together with that, foreign affiliates in insurance in Slovakia, Romania and Bulgaria were also sold. In terms of market shares, the Montenegrin bank is a market leader, and the Bulgarian bank also has a relatively high market share: almost 14 per cent and is a market leader in the country. In other countries, the local subsidiary of OTP is of minor importance with 0.4 to 3% market shares, with significant operations only in certain niche segments. (Raiffeisen Research, 2015) Altogether, it has 11.9 million customers in the region and thus it can be regarded as one of the leading banks of the region.<sup>3</sup> The bank's total employment in 2014 was almost 36000 persons.

## 4.2 MKB

MKB (Magyar Külkereskedelmi Bank, Hungarian Foreign Trade Bank) was established in 1950 for managing currency transactions connected to foreign trade. In 1987, with the introduction of the two-tier banking system in Hungary, it became a universal bank with extending its operations. Its privatisation process took place between 1994 and 1996. In 1994, Bayern LB (25%) and EBRD (16.7 %) gained minority share. In addition, in 1994, the Deutsche Investitions- und Entwicklungsgesellschaft (German Investment and Development Society) acquired 8.3 % of the shares. In 1996, BayernLB bought an additional 25.8 %. Through further acquisitions and increases in the base capital, Bayern LB became the main owner. At present, it is owned by Bayerische Landesbank, München, Germany (89,89%) and P.S.K. Beteiligungsverwaltung GmbH, Vienna, Austria (9.77%).

In 2011 it was among the leading banks in Hungary, especially in corporate lending and corporate deposits. It was market leader in factoring (25.3% market share) (Molnár, Holló, 2011). However, the bank made considerable losses during the last years of its Hungarian operations.

<sup>2</sup> See <https://www.otpbank.hu/portal/en/IR/Shares/OwnershipStructure>

<sup>3</sup> <https://www.otpbank.hu/portal/en/AboutUs/History>

In terms of acquisitions, at first it acquired a domestic bank: Konzumbank in 2003. In 2005, the first foreign acquisition of the affiliate was realised in Bulgaria, where it acquired the majority of the shares of Unionbank, and in 2006, Romexterra Bank in Romania was bought. The acquisition price was not disclosed in neither cases.

The parent bank, Bayerische Landesbank incurred large losses during the financial crisis because investments into sub-prime mortgage securities in the US. One of the conditions of the following government bailout set by the relevant authorities of the European Union in 2012 was to sell the Hungarian subsidiary, MKB Bank before 2016.<sup>4</sup> Before that, as it was already mentioned the two foreign banks owned by the Hungarian affiliate were sold.

MKB was sold to the Hungarian government for 55 million euros, and the parent wrote off 270 euros loans given to the subsidiary. Before selling it, the parent had to cut-up the Hungarian subsidiary bank and separate bad loans.

## 5. Various characteristics of financial OFDI from Hungary

As it was already pointed out, the two most important investors in financial services are OTP and MKB, they are responsible for the overwhelming majority of outward FDI in the sector. OTP Garancia, the insurance company was part of the OTP Group, when it realised its foreign direct investments, thus the characteristics of its OFDI are the same as those of OTP. The French Groupama took over OTP Garancia in 2008 together with its foreign affiliates in Slovakia, Romania and Bulgaria and kept the Slovakian subsidiary, while sold the others.

As far as the timing of OFDI in financial services is considered, OTP was the first to start its acquisition in Slovakia. The abrupt impact of the financial crisis is apparent from Table 4.

Table 4 Timing and geographical locations of investments by OTP and MKB

|            | 2002     | 2003     | 2004                       | 2005                   | 2006   | 2007          | 2008                                    | 2013 | 2014                     |

Source: own compilation based on [www.mkb.hu](http://www.mkb.hu) and [www.otp.hu](http://www.otp.hu)

The following areas and characteristics of the foreign expansion of the two banks will be analysed in this section: direct versus indirect nature of the foreign investment and foreign investor; ownership advantages and strategy; motivation; entry mode; choice of location; impact of/on the home economy and the impact of the crisis.

#### 4.1. Indigenous versus indirect investors

It is important to distinguish between direct and indirect investors. Direct investors are domestically owned firms, while indirect investors are local affiliates of foreign parents. On the basis of the short descriptions of the banks it is obvious, that basically all OFDI from Hungary in the financial services sector can be evaluated as indirect, because both investors are in majority foreign ownership. However, it is important to note the difference between the two cases. In the case of MKB, it is obvious, that the bank is controlled by its major investor. If we simply take the level of foreign ownership at face value and equal it with the level of foreign control, then also OTP should be considered a foreign controlled bank. (This is the approach taken for example by Altzinger et al. (2003) or Rugraff (2010), where an above 50 % foreign ownership is taken as foreign control.) But while OTP is majority foreign owned, it is obviously not foreign controlled: it is not the foreign owner but the mainly Hungarian management which is taking all strategic decisions, including foreign acquisitions. In the senior management (CEO and 6 deputy CEOs) and the members of the Board of Directors (3 executive and non-executive members) there are no foreign citizens; nor are there any foreign managers reporting directly to the executive director. The official language of the company is Hungarian. Thus OTP while on paper it is majority foreign-owned, all decisions of strategic importance are taken by the Hungarian management residing in Hungary, including strategic decisions concerning among others foreign investments. Therefore, while the company can be classified as an “indirect” investor, due to the foreign majority ownership, we would rather call it qualifyingly a “virtual indirect” investor, because there is no single (or an identifiable group of) foreign investors holding a clear majority. (Sass et al., 2011)

“Virtual indirect” investments understandably are much closer in many characteristics to direct than to indirect investments. The most important distinguishing factor between “virtual indirect” and direct investments can be the higher exposure to risk in the case of “virtual indirect” investors, because they are more dependent on foreign/international capital and they are therefore more directly dependent on changes in the business environment in more than two countries. In the case of direct investors, it is understandably mainly the home and the host countries’ business environment which has a direct influence on the decisions and operation of the parent company. For “virtual indirect” investments, there can be further influencing factors in terms of the third country which acts as a mediator in the investments and/or further countries from which significant holders of shares are present in the ownership structure of OTP. In that case a minor influence can be attributed mainly to the French

Groupama, which operates in a similar sector as OTP. However, its voting rights are limited. Otherwise we could say that direct and “virtual indirect” investors are very similar to each other.

Why is it important to distinguish “virtual indirect” from indirect investments? (For more details see Sass et al, 2011). First, the motivations of investing abroad may be different in the case of indirect and “virtual indirect” (or direct) investments. Motivations usually partly reflect the relative competitive advantages of the home and the host countries. Thus in the case of the “virtual indirect” investments, the competitive advantages of the “real” home country must be taken into account. Second, their impact on the home country can differ from each other to a great extent, for example this has clear consequences for profit repatriation, transfer of capital, which again is realised between the host and the “real” home country. Third, the sustainability of foreign investments, the footlooseness of the investor company can also differ in the case of indirect and “virtual indirect” investors. As Rugraff (2010) points out, the outward FDI path of a given country may prove to be unsustainable or highly sensitive to strategic business decisions taken in another than the immediate home country of the investment in the case of indirect investments. This may result also in a high volatility of both inward and outward investments. OFDI realized by foreign affiliates residing in Hungary may prove to be more footloose than those realized by local investors, as the strategy of the multinational is determined by the parent company residing in a different country. However, in the case of “virtual indirect” investments, the home country where these decisions are taken, where the parent company is residing and the business environment of which influences to a great extent these decisions equals to the immediate home country of the investing company. Thus the high presence of “virtual indirect” investments in itself does not necessarily increase the volatility of OFDI.

Fourth, policy implications may also differ in the two cases. Governments of countries which are home to big multinationals support their “fellow country companies” especially of large size or if they are deemed to have strategic importance in their foreign operations through lobbying and exercising political influence. In that case, clearly, the ultimate investor matters. In the case of “virtual indirect” investors, the ultimate investor country equals to the immediate investor country. Fifth, statistical and data collection considerations can also be important. The presence of “virtual indirect” investors may result in false estimations of direct investments abroad; see e.g. UNCTAD (2006), p. 108.

## **4.2. OA/intangible asset and strategy**

Foreign expansion through FDI is always connected to greater risk than domestic activities, including possible factors which cannot be managed on the basis of experience gained in the country of origin. Thus the bank needs special resources in order to be able to internationalise successfully. It is important to see what are those intangible assets or competitive advantages which enable these banks to successfully enter a new market and efficiently compete with incumbent banks. Such ability can stem from specific human and financial resources at hand, banking techniques, specific banking experiences, organisational skills, skilled personnel, etc. (Mutinelli, Piscitello, 2001)

The Hungarian economy provided a special business environment for OTP to be able to internationalise. The presence and operation of international competitors occurred the first here as Hungary was the first among transition economies to privatise banks to foreigners. With the appearance of ‘Western-style’ banking, existing, non-privatised banks had to face an increasing level of competition. Hungary was the first among former transition countries to open up its economy to FDI, including FDI in the banking sector. This has resulted in improved service and products for local affiliates of multinationals and also for Hungarian firms, together with the introduction of innovative financial products to the Hungarian consumer, such as consumer credits. (Akbar, McBride, 2004) Both the method and the timing of privatization matter to performance; specifically, voucher privatization does not lead to increased efficiency and early-privatized banks are more efficient than later-privatized banks. (Bonin et al., 2005) These factors all played a role in shaping the ownership advantages of OTP. In 1992, Sándor Csányi, was appointed chairman and CEO of OTP Bank, who with his management team started to reorganise and modernise the operation of the financial institute in this increasingly “market-like” business environment. By the end of 1994, OTP had reduced the number of managers from more than 200 to 65, and many of these were replaced by young, talented managers. The bank slashed more than 8,000 jobs by the end of the decade. It centralised its back-office operations and developed and introduced its own IT. It was the first to appear on the Hungarian market with novelties such as debit cards, mobile telephone banking services, and Internet banking services. Its dominant position in Hungary and the successful reorganisation of activities resulted in strong capitalisation, which made OTP an attractive target for acquisitions. This push factor together with the accumulated knowledge about restructuring and operation in an evolving market economy environment induced the bank to carry out its first foreign acquisition in a neighbouring country with a significant Hungarian minority population, in Slovakia. It also played a role in further acquisitions. This type of ownership advantage could result in successful foreign acquisitions only around until 2005, because after that there were no privatisation-related “target-banks” in the region. Dynamically, by that time, OTP could change its ownership advantage and rely more on its knowledge about operation in an evolving market environment and it could move in and specialise in certain market niches in its foreign operations, especially in countries, where it had only a very low local market share.

In the case of MKB, the “story” is completely different. The German parent bank realised the opportunities the region had to offer already at the beginning of the years 2000. It had an unsuccessful attempt at acquiring a bank in Croatia, where there were management errors as well. After that, in 2005 a decision was taken, that with close parent control, the Hungarian bank, the management of which is much more familiar with both the region and the modus operandi in it, will be responsible for the acquisitions in the region. The parent bank made the final decision and looked for possible target banks as well. The parent selected the target countries, which were Bulgaria, Croatia, Romania, Serbia and Slovakia on the basis of having there close Hungarian ties. Another reason why the Hungarian subsidiary was selected was that foreign acquisitions would target retail and SME banking, in which the Hungarian subsidiary had considerable experience (the parent dealt mainly with large-sized clients). (Connected to that the Hungarian subsidiary launched a new retail model in Hungary in 2005.) At the end, MKB acquired two foreign banks, the original target was more, but in Serbia, they were outpriced by Greek banks, then the crisis made further acquisitions impossible and the parent even had to sell its Hungarian subsidi-

ary, as we shall see later. Thus the ownership advantages of the Hungarian subsidiary again are connected to a special (local/regional) knowledge, which the parent bank does not own.

According to the theory, certain ownership advantages of firms or banks follow rather than lead internationalisation, because they may pursue asset seeking strategies before converting to market seeking ones. It may also happen that assets and markets are sought for simultaneously. In the case of OTP and MKB, we could not see this type of changes.

### **4.3 Impact of/on the home economy**

Impact of the home economy is especially important in the case of OTP in shaping the (initial) ownership advantages of the bank, thus providing it with transaction-based advantages. First, the mode of privatisation gave an opportunity and resulted in the experience for the management to be able to privatise and restructure formerly state-owned banks. Foreign expansion based on that experience than was the basis for gaining further experiences in the various stages of the post-transition business environment. The mode of privatisation acted as a kind of push factor because being on the stock exchange and having strong capitalisation made OTP an easy target of acquisition, and thus induced the management to strengthen its position by foreign expansion.

Impact on the home economy: according to all the interviewed experts, this is minimal, a minimally positive impact is provided by slightly higher employment. Synergies and thus decrease in costs are minimal. Centralisation of certain back office activities was of very small size in the case of OTP, thus resulting in a small increase in employment. The indirect impact of making the bank more stable due to foreign operations and the possibility of financing home country losses from the gains abroad may be more important, especially that in Hungary the banking sector is put on high burdens from 2010 on.

### **4.4 Motivations**

The motivation in both cases is clearly market-seeking, the efficiency-seeking motive is not present. First of all, representatives of both banks said that their main targets are local customers, as the representative of MKB put it: “90% of customers is completely local”. During the interviews, none of the interviewed bank representatives deemed it important that there would be significant benefits from synergies or economies of scale and scope. OTP Bank made an attempt to centralise a few back office activities, but it was not possible for all the subsidiaries due to local regulations prohibiting the transfer of customer data abroad. In a few cases, there were common purchases of inputs (e.g. machinery, software), but this is also more an exception than the rule as the experience is that affiliates could attain better bargains locally. There are a few examples of sharing best practice in key activities, such as risk management, and new product development and allocating funds effectively, which is important for catching-up and remain competitive in international markets, but overall, the local subsidiaries are basically independent.

An interesting case is the motivation to follow important clients abroad – either by the bank or by its customers. According to the interviews, in the case of OTP, in countries, where its market share is small and operates mainly in niche-markets, that is true only for certain activities, but the bank could not become a primary bank for these important Hungarian foreign investor companies (e.g. MOL, Richter). However, it is not their primary bank neither in Hungary. In the case of MKB, the “follow” client” motivation was present for some smaller Hungarian companies, and for certain German ones, but in the latter case, this was not automatic, the local subsidiaries had to contact those German companies, which were present locally. In terms of the motivations of the banks to go where important investor companies from their own home countries are present, was not the case.

#### **4.5. Entry modes and choice of location**

As far as the entry modes are concerned, emerging multinational banks are more inclined to set up small ventures in “unknown” territories, even in the form of greenfield investments. (Petrrou, 2007) On the other hand, in the banking sector, acquisition is the main entry mode, as it provides ready assets, knowledge, reputation, access know-how in technical areas, and gives an “easy way” to increase size (Dunning, Lundan, 2008). In the case of the two Hungarian investors, acquisitions either from foreign or local owners, or from the state (privatisation) are the dominant entry modes in countries, which are geographically and culturally very close to Hungary. As we saw, in the case of OTP, its competitive edge laid in the capacity and ability to transform formerly state-owned, uncompetitive and overstaffed banks into competitive ones. Thus until 2005, privatisation-related acquisition was the main entry mode. Even for greenfield purposes, acquisitions are used, as was the case when OTP acquired a Romanian bank “for the licence”, as its previous and later attempts proved to unsuccessful in acquiring a larger Romanian bank in the framework of privatisation. Later on, as the ownership advantages of OTP changed and as privatisation targets disappeared, OTP’s entry mode changed to acquisitions. On the other hand, for OTP Garancia the entry modes were mainly through greenfield investments, connected to the local affiliates of the OTP Bank, low investment requirement makes possible a greenfield entry. For MKB Bank, both foreign banks were acquired independently of privatisation (and the failed attempt was also an acquisition).

As far as the geographic locations of foreign investments are concerned, both banks concentrate on their immediate regions. One common reason for that is the relatively low physic distance. For OTP, according to the interviews conducted with the representatives of the bank, when it acquired the Slovakian bank, one of its aims was to serve local Hungarians. A similar goal was to be achieved in Romania, and to a lesser extent, in Serbia, where the affiliate is headquartered in Novi Sad (in Hungarian Újvidék) – with a Hungarian minority population. (In all these three countries, there is a Hungarian minority population of considerable size.) However, according to the interview, at present Hungarians are clients of the local OTP affiliate in greater proportion only in Romania. The second common reason for the two banks is the low psychic distance due to common socialist heritage and the common elements of the consequent transition process. These banks have a competitive advantage due to their knowledge about how a “socialist bank” operated and how to transform it into a

competitive Western type bank. This obviously played an important role in the case of the Bulgarian bank bought by OTP, according to one interview, this bank was the equivalent of the Hungarian OTP in Bulgaria and due to the later start of Bulgaria in the transition process, OTP could use all its accumulated knowledge there. In the case of MKB, according to the interview, after some failed attempts of acquisitions in the region, the German parent bank decided to rely on the knowledge and experience of the Hungarian subsidiary, and thus it was assigned the responsibility for the takeover of the Romanian and Bulgarian banks. Thus especially in the case of OTP, internationalisation is obviously taking place in “stages” (Johansson and Vahlne, 1977), in terms of going from one location with a lower psychic distance to another one to a higher one and so on. In the case of OTP, confidence and experience gained in geographically closer countries provided the basis for changes in intangible assets and thus in ownership advantages and enabled the bank to access further markets with higher psychic distance, as for example Russia.

#### **4. 6 The impact of the crisis**

As we could see in Table 4, the crisis brought considerable changes for both banks: it first stopped their acquisitions in the region. (On the other hand, acquisition targets were missing, and the existing ones were too expensive reflecting the local problems of banking in the countries of the region.) The crisis induced OTP to sell the insurance arm and around 8% of its shares to the French Groupama for around 600 million euro – this helped OTP to weather the crisis and the consequent negative changes in the Hungarian banking environment. OTP could not really restart its regional expansion since the crisis, it was first in 2014, when further acquisition of shares in a partly-owned by OTP bank in Romania was announced. However, even that transaction was of minor importance in terms of its value.

In the case of MKB, the parent bank had to sell its Hungarian subsidiary already during the crisis, due to fulfilling a condition of its bailout by the German government carried out in 2008. Because the bank could not have been sold in one part, the German parent bank, Bayerische Landesbank first induced the Hungarian subsidiary to sell the two affiliates: the Bulgarian one in 2013 and the Romanian one in 2014. Later on, the Hungarian subsidiary itself was sold to the Hungarian state for 55 million euros in July 2014.<sup>5</sup> The transactions resulted in relatively large losses for the German bank, however, that was the condition of the bail-out posed by EU antitrust rulings. Thus MKB Bank ceased to exist as a multinational bank during the crisis – and due to crisis-related developments in the parent bank.

## 6. Conclusion and further research

The paper examines in detail the foreign investment activities of the leading investors and changes in it during the crisis. The methodology applied is detailed case studies of the main investor banks, based on semi-structured interviews with leading managers as well as other information collected from specialised newspapers and journals and the bank balance sheets. As far as the preliminary results are concerned, we distinguished indirect and virtual indirect investors: while OTP Bank is foreign majority owned, the strategy of the bank is determined by its controlling owner(s), which are the members of the Hungarian management due to the dispersed ownership structure (no foreign investor has more than 10 %). On the other hand, MKB Bank was a 100% foreign-owned bank with a German owner in the pre-crisis period, the important role of the Hungarian management is also shown when determining the foreign investment strategies of the Hungarian subsidiary. Thus, while the two cases would be clearcut cases of indirect investments, their closer analysis reveals important “deviations” from the textbook case.

In terms of the ownership advantages (OA) of the banks, we show the direct (MKB) and the indirect (OTP) connection between inward and outward FDI in terms of enabling the banks to develop their own OAs with experience in privatisation and restructuring of formerly state-owned banks and with learning how to operate successfully in a developing market economy environment with numerous competitors. We show that their motivation to invest is mainly market-seeking. Entry modes are acquisition in certain cases related to privatisation. In location choice, the importance of psychic distance is underlined in a wide sense (including a slightly belated progress compared to the home country towards the establishment of a market economy). We show the impact on the home economy being minor mainly in terms of benefitting from synergies, small employment creation in the parent bank and profit repatriation helping the parent bank (OTP) during the crisis. The direct impact of the crisis is shown for the performance of the banks and their internationalisation strategies and its indirect impact on changes in the ownership structure of MKB.

Further research is needed in terms of relating the characteristics of foreign expansion of the two banks to those of developed country banks and emerging multinational banks and to show the unique features of the former. Furthermore, the level of success of foreign subsidiaries needs to be analysed in order to assess the success of foreign expansion.

*Cybersecurity receives great importance to society in general in multiple entities takes benefit from the use of networks and computer systems for storage, production and processing of critical data to its development. It is therefore of paramount importance to encourage both teachers and students in higher level to dedicate themselves to the formation of knowledge in this area. The Cyber Challenge aims to generate new skills, through the formation of networks in the cyber security area, encouraging actors from education to human resource training in a strategic area of technology for development. The first results of this strategy shows that it is promising for proper training of cybersecurity professionals.*

## **1. Introduction**

In Brazil there is a significant gap in what is called the innovation function, here translated from the relationship between the entrepreneurial effort of Brazilian businessmen and national spending on research and development (R & D) (Zawislak; Castro-Lucas; Souza, 2007). These authors presented a possible explanation for this gap: the absence of a scale innovation in Brazilian business culture. From there, it can be inferred that the implementation of an innovative culture need to start a new educational base.

Given this situation, the question arises: how to implement a change in the educational process in order to have the development of individuals in strategic positions, compared to innovative contexts? Or, how to develop new relationships between social groups in a dynamic market and in constant transformation? And finally, how to develop the new imaginary individual to enable attitudes that are likely to generate social value?

Ways of living, way of doing things, ways of thinking, creating and following rules and maintain moral, political and religious positions define, according to Da Matta (1984), the culture of each social group. These lifestyles define the relations between social actors such as construction of social practices, specifically the work. This confirms the importance of thinking culture as a social construct, dynamic, carried out from the history of relations of social groups in different times and spaces, not fully integrated.

In this line of thought, generate and transfer knowledge, information, skills and values are cultural events that build new social identities. However, it is relevant to ask to

what extent these manifestations are indicative of people who allow themselves to live experiences, organize and conduct practices, act courageously and creatively, committed to innovation, able to plan their lives and, therefore, their actions, forming social networks in which to move independently. Or how you can develop different attitudes facing what Delors (1996) shows how tensions between global and local, tradition and modernity, the long and the short term?

The demands resulting from the information age and the constant quest for knowledge in this system generate the need to create conditions for the teaching-learning relationship occurs in order to generate proactive people. In order to prepare individuals to make decisions autonomously and innovative way, it is essential that trainers/teachers are trained for the incorporation and use of new technologies, innovating the very didactic and methodological process and making room for multiple learning paths.

Thus, this research aims to evaluate a new way of working with undergraduate students of computer science departments, Computer Engineering, Mechatronics and Software Engineering at the University of Brasilia, and similar courses of Colleges of Brasilia and surroundings they can act in a new way in the action-reflection process, from the conceptual basis of the Service Innovation Theory, enabling students to be protagonists in the process of changing attitudes to new situations and thus develop strategic skills cyber security for the Brazilian market.

## **2. Theoretical Background**

Given the size of addiction that almost all nations are exposed when it comes to connectivity in the last decade, many nations now include the issue of cyber security in their national defense plans, where the principle is not only cover the geographical boundaries of a country, but give it the means to protect national critical assets face the dangers of connectivity without boundaries.

The permanent and growing competition for world leadership in cybersecurity area, giants like US and China catch daily clashes. In the perception of the Academy of Military Sciences of China (2011), the world is at war, while nuclear war was a strategy of the Industrial Age, the war of internet is a product of the Information Age, and their conflicts tend to be highly destructive, seriously threatening national security and the very existence of the state.

Thus, governments, schools and businesses around the world began to worry about train professionals with specific expertise in this area. One of the certificates present in the cyber security market is the Certified Ethical Hacking (CEH) of the EC Council, which aims to train professionals to act against cyber terrorism and demands of information security. In Brazil, however, this topic has been visited just a few years, still relying on low priority in national investment, both in private and in public.

Given the above, this research has the general objective of developing an information security teaching methodology and electronic warfare, from exposure to tasks consist of computer networks available scenarios in a simulation environment, encouraging students to generate knowledge and improvement ideal techniques. This work aims to build a teaching and assessment model for cyber defense scenarios.

## **2.1. Modeling Teaching and Learning Strategies**

The education sector has suffered several problems in order to meet demands arising from new technologies of education and knowledge. In this context, one of the great challenges of the education system is to create conditions so that the process of teaching and learning to occur effectively, generating skills that incorporate and use new technologies, innovating in the educational and methodological process, as well as forming networks of prepared individuals to make decisions autonomously and innovative way.

The question, therefore, is much more than building knowledge, is to create ambience to develop skills that enable people to experience experiments, conduct practices, act courageously and creatively, committed to innovation, able to plan their actions, forming social networks in which to move independently. As an example, Masztal (1986) proposes the technique of cyber sessions where small groups of participants need to respond quickly to pre-planned questions within a specified period of time. So the question is: how to use innovative teaching techniques to develop skills from points as against tradition and modernity; long and short term, opportunity and necessity?

Competence is understood in this work according to Durand (1998), the triad of knowledge, skills and attitudes (CHAs) comprising an integrated manner not only technical, but also social and emotional aspects related to work and life. Knowledge corresponds to know what and why to do, it refers to assimilated and structured by the individual information, allowing them to understand the world. The ability refers to knowing how to do something at the right time, that is, the ability to act according to pre-defined objectives or processes, involving techniques and skills. The attitude with respect to emotional and social aspects related to work. It includes the identity of the individual with the organization's values, therefore their commitment and motivation to meet the standards of behavior expected to achieve results at work with quality.

## **3. Teaching Techniques and Aims**

### **3.1. The Project: Cybersecurity Course**

The Cybersecurity Discipline Project seeks to relate theory to practice understood as inseparable dimensions for a reflexive analysis of reality. On the other hand, this project in it took into account mission, future vision, values that can guide the process of teaching and learning, especially those who are facing human development, social inclusion and social responsibility. In addition, the four pillars of education - learning to be, to do, to live and to know - were taken as focal guidance for the development of this work.

The discipline of project includes articulated and flexible strategies that underlie the actions of teachers and students, aimed at training people participatory, creative, innovative and critical dimensions, these constituents of a competitive edge attitude.

Cybersecurity discipline in its objectives, goals, strategies and activities focus on the development of attack attitude, this dimension that aims to develop people as well as participatory, critical, reflective, and creative, they are committed to innovation and to

the exercise of social responsibility. This was done initially thought the generating principle that guides the development of disciplined and all activities which are geared to the themes entrepreneurship and innovation.

### **3.2. Principle Course Generator: Teamwork and the Logic Action – Reflection – Action**

People think, act and feel differently, and most of the time, living the same situations and problems, seek different solutions, making it essential to consider the teaching-learning processes the differences in ways of thinking and acting of the actors. In a contemporary context, the requirement to work as a team and find quick and effective solutions becomes imperative the use of learning techniques that maximize this type of task (Moskovic, 1996).

In this line, the strategies will be considered that students have adopted the group, each adapting their existing cognitive structures. What allows the generating principle of this development plan follow the logic Action - Reflection - Action, Action and the experiences, knowledge and values existing in the cognitive structure of the students; Reflection time of transfer, creation of ideas and information and integration of the cognitive structure of students, basing new information. From this interaction follows a new phase of action now aggregate of new knowledge and values, resulting in the growth and development of the actors involved in the teaching-learning process. With this principle is expected to create conditions for teaching - learning process, significant, with materials and sound technology and related knowledge to students.

### **3.3. The Course Implementation Process**

The teaching-learning process will be through connections between events, facts and concepts. The concepts will form conceptual systems, or set of logically connected concepts. The facts can mean the very events that occur spontaneously or provoked. On the other hand, they may also refer to the registration event, for example, as a match or verbal statements and responses based on mathematical event records (Gowin, 1970).

Thus, the teaching-learning process happen by interrelation between facts and concepts mediated events that trigger questions-questions, which identify students' interest, giving focus to work. Importantly, this process is not linear and takes place in the interaction of thinking to do, "the construction of knowledge and its convergence on objects or events" (Moreira, 2006). This is achieved by the concept of interaction with the method where thinking is bound to principles, basic concepts and worldview, and to the values, knowledge, experiences, interpretations, data transformations. The interactions of thinking to do develop through issues that lead to holding events which become the focus of the work. Learning view this way can be called meaningful in which to Moreira (2006), the production of knowledge is the result "of the constructive integration of thinking, feeling and doing (acting, acting) in a context".

The strategies for the implementation of discipline revolve around the playful process, problem solving, generating innovative ideas, development of perception capacity; developing the ability to work in teams and leadership, generation and application of new forms of knowledge from prior knowledge, new information and

creativity (Silveira; Ataide; Freitas, 2009). Moreover, it is foreseen to develop future visions to be found new ways and alternatives of life and social integration of students.

With playful are articulated cognition, affection, motivation, creativity and socialization that will act in self-concept, self-determination and self-esteem. With organization, dynamism and planning the game prepares for teamwork and encourages decision-making, favoring the learning process. The playful activity allows the general education of students, implementing values for the formation of partnerships, social networks and coexistence.

Problem situations arise every day in people's lives, making necessary the development of previous abilities and skills focused on solving these problems. This development provides students to identify problems, preferences, feelings, frustrations, and seek solutions and new ways to overcome challenges and obstacles.

The generation and application of new forms of knowledge from prior knowledge allow the creation of ideas, acquiring experience, processing of information, the development of practices to life; the clearer perception of social reality and the changes of contexts. Change and learning "go hand in hand" and how innovation is changing, learning, say Davila, Epstein and Shelton (2007), it is an "intrinsic part of the innovation process".

Learn to act, to make it happen, can be developed in teamwork where the participants generate ideas, develop shared visions of the future, seeking new paths and ways to improve their environment, their actions and their lives. The generation of innovative ideas happens more collaborative, challenging, creative environments. This structured environment to learn and become, investing in innovation. In addition to these strategies an important step in the discipline proposed here is the formation of a value system driven by the learning communities context of culture and that can be implemented intra and extramural this community.

The operationalization of discipline in order to develop entrepreneurial attitude aims to make students able to develop various skills. Among them, the most important is to develop teamwork in order to generate positive impact to solve everyday problems, from innovative solutions. This is done by identifying opportunities presented within the context and the ability to learn and share lessons from experiences.

Group work usually involve at least one person with leadership characteristics. These people are expected to take initiative with determination and know acting and directing others to be persistent. Also, theirs is also expected a greater ability to identify errors and their causes, committing to the actions to be developed and performing positive feedback to your team.

Finally, it is expected that each student is motivated to undertake research, search, report and write information, this being primarily intrinsic motivation. Despite the leading role, it is expected that all students have critical sense to plan, set goals and targets in the proposed actions. It is not necessarily expressed in a specialization of each of the skills needed to develop and create attack networks for each student, but a general understanding to analyze the presented environment, identifying interesting points, difficulties, features, obstacles and challenges which the student is able to intervene.

For the discipline's objectives are achieved, certain expectations are postulated on educators. They should be able to create ambience for the development of activities in order to bridge the gap between reality and simulated cyber scenarios. Such activities should be accompanied by pre-programmed oriented which sought to clarify the best way possible doubts that can be expressed by the students. The teacher should also plan and record actions taken in the discipline, as well as participate in the activities of the teaching-learning process of study and evaluation meetings. That way he will be able to ensure that the expectations of students are met. Finally, they must participate in continuing education activities, updating and acquiring skills for the development of the discipline.

### **3.4. Working Method**

It was provided to the teams a world-class computing environment for simulation of attack and defense scenarios. This is the Cyber-Range-In-A-Box (CRIAB), a technology developed by Boeing and available from Maxtera, Brasilia company specializing in information intelligence, for the simulation of computer networks and exploiting vulnerabilities.

The challenge consisted on the execution of a set of 15 tasks distributed over five different targets (hosts in the range), with three tasks to be executed in each target. These three tasks to be executed after taking control of the host (that is, after acquiring root/administrator privileges) were to establish an inverse remote shell from the host; to change, in the host, a disk file requiring root/administrator permission; and to bring down or bring up a system service on the host.

The proposed range consisted of a simple network with four hosts behind a router. Teams were informed only about the external router interface IP address. The hosts in the range ran different operating systems and services, providing several different opportunities for attacks. The range topology is shown next.

Each team received a similar set of tasks, with the same level of difficulty and the same value in points, to be executed over a total of five accesses to the CRIAB environment, each of them consisting of a period of four consecutive hours. Each access was supposed to be performed through wireless communication using the team's own laptop. To summarize the intensity of challenge, each team was required to execute 15 tasks, requiring control of five hosts, during a period of 20 hours.

After finishing all its accesses to the CRIAB environment, each team was supposed to turn in, within 24 hours, a Final Execution Report. This report should contain the description of the attacks perpetrated by the team and the tasks it was able to successfully accomplish. The evaluation of the report was done following these percentages: fifty percent for technical correctness; thirty percent for good concatenation of ideas; and twenty percent for writing correctness in Portuguese.

The total number of points achieved by a given team would be given by the expression  $PT = n * 10 + Pr$ , where  $n$  is the number of tasks successfully accomplished by the team, 10 is the number of points for each successful task, and  $Pr$  is the number of points awarded to the report. The winning team was the one to achieve the greater number of total points.

## 4. Results

All teams managed to identify all target hosts in the range and perform at least one task. A summary of their achievements is shown in Table 1 below.

Table 1 – Summary of each team achievement on the challenge. Are showed a letter to identify each team, the number of valid targets and valid tasks, quality of the final report and some comments on their overall performance.

| Team | Valid targets | Valid tasks | Report  | Comments  |
|------|---------------|-------------|---|---|
| A    | 3             | 3           | Technically detailed, with logs                 | Focus on methodology and activities; developed some code and scripts to perform attacks |
| B    | 1             | 2           | Simple report                                   |   |
| C    | 1             | 1           | Simple report                                   | Tried to follow the Offensive Security Methodology                                      |
| D    | 1             | 3           | Very detailed and well organized, although long | Methodologically sound, focus on planning and management                                |
| E    | 1             | 2           | Simple report                                   |   |

Two teams clearly outperformed the others. Team D, although they identified all target hosts in the range, they were able to control only the router. Their report shows they managed the challenge as a project, taking each slot as a phase with thorough planning and preparation for the next slot. They were the runners up.

Team A won the challenge. Not only did they perform most in terms of valid tasks but they used some clever strategy. After controlling the router, Team A discovered the target network (20.0.0.0) and two other networks (198.18.0.0 and 10.50.184.0) which were the range configuration network to be the . Then they explored hosts on those two extra networks. They controlled the hosts in the range configuration network, launching a taylor attack, and identified that one of these hosts, which we call here host X for the sake of reference, was running Cacti. Although they haven't found vulnerabilities to explore, they downloaded the Cacti's code (from the Internet) and audited it. They managed to find a code vulnerability which they could exploit, wrote PoC code and ran it successfully, gaining root access of host X. Then, they found XML files in host X that defined the hosts in the range. With that information, they could control all target hosts in the range. Even so, they claim they couldn't find the Windows hosts, which didn't respond to ARP and Ping probes.

From the point of view of cyber warfare no difference was perceived between the simulator and reality (real systems). Thus, they can be considered identical. Also, the participating teams were seriously engaged into the Challenge and, in general, were able to get through the technical obstacles placed in their way. This observation

points to the possibility of the formulation of new Challenges in the future involving greater complexities. New Challenges in future activities and cyber contests can be envisioned using the CRIAB. It can be used to develop skills related to the training of technical teams in specific technologies through a cyber-contest focusing on Web applications and the exploitation of their vulnerabilities.

Given that the current cyber contest focused on system penetration, other contests could focus on system hardening (designing systems that cannot be broken into), or on both system hardening and system penetration. For example, there could be a contest in which two types of teams would compete, one designing a hardened system that is difficult (ideally impossible) to be penetrated and another attempting to break the system designed by the first team.

An interesting observation to be made is that it became apparent that the time span of 20 hours to perform 15 tasks distributed over 5 distinct hosts was quite a strenuous job. The competing teams spent much more time striving to take control over the hosts in which the tasks were to be performed than in performing the tasks themselves. Another interesting observation was that the fact that there were intervals in between each team's accesses to the simulation environment (CRIAB) was an important factor that allowed the teams to reorganize themselves and prepare for the next access.

During the preparation of the CRIAB for the contest it was apparent that the effort to configure and set up the simulation environment is still quite involved, demanding considerable time. This seems to suggest that the CRIAB would benefit from a more user-friendly interface (GUI). Also the use of off-the-shelf configuration templates would be recommended. While it is important to keep the step-by-step approach so that experts would feel free to create and innovate, the above mentioned suggestions, if implemented, would allow non-experts to be able to configure the CRIAB without much difficulty and experts to do it in less time, if they choose to.

Finally, the fact that one team was able to find the range configuration network and, more critically, the CRIAB control network, indicates that some engineering effort should be devoted to hide these networks from users precluding them to be tampered with.

## **5. Conclusions**

The experience provided by the I Cyber Security Challenge College aimed at generating training and development teams in the following topics: a) the cyber war point of view, no difference was seen between the simulator and reality (real systems). They can be considered identical; thus participating teams were seriously engaged Challenge and, in general, were able to overcome the technical obstacles placed in their way. This observation points to the possibility of new events of this size formulation, and involving greater complexity; b) the different types of cyber activities and contests in the future can be predicted using the CRIAB, which allows: training of technical staff in specific technologies; cyber contest focusing on Web applications and other forms of exploitation of computing environments.

Thus, the results show that this challenge reached the proposed objectives, positively impacting those involved in the actions, and meeting the requirements required by

the Notice. As a suggestion for future agenda, the laboratory of Maxtera in order to develop skills and generate human resources capable to work in the cyber security area, share of interest in relation University - Company for the viability of new research and discussions, as well as the development of new features for CRIAB, and other security platforms proposals.

# Developing digital self-care services in health care through value propositions

*Eija-Liisa Heikka<sup>1</sup>, Salla Saraniemi<sup>2</sup> & Pauliina Ulkuniemi<sup>3</sup>*

<sup>1</sup>Oulu Business School, <sup>2</sup>Oulu Business School, <sup>3</sup>Oulu Business School

*The objective of the present study is to examine how value propositions for new eHealth self-care services can be used in developing services. We discuss theoretical knowledge from service research related to value proposition and self-care to form an understanding of the value creation process of a customer using digital self-care services in diabetic treatment. A qualitative research method is applied to empirically study the way entrepreneurs of startup companies developing digital self-services in healthcare make sense of the value propositions and use these to develop their business. The findings of the present study indicate that value propositions of such services emphasize the ease of use of the equipment and services that help customers to improve their life and treatment of their disease and offer peer support.*

## 1. Introduction

In using services that support the well-being and health, typically the overall goal of the customer is to achieve a balanced and full life. Achieving good life quality concerning experienced health is of course a complex process including a variety of different aspects, but from the service development perspective, it can be examined through the concept of value creation process adopted from the current theoretical discussion within services marketing discipline. Closely related to value creation process, the concept of value proposition, on the other hand, has been introduced to help the service providers to support the value creation of the customers and more importantly, to communicate the potential value of its services to the customers. According to Frow et al. (2014) in increasingly interconnected and networked world, developing value propositions is fundamental, but despite of significant interest towards value propositions, there is still relatively little theoretical understanding.

As one of the new areas for application of information technology, health services and business opportunities related to these have raised a lot of interest among practitioners and academics, as well as decision-makers of societies recently. Health is not a commodity which people collect from the doctor and bring home. Instead, health and well-being arise from our genetic inheritance, the circumstances of our lives, the manner of our living and from the interventions of the health service (Cayton, 2006). According to Elg et al., (2012) concepts such as patient-centred care, patient involvement and patient participation are widely discussed in the health-care literature.

However, according to Fredericks et al (2012) at the organizational level, patient-centred care is a merging of patient education, self-care, and evidence-based models of practice and consists of broad domains of intervention including communication, partnerships, health promotion, and physical care. As a result of the unexamined discourse of knowledge and power in health care, the possibilities of patient-centred care have not been fully achieved.

Technology-based health services represent a broad variety of different kinds of services, but as one of the key aspect of these kinds of services, the self-care has often been emphasised. In health services, self-care in treatment and following the course of diseases has an increasingly important role in controlling the diseases. As one example of treatment in which the self-care is particularly evident and employed, is the treatment of diabetes, a disease in which fears concerning health are present every day in diabetic's life. Daily activities that diabetics need to do include, for instance, measuring blood sugar levels before and after every meal and calculating the amount of insulin for every meal. In addition, exercising and nutrition are also an important part of treatment of diabetes. Therefore, there is huge demand for self-care services to support the self-care of diabetics. This study has to offer some interesting implications from managerial perspective as well by providing insights into what kind of services could be developed based on value propositions for new eHealth self-care services.

Developing health services in general and self-care services in particular require a multitude of expertise from the service provider, including medical and technological expertise, but also service business knowledge and in-depth understanding of the customer. Intertwining all these areas of expertise can represent a challenge in many service organizations aiming to commercialise new services within this area. Achieving good life quality concerning experienced health is of course a complex process including a variety of different aspects, but from the service development perspective, it can be examined through the concept of value creation process adopted from the current theoretical discussion within services marketing discipline. Closely related to value creation process, the concept of value proposition, on the other hand, has been introduced to help the service provider to support the value creation of the customers and more importantly, to communicate the potential value of its services to the customers.

The objective of the present study is to examine, how value propositions for new eHealth self-care services can be used in developing services. To form a preliminary understanding, we will discuss theoretical knowledge from service research related to value proposition as well as literature focusing on self-care to form an understanding of the value creation process of a customer using digital self-care services in diabetic treatment. A qualitative research method is applied to empirically study the way entrepreneurs of startup companies developing digital self-services in healthcare make sense of the value propositions and use these to develop their business.

In the next section, we will take a closer look at the theoretical literature on self-care and value propositions to gain an overview of the value creation process of *the customer using digital self-care services in treatment of diabetes*.

## **2. Understanding the value creation process and building value propositions upon that**

Lin et al. (2009) emphasize that in developing any services, the value creation process of the customer needs to be carefully detected. According to Nordgren (2009) as a value creator the customer influences his/her health and life quality to a degree that is relevant in health care. Value is created in the recreation of the value creation process and in interaction between the service provider and the customer who is usually the patient in health care context. An overall aim should be to create value by complementing, supporting and matching the value creation process of the customer. In practice, a possible support system for how health care services could be integrated fitting the value creation process of the customer is lacking.

McColl-Kennedy (2009) define customer co-creation in healthcare service as “activities with self or in collaboration with members of the service delivery network including self, family, friends, other patients, health professionals and the outside community”. This conceptualization of co-creation is consistent with the discussion of the customer value creation process as a series of activities performed by the customer as part of activities to achieve a certain outcome. According to Zainuddin et al. (2013) health service providers and customers are jointly responsible for the successful creation of value, leading to desirable outcomes for all stakeholders involved.

According to Cayton (2006) self-care means greater personal responsibility, a requirement to become active rather than passive in the pursuit of personal well-being and quality of life. Cottam & Leadbeater (2004) describe that the average person with diabetes spends about three hours a year with doctors, checking prescriptions and issues concerning general health. However, diabetics spend thousands of hours a year self-managing their condition. Therefore, it would be productive to offer diabetics services such as peer-to-peer support, better training and tools to cope with diabetes. In addition, it would be more productive still to encourage lifestyles, habits and the necessary supporting services that prevent individual developing diabetes (type two) in the first place.

Laing et al. (2011) point out that the Internet has opened up new virtual spaces for consumers to address issues of mutual interest, which offers customers the opportunity to exchange information relating to their shared field of interest. Health care is one of the sectors in which emerged virtual communities of interest provide health care customers an opportunity to share experiences and offer opportunities to undertake self-service activities independent of health care professionals and expertise. Hence, these kind of eHealth communities and services provide a range of new value

propositions. For health care customers and professionals, the utilisation of such virtual communities in the information society influences significantly the service encounter. Frow et al. (2014) describe the role of value propositions in an ecosystem as a shaper of resource offerings. They conclude that value propositions contribute to the well-being of an ecosystem as they provide a mechanism for balancing resource sharing. They also suggest the following five key premises concerning value propositions: “(1) value propositions are a co-created and reciprocal mechanism through which actors offer and attract resources, (2) value propositions in ecosystems arise from the value potential inherent in actors’ resources, (3) value propositions influence the composition of networks, specifically determining with whom actors choose to engage, shaping the nature of market interactions, (4) value propositions may change over time and shape resource integration within the service ecosystem, and (5) value propositions act as a balancing mechanism in the service ecosystem”.

In the next section, we the research methods of this study are discussed in more detail in order to find out the way entrepreneurs of startup companies developing digital self-services in healthcare make sense of the value propositions and use these to develop their business.

### **3. Methodology**

This study utilized qualitative research methods to carry out the objective of this study. This study includes several different companies, which enables exploring and comparing multiple perspectives related to the research phenomenon of this study. Qualitative methods enable gaining the most complete picture from the research phenomenon of this study (Yin, 2013). The case study methods are being rediscovered in research concerning health services. Need for case studies in the health services context is driven by developments in managed care systems that link multiple components in new ways, producing "mega-systems" of great complexity. Further, the systems' rules are continually and rapidly changing. Finally, important corporate affiliations and motivations are extremely difficult to track, much less to understand. All of these conditions favor the use of case studies, over other empirical methods. (Yin, 1999.)

#### **3.1. The research data**

The empirical data consists of interviews of 10 entrepreneurs of start-up companies developing digital self-care services in healthcare. All the companies are located in Finland operate in the health services sector and are either in the market already or aiming at developing services to enter the market. This specific research setting has been selected due to the fact that these examined companies enable the exploring and comparing of multiple perspectives related to the research phenomenon of this study. The interviews of this study are presented in more detail in the table 1 below.

Table 1. The interview data.

| <b>Company</b> | <b>Type of data</b>      | <b>Interviewee</b> | <b>Date</b> | <b>Duration</b> |
|----------------|--------------------------|--------------------|-------------|-----------------|
| Company 1      | Semi-structure interview | CEO                | 2.3.2015    | 64 min          |
| Company 2      | Semi-structure interview | CEO                | 3.3.2015    | 77 min          |
| Company 3      | Semi-structure interview | CEO                | 4.3.2015    | 59 min          |
| Company 4      | Semi-structure interview | CEO                | 6.3.2015    | 52 min          |
| Company 5      | Semi-structure interview | CEO                | 9.3.2015    | 57 min          |
| Company 6      | Semi-structure interview | CEO                | 10.3.2015   | 46min           |
| Company 7      | Semi-structure interview | Co-founder         | 11.3.2015   | 54 min          |
| Company 8      | Semi-structure interview | CEO                | 25.2.2015   | 63 min          |
| Company 9      | Focus group workshop     | CEO                | 14.1.2015   | 229 min         |
| Company 10     | Focus group workshop     | CEO                | 11.3.2015   | 161 min         |
| Company 11     | Focus group workshop     | CEO                | 11.3.2015   | 87 min          |

### **3.2. Data collection**

The primary research data of this study consists of qualitative semi-structure interviews and workshops. Altogether 11 interviews have been conducted over a period of 3 months. In addition to the 9 semi-structured interviews, also 3 focus group workshops were used as primary data in this study. The interview data has been supplemented with secondary data such as meetings and workshops.

### **3.3. Data analysis**

The empirical data was recorded and all the interviews and focus group workshops were first transcribed. The analysis started by reading each transcript and by comparing transcript with other transcripts searching for similarities and differences. The interviews have been analysed by theme-based categorizing to address the objective of this study.

These categories included following issues: (1) what kind of ideas concerning digital services can be recognized from the data?, (2) what kind of actors are mentioned in the data concerning network of diabetes self-care?, (3) what kind issues are related to diabetes self-care?, (4) what kind of challenges the interviewees recognized concerning revealing personal data?, (5) what kind of value propositions can be recognized?, (6) what kind of customer values, benefits and needs can be recognized from the data?, and (7) what kind of possible business models can be recognized from the data?

The analysis included multidisciplinary perspective, which enabled analysing the empirical data from various perspectives. In the next section the key findings of this study will be discussed.

## **4. Analysis**

The aim of the empirical analysis was to identify the way entrepreneurs of startup companies developing digital self-services in healthcare make sense of the value propositions and use these to develop their business. Some of the entrepreneurs are also diabetic themselves, which enables them to reflect their services through their own experiences as a diabetic.

As a result of the analysis, we identified five services (Reducing the fear concerning health, Generics testing, Enabling continuous learning, Personal trainer and Peer support facilities). In the following, we have divided the analysis chapter into sub-sections based on the themes that rose from the data based on the objective of the present study that is how value propositions for new eHealth self-care services can be used in developing services.

The interviewees felt that at the moment there are huge possibilities in the health care markets. It is actually one of the rare markets that is still growing despite the current economic situation. In addition, nowadays people constantly want to develop themselves, feel better and be happier, which of course creates opportunities in the health care markets.

#### **4.1. Reducing the fear concerning health**

Fears concerning health, such as fear of losing eyesight or a limb, are present every day in diabetic's life. There was clear demand for services that could reduce the fear concerning health issues of diabetics. This basic value element is an important notion, which helps the entrepreneurs of startup companies to develop digital self-care services and create value propositions based on the real need of the customers. One interviewee, who is a diabetic, summarized his constant worries concerning health:

"If I cannot keep my blood sugar levels steady, I might lose my eye-sight or my limb might be amputated."

#### **4.2. Genetics testing**

It was seen as an important value element that people can test his or her risk factors to type one diabetes. This creates huge opportunities for start-up companies to utilize in their service development. One of the interviewees mentioned that people are interested not only to test themselves but also their children:

"Nowadays, parents can test their new-born babies' risk factors to the type one diabetes."

#### **4.3. Enabling continuous learning**

In health services, self-care in treatment and following the course of diseases has an increasingly important role in controlling diseases. Self-care is particularly important in treatment of diabetes. Daily activities that diabetics need to do include, for instance, measuring blood sugar levels before and after every meal and calculating the amount of insulin for every meal. Therefore, there is huge demand for self-care solutions for diabetics. One possible service could be an application using personal data to provide treatment instructions and recommendations for diabetics related to e.g. nutrition and physical activity.

"All this must be constantly learned, and constantly my body changes. Although I would learn how all these issues would influence, the next year they influence differently."

#### **4.4. Personal trainer**

Exercising is also an important part of treatment of diabetes. Nowadays, diabetics receive some help to nutrition, but still not enough help related to physical activity. There was also demand for personal training services especially specialized in providing guidance to diabetics.

"With nutrition you get some help nowadays, but with exercise hardly yet."

#### **4.5. Peer support facilities**

There were also huge demand for services that would be built around digital service and related applications to facilitate peer support, which was seen very important for diabetics to share information on self-care, and to deal with changing situation and emotional stress.

“We have this local peer support group, where we share the difficulties that we face. – and we discuss about exercising and about newest equipment and applications.”

However, also challenges related to utilizing personal data in developing services emerged clearly from our data. These challenges relate to customers’ reluctance to reveal personal data and to their concerns over how their personal data is used and shared.

“If I send my personal data to somewhere and someone makes an analysis of it, I don’t really trust those. --- We have thought a lot about what kind of permissions will be needed from individuals or is it needed at all to use the data in aggregate form. “

According to the analysis of the interview data of this study, customers prefer value propositions that promise easy use of equipment and services, and possibility to have a balanced and full life. These value elements help to understand better the value creation process of the customer using digital self-care services in treatment of diabetes.

In the next section we will discuss about the findings and describe both theoretical and practical implications of this study. This study is concluded with evaluating the limitations of this study and by providing future research ideas.

### **5. Discussion**

The findings of our analysis suggest that value propositions need to be integrated into the service development of the digital self-care services in health-care. We were able to identify different services and examine the emerging value propositions related to these services as they were perceived by the entrepreneurs. It is not a surprise that the ease of use is critical in such services, but one of the key arguments that the present study makes is related to the usefulness of the value creation process approach in developing these kinds of services. Within this specific context, it is crucial that the service providers take a broad view on the customer’s value creation process to provide services that add value to the broader processes than merely those that the service is directly connected to. The overall aim of the customer in his/her value creation process is not to monitor blood sugar levels but to live a full and healthy life. The services should support the customer in this. The customers prefer value propo-

sitions that promise easy use of equipment and services, and, more importantly possibility to have a balanced and full life. Value propositions based on this are more effective than mere descriptions of the individual service, but of course, on the other hand, the customer needs to feel that the use of individual services advances the overall aim.

There was demand for service application using personal data to provide treatment instructions and recommendations for diabetics related to e.g. nutrition and physical activity. There was also demand for digital services and related applications for diabetics to facilitate peer support, to share information on self-care, and to deal with changing situation and emotional stress. There was also demand for personal training services specialized in providing guidance to diabetics. However, also challenges related to utilizing personal data emerged clearly from our data. These challenges relate to customers' reluctance to reveal personal data and to their concerns over how their personal data is used and shared.

The entrepreneurs of start-up companies recognized that the customer valued services that enabled them to reduce their fears concerning health, possibility to test risk factors to type one diabetes, tools that enable continuous learning concerning diabetes and its self-care, need for personal training and peer support facilities. These value elements form the basis for creating right kind value propositions for the targeted customers (diabetics and families, who have diabetic children) and developing their business and services to better correspond to the needs of the customers and to the current demands in the health markets.

We recognised that the customer is in the centre in developing services based on value propositions for new eHealth self-care services, and the value propositions support the value creation process of the customers.

### **5.1. Theoretical implications**

Our study adds to the existing knowledge on value propositions, especially by demonstrating that in developing digital self-care services in health care, the value proposition is a critical tool in service development. This study contributes to the knowledge of how value propositions for new eHealth self-care services can be used in developing services.

### **5.2. Managerial implications**

This study also carries several practical implications. The service providers and especially start-ups targeting their services to the health markets may benefit from gaining practical insights what kind of possible services targeted to diabetics have demand in the health markets.

### 5.3. Limitations and future research

Every research has its own limitations and this study is not an exception. There are limitations especially concerning generalization of the results of this study, for example, beyond the context of eHealth services. Generalization is also limited because the research data was collected in only in Finland, which makes it difficult to generalize the results as such to another country.

There are also certain limitations concerning interviews as sources of evidence (Yin, 1999). There might be, for example, bias due to poorly constructed questions and due to reflexivity the interviewees might give an answer that the interviewer wants to hear. Limitations concerning the questions have been minimized due to triangulation, which means several people have been involved in the formulating the questions.

Interesting future research possibilities include, for example, exploring the value creation process of the customer in health services in more detail to make it easier to target certain services to specific segments.

**Obstacles of Innovation and innovation capabilities of knowledge intensive business service sector in Palestine.**

**Rabeh Morrar, An-Najah National University**

**May Abdelhadi, Master student, An-Najah National University**

## **Introduction**

The last two decades has experienced a growth in the number of papers that discuss the importance of knowledge intensive business service (KIBS) sector in the modern economic, and the increasing role that innovation can play to develop this sector and to enhance the role of service sector to enhance economic growth. However, in comparison to the manufacturing sectors, KIBS still not studied intensively by researchers and analysts of innovation and technological change, and their future development has rarely been considered in terms of policies and roles in their respective innovation and productive systems (Muller & Doloreux, 2007), mainly in developing countries.

Most of previous studies stress the close relationship between economic development and the growth of KIBS (Miles et al., 1995; Den Hertog, 2000; Schricke et al., 2012). Czarnitzki and Spielkamp (2003) denote that the importance of the KIBS roles as “bridges of knowledge’ and Innovation bridges which is “connecting the manufacturing sector with science and customer”, which also confirmed by Muller and Doloreux (2007) who emphasize the roles and functions of KIBS in creating and diffusing knowledge and fostering regions as innovation systems.

The Palestinian economy is considered as a service economy at which the services sector constitute the highest rate of the GDP and employment, which is considered a great opportunity to invest in. Palestine has limited natural resources and couldn’t compete in mass-production; therefore it should recognize the potential for the service sector which has less restrictions and limitations.

Among the service activities, KIBS is considered one of the most innovative subsectors which employ higher knowledge and technology (mainly information and communication technology) in comparison with other services and also manufacturing sector. KIBS in Palestine is divided between ICT, technical engineering, legal services, real estate, consultancies, and financial services. These services are also considered as a complementary for other sectors, therefore it could contribute positively in fostering the growth of productivity of many other sectors and as a result the overall economic growth.

Regardless of the political instability and the strict constraints Israel impose on the Palestinian economy, there is huge challenges to prompt the innovation capabilities in KIBS firms in

Palestine, some are internal (for example, the lack of understanding of innovation, lack of resources and the availability of skills and expertise among employees), and others are external to the firm (for example, knowledge and technology infrastructure in the country, external fund from government). Innovation limitations or barriers are also extent from cost factors, knowledge factors to market factors. Each of these barriers might hamper the ability of firms to produce innovation (product, process, organizational and marketing innovation).

In this work we will study to which level the barriers of innovation harm the innovation capabilities of firms in KIBS, i.e. the impact of innovation obstacles on the ability of firms to introduce innovation. In the first section we presented a literature review which includes a certain number of key theoretical and empirical arguments concerning the barriers of innovation and its impact on innovation behavior. In the second section, we introduced a descriptive statistics about KIBS sector in Palestine and the innovation capabilities or performance of the different KIBS activities. In section 3, we introduced the model and both dependent and independent variables with a descriptive analysis on each of them, also data source and analytical method. In the fourth section, we summarized the results of the empirical analysis and provide appropriate recommendations.

## **1. Literature review**

Many articles have been clarified the reasons of innovation barriers and their impact on innovation capabilities for both developed and underdeveloped countries. The estimates of the effects of obstacles on the propensity to innovate are often unsatisfactory. Against the most indicated assumption of the negative impact of innovation obstacles on the ability of firms to present innovation, some researchers found a positive impact. Baldwin and Lin (2002) and Tourigny and Le (2004) explained the significantly positive coefficient associated with the variable obstacles of innovation. According to them, the obstacles of innovation indicate how successfully a firm can overcome these obstacles, which means that the innovation barriers motivate firms to introduce more efforts to overcome these barriers and so increase their innovative capabilities. Savignac (2008) explained the unexpected positive coefficient from the combination of two sources of bias: the endogeneity of obstacles due to unobserved factors

affecting both obstacles and the propensity to innovate has to be dealt with, and the inclusion of firms which not involved in innovation in the sample of interest, i.e. the sample of interest should only include the firms that are involved in innovation and that we label innovation willing firms.

Revealed and deterring barriers were studied by D'Este et al (2012). Data from the 4<sup>th</sup> UK community innovation survey has used to investigate the relationship between firms' engagement in innovation and their assessment of the barriers to innovation. The study reveals that in the cases of cost and market barriers, the relationship between assessment of the barriers and engagement in innovation activities is characterized by a non-linear relationship. Plotnikova et al. (2015) study the causes of innovative resistance and the parameters of existing barriers. Obstacles to investment into innovations are divided into 3 main groups; the group determined by the state action and infrastructure; the group depending on the form of activity support; and the group connected with education and management. The study shows that there are no signs of reducing the barriers to be efficient investment activity of the state. All the groups are characterized by the presence of parameters of an attribute appearance, but their change is not enough for a successful investment activity

The barriers to innovation that influence the innovation capability of Portuguese industrial firms have been studied by Silvia (1999). The data used in this study were collected by the OCT and population includes all the industrial firms with less than 20 employees. Many variables or factors such as the high economic risk, high cost of innovation, lack of financing and others are examined. The results show that firms innovate are those that have more perception of the barriers to innovation and the majority of the variables associated with the barriers to innovation present a negative signal which means these variables are considered as factors that difficult or limit the development of innovation activities

According to Cordeiro and Vieira (2012) about the barriers to innovation in SME's. They found that many barriers to innovation faced by the participants, such as the current economic climate, the limitation of monetary resources, the reduced risk-taking culture, the mechanical performances, the routine and cemented processes to change, and the high costs. Some factors born outside the firm are considered more difficult to overcome and the more important barriers that firms face, companies consider themselves not to be very innovative, that they essentially face internal and external barriers

Obstacles to innovation faced by French manufacturing firms has been investigated by Galia and Legros (2004). The paper used the data from the second French community Innovation Survey CHS2. It focuses on obstacles in the postponed projects and abandoned projects. Possible interrelationships and commentaries between obstacles to innovation are studied as well. The findings of this study shows that the firms postponing projects are more prone to face obstacles linked to economic risk, lack of skilled personnel, innovation costs, lack of customer responsiveness, lack of information on technologies and organizational rigidities, whereas firms that abandoned projects tend to more subject to economic barriers than to organizational ones .

The impact of hampering innovation factors on innovation performance for European countries were studied by Sipos et al. (2013). They analyze the impact of hampering innovation factors on innovative performance both within innovative and non-innovative factors. Second, grouping the European surveyed countries in four main categories, pointing out the countries' innovative performance perspectives. The study identifying the correlation between each of the important factors of hampering innovation activities, such as lack of information on markets ,technology and qualified personnel, markets dominated by established enterprises, and the difficulty in finding cooperation partners. the study reveals that for innovative companies there is a very strong negative correlation between the lack of information on markets and the innovative performance, the lack of information on technology affected the innovation activities, markets dominated by established companies was a highly important hampering innovation factors only for a relative small share of innovative companies belonging to countries with high innovative performance, a larger share of innovative companies from countries with weaker innovative performance blamed the difficulty in finding cooperation partners for innovation as being a highly important factor of hampering their innovation activities, and in the innovative enterprises' case, the innovative performances obtained were influenced by the lack of qualified personnel. Karahan and Karhan (2013) are tried to determine the activities of Turkish entrepreneur in making innovation, improving new product and process and using new technologies and obstacles that they come across. The effects of innovation and the factors that prevent firms to implements the innovations are explained in the study. It reveals that the most important tools for innovation are research-development activities, industrial sector is more advanced than the service sector and innovations in the industrial sector both in the service sector were mostly made in product innovations.

Hadjimanolis (1999) conducted a study concentrates on the barriers to innovation in less developed countries. A cross-sectional approach was used to determine any variations in innovation performance and characteristics caused by industrial sector specific factors. Five industrial sectors were chosen, a questionnaire and interviews for the questionnaire completion were conducted. Internal and external variables were included in the study. The study has revealed a number of barriers to innovation as perceived by the managers, also some weakness in the socioeconomic context; such as financing new product development or local construction of machinery, shortage of specialized technical labor and weakness in the supply of technical services. Athanasios and Dickson (2001) also analyze the concept national innovation policy (NIP) and puts forward arguments supporting the need for a NIP for small developing countries like Cyprus. A large purposive sample of 140 Cypriot firms was compiled for a survey of owner/managers' attitudes toward NIP, a cross-sectional approach was used with five industrial sectors chosen. The study founds an ambivalent attitude towards NIP and inefficiency in design and implementation of innovation policy measures

In Palestine, there is no considered literature about innovation, only some reports and short articles published by private firms and non-government organizations which describe the reality and challenges of innovation in the Palestinian areas. For example, Mercy Corps (2013) mentioned that the uniqueness of the Palestinian context creates a challenge for innovation development, reflecting from the developing countries obstacles, it also emphasizes that the affordability and accessibility to the technical skills required for the innovation development and R&D considered a main cause for the lack of these skills and expertise. Another report developed by solution for development consulting for PITA (2012) mentioned that the main obstacles to sectoral growth of ICT sector in Palestine was the low market demand and lack of skills required for new product development, the weak ecosystem for entrepreneurs and innovation, limited access to external markets and small domestic market, and limited access to finance.

## 2. Nature of KIBS sector and its innovation performance

KIBS sector are classified into 14 activities (see table 1 below). Here is a short description about each of them. The computer networking and the computer software and programs fields are considered part of the ICT sector which is a significant growing sector and have a great potential, it includes about 13% of firms in KIBS. Table 1 shows that 43 of the survived companies reported working in computers software and programming which represent 16.7% from the total KIBS firms, knowing that some of the firms could be working in programing and software and provide network services as well. Telecommunication includes 20 firms (7.6%), and mainly includes the landlines and internet providers. where Management consultant includes 24 firms (9.1%), and includes companies providing management solutions, research and assessments. Accounting and bookkeeping and other financial services, where 3.8% and 1.5% of the companies, respectively reported providing these services, some companies would provide these two services together. Building services and technical engineering service and design are also considered an overlapped sector where 15.6% and 16%, respectively, of the surveyed companies reported providing these services. 7 firms reported working in the legal services, and only 2% of the KIBS firms were provided the temporary labour recruitments, depending on the limited availability of this field. While only one company reported working in environmental services due to the limitation of this field. Around 5% of firms were providing the R&D services which is considered a great percentage to study as a source of innovation. Almost 13% of firms were providing marketing and advertising services and this is also a great potential sector to assess. In addition to 12.5% of the companies are providing training services, this might also overlap with the management consultant somehow, but still have a great potential to unlock their innovation

**Table 1:** The classification of KIBS firms in Palestine

| KIBS areas  | Number of firms | percentage |
|---|-----------------|------------|
| Computer networks/telematics (e.g. on-line databases) | 34              | 12.9       |
| Computer Software & Programs                          | 43              | 16.3       |
| Telecommunications                                    | 20              | 7.6        |
| Management Consultancy                                | 24              | 9.1        |

|   |    |      |
|---|----|------|
| Accounting and bookkeeping  | 10 | 3.8  |
| Building services   | 41 | 15.6 |
| Technical engineering service & Design                                    | 44 | 16.7 |
| Temporary labour recruitment services <sup>5</sup>                        | 5  | 1.9  |
| Legal services  | 7  | 2.7  |
| Environmental services  | 1  | 0.4  |
| Financial services (e.g. securities and stock-market-related activities); | 4  | 1.5  |
| R&D Consultancy and "high-tech boutiques"                                 | 14 | 5.3  |
| Marketing/advertising   | 34 | 12.9 |
| Training centers  | 33 | 12.5 |

Table 2 shows the innovation output (product, process, marketing, organizational) for the 14 KIBS subsectors. Regarding technological innovation (product and process innovation), we find that telecommunication and technical engineering service & Design firms are the most innovative. This might be explained by the high financial and technical capabilities of these firms, and the availability of skills and technologies needed for such innovation. The innovation capabilities of marketing and advertising firms are consistent with the simple nature of product innovation in this sector. Firms in accounting and bookkeeping, labor requirement services, legal services, environmental service, R&D services, and training sector have no technological innovation output. These sectors are considered new and very small sectors with low employment of knowledge and technology.

Computer networks/telematics, computer software & programs, and marketing sectors perform better than other KIBS sectors in regards with non-technological innovation (marketing and organizational innovation). This might be explained by the low cost and the non-technical competences and skills that required for such innovation. Also, the workers in computer sector (software, hardware, and networks) are considered high skills labor with high level of knowledge and competences. Similar to technological innovation, most of firms in accounting and bookkeeping, labor requirement services, legal services, environmental service, R&D services, and training sector never implement marketing and organizational innovation in 2014 and 2015.

**Table 2:** innovation performance of KIBS firms

| KIBS activities   | Number of firms    |                    |                      |                           |
|---|--------------------|--------------------|----------------------|---------------------------|
|   | Product innovation | Process innovation | Marketing innovation | Organizational innovation |
| Computer networks/telematics (e.g. on-line databases)                     | 1                  | 1                  | 16                   | 10                        |
| Computer Software & Programs  | 1                  | 1                  | 12                   | 6                         |
| Telecommunications  | 3                  | 3                  | 9                    | 5                         |
| Management Consultancy  | 1                  | 1                  | 2                    | 2                         |
| Accounting and bookkeeping  | 0                  | 0                  | 1                    | 0                         |
| Building services   | 2                  | 1                  | 2                    | 2                         |
| Technical engineering service & Design                                    | 6                  | 3                  | 2                    | 3                         |
| Temporary labour recruitment services                                     | 0                  | 0                  | 0                    | 0                         |
| Legal services  | 0                  | 0                  | 0                    | 0                         |
| Environmental services  | 0                  | 0                  | 0                    | 0                         |
| Financial services (e.g. securities and stock-market-related activities); | 0                  | 0                  | 0                    | 0                         |
| R&D Consultancy and "high-tech boutiques"                                 | 0                  | 0                  | 2                    | 1                         |
| Marketing/advertising   | 3                  | 3                  | 10                   | 8                         |
| Training centers  | 0                  | 0                  | 0                    | 0                         |

### 3. Empirical model, data and estimation method

As we mentioned earlier, we will use the data about innovation and obstacles of innovation in KIBS in Palestine in order to explore the impact of innovation obstacles on the ability of firms to introduce four types of innovations (product, process, organizational and market innovation). We will take into account the fact that obstacles of innovation are divided into three set of factors: demand, knowledge and cost factors. Before we estimate the impact of obstacles of innovation on innovation capabilities, we will provide a descriptive view of the data set and the survey characteristics, and some descriptive statistics about the dependent and independent variables used in the model.

### **3.1 data**

The data was collected using a survey for 400 firms in KIBS sector from a total of 1500 KIBS firms in Palestine, with a response rate of about 65% or 263 firms. The sample was geographically limited with firms in West Bank and not in Gaza strip and Jerusalem due to the constraints imposed by Israel on implementing survey in Jerusalem and the Siege imposed against GAZA which is limiting the data collecting from Gaza. Also the reality of KIBS in Gaza is very poor due to 10 years of siege and three successive wars. The firms were surveyed about their innovation behavior in both 2014 and 2015.

### **3.2 Dependent variable**

Our goal is to measure the effect of hampers of innovation on the ability of firms to introduce innovation. Obstacles of innovation therefore will be our independent variable, and innovation output is the dependent variable. We use the innovation output index where a firm's innovation output is represented by four dummy variables. Each of these variables is equal to one if the firm introduced a product, process, market or organizational innovation. This taxonomy of innovation output is based on the classification of innovation output used in the community innovation survey (CIS) which measures the performance of innovation in European countries, Norway and Iceland.

Table 3 shows the percentage of firms introducing different types of innovation. We find a very weak innovation performance in KIBS firms in Palestine, where only 15 firms from 263 (5.3%) introduce product innovation, 10 firms (3.8%) introduce process innovation, 38 (14.4%) introduce marketing innovation and 25 firms (9.5%) introduce organizational innovation. This reflects the reality of business firms in Palestine which are mainly small firms less than 10 employees and having low ability to introduce new services.

We find that non-technological innovation (marketing and organizational innovation) has the highest score for innovation performance. This is consistent with the fact that non-technological activities are the most important innovation activities in services generally and KIBS basically.

Also, the low cost of marketing and organizational innovation in comparison with other types of innovation.

**Table 3:** innovation output in KIBS firms in 2014, 2015

|                           | Number of firms | Percentage |
|---------------------------|-----------------|------------|
| Product innovation        | 14              | 5.3%       |
| Process innovation        | 10              | 3.8%       |
| Marketing innovation      | 38              | 14.4%      |
| Organizational innovation | 25              | 9.5%       |

### 3.3 Independent variable

Obstacles of innovation are our main independent variable. They are divided into three factors: cost factor, knowledge factor and demand factor, where each factor includes a set of indicators (see table 4 below). Table 4 shows that knowledge factor represented by technology infrastructure (62%) and knowledge base (62%) are the most important hampers of innovation in Palestine, this might be explained by the weak of technology infrastructure and the very small size of ICT sector and very low investment in this sector due to the political situation in the Palestinian areas. Cost factor represented by the high cost of innovation (61%) and lack of fund from outside the firm (60.1%) are also among the most important hampers of innovation. This might be explained by the fact that most of KIBS firms (more than 85%) in Palestine are considered small firms employ less than 20 employees (see table below) and might not be able to provide or to allocate money for innovation. Most of the firms denote that many of the innovative KIBS are not exist in the market (only 27% find that no need for innovation due to prior innovations is considered an obstacle for innovation).

**Table 4:** obstacles of innovation in KIBS in Palestine in 2014, 2015

| Obstacles of innovation |   |       |
|-------------------------|---|-------|
| Cost factor             | Lack of funds within your enterprise                      | 35%   |
|                         | Lack of finance from sources outside your enterprise      | 60.1% |
|                         | Innovation costs too high                                 | 61%   |
| Knowledge factor        | Lack of qualified personnel                               | 33.5% |
|                         | Lack of information on technology                         | 36.9% |
|                         | Lack of information on markets                            | 36.1% |
|                         | Lack of technology infrastructure in Palestine            | 62%   |
|                         | Lack of knowledge base in Palestine                       | 62%   |
|                         | Difficulty in finding cooperation partners for innovation | 53%   |
| Demand factor           | No need due to prior innovations                          | 27.8% |
|                         | Weak of competition                                       | 57%   |
|                         | Uncertain demand for innovative goods or services         | 55%   |

In addition to obstacles, the model includes a certain number of control variables: age of firm, firm size, and if firm export or not. Firm size is considered one of the key control factors, and it is measured by number of workers. As we have mentioned previously, table 5 below shows that around 85.2% of firms employ less than 20 employees, while only less than 1% employ more than 100 of employees. This definitely shows that Palestinian KIBS sector is considered small or medium sector. Most of empirical studies find a positive relationship between firm size and innovation performance.

**Table 5:** Number of workers in KIBS in Palestine

| Number of workers | Frequency | Percent |
|-------------------|-----------|---------|
| 1- 20             | 224       | 85.2    |
| 21- 50            | 21        | 8.0     |
| 51- 100           | 16        | 6.1     |
| More than 100     | 2         | .8      |

Firm age is another control variable which might affect innovation performance of KIBS. Old firms might have more experience and market share that might reflect on the financial capabilities and so innovation. Data shows that only 20% of KIBS was existing before Oslo agreement in 1993 which means that KIBS in Palestine is considered a modern sector. The last control variable is the export. Firms which export their services might have more ability and propensity to innovate due to high competition in international market and also the fluctuation of revenues from out of Palestinian market.

### **3. Discussion of the results of the empirical analysis**

In this section we present and discuss the results of our empirical investigation, i.e. the impact of innovation obstacles on the innovation performance of KIBS firms in Palestine. Binary choice logit model is employed to estimate the relationship. Model is run separately for every dependent variable (product, process, Organizational and marketing). Each of dependent variable has two possibilities; to innovate or not.

Table 6 presents the results of model estimation. It shows that in case of product innovation, cost factor is the most important obstacles of innovation, which support what we have mentioned previously that more than 60% of KIBS firms in Palestine find that high innovation cost and lack of external fund are limiting their innovation capabilities or hamper them to do innovation.

Demand factors represented by weak of completion and uncertain demand for innovative products are negatively impact the ability of firm to do innovation. This is might be embedded to the uncertainty generally exist in the Palestinian economic due to the political instability and high fluctuation in income and employment. More than 200 thousands public employees haven't receive their salaries along six months in 2014 because of the punishments Israel imposed against Palestine by not transferring the tariff taxes which they collect in behalf of the Palestinian side as signed in Paris agreement the economic part of Oslo agreement.

A similar result for process innovation is obtained. Cost factor is the most hamper of process innovation followed by demand factor. This confirms what we have mentioned previously that demand for technological innovation (product and process innovation) is low due to high related cost, mainly high percentage of Palestinian new services are coming through imports, mainly from Israel (According to Palestinian central bureau of statistics around 80% of Palestinian imports come through Israel) which considered costly regarding to the low income and high ratio of unemployment in Palestine in comparison with that in Israel, which meanwhile negatively affect the demand for product and process innovation.

Knowledge factor is not significant as a hamper of innovation in both product and process innovation. This might be explained by the low ratio of product and process innovation in KIBS firms and so the decrease of demand for related knowledge and technologies. Also, service sector in Palestine is still considered new and new product development is growing slowly. The significantly of knowledge factor in marketing and organizational innovation confirms this result.

None of the control variables has significant impact on product and process innovation. This might be justified for the age variable knowing that most of KIBS are considered new as we have mentioned previously, so there is no age advantage might be present in case of product and process innovation. Data shows that only two firms among the KIBS firms established before 1993 have product innovation. Large firms have no advantage on small firms regarding product and process innovation. This result contradicts many of the studies which significant and positive advantage for large firms regarding innovation. The insignificant impact of export on product innovation might be explained by the low ratio of exports in KIBS sector, only 14% of KIBS

export their products, and only 1% of exporting firms (only 3 firms) have product innovation, and less than 1% of exporting firms (only one firm) have process innovation.

Regarding marketing and organizational innovation, table 6 shows a negative impact for both cost and demand factor, where cost factor seems to be more hampering innovation in comparison with demand factor. While, knowledge factor indicate an unexpected result through its positive impact the innovation capabilities of KIBS firms. This might be explained by what Tourigny and Le (2004) found that obstacles of innovation indicate how successfully a firm can overcome these obstacles. In other words, the lack of knowledge base and technology infrastructure in Palestine, lack of qualified personnel and information on technology push firms to overcome these obstacles by finding innovative solutions for their marketing practices. Also, non-technological innovation (marketing and organizational innovation) in Palestine does not require heavy technologies or high developed knowledge and technology infrastructure. It depends mainly on using some new skills and experiences that might be obtained by simple and low cost tools and approaches.

**Table 6:** The impact of obstacles of innovation on innovation activities in KIBS firms

|                           | Dependent variable |                    |                      |                           |
|---------------------------|--------------------|--------------------|----------------------|---------------------------|
|                           | Product innovation | Process innovation | Marketing innovation | Organizational innovation |

sig at 0.01 \*\*\*

sig at 0.05\*\*

sig at 0.10\*

Regarding control variables, we find that firm size positively impact marketing and organizational innovation. This is consistent with literatures which stress that large firms are more able to produce new innovation output. In Palestine large firms in KIBS are mainly represented by telecommunication companies (PalTel and Wataniyya), and some IT firms, which has more capabilities in innovating new marketing solutions and new strategies, plans and administrative competences. Old firms has disadvantage in organizational innovation, which might be explained by the novelty of KIBS sector and most of innovative firms in telecommunication and IT are modern firm instituted after Oslo agreement and establishment of Palestinian authority.

## Conclusion

In view of the limited previous researches and the analysis of the result generated through this study, there is a significant association between innovation performance and the obstacles of innovation the firm may face. This study find an evidence that the obstacles are hampering the innovation in different levels, considering the different types of innovation that was assessed in this study, the cost factor (includes lack of funds and lack of finance from outside the firm and the high innovation cost) is the factor with the greatest negative impact on the product and process innovation as well as the organizational and marketing innovation, followed by the demand factor which was reflected by the weak competition and uncertainty and impact of the prior innovation. On the other hand the knowledge factor had a positive impact in number of firm focusing on organizational and marketing innovation which were able to overcome it and address it.

Knowing the complexity of the Palestinian context and the potential of innovation in the Palestinian economy, different actors can unlock this potential and contribute to the innovation development in Palestine:

- 1) The Palestinian authority could create a better enabling environment through facilitating the importing of innovation from foreign countries and also encourage the companies for more innovation through incentives and more safe space with minimal risks from their side
- 2) The Palestinian authority could also contribute to minimize the cost factor impact on the organizations by facilitating better infrastructure and invest more in the research and provide support or incentives for innovative firms, in addition to that more private public partnerships could have greater impact on different levels.
- 3) The firms could also invest in non-technological innovation with longer term change, like market and organizational which will have impact on the product and process innovation on the longer-term
- 4) Firms could benchmark innovation from other semi-cultural firms with similar context, in addition to that creating the demand for innovation as possible.
- 5) Firms could create partnership for technological innovation that could minimize the risk and maximize the impact.
- 6) Creating the awareness about the innovation contribution to the organizational performance and economy will attract the investors and different actors to address the challenges and tackle these obstacles.

# **Sustainable business models in service? A study of Norwegian knowledge-intensive service companies**

## **Abstract**

Sustainability is considered one of the main drivers of innovation in the contemporary economy. While service companies dominate contemporary economies, they are often seen as lacking in awareness and action towards sustainability concerns. The aim of this study is to investigate current practices concerning and attitudes towards sustainability and business model innovations for sustainability in Norwegian knowledge-intensive service sector firms.

We conduct a survey of 103 such companies and provide insight into their motives for sustainability work, the sustainability-related changes they make to their business models, as well as how they perceive the influence of these practices on their performance along financial, social and environmental performance dimensions. Our study suggests that while the companies that manage to reap direct or indirect financial benefits from sustainability work do not engage more comprehensively in terms of resource use, but that they make more changes both in products, services and procedure, as well as in their relationships to key stakeholders. Our study thus contributes to the understanding of sustainability practices in service companies, as well as to the relationship between sustainability performance and financial performance in such companies.

Business model innovation; Service; Sustainability

# **Sustainable business models in service? A study of Norwegian knowledge-intensive service companies**

## **Introduction**

Sustainability is considered one of the main drivers of innovation in the contemporary economy (Nidumolu et al., 2009). Practitioners are to an increasing degree becoming aware of the potential inherent making sustainability a part of their core activities through business model innovations (Eccles & Serafeim, 2013; Wells, 2013; Boons & Lüdeke-Freund, 2013). Concurrently, business researchers are making an increasingly strong case for the business potential of such sustainable business models, through both conceptual work (Jørgensen & Pedersen, 2015; Porter & Kramer, 2011) and empirical contributions (Eccles et al., 2014; Kiron et al., 2012; Khan et al., 2015).

Service companies dominate today's economies – the service sector constitutes a larger proportion of the value-added in the world than goods-producing industries.<sup>1</sup> Given this, service providers will need to play a key role in the quest for sustainable societies. However, the economic dominance apparently does not translate into leadership in the race towards a more sustainable future: While both practice of and research on sustainability efforts in goods-producing industries are abundant, this does not appear to be the case for service providers (Gulbrandsen et al., 2015, Bocken et al., 2014; Kiron et al., 2012). More knowledge of sustainability initiatives within the service sector is therefore highly sought-after.

The aim of this study is to investigate current practices concerning and attitudes towards sustainability and business model innovations for sustainability in Norwegian knowledge-intensive service sector firms. Survey-data collected from a sample of 103 Norwegian knowledge-intensive service companies provide insights into companies' motives for engaging in sustainability, the concrete measures introduced by companies, the companies' judgment of their own success (both in terms of financial return on investments in sustainability, and in terms of positive environmental and social effects), and their intentions for future investments in sustainability. The paper thus gives insight into the prevalence and

---

<sup>1</sup> In 2013 the world average value-added of the service sector in a nation's GDP was 58.1 percent (World Bank, 2015). The share is even higher in the developed countries.

characteristics of business model adaptations and innovations, and how they relate to strategic leadership (Strand, 2014) and organizational design (Birkinshaw et al., 2014).

Our results indicate a clear pattern as to which companies report positive financial effects from their sustainability efforts. We find that such “harvester”<sup>2</sup> companies are more likely to (1) anchor their sustainability measures in organizational support systems, (2) make substantial changes to services and processes, and/or to their relationships with stakeholders, (3) use resources right, rather than use more resources, and (4) have a coherent system of sustainability work, from strategy to control and reporting. Furthermore, we find evidence in our sample that service companies are planning to increase their investments in sustainability – this implies that current competitive advantages may become tomorrow’s hygiene factors.

The contribution of our study is mainly descriptive, in the sense that we give an overview of the current state of affairs concerning sustainability and business models innovations for sustainability among service providers. Given the patterns we identify, there is a potential prescriptive element as well – we provide knowledge from successful early adopters of sustainability. This knowledge may be used by practitioners and researchers to guide the management of sustainability challenges and opportunities among service providers.

### **Theoretical framework and existing research**

Any company has a business model that can be described as “the story of how the business exploits business opportunities to create, deliver, and capture value” (Jørgensen and Pedersen, 2013). A business model is thus, in short, the conceptual framework for how the company seeks to create profitability, by exploiting business opportunities that allow the firm to offer and deliver value to customers at a price that leaves the business with an acceptable profit (Zott et al., 2011; Johnson, 2010).

Increasingly, sustainability concerns are becoming integrated into companies business models, as they attempt to pursue sustainability-related objectives while at the same time attaining profits. Several authors have explored the ways in which these two goals may be aligned, and in fact even reinforce each other (e.g. Porter and Kramer, 2011; Eccles &

---

<sup>2</sup> The term is taken from Kiron et al. (2012).

Serafeim, 2013; Jørgensen and Pedersen, 2015). Any business model has externalities, which implies that all companies have positive and negative side-effects that leave either a positive or a negative footprint on society and the environment (cf. Laffont 2008). By designing business models that have a better net footprint than competitors, companies can cater to the preferences of customers, employees, investors and other stakeholders who may value such characteristics of the company and its brand. As described above, this may entail (1) designing value propositions that enable consumers to lead more sustainable lifestyles (B2C) or enable other companies to reduce their ecological footprint (B2B), or (2) delivering these value propositions in ways that are more sustainable (Gulbrandsen et al., 2015).

In the existing research on companies that innovate for sustainability, the potential for aligning financial performance and sustainability performance is emphasized. Eccles et al. (2014) find that companies that are denoted as “high sustainability firms” outperform so-called “low sustainability firms” financially. High sustainability firms are characterized by anchoring sustainability at board and executive levels; dedicated strategies for sustainability and customized KPIs to measure sustainability performance; long-term horizons; high prevalence of sustainability reporting, and so on.

In a large-scale global survey of CEOs, Kiron et al. (2012) find that there is a distinct group of business organizations – «harvesters» – that manage to capture value from investing in sustainability. Harvesters have typically made significant changes to goal structures, organizational design and so on, in order to promote sustainability performance, and they self-report that they reap financial benefit from making such changes.

In a study of sustainability performance, Khan et al. (2015) reveal a relationship between the materiality of sustainability concerns addressed by companies, and their ability to reap financial gain from such investments. Companies that invest in tackling material sustainability concerns outperform those that do not. They also outperform companies that both invest in material and immaterial sustainability concerns. This shows that the financial benefit of investing in sustainability depends on investing in the right measures, rather than the comprehensiveness of the sustainability measures.

These prior studies provide valuable insight into how financial performance and sustainability performance are related, as well as into the characteristics of companies that are able to align

these two performance dimensions. However, while these studies shed light on the characteristics of companies that are performing well along both performance dimensions, they to a lesser extent illuminate the changes companies are making in order to attain such objectives. In this study, we therefore investigate companies making changes to their business models in ways that are relevant to their sustainability performance. We investigate such business model adaptations and innovations and aim to shed light on how they relate to their financial performance, as seen by the companies themselves.

## **Method**

In order to capture the prevalence and nature of business model adaptations and innovations for sustainability among service companies, we designed a comprehensive survey. The survey was distributed to a sample of knowledge-intensive service companies that are members of the Norwegian trade and employers association *Abelia*<sup>3</sup>. *Abelia* is associated with Norway's largest employers' organization; the NHO (Confederation of Norwegian Business and Industry). *Abelia* is a non-profit and non-political organization funded by its more than 1650 member companies.

We conducted the survey in the spring of 2014, and data was collected using an online survey instrument. *Abelia* distributed the survey on our behalf, and sent a reminder to non-responders, which is likely to have improved our response rate. The study population is Norwegian service firms, and the study sample consisted of 360 *Abelia* member companies. 103 companies completed the survey (we elaborate on the sample in the Results section below).

The survey consisted of 87 items, some of which were Likert scales and some of which were open-ended questions where respondents could write their own responses. The survey comprised the following categories of questions: (1) general information about the company, including information about finances, organization and governance; (2) the company's sustainability-related commitments, such as employees, strategies, principles, etc.; (3) the company's views on sustainability and their motives for engaging in sustainability work; (4) business model changes related to sustainability concerns; (5) the company's views on the

---

<sup>3</sup> For information about *Abelia*, see [www.abelia.no](http://www.abelia.no).

effects of this work, both for the company itself and for its stakeholders; and (6) the company's expectation about sustainability in the future, and their own work in that regard.

The descriptive information about the companies allow us to compare and control for differences in company characteristics such as size, financial performance, the number of female members of the top management team, and so on. The open-ended questions were intended to allow respondents to bring forward relevant information that was not captured by our survey questions. The remainder of the survey questions were designed to capture central constructs of theoretical interest, including the company's motivation for investing in sustainability work, the nature and characteristics of the changes made to the company's business model in relation to sustainability concerns, as well as the sustainability performance of the company.

### *Measures*

The survey comprises a number of single items that capture specific characteristics of the companies' work with sustainability. These items are all based on a 5 point Likert scale from "Completely agree" to "Completely disagree". Examples of such items are "*We dedicate a lot of resources to working with sustainability*" and "*Our customers view us as a responsible company*". Table 1 summarizes the items that relate to the various constructs that we aimed to capture in the survey. For each of the categories, we have listed the items used, as well as whether they are continuous or categorical variables.

[Insert Table 1 here]

As will be described in the results section, we conducted factor analyses for (1) the items intended to capture motives for investing in sustainability and (2) the items intended to capture sustainability-related changes made to the business model. For the items related to the effects of sustainability measures both for the company itself and for stakeholders, we used simple sum scores of the associated items. These analyses are described further in the results section.

## **Results**

In this section, we present our results. First, we outline descriptive statistics of the sample. Second, we conduct factor analyses to reveal underlying dimensions of some of the key constructs. Third, we introduce a distinction between companies that attain benefit from investing in sustainability and those that do not. On this basis, we compare the two groups of companies along the key dimensions of the survey. Finally, we conduct a multiple regression to investigate if our results hold when controlling for relevant factors.

### *Study sample and descriptive statistics*

Our survey was distributed to 360 companies that are members of the trade association Abelia. 103 companies responded to the survey, which gives a response rate of 29%. 87% of respondents were managers. 69% of respondents were male. In our sample, 67% of the companies were primarily business-to-business companies.

A variety of industries were included in the sample. The three biggest industries among the respondents were the following: R&D and teaching companies, which represent approximately 30% of the sample; consultancy companies, which represent approximately 15% of the sample; and IT and telecommunications companies, which represent approximately 10% of the sample.

Figure 1 shows which concrete organizational measures have been put in place in order to promote sustainability work in the companies. As shown in the figure, 24.3% of the companies have a dedicated employee working on sustainability; 8.7% of the companies have a dedicated unit working on such issues; 26.2% have committed to the UN Global Compact principles; 48.5% have a dedicated strategy for sustainability; 19.4% have KPIs for sustainability performance; 8.7% have financial incentives tied to sustainability performance; and 29% report on sustainability performance in an external report.

*Figure 1: Business model components for sustainability*

### *Factor analyses*

In order to reveal underlying dimensions of some of our key constructs, we conducted factor analyses on the items that reflected (1) motives for investing in sustainability, and (2) the changes made in the business models of the companies. Table 2 shows the factor analysis of items reflecting motives for investing in sustainability, and includes both the pattern and structure coefficients.

[Insert Table 2 here]

As shown in Table 2, three factors were extracted. The first factor includes six items associated with various market-related benefits for the company both related to product and factor markets. The factor includes motives such as improved reputation, attending to customers' needs, building legitimacy and attracting employees. We label this factor "market benefits". The second factor includes three items that capture characteristics of the company that relate to governance or management control. The items reflect risk management, cost reduction and adaptations to resource scarcity. We label this factor "governance". The third

factor includes three items that capture pressures from important stakeholders in the form of owners, competitors and collaborators. We label this factor “external pressure”.

Table 3 similarly shows the factor analysis of items reflecting changes made to the business models in order to promote sustainability. Two factors were extracted. The first factor comprises five items reflecting changes made to product or service offerings, work processes and input factors. We label this factor “internal changes”. The second factor comprises four items reflecting changes in the relationship to external stakeholders. We label this factor “relational changes”.

[Insert Table 3 here]

### *Comparisons between harvesters and non-harvesters*

In order to investigate the difference between companies that report to reap financial benefit from their investments in sustainability and those that do not, we calculate a sum score. In the survey, the following items capture the ways sustainability measures positively influence the performance of the company: (1) sustainability measures may reduce costs, (2) sustainability measures may reduce risk, (3) sustainability measures may provide new business opportunities, (4) sustainability measures may make employees more committed and/or motivated, (5) sustainability measures may impact the value of the firm, (6) sustainability measures may positively influence corporate reputation. Each of these items were scored on 7 point Likert scales from “Completely agree” to “Completely disagree”. For the sum score, these were scored as 7 and 1, respectively, which implies that the sum score for each company ranged from 6 to 42. In our analyses, the “harvesters” are the companies that have a sum score higher than 29.

In Figure 2, we show the difference in the degree to which harvesters and non-harvesters<sup>4</sup> have adopted the various business model components for sustainability that we described for the full sample in Figure 1 above. As the figure shows, the harvesters have overall adopted more of these organizational characteristics. All differences are statistically significant

---

<sup>4</sup> We use the distinction between harvesters and non-harvesters, as introduced by Kiron et al (2012).

( $p < 0.05$ ), except the differences in the use of financial incentives and the reporting of sustainability performance.

*Figure 2: Comparison of business model components for sustainability between harvesters and non-harvesters*

In Figure 3, we compare the changes made to business models for each of the two factors that were found in the factor analysis above. In order to compare the two factors, we use the sum score for the items associated with each factor. As shown in Figure 3, harvesters make more changes both to products, services and processes (the “internal changes” factor) and in relationships to stakeholders (the “relational changes” factor). Both differences are statistically significant ( $p > 0.001$ ).

*Figure 3: Comparison of the degree of business model change between harvesters and non-harvesters*

In Figure 4, we similarly compare the harvesters and non-harvesters with regard to their assessment of the effects of their changes on their sustainability performance. Three effects are considered: (1) the degree to which the company's sustainability work improves their environmental performance, (2) the degree to which the company's sustainability work improves their social performance, and (3) the degree to which the company's sustainability work improves their stakeholder engagement. For all three outcomes, harvesters report a bigger effect of their sustainability work. The differences are all statistically significant ( $p > 0.001$ ).

*Figure 4: Comparison of social and environmental goal attainment between harvesters and non-harvesters*

In Figure 5, we compare the harvesters and non-harvesters with regard to their expectations about how sustainability will impact their business in the future. Four issues are considered: (1) whether or not sustainability work will be a more extensive part of their company in the future, (2) the degree to which sustainability performance will impact their profitability, (3) whether or not there will be more governmental regulations and incentives related to sustainability performance, and (4) the degree to which sustainability work will be a source of competitive advantage. For all four issues, harvesters have bigger expectations of the importance of these issues in the future. The differences are all statistically significant ( $p > 0.001$ ).

*Figure 5: Comparison about expectations about the future between harvesters and non-harvesters*

### *Multiple regression*

Finally, we conducted a multiple regression in order to investigate the characteristics that distinguish harvesters from non-harvesters in our sample. The dependent variable is the sumscore for harvesting, i.e. the sum of the scores for the items that indicate that the company's sustainability work has led to: (1) reduced cost, (2) reduced risk, (3) new business opportunities, (4) higher value of the company, (5) more motivated and/or committed employees, and (6) improved corporate reputation.

The independent variables were as follows: (1) the three motivation factors from the factor analysis, (2) the two business model change factors from the factor analysis, (3) the level of resource allocation to sustainability, (4) dummy variables for each of the business model components for sustainability.

*[To the reviewers: The presentation of this part of the analysis is still incomplete, but will be completed prior to the RESER conference. Generally, the multiple regression shows that most of the relationships explored above still hold when these variables are investigated*

*simultaneously. We apologize for failing to finish this part of the analysis in time for the deadline]*

## **Discussion and conclusion**

This study has aimed to investigate current practices concerning and attitudes towards sustainability as well as business model innovations for sustainability in Norwegian knowledge-intensive service sector firms. Based on a survey of 103 knowledge-intensive service companies, we have provided insight into the prevalence of sustainability-related practices, the stated motives for such practices, the types of changes they make to their business models, and the implications thereof for the companies themselves as well as for their stakeholders.

Our study is cross-sectional, which implies that we only provide a snapshot of such practices. However, the companies provide retrospectively oriented information about the motives for their current practices, as well as future-oriented viewpoints on their expectations for sustainability work in the future of their company. Thus, we aim to shed some light also on the dynamics of sustainability work in service companies.

Our study reveals that some of the common sustainability practices seem to be somewhat prevalent in service companies, while the comprehensiveness of such practices seem to be somewhat limited. While almost a half of the companies have a sustainability strategy, almost a third of the companies have sustainability reporting and approximately a fourth of the companies are committed to UN's Global Compact and have a dedicated employee working on sustainability, there are fewer companies that have dedicated KPI's or financial incentives tied to sustainability performance. This suggests that the harvesters among Norwegian service companies share similar characteristics as the harvesters analyzed in the international survey by Kiron et al. (2012).

Interestingly, when we distinguish between companies that self-report to reap financial benefit from their investments in sustainability ("harvesters") and those that do not ("non-harvesters"), we find that the former group is significantly more likely to have introduced these sustainability-related practices, excluding financial incentives and sustainability reporting. There is no significant difference in the degree to which companies report to spend

a lot of resources on sustainability practices, which implies that spending resources in the right way is more important than how much is spent on such practices. This is in line with the findings of Khan et al. (2015).

By means of factor analyses, we revealed underlying dimensions of both the motives for investing in sustainability and the changes made to business models reported by the companies. The factor analysis of companies' motives revealed three main motives: (1) market benefits, which includes direct and indirect financial benefits from sustainability work; (2) governance, which includes risk management and control-related reasons for working with sustainability; and (3) external pressures, which includes various forms of expectations and pressure from key stakeholders to work with sustainability. The factor analysis of business model changes revealed two factors: (1) changes to products, services and processes, and (2) changes in relationships to stakeholders.

When comparing harvesters and non-harvesters, we find that harvesters make more changes along both these dimensions. Moreover, the harvesters report significantly higher expectations that sustainability will be important to the performance of the company in the future. Thus, they signal an intent to invest further in increasing their sustainability performance.

Our study suggests that there are systematic differences in the sustainability practices of service companies, and that these differences are associated with the degree to which the companies experience positive effects on their financial performance following from their sustainability work. Our findings suggest that the motives for investing in sustainability seem to be more strategic than morally motivated, and the changes made to business models are to a large extent tied to characteristics of the companies' core resources and activities. This suggests that sustainability work among service companies is becoming more of a mainstream activity.

The findings of this study should be interpreted prudently, since they build on self-reported data. In particular, the perception of the degree to which sustainability practices lead to direct or indirect financial benefits are difficult for the respondents to properly assess. For this reason, future research should aim to investigate further the relationship between the motives and business model changes revealed in this study on the one hand, and actual measures of financial performance on the other. This could produce more robust findings on how concrete

business model adoptions and innovations influence financial performance. Moreover, further research should delve deeper into the potential differences between service companies and other companies (e.g. in manufacturing etc.), in order to investigate whether the differences in perception of these sectors' attention to sustainability performance is actually present also when it comes to their concrete sustainability practices. Such insights could inform the development of measures within the industries as well as among policy makers.

## **E2: Innovation and development in healthcare**

*Chair: Doris Schartinger*

# XXV. International RESER Conference

## Social innovation in Austrian health care: concepts and practice

*Doris Schartinger<sup>1</sup>*

<sup>1</sup>AIT – Austrian Institute of Technology GmbH

### Abstract

Social innovation (SI) relates to new responses to pressing social demands by means which affect the process of social interactions. This paper has a special focus on social innovation in healthcare. It is a conceptual paper which is aimed at preparing the ground for empirical field work. The guiding question is: Are there patterns observable where social innovations in Austrian healthcare (most likely) occur? The paper follows a threefold approach, based on existing studies and data of Austrian healthcare: First, the view on health care markets, secondly, the view on the health care system, and thirdly, the view on health problems. The methodology proposed in this paper shall provide guidance to comprehensively screen and identify social innovation projects in Austrian healthcare, labelled as social innovations or not.

### 1. Introduction

The burning question concerning social innovation is if they can (and should) be advanced on the basis of support schemes which overcome the notion that every social innovation project is singularly knit into its constellation of agents, networks and institutional context. Still, if support schemes are necessary they should be recharged from empirical evidence on patterns of barriers and opportunities common in numerous social innovation projects. This requires empirical evidence over a multitude of social innovation projects.

There are a variety of definitions that emphasize differentiated aspects of social innovation. The Bureau of European Policy Advisers defines social innovation (SI) as *relating to new responses to pressing social needs and creating new social relationships or collaborations. Hence, social innovations are innovations that are social in both their ends and their means* (BEPA, 2010).

The SI DRIVE project outlines a comprehensive working definition for the first phase of the project in order to refine it in the course of the project on the basis of empirical evidence. Social innovation is seen as

- a new combination or figuration of practices in areas of social action;
- prompted by certain actors or constellations of actors;
- with the goal of better coping with needs and problems than is possible by use of existing practices.

Richez-Battesti and Vallade (2009, cited in BEPA (2010)) stress that a social innovation can be a product, production process, or technology (much like innovation in general), but it can also be a principle, an idea, a piece of legislation, a social movement, an intervention, or some combination of them.

The Stanford Social Innovation Review (Phills, Deiglmeier, & Miller, 2008) defines social innovation as 'a novel solution to a social problem that is more effective, efficient, sustainable, or just than existing solutions and for which the value created accrues primarily to society as a whole rather than private individuals. This corresponds to the argument of positive externalities derived from economic theory. Positive externalities are seen as the source of partial or total market failures and usually justify policy interventions. In this definition, positive externalities are seen as a prime motivation for social innovations.

Within the CRESSI project social innovation is positioned as a solution to some of the causes of and problems arising out of marginalisation, where marginalisation is a social process through which personal traits are transformed into potential factors of disadvantage. Within the context of high public debt and fiscal austerity, social innovation is increasingly seen as a means by which to overcome the scarcity of resources and the persistence of socio-economic challenges (Chiappero & Von Jacobi, 2015).

Despite the variety of definitions, for this paper I outline SI as

- solving needs is a first order goal (intentionality). Per definitionem needs must be satisfied for human beings in order to avoid serious physical or mental harm, where harm also comprises barriers to individual aspirations or social inclusion. In this sense, needs are objective, universal and transcultural (Hodgson, 2007: 7)
- handling problems, needs in a new way (innovative solution)
- relating people, processes, resources (technologies) in a new way (service architecture)

The field is practice-led. The aspiration to cover all aspects of the rich variety of social innovation projects we can find in practice explains the multitude of definitions that exist.

Intentionality seems important as many innovation projects have some social impact as a wider effect. But it is worthwhile thinking if innovation projects explicitly set up to solve social problems (e.g. of marginalization, of social determination etc) encounter barriers in a systematic way as patterns instead of viewing them as the product of singular achievements and pure luck.

This paper has a special focus on social innovation in healthcare. It is a conceptual paper which is aimed at preparing the ground for empirical field work. It is part of a research project (Social Innovation: Driving Force of Social Change (SI-DRIVE; <http://www.si-drive.eu/>)) that wants to enhance the theory on SI in developing a typology of social innovations and their relationships to transformative societal change and policy making.

The goal of this paper is therefore to provide conceptual guidance for a selection of social innovation projects in Austrian healthcare, so that the screening, identification and selection of social innovations in Austrian healthcare is as systematic as possi-

ble. The guiding question of this paper is: Are there patterns observable where social innovations in Austrian healthcare (most likely) occur?

In order to answer the above question I will follow a threefold approach, based on existing studies and analyses. This paper will first provide different views on Austrian health care (chapter 2): First, the view on health care markets, secondly, the view on the health care system, and thirdly, the view on health problems. In chapter 3 I will give a first overview of who engages in social innovation in Austrian healthcare and who uses the term “social innovation”. Chapter 4 screens social innovation projects submitted for a social innovation award according to the different views on Austrian healthcare provided before. Chapter 5 discusses the results and concludes.

## 2. Different Views on Austrian Health Care

### 2.1. The view on health care markets

Irrespective of whether funding is public or private, health care is always an economic process that generates output in the form of healthcare services on the basis of inputs. Health care systems may therefore be considered as health care markets.

I start out with results from an Austrian health satellite analysis which defines markets in healthcare (Czypionka, Schnabl, Sigl, Zucker, & Warmuth, 2014) and provides us with an overview of products and services in healthcare.

The core markets in healthcare are represented by the OECD system of health accounts, which provide a set of internationally comparable health accounts in the form of standard tables and define internationally harmonised boundaries of health care and basic categories thereof (OECD, 2000). Whereas the original manual of systems of health accounts demarcates health care along three axes: 1. health care by function, 2. health care service provider industries; and 3. sources of funding health care (OECD, 2000), the revised manual (OECD, 2011) also provides a classification of health care products.

A health care product can consist of both goods and services and has the primary purpose of improving, maintaining or preventing the deterioration of the health status of persons or mitigating the consequences of ill-health (OECD, 2011, p465).

Table 1: Overview of health care products

|                      |   |
|----------------------|---|
| 01 Hospital services | Short- or long-term hospital services for patients admitted for a minimum of 24 hours, i.e. medical, diagnostic and treatment services. The services are directed to inpatients and are carried out under the direct supervision of medical doctors, specialist medical professionals as well as traditional and complementary medical professionals.   |
| 02 Day care services | Short-term “hospital” services for admitted patients for less than 24 hours (day care), i.e. medical, diagnostic and treatment services. The delivery of day care services is not limited to hospitals, but can also be delivered in ambulatory premises or self-standing centres. This also includes pharmaceutical services, nursing services and laboratory and technical services delivered to day care patients as part of the bundle of services. The services are directed to day care patients and are car- |

|  |  |
|--|--|
|  | ried out under the direct supervision of medical doctors, specialist medical professionals as well as traditional and complementary medical professionals  |
| 03 Medical and dental practice services                    | General and specialised medical services consisting in the diagnosis and treatment by medical doctors (Generalist medical professionals, Specialist medical professionals as well as Traditional and complementary medical professionals) of physical and/or mental diseases or health needs.  |
| 04 Other medical services                                  | Services provided by authorised persons, other than medical doctors in the fields of Midwives' services, Nursing services, Physiotherapeutic services, Ambulance services and Medical laboratory services delivered as part of the composite package. This subcategory excludes all the services delivered to inpatients and day cases as part of the package of services, i.e. the service bundle consumed.   |
| 05 Residential care services                               | Services provided in nursing homes, homes for the elderly and disabled, services provided for mental retardation, mental health and substance abuse and other residential care services, with respect to the medical, nursing, ancillary and ADL (activities of daily living) components.  |
| 06 Nursing care services without accommodation             | All nursing, ancillary and ADL (activities of daily living) services provided by authorised and unauthorised persons delivered to children and adults with a large dependency for activities of daily living and instrumental activities of daily living (IADL). Included are services provided by volunteers (for their remunerated services).  |
| 07 Retail trade services in medical products               | This item comprises medical goods dispensed to outpatients and the services connected with dispensing, such as retail trade, fitting, maintaining and renting of medical goods and appliances. Included are the services of public pharmacies, opticians, sanitary shops and other specialised or non-specialised retail traders, including mail ordering and teleshopping. This group covers medicaments, prostheses, medical appliances and equipment and other health-related products provided to individuals, either with or without a prescription, usually from dispensing chemists, pharmacists or medical equipment suppliers, and intended for consumption or use by a single individual or household outside a health facility or institution. Included is the information and education service provided as part of the (simple) product delivery. |
| 08 Preventive services                                     | Prevention is any service that reduces the burden of mortality or morbidity from disease. This takes place at primary, secondary and tertiary prevention levels. Primary prevention anticipates the emergence and lessens the severity of diseases. Most population-based health promotion activities are primary preventive measures, e.g. vaccination. Secondary prevention activities are aimed at early disease detection, thereby increasing opportunities for less costly and invasive interventions to prevent progression of the disease and emergence of symptoms, e.g. screening for TB, diabetes, breast cancer, etc. Tertiary prevention reduces the negative impact of an already-established disease by restoring function and reducing disease-related complications. In SHA, prevention is limited to primary and secondary prevention.        |
| 09 Governance, management and health system administration | The focus of these services is on the health system rather than directly on health care. They are considered to be collective, as they may not be allocated to specific individuals but benefit all users. They direct and support the functioning of the health system. These services are expected to maintain and increase the effectiveness and efficiency of the health system and may enhance its equity. This includes <i>Administrative services regarding mandatory schemes</i> .   |
| 10 Health insurance, ex-                                   | The administration of private health insurance essentially involves the  |

|   |   |
|---|---|
| cept mandatory schemes  | health insurance service and the service charge <sup>9</sup> for this. This covers expenditure on sales, the enrolment and policy service, claim adjudication, actuarial functions, legal support services, investment functions, corporate overheads and risk charges. |
| 11 Health and social care goods and services produced by households for own use | This item contains all services generated within the household for own final use, which are reimbursed or the subject of transfers. It usually refers to care provided on a long-term basis through relatives and friends.  |
|   |   |

Source: OECD (2011)

A wider perspective to identify health markets is to ask whether purchasing decisions are to some extent subjectively based on health considerations. Here, health care products need not be supplied by health care service providers in the narrow sense, and therefore these health care products do not appear in the statistics of health care expenditures according to the systems of health accounts. For Austria Czypionka et al (2014) demarcated the wider health care markets on the basis of input-output-tables and additional material to estimate the subjective health motivation of purchasing decisions<sup>1</sup>.

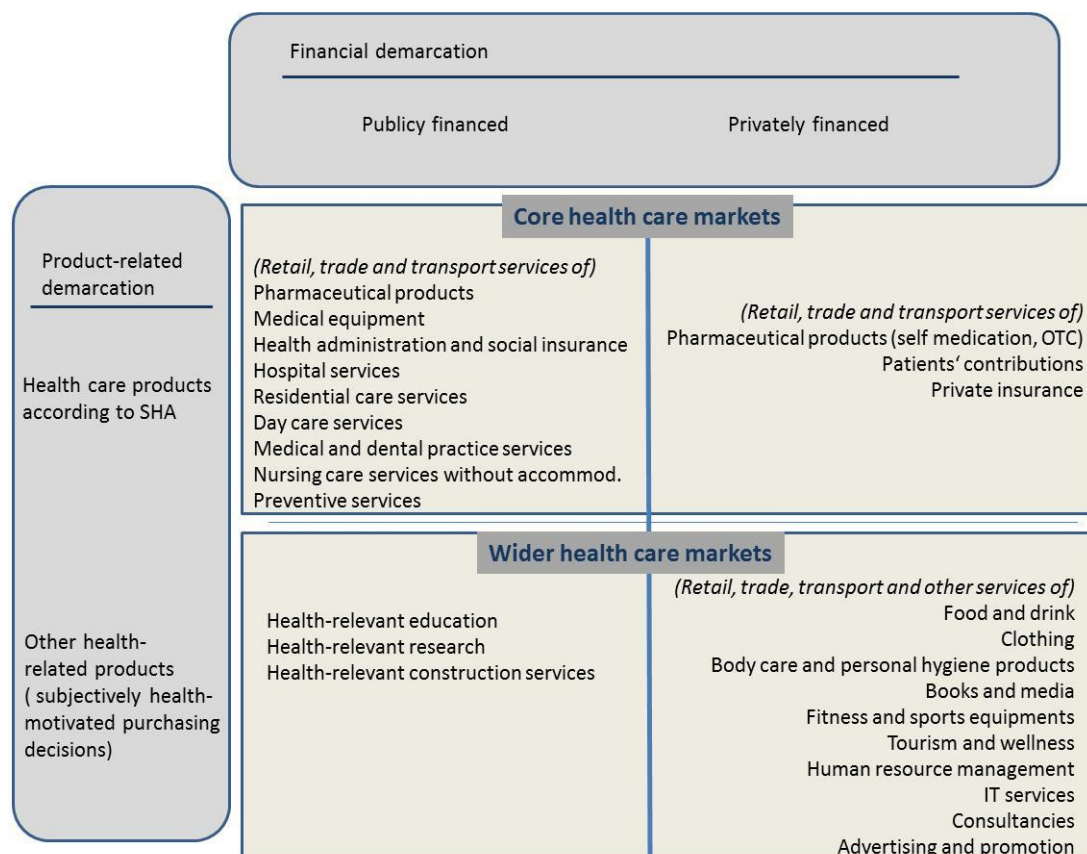

Consequently, the following goods and service markets have shares that are related to health (Czypionka et al, 2014, 70ff):

- Retail trade services of food and drink (contains also organic food and drink)
- Retail trade services of clothing (contains also protection items like helmets, protection gloves etc), sports clothing)
- Retail trade services of body care and personal hygiene products
- Retail trade services of books and media
- Retail trade services of pharmaceuticals (in the wider health care market only non-registered OTC products, otherwise products are part of the core health markets).
- Retail trade services of fitness and sports equipment
- Sports and recreation services
- Tourism services
- Wellness services
- Employment and recruitment services, job services (in health professions, for patients etc.)
- Retail and trade
- Transport (of individuals to and from health relevant activities, but also transport of health-relevant goods)
- Associations, self-help groups, syndicates
- IT services (health IT solutions)

<sup>1</sup> E.g. Expenditures on organic food are motivated by health reason to 41 per cent and have a market share of 5 per cent, hence approximately 2 per cent of the organic food market is part of the wider health care market.

- Consulting services (e.g. legal and tax advice for health care service providers)
- Advertising and promotion (for health-relevant goods and services)
- Health-relevant education and research (Schools , academies educating health professionals, universities etc, and research in biotechnology, psychology, biology and pharmacy).
- (Health-relevant) construction services

Figure 1: Health care markets

Source: Based on Czipionka, Schnabl, Sigl, Zucker, and Warmuth (2014)

## Challenges

The view on wider health care markets enables a more comprehensive view on health care, indeed examples show that social innovation projects can be met in many of the above areas areas. However, it does not provide us with a view where to systematically find social innovations. Still, it is an attempt to open up, and at the same time demarcate the health care area.

A wider view on health markets makes more obvious that also social innovation in health may take place outside the core sectors. An example is the following, see Box 1.

Box 1: Residence as a source of energy - an example for a social innovation project in health

### **Residence as a source of energy (Kraftquelle Wohnen)**

**Project idea** Living spaces exert a significant influence on health, perception, feeling, thinking, personal development and growth. In addition to protection from the weather as well psychological and physiological needs must be satisfied in order for a habitat to be suitable for human beings.

Our offer is aimed at people with mental or physical disorders / disabilities, who suffer from their existing living conditions. People eligible for our project are those who are unable to modify their residential premises in a suitable way without professional assistance.

**Project goals** The project aims at a sustainable and healthy change in the living conditions of the clients. Our effort is aimed at establishing the project as integral part of the health and social system, because our project can satisfy a missing link between health and social care settings.

**Organisation** Organised as a non-profit association, the project team consists of the chairwoman of the association, a project manager, employed workers, volunteers, also volunteer craftsmen and an evaluation team. Furthermore, the NPO entertains multidisciplinary collaborations with the university clinic Innsbruck, department of clinical psychology, different Christian charities, the provincial residential building cooperative. The NPO is financed by own contributions, donations, sponsorships, some public funding etc.

## **2.2. The view on the health care system**

Health care systems, in order to satisfy human health needs, have to fulfil certain functions, which have been classified by the OECD (2000, 2011). Here, the first-level categories of the functional classification aim to distribute health consumption according to the type of need of the consumer.

The classification of health care functions at the first-digit level is the following (OECD, 2011, p75):

HC.1 Curative care

HC.2 Rehabilitative care

HC.3 Long-term care (health)

HC.4 Ancillary services<sup>2</sup>

HC.5 Medical goods (non-specified by function) <sup>3</sup>

HC.6 Preventive care

HC.7 Governance and health system and financing administration

HC.9 Other health care services not elsewhere classified (n.e.c.)

<sup>2</sup> non-specified by function, e.g. laboratory diagnosis, imaging etc, which are not attributable to other functions like cure, care, prevention etc.

<sup>3</sup> Medicines and other medical goods are frequently a component of a package of services with a preventive, curative, rehabilitative or long-term care purpose. In inpatient, outpatient and day care consumption, they are not usually identified separately, except possibly at a more detailed level. [...] This category aims to include all consumption of medical goods where the function and mode of provision is not specified (OECD, 2011, p97).

The Austrian Health System Review (Hofmarcher & Quentin, 2013) thoroughly analyses health care in Austria on the system level and identifies strengths and weaknesses in provision and integration of supply and services with the necessary functions of health care systems.

In Austria, the provision of health care, financing and governance of the health care system is a mainly public function. Austrian health policy fosters equal access to high-quality care for all, irrespective of income, age and gender. Social health care insurance funds fulfill a crucial role here, as they guarantee access to a wide array of health and social care services. However, the level of user-charges and direct payments is also relatively high compared to other countries (Hofmarcher & Quentin, 2013: p. xxix).

In 2012 total health expenditure on health in Austria has been 11.5 per cent of GDP. Around 24 per cent of total health expenditures in 2012 were financed by private sources (62,2 per cent of private financing is out-of-pocket), 76 per cent of total health expenditures in 2012 were financed by public sources. Among the public sources, the social health care insurance funds are the most important source of financing (WHO, Statistik Austria [www.statistik.at](http://www.statistik.at)).

The social health care insurance is a mandatory insurance and covers almost a hundred per cent of inhabitants in Austria. There is no competition between the various social health insurance funds, as it is based on membership of an occupational group or place of residence. Health care is delivered **in case of need** to those insured within the social health insurance system according to a service catalogue. The services according to the service catalogue are provided by physicians in the inpatient and outpatient sectors. Which benefits to be included in the service catalogue is annually negotiated between the physicians' chambers at the Länder level and the Federation of Austrian Insurance Institutions (Hofmarcher & Rack, 2006: p. xxi).

Through the social health care insurance all members of the population (99,9 per cent) have relatively unrestricted access to all levels of care (general practitioners, specialists, hospitals). This entails that it is often up to the patient which care option he/she chooses and patients may encounter difficulties finding their way through the highly fragmented supply chain of health care services in Austria.

Longterm care is Social insurance health care funds only accounted for 0,7 per cent of longterm care expenditures in 2010 (Hofmarcher & Quentin, 2013: p. xxiii).

## Challenges

Costs of the health care system are high in Austria, in absolute terms as well as in percentage of GDP they are above EU15 average (In 2012, Austria is ranked third concerning Total health expenditure (THE) % Gross Domestic Product (GDP) in EU 27 behind the Netherlands and France, see NHA indicators by WHO (2014b)).

In general, in Austria life expectancy is continually rising. But healthy life expectancy is 2 years below EU average (59,7 in Austria compared to 61,6 EU-27). Considering gender, the gap in healthy years of life between Austria and EU-27 average is more pronounced for men than for women (see data sheets for OECD, 2012).

With health care cost rising continuously, it is an inherently difficult process to decide which benefits have to be included in the service catalogue financed by social health insurance.

Spending on preventive medicine is relatively low: Health insurance funds do invest in prevention, but only after they have met their statutory requirements for curative medicine (Hofmarcher & Quentin, 2013: p.268f).

Although social health insurance coverage is comprehensive, access to healthcare services still varies and is determined by factors other than coverage. There are clear social inequalities in the consumption of certain medical services, e.g. dentistry, preventive services. Different social factors impact on health literacy which in turn impact on the consumption of different medical services (see also discussion on social determinants of health, e.g. WHO, 2010).

Psychiatric and psychosocial care is characterized by high variety of provision across Länder. In an outpatient setting, access to specialist services, particularly for children and young people, is insufficient. For consultation of registered psychotherapists (i.e. non-physicians) the proportion of costs that have to be carried by the patients out of pocket, is high (Hofmarcher & Quentin, 2013: 207f).

In Austria in general, and as well for certain services, the level of out-of-pocket payments for medical services is also rather high compared to Denmark, Sweden or the Netherlands (Hofmarcher & Quentin, 2013: 243), with 1,7 per cent of GDP very close to European average of 1,8 see (WHO, 2014b). Models of cost sharing result in considerable out-of-pocket contributions from patients, e.g. in dentistry.

Furthermore, international studies confirm that higher income groups receive preferential treatment in the Austrian health care system. Furthermore, social inequality arises as there are indications that private payments to physicians are used to shorten waiting times for publicly financed treatments. Furthermore private insurance openly claim to offer shortened waiting times for treatments, which was criticized as being in breach of the law (Hofmarcher & Quentin, 2013: 249f).

In terms of the health care system itself: Concerning the workforce, Austria is well equipped with physicians in terms of numbers (48,3 physicians per 10000 population in Austria compared to 33,1 regional average). However, in Austrian media there are recurrent discussions about the regional distribution of physicians, as peripheral regions in Austria have difficulties in attracting physicians, specialists in particular (Gebhard, 2014). The WHO Austrian health profile reveals that there are not as many nurses and midwives active in Austria as the regional average (79,1 compared to 80,5) (WHO, 2014a).

### **2.3. The view on health problems**

A third approach provides a view on health problems in Austria: The prevalence of certain disorders may be the basis for social innovation projects, or the low spread of others. This will be based on WHO and OECD data and country comparisons.

#### **Challenges**

One of the main problem areas in Austria are noncommunicable diseases. Years of life lost due to noncommunicable diseases is particularly high, with 88 per cent of years of life lost due to NCD Austria is 8 per cent above regional average (WHO, 2014c). Cardiovascular diseases is the most frequent cause of deaths (43 per cent of total deaths), followed by cancer (27 per cent). Diabetes and chronic respiratory dis-

eases account for 4 per cent of total deaths each, 14 percent other NCD. In terms of prevention, Austria is below regional average in DTP3 immunization among 1-year-olds as well as measles immunization among 1-year-olds. Tobacco use among the population over 15 is far above regional average, for males as well as for females (WHO, 2014a).

Although alcoholism does not seem striking in WHO statistics, it is felt to be a problem in Austria and is reported about in media regularly as Austria's most common form of addiction. Around 10 per cent of the Austrian population become alcohol addicts during their lives, around 5 per cent are chronic alcohol addicts (Bundesministerium für Gesundheit, 2009: 140f).

According to the Austrian Health Survey 2006/2007 by Statistics Austria 471000 people (174000 men and 297000 women) have physical problems with basic activities in their lives such as eating, washing, getting dressed (Hofmarcher & Quentin, 2013: p 199). In Austria, a need-based longterm care allowance exists and is improved constantly (e.g. Federal Longterm Care Reform Act 2012). Still, there are shortcomings in terms of 24-hour care at home for severely mentally impaired patients, particularly for those with dementia and severely disabled children and young people according to Austrian Media. Furthermore, the structure of longterm care provision is under constant discussion, with first) an estimated 59 per cent of beneficiaries (Hofmarcher & Quentin, 2013: p. 202) [of the longterm care allowance, Anm.] mainly being cared for by family members (80 per cent women) and secondly, an informal market for care at home having grown alongside the informal care provided by families. This informal market for care at home seems to rely on migrant carers from Slovakia to a high extent.

### **3. Screening Social Innovation in Austrian Health Care**

#### **3.1. Who uses the term**

While "social innovation" as a term is not used in official Austrian health policy, a multiplicity of aspirations to improve the coordination and governance of the public healthcare system are taking place that would conceptually qualify as social innovations. There are constant negotiations and activities to expand services covered by social insurance, to widen and adapt the structure of services offered to health needs of the population, while staying affordable. Still, as the Austrian health care system is very fragmented in administration and financing, every step of change seems an enormous effort. The wording used includes, but is not restricted to, terms like "reforms", "initiatives", "improvements", "structural measures" etc.

Innovative approaches to improve health care in Austria, which include social innovations without using the term are e.g. improved coordination between ambulatory and inpatient care, expansion of services to encourage 24-hour care at home, legislation and services which encourage group practices, often with multidisciplinary teams, e-medication as a pilot has started, programmes for integrated care have been developed and implemented, like the diabetes disease management programme Therapy actively Diabetes (for an overview of reforms see Hofmarcher & Quentin, 2013).

The strategic framework for health care provision in Austria is increasingly based on discussions and conceptual approaches promoted by the WHO, like the Health in All Policies approach, discussions on social determinants of health, health literacy etc. There is a current discourse in Austria, orchestrated by the Ministry of Health, for the strategic framework concerning the coordination of health promotion and prevention to encompass health targets. Ten health targets have been formulated, many of which will impact on social innovation in Austria ( for health targets see <http://www.gesundheitsziele-oesterreich.at/health-targets-for-austria/> ).

The term social innovation in Austria is mainly institutionalised through a private foundation, the Unruhe Privatstiftung. This private foundation annually issues a prize for social innovations, the SozialMarie, an academy award for social innovation projects (see Box 2) This private foundation explicitly uses the term social innovation, whereas official Austrian policy also engages in social innovation, but does not use the term.

**Box 2: Institutionalising social innovation in Austria – an academy award for social achievements**

The Unruhe Private Foundation about social innovation (2013)

*"Social innovation drafts solutions to pressing social challenges. It provides room for new approaches, gives innovative answers and lays new paths. Social innovation either reacts to a new social question or it solves a known problem by a new practice. Action can be taken by the affected social group itself, it must in any case be appropriated and co-implemented by those concerned. In this manner, social innovation creates sustainable, exemplary solutions that inspire others."*

SozialMarie – a prize for social innovation

The SozialMarie is the oldest prize for social innovation in Europe and honours outstanding projects in the field of social innovation every year since 2005. Beyond a financial recognition adding up to 54,000 Euros, the SozialMarie primarily offers a public platform for projects that provide innovative answers to societal challenges by means of new approaches.

A courage injection for creative social projects

Beyond the novelty of solutions for social problems, the selection criteria primarily include the extent to which respective target groups are reached and the effectiveness of implementation. The SozialMarie is a premium seal of quality for good and effective social innovation. By means of this prize, the goal is to encourage networking amongs projects and bring the discussion regarding social innovation forward.

SozialMarie Audience Award

The SozialMarie Audience Award is given out every year to three projects submitted from all over Austria, Hungary and the Czech Republic - countries that belong as total to the submission area by SozialMarie calls. Only audience decides about the prizes and can vote three times, once per country.

Source: Website of the Unruhe private foundation [http://www.sozialmarie.org/the\\_prize\\_sozialmarie](http://www.sozialmarie.org/the_prize_sozialmarie) , last accessed January 13<sup>th</sup>, 2015.

## 4. Health care and social innovation in Austria

### Data

The following analysis is based on project submissions to the social innovation prize SozialMarie from 2012 to 2015. In that period 79 projects were submitted from project organisers located in Austria that were labelled health/ care<sup>4</sup>. One project had to be omitted, which results in 78 projects for further analysis.

There is likely to be a selection bias in the self selection mechanisms of the project submissions. In principle, the call for projects is open to all project organisers from commercial companies, by the social economy (civil society initiatives, NGO, NPO, associations) or by public administration that address current social problems. Eligible projects must have been implemented for a sufficient period at the time of filing, while still running. However, the distribution of project applicants by type of organisation is skewed. Out of 78 submitted projects, nine (11,5 per cent) were submitted by commercial companies, six by public administration units (7,7 per cent) and 63 (80,8 per cent) by organisations from civil society.

Figure 2: Type of project organisers in project submissions of social innovation award

Source: Projects submissions on <http://www.sozialmarie.org/> , own calculations.

### Results and discussion

Relating to the demarcation of health care markets and products, where products refer to goods and services, it seems that the majority of health care projects submitted for the social innovation award refer to the wider health care markets (see Table 2). Bearing in mind the distribution of project organisers above, it may be a working hypothesis that social innovation projects organised mainly by civil society have a high inclination towards the wider health care markets. This could change if we con-

<sup>4</sup> <http://www.sozialmarie.org/>

sider that especially in the public realm social innovation takes place, but projects may not be subsumed under the very term. Most likely these social innovations in the public realm would contribute more to the core health markets.

In the core health care markets the majority of social innovation projects is carried out in specialised medical services by different sorts of health professionals. This refers to animal therapies, nature therapies, etc, to psycho-social care in various special situations like violence, dementia, eating disorders, or to specialised services in crises or for especially vulnerable groups, e.g. psycho-social care for families of a terminally ill child, psycho-social care for infant refugees, etc.

In the wider health care markets, consultancy and advice is dominant. There are mainly two forms of consultancy and advice, one in the form of coaching to motivate people suffering from ill health to cope with their illness, socialize, reconcile ill health with their jobs etc. Another form of consultancy and advice is guidance, i.e. nurses, peers, relatives guide patients and their relatives through the supply chain of Austrian health and social care, which has a multitude of offerings that may be difficult to survey when (newly) diagnosed. Social innovation projects in education and training also account for a high share between 2012 and 2015. These projects relate to training measures for health professionals on the one side, as these are subject to high pressures and often have to keep up with new developments and constantly have to adapt their competences (mobile childcare in all conditions and phases of these conditions, AIDS, dementia etc), but also educational projects relating to health literacy (e.g. food) or social competence and mutual understanding between generations.

Table 2: Health social innovation projects 2012-2015, by health care product

|   | Health care products/ sectors             | Number of health social innovation projects 2012-15 |
|---|---|---|
| <i>Core health care market</i><br>35 %  | <i>03/04 Specialised medical services</i> | 19  |
|   | <i>03/04 General medical services</i>     | 1   |
|   | <i>05/ Residential care</i>               | 6   |
|   | <i>06 Nursing mobile care</i>             | 2   |
| <i>Wider health care market</i><br>65 % | Consultancy, advice (coaching)            | 12  |
|   | Education/training (e.g. food)            | 16  |
|   | Consultancy, advice (guidance)            | 6   |
|   | Tourism, recreation services, sports      | 6   |
|   | Selfhelp initiatives/groups of relatives  | 4   |
|   | Employment services                       | 3   |
|   | Accommodation                             | 3   |
|   | Transport services                        | 1   |
|   | IT services                               | 1   |
| Total                                   |   | 78  |

Source: Projects submissions on <http://www.sozialmarie.org/> , own calculations.

Considering health care systems and their functions (see , the analysis of social innovation project submitted for the social innovation award shows that 56 per cent may be subsumed in the classification of health care functions at the first-digit level by the OECD (2011). Curative care is when the symptoms correspond to an acute condition, a remission or cure (HC.1) is sought and expected. The one curative project in Table 3 relates to the project AmberMed (see Box 3). Many conditions cannot, however, be completely cured and lead to chronic conditions with some degree of functional decline, which makes rehabilitative care and also preventive care (and a mix thereof) necessary. Curative care is a major public health care function in Austria and plays a minor role in the below analysis, which is mainly based on social innovation projects by civil society. However, rehabilitative, longterm and preventive care rank high and are almost equally distributed.

**Box 3: AmberMed - an example for a social innovation project in health**

**AmberMed**

**Project goals** AmberMed provides outpatient medical care for people without social insurance, in particular asylum seekers, people with a migration background and Austrian citizens without social insurance. The assistance is offered in acute but also in chronic diseases.

**Organisation** Since 2006 this project of the Diakonie Refugee Service in cooperation with the Austrian Red Cross offers infrastructure and the medications. The Diakonie Refugee Service as main implementing body employs the core project team, is responsible for the coordination of the project, the support of the volunteers and the further development of the project. Doctors work on a voluntary basis and their medical advice is translated by voluntary interpreters. Everybody who is in need will receive medical support, no matter whether they are legal residents. A high proportion of patients does not know if they will be able to stay in the country at the time of consultation.

Diakonie Flüchtlingsdienst (Diakonie Refugee Service) is an NGO that engages in the counseling, support, housing, education and medical as well as psychotherapeutically treatment of asylum seekers, refugees, migrants and Austrian citizens. It is part of Diakonie Österreich which is the welfare body of the protestant churches. It is one of the five biggest Austrian welfare organizations.

Source: <http://derstandard.at/1269449290816/Man-kann-die-Kranken-nicht-einfach-wegschicken> and <http://www.sozialmarie.org/>

Further 44 per cent are social innovation projects that relate to health care, but cannot be directly subsumed under the OECD functions. One illustrative example is drug addiction, where public health care offers various services and support for drug withdrawal. These service offerings are more concentrated on actual therapies, when detoxification is accomplished they stop at some point and dismiss people into the world outside again. But there are sensitive phases of social reintegration apart from detoxification and psychological therapies where social innovations by civil society organisations may play a decisive role as they lead people to find new ways and above all new social relations and daily activities, away from their old networks and routines (which mainly related to drugs). Re-integration projects of various kinds account for 13 out of 78 in the present analysis. Projects labelled *Access to healthcare* often relate to projects that address social inequalities in the consumption of certain medical services (see section challenges in 2.2 The view on health care systems). Different social factors (e.g. migration background) impact on health literacy or on knowledge about newly entered healthcare system which in turn impact on the con-

sumption of different medical services. Social innovation projects e.g. offering peer support try to find a solution here.

Table 3: Health social innovation projects 2012-2015, by health care function

|  | Functions                 | Number of health social innovation projects 2012-15 |
|--|---------------------------|---|
| <i>Health care function according to OECD (2011)</i><br>56 % | HC.1 Curative care        | 1   |
|  | HC.2 Rehabilitative care  | 13  |
|  | HC.3 Longterm care        | 15  |
|  | HC.6 Preventive care      | 15  |
| <i>Health care function beyond OECD (2011)</i><br>44 %       | Re-Integration            | 13  |
|  | Support in crises         | 9   |
|  | Health personnel measures | 7   |
|  | Access to health care     | 5   |
| Total  |                           | 78  |

Source: Projects submissions on <http://www.sozialmarie.org/> , own calculations.

Considering health problems addressed in social innovation projects submitted for a social innovation award from 2012-2015, it is striking that not those conditions where Austria stands out in international statistics seem to motivate the social innovation projects in healthcare, at least those organised by civil society. Non-communicable diseases like diabetes, cancer and cardio-vascular diseases account for a minority of social innovation projects in the present data set. The majority of social innovation projects are motivated by psycho-social care, i.e. maladjustments of some sort that may have an obvious cause (violence, terminal illness, political persecution) that is addressed by the projects or may be only detectable through symptoms (eating disorders, ADHD/ADD etc). As described in 2.3 The view on the health problems, in psychiatric and psychosocial care access to specialist services, particularly for children and young people, is insufficient and for consultations of registered psychotherapists the proportion of costs that have to be carried by the patients out of pocket, is high (Hofmarcher & Quentin, 2013: 207f). This seems reflected a lot in social innovation projects relating to health. Ranked second in Table 4 are preventive measures addressing healthy people. This also corresponds to weaknesses in Austrian public healthcare, where preventive measures are only financed once statutory requirements for therapeutic measures are fulfilled. Furthermore, social innovation projects in dementia often relate to projects addressing old age in general, longterm conditions and psychological care for nurses and relatives burdened with longterm and home care.

Table 4: Health social innovation projects 2012-2015, by health problem

| Health problem        | Number of health social innovation projects 2012-15 |
|-----------------------|---|
| Psycho-social problem | 19  |
| Healthy               | 11  |
| Dementia              | 9   |

|  |    |
|--|----|
| Terminal illness                               | 8  |
| Longterm conditions/Disabilities               | 7  |
| Psychological care (for carers, longterm care) | 7  |
| Old age  | 5  |
| General  | 5  |
| Shortterm conditions (infections, OPs etc)     | 2  |
| Cancer   | 1  |
| Diabetes                                       | 1  |

## 5. Conclusions

This paper has a special focus on social innovation in healthcare. It is a conceptual paper which is aimed at preparing the ground for empirical field work. The goal of this paper is therefore to provide conceptual guidance for a selection of social innovation projects in Austrian healthcare for in-depth case studies, so that the screening, identification and selection of social innovations in Austrian healthcare is as systematic as possible. The guiding question of this paper is: Are there patterns observable where social innovations in Austrian healthcare (most likely) occur?

In order to answer the above a threefold approach is applied: Existing and available social innovation projects are analysed first, with a view on health care markets, secondly, with a view on the health care system, and thirdly, with a view on health problems. Social innovation projects submitted for a social innovation award were screened according to the different views on Austrian healthcare provided before.

The analysis leads to the following preliminary findings:

In 81 per cent of the project submissions, labelled health/care, for the social innovation award the project organizer comes from civil society, which is also conditioned by the goals stated by the private foundation that has implemented the award: It wants to award achievements in social work, make innovative solutions in social visible and presented in a positive way (Sutterlüty, 2008). But social innovation in public sphere and companies may be underrepresented, as actors there use other terms like corporate social responsibility, reforms, structural measures etc.

Relating to the demarcation of health care markets and products, where products refer to goods and services, it seems that the majority of health care projects submitted for the social innovation award refer to the wider health care markets (65 per cent), not the core markets (35 per cent). This may correlate with the high proportion of project organizers from civil society.

Concerning functions, it seems that there are various contexts/challenges that make social innovation necessary in addition to existing policy and health and social ser-

vices. Social innovation projects screened were often found to fulfill the following functions:

- Social innovation projects as remedies to existing services: Public social and health care services exist, but are not used by the target group. Statistics in this case often hide the problem and may lead policy responsables to wrong conclusions that the service is not needed, but civil society organisations working in the field perceive that the needs of the target groups are not addressed properly (e.g. for homeless).
- Social innovation projects as phasing out of public health care services, where health care services exist but would need social care service to complement them, e.g. for sensitive phases of re-integration (e.g. in drug withdrawal).
- Social innovation projects solving problems appearing on the edge of society, where the problem realization is too recent and problems need different/additional approaches than those established. Social health care could not yet respond, here civil society organisations like charities are often more flexible (e.g. children carers).
- Social innovation projects smoothing access to healthcare, as this is also socially determined. Social insurance in Austria is comprehensive, but marginal social groups may fall out of the system (e.g. asylum seekers) or persons with migration background are not familiar with health care system of new country and do not realize options.
- Social innovation projects to boost preventive health care services, as preventive services offer vast possibilities but cannot all be covered by social health care insurance in the present form. Social healthcare insurance funds do invest in prevention (mainly vaccinations), but only after they have met their statutory requirements for curative medicine (Hofmarcher & Quentin, 2013: p.268f). Diseasemanagement programmes were a huge step and took decades of negotiations to get operationalised within public health care.

Considering health problems addressed in social innovation projects submitted for a social innovation award it is striking that not those conditions where Austria stands out in international statistics seem to motivate the social innovation projects in healthcare, at least those organised mainly by civil society. Non-communicable diseases like diabetes, cancer and cardio-vascular diseases account for a minority of social innovation projects in the present data set. Still, social innovation projects seem to reflect weaknesses of the Austrian health system: The majority of social innovation projects address psycho-social care, especially for children and young people, dementia, and the situation of carers for patients with dementia and other long-term illnesses.

For a selection of projects to depict social innovation in Austrian healthcare I conclude that at least social innovation in public organisations should be represented more. This will most likely impact on the distribution of core and wider health as it may be assumed that public organisations also considerably innovate socially in the core healthcare sectors.

# Non-Invasive Prenatal Test: An “invasive” innovation in prenatal testing

*Henni Tenhunen, An Chen*

Aalto University School of Science, HEMA Institute

*Non-Invasive Prenatal Testing (NIPT) is a relatively new offering in prenatal testing. Hospital District of Helsinki and Uusimaa (Finland) started to provide NIPT alternative in January of 2015. The purpose of this study is to investigate the disruptive elements of NIPT in prenatal testing services. This exploratory study shows that the use of NIPT creates certain challenges for both the consumers and the service providers. We argue that genetic counselling is essential and should be tightly integrated to the patient-provider relationship and to the supported peer to peer networks as a way to organize service production and delivery. Our research develops new insights into the use of NIPT and also enriches the research of service innovation with the focus on the implementation of innovation in knowledge intensive services.*

## 1. Introduction

### 1.1. NIPT background

Prenatal screening and testing for chromosome abnormalities is an essential part of antenatal care for the best reassurance for the pregnancy and to protect the unborn. The screening, testing, diagnosis and intervention are integrated and add value in the service chain (Oepkes et al., 2014). For decades, in case of a screening-based risky case, only invasive diagnostic tests (e.g. *chorionic villus sampling* and *amniocentesis*), entailing a miscarriage risk, were offered (Allahbadia et al., 2015). New generation technologies, e.g. genetic and genomic technologies, facilitate innovative services to provide safer and easier screening with higher precision. Since its introduction to clinical practice in Hong Kong in 2011, Non-Invasive Prenatal Testing (NIPT) based on next-generation sequencing of cell-free DNA in maternal plasma has quickly spread on the landscape with its high sensitivity, specificity and little risk of pregnancy loss to assess the most common fetal aneuploidies-Trisomy 21 (Down syndrome), Trisomy 18 (Edwards syndrome) and Trisomy 13 (Edwards syndrome) (Allahbadia et al., 2015) (Kellogg, Slattery, Hudgins, & Ormond, 2014). NIPT is a prominent application of personalized medicine (PM), a field using diagnostic tools to identify specific biological markers to provide the right treatment in the right dose to the right patient at the right time.

However, despite of the admirable advantage, NIPT still has not been considered as the replacement of the currently conventional screening approaches that can assess a

wider range of chromosome abnormalities beyond those assessed by NIPT (Hui & Hyett, 2013) (Long & Goldblatt, 2014) or the diagnostic testing methods that are more accurate and effective in detecting genetic disorders with more affirmative results (Ryu & Kim, 2015). Because NIPT's false positive rates, follow-up invasive diagnostic testing is necessary to confirm the presence or absence of the abnormality (Oepkes et al., 2014). In this way, NIPT is usually provided as an option with non-absolute advantages in the prenatal screening and testing paradigm. NIPT is not a diagnostic test but an advanced screening test (Ryu & Kim, 2015).

## **1.2. Research context and objectives**

In the recent five years, technical disadvantages and clinical limitations of NIPT have been deeply and widely investigated. But the study of the social effects of NIPT application is still far from being sufficient. Our major point of interest in the present study is the possible interruptions caused by NIPT application in the established business models and service operations and practices in maternal and natal healthcare. We suspect that the application of this non-invasive technology would produce invasions to the current service network and transform the value chains in prenatal testing.

Hospital District of Helsinki and Uusimaa (HUS) started to formally provide this innovative testing approach in January of 2015 as an alternative screening method for the detection of fetal chromosome aneuploidies to the women with increased risk factors. Several private clinics in Finland also offer NIPT. We focus on this case, make efforts to explore the application of NIPT from both the provider's view and the consumer's view and detect the possible interruptions and disruptive elements caused by the entrance of NIPT in current prenatal testing service in the district of Helsinki and Uusimaa. More specifically, we are studying the degree of disruption in prenatal testing services market by modelling and comparing the processes before and after the adoption of NIPT. This is based on the postulation that disruptiveness is one possible attribute of innovation. Innovation attributes affect its rate of adoption, i.e. the relative speed with which an innovation is adopted by members of a social system (Rogers, 2010). As disruption is not necessary binary, the degree of disruption can be studied as a variable in connection with the degree of precision or invasiveness. In addition, we would like to propose possible solutions for converting the interruptive innovation to a constructive innovation.

Our research develops new insights into the application of NIPT with a more practical and phenomenological view and also enriches the research of service innovation with the focus on the implementation and interruptions of innovation in knowledge intensive services. There are several reasons why this type of study is warranted. Health services management is facing many challenges related to rising demands, changing environments and stricter budgets that necessitate the exploration of innovative solutions. This means acquiring deeper understanding of the innovation diffusion process and the disruption opportunities in health care services. Personalized medicine and the use of genome data in clinical practice can fundamentally change the integration, coordination and control of health services. Genomic innovations and

technology create both new opportunities and challenges for all the stakeholders from patients to the producers.

## **2. Diffusion of innovations in health services**

### **2.1. Innovation attributes – disruptive or complementary?**

NIPT raises questions of how innovations, and genomic innovations in particular, diffuse in the provision of healthcare services. According to Rogers, innovation attributes, such as relative advantage, preventiveness, and compatibility, affect innovation's rate of adoption. The innovation diffusion process can take many forms: there are for example centralized (top down), and decentralized (client-controlled) diffusion systems. Innovation sub-processes in organizations can be divided into (1) initiation and (2) implementation phases (Rogers, 2010). Disruption in turn is an innovation making things simpler and more affordable. The three enablers of most disruptions are: 1) a simplifying technology, 2) a business model innovation, and 3) a disruptive value network. Examples of health care business models include Solution Shops, Value-Adding Process Businesses, and Facilitated networks (Christenson, Grossman, & Hwang, 2009).

In this study the degree of disruption is seen as a variable and this line of thought is applied to the use of the NIPT in prenatal screening services to investigate the effects and implications of an emergent technology and related services. How does the genomic innovation diffuse? We ask if NIPT-based services represent more of a disruptive or complementary innovation. Which attribute is the one that dominates in the current maternal care services ecosystem? Can NIPT disrupt the prenatal testing market under certain conditions, and if so what is the impact on e.g. value propositions, channels, key partnerships and customer choices? How are the elements of invasiveness and precision connected to the analysis of the disruption opportunities? The answers are searched via process comparisons before and after the entrance of NIPT in maternal and natal healthcare services. In this paper we focus on a public health organization and try to identify and categorize the ways in which this genomic innovation affects the patient choice environment and managerial integration, coordination and control in a large university hospital.

### **2.2. NIPT application in Finnish healthcare**

HUS is the first Finnish public health organization where NIPT has been introduced. At HUS, NIPT is presented as one of further tests, including *Chorionic Villus Sampling* (CVS) and *Amniocentesis*, for indications including an increased risk ( $\geq 1:250$ ) of chromosomal abnormalities based on the first trimester screening and assessment, abnormal result in the second trimester serum screening, fetus' swelling neck (reaching 3-3.9 mm), a high maternal age ( $> 40$  yrs) and a previous pregnancy with a trisomy. General check-up will be followed up if the result of NIPT is negative. Abnormal result in NIPT can be confirmed by further diagnostic test (CVS and Amniocentesis). It means

that the initial screen-positive subgroup does not necessarily undergo a diagnostic test directly based on their preference but is offered with a further selection, which aims to improve women's reproductive choices and reduce the number of patients who will be subjected to unnecessary or unwanted interventions (Long & Goldblatt, 2014). But meanwhile, people choosing NIPT may have to wait longer for confirmative answers. Figure 1 shows the main process of NIPT application at HUS.

*Figure 1. NIPT application in public health service (HUS).*

The latest statistical data show that since the introduction of NIPT, nearly 77% of the patients that were given counselling chose NIPT and around 23% of them chose the conventional tests. There are several cases of rejecting the further tests after the screening. The introduction of NIPT has reduced the number of invasive diagnostic procedures (circa 700 procedures per year previously) and thus also the risks of miscarriage have decreased (van der Meer, 2015).

The adoption of NIPT has introduced a new level of logistics, as the use of NIPT involves taking blood tests and also midwife counselling before and after the test. Because analyzing the samples is not feasible in Finland at the moment, the samples are sent to the United States via Belgium. The blood samples are taken on Mondays

and Tuesdays and the samples for the test are sent by Express mail to GENDIA's lab in Antwerp, Belgium, and the samples arrive there within 2 days. Getting the results from the NIPT can take up to three weeks, ten days being the average waiting time. This can be too long for those approaching the latest possible termination week. HUS is currently the only public health organization offering NIPT but there are plans to adopt NIPT in other university hospitals as well. In conjunction with the NIPT a new Fetomaternal center was founded at HUS and the purpose is to gather together interdisciplinary competences related to fetomaternal care. Women who have higher risk factors can come to FMC for NIPT from all over Finland (van der Meer, 2015).

### **3. Methodology**

#### **3.1. Research approach**

The use of genome data in clinical practice illustrates the transition from intuitive medicine to precision medicine. As far as we know, there is no structured innovation diffusion analysis regarding the disruptive elements and challenges related to the implementation of this new innovative service based on NIPT technology. The use of a new emergent technology creates a research frontier that is studied with an exploratory research approach. Exploratory research is conducted for a problem that has not been clearly defined and it can be used to gain significant insights into a given situation and familiarity with a phenomenon in order to formulate a more precise problem or develop hypothesis. Exploratory research is suitable for this study because it is flexible and can address research questions of all types. (Shields & Rangarajan, 2013)

#### **3.2. Methods: Interviews and Netnography**

We interviewed practitioners involved in the provision of NIPT services (e.g. midwives, technicians, specialists, and geneticists). We encouraged the practitioners to compare their daily work before and after the NIPT and inquired them about the disruptive potential of the services based on this genomic innovation. The conversations were organized around several issues: changes in the workflow, informed choice of mothers and families regarding genetic tests, counselling practices and estimations of further development.

We planned to conduct in-depth interviews with women and families (mainly from the high risk subgroup) living in the HUS region, who had undertaken or rejected NIPT or other prenatal testing services. Since our research application to ethical committee was still in the process of review, the original research plan was compromised and we had problems to access the patient base without the approval. Thus we utilized our personal relationship to contact with mothers who had experiences of prenatal screening and testing (with NIPT or without NIPT) and explored their experiences, expectations and opinions regarding NIPT and its application. Totally, we learned from 2 mothers who undertook NIPT, 2 mother who chose conventional tests before the introduction of NIPT and 4 mothers who got normal results at the early-stage screenings.

In order to enrich the data in the context, we applied netnography (Kozinets, 2002), which has been widely used in recent consumer and market research, as a data collection strategy. Online communication (e.g. internet-based forums, online chat rooms and blogs) has been significantly influencing the life of the contemporary consumers and marketers. It provides relatively objective information on expectations, experiences, decisions-making and consumption behaviors of consumers or consumer groups (Kozinets, 1998). Netnography is interpretive method devised to investigate online communities and communications in a faster, simpler, and less expensive way than traditional ethnographies, and it is more naturalistic and unobtrusive than focus groups or interviews (Kozinets, 1998) (Kozinets, 2002). In this study, we sought for online discussions in Finland regarding NIPT by searching google with the keywords "NIPT foorumi", "NIPT testi", "NIPT keskustelu", "NIPT blogi", and "Nipt tutkimus". Vauva and Kaksplus were the two main websites where people discussing maternal and natal services, with some threads specific to NIPT.

We analyzed practitioners' interviews, consumers' interviews and netnographic data. Practitioners' and consumers' views on the interruptions caused by NIPT in prenatal testing service were separately and thematically organized and presented.

## **4. Findings**

### **4.1. NIPT application opportunities and challenges perceived by mothers and families**

Our data reveals that the majority of women praise NIPT for its positive advancement in prenatal testing, emphasizing the zero risk of miscarriage and its easiness in practice. Some women in the normal group comment that the introduction of NIPT as an option for further tests after the initial screening can increase their autonomy in reproductive decision making.

However, as NIPT is offered after the early screening as an optional further test to women categorized into the high risk group, these women and families who are going through the traumatic experience face the choice challenges. First, safety, accuracy and certainty are the essential considerations of women and families in making decisions on prenatal care services. Since NIPT and conventional tests have their own strengths and weaknesses at these aspects and they cannot serve all goals, mothers and families have to make trade-offs. In Figure 2 the prenatal testing methods are mapped based on their invasiveness (safety) and precision (accuracy and certainty). This diagram illustrates the service ecosystem of prenatal screening and diagnostics from the consumer decision making perspective. It shows how innovation attributes of invasiveness and precision are emphasized in each of the testing services.

Second, making meaningful and informed choices and decisions requires thorough information. Women have difficulties to concentrate and rationally process the

information on prenatal screening and make choices in an anxious state of mind that they have never prepared to face. Some women even refuse to search for information online or offline, because they want to avoid the scary texts and shocking pictures, which increase their anxieties. In addition, women and families appreciate more experiential information, not just scientific or statistical information about the prenatal testing methods. But since the high-risk subgroup that needs the further tests is minor and the NIPT application in Finland is at early stages, it is impossible for women and families to find a vast amount of experiential information online or offline. Thus, to some extent, the unique and appealing aspects of NIPT do not always bring freedom to women and families, instead NIPT application could complicate women's decision-making processes in prenatal care and women may require more resources and support to make choices that align with their needs and preferences in such out-of-expectation situations (Farrell, Agatisa, Mercer, Smith, & Philipson, 2015).

*Figure 2. Invasiveness (safety) – Precision (accuracy and certainty) diagram of prenatal screening and testing methods.*

## **4.2. NIPT application opportunities and challenges perceived by practitioners**

From the viewpoint of the service providers the use of NIPT entails both opportunities and challenges. In the interviews the following advantages and opportunities of NIPT were mentioned: its cost-efficiency and safety, the fact that it empowers women via wider reproductive freedoms and that it reduces the need for invasive tests and thus the risks for miscarriage are smaller. Amid these positive reviews we wanted to dig deeper and ask the service providers about the challenges related to NIPT.

The practitioners brought up the issue of slightly more complicated logistics due to NIPT, most notably the long waiting times, as the blood samples are only taken on Mondays and Tuesdays and sent abroad for analysis. The results then also affect scheduling of counseling with the geneticist and midwives and of the possible invasive diagnostic tests. The midwife we interviewed pointed out that midwives currently take on most of the NIPT counseling and in this work they face certain difficulties based on the fact that patients represent a very heterogeneous group: some are highly educated, some need a lot more explaining starting from the basics, some do not understand the strongest common language properly, and then there is the challenge of always maintaining a neutral, unbiased tone in the counseling, not recommending any specific options, merely explaining their meaning and scope. Same has to be achieved also when there is a translator involved delivering the message.

In order to gain insight into the disruptive elements of the NIPT based services, we inquired the opinion of the geneticist and other professionals about whether and to which extent NIPT could disrupt the prenatal testing market and replace the other screening and diagnostic tests. The consensus at this point of time was that although NIPT has decreased the number of invasive procedures and will continue to do so in the future as the technology gets more accurate and wide-ranging, it cannot entirely replace the other prenatal testing methods. Therefore, it will likely remain a complementary innovation for the most part, as long as diagnostic certainty is required for the termination of the pregnancy. In Figure 3 NIPT is positioned in relation to its disruptiveness and precision based on the interviews.

The practitioners explained that the use of NIPT generates an interesting new challenge. The fewer invasive operations there are, the less experience the physicians get and thus the higher the risks in the remaining invasive procedures. The natural solution to this dilemma is to centralize the invasive testing services in the hands of the most experienced physicians who specialize in these procedures. This means that many physicians lose one previously relevant part of their work, which can be seen as a disruptive element of the NIPT-based service. Allahbadia et al. (2015) state that the use of NIPT in low-resource settings has the potential to reduce the need for skilled clinicians doing invasive testing.

*Figure 3. Disruption – Precision diagram of NIPT.*

## 5. Discussion

### 5.1. Complications related to service operation and decision-making

Challenges in maternal and natal healthcare could be solved by new technology, but the introduction of a new technology may create new challenges. In our case, NIPT application increases the safety in prenatal further screening and testing and brings autonomy for women and family, but it also complicates the service operation and generates choice challenges. Simply applying the new technology to current business models or service chains does not guarantee at all that the true value of the technology will be obtained. This is because the innovation's attributes affect how the innovative service is adopted in healthcare organizations and to what extent it replaces and disrupts the existing market offerings and creates new value propositions, business networks and customer segments.

In the case of NIPT the diffusion process is in the early stages and has been a combination of centralized (top down) and decentralized (client-controlled) diffusion, because the expectations to adopt NIPT at HUS have partly been generated by the use of NIPT in the private clinics. As the service is now available both in the private and public sectors, the disruptive opportunities have increased remarkably, although the complementary elements still dominate as long as the diagnostic invasive tests are required for the termination of pregnancy, and the early screening detects a wider range

of abnormalities than NIPT, although with much lower accuracy. Thus we observe that not all the enablers of disruption have materialized fully: 1) the technology is not sufficiently simplifying, 2) the service is built on existing management traditions, and 3) the role of supporting value networks in the innovative service provision has not been understood and feels distant and unfeasible to the practitioners.

## **5.2. Solutions: increased counselling tied to supported peer-to-peer networks**

To address the complications caused by NIPT, we propose management and decision-making support solutions that facilitate the beneficial use of this safety-increasing and procedure-simplifying technology for all the stakeholders. Regarding integration, midwives, geneticists and genome data specialists partly disrupt the traditional role of the surgeons and physicians due to the smaller need to use invasive operations to detect abnormalities in pregnancy. Genetic counselling is and will have to be even more tightly integrated to the patient-provider relationship in the prenatal testing environment. When it comes to coordination, supported peer-to-peer networks can be used to organize service production facing the mass customization dilemma. Finally, as for control, the non-invasive prenatal testing lowers the technical and other thresholds for acquiring genomic data about risk factors and this disrupts the way in which risk is avoided.

In the world of cutting-edge genomics and precision medicine, the introduction of NIPT has to be supported by the rapidly changing information and the availability of information on NIPT and other prenatal screening and testing methods in an objective and appropriate form (Long & Goldblatt, 2014). But merely providing scientific information related to the prenatal tests and helping women and families to understand the tests is not enough. The demand for counselling is increased as NIPT is introduced. Informed choice requires a comprehensive and thorough counselling in this problem-driven choice situation. Counseling services can be expanded in three ways. First, some counselling services regarding further tests should be offered before or during the initial screening and the possible result of the initial screening should be well explained beforehand. It may help to reduce the shock of women and families when they are informed with the need of further testing. Second, the theoretical information on the comparison between NIPT and conventional test methods is not enough for women and families to make informed choice. The possible results and following procedures, treatment and social services should be explained, so that women and families could be somehow prepared for the possible situations. Sensitive information, e.g. stories about how other women went through similar situations, may help pregnant women make easier decisions. Third, psychological counselling and support is required, especially during the weeks when women and families are waiting for the NIPT result. Stress, depression and anxiety are harmful for the women's health and fetus development. Women undergoing prenatal diagnostic procedures experience more psychological distress (Suzumori et al., 2014), which cannot be underestimated. It is important to listen to women's worries and give enough psychological support.

The problem of mass customization emerges when there are more options and more specific genetic information available, because this information cannot be rationally used by the consumers without appropriate counselling and help, which in turn brings more costs for organizing the services. We consider that there are many ways to solve the efficiency problems related to the need for increased counselling and one of them is to create a trust-inducing environment, a facilitated network based on powerful online tools and platforms, where women and families, practitioners, and relevant third parties co-create and add value by sharing their personal and professional information about prenatal testing and maternal care. This would be a sophisticated decision-making support platform and a research center that also connects similar cases, patients struggling with same kind of concerns, with each other, and hence addresses the psychological counselling issues. This type of establishment of supported networks, based on the willingness of mothers and families who have experience of further tests, will bring benefits: more experiential information from users and more social support. It is crucial for attaining larger value networks and better innovation diffusion to open more channels to discuss NIPT and the user's experiences.

## **6. Conclusions**

### **6.1. Summary and contribution**

This study provides important insights about the introduction of NIPT into prenatal care. NIPT is supposed to be a powerful screening test, appreciated by users and practitioners alike for its non-invasiveness. However, with this study, we discover the "invasive" elements in its application. We identify both the opportunities and problems related to the introduction and implementation of this new innovative service based on NIPT technology. This study demonstrates that NIPT introduces new challenges for pregnant women in decision making and for healthcare practitioners who are concerned about service efficiency and productivity, especially regarding the mass customization dilemma. These findings call for effective mechanisms to ensure that pregnant women or families are psychologically and intelligently prepared to make informed decisions about NIPT and improve the service operation and provision with the introduction of NIPT. Our proposal is that comprehensive and thorough counselling should be tightly integrated to the supported peer-to-peer networks as a way to organize service production and delivery. The new service production process, increasingly based on precision medicine, is moving from intuitive solution shops to supported peer-to-peer networks. In these networks the users can find directly comparable cases and this is one of the ways to solve the mass customization and patient choice dilemmas. The results of this research can be employed to handle management and choice challenges in maternal and natal health care service production that involves the use of new genomic innovations.

## 6.2. Limitations and further research

However, we acknowledge that the study has some relevant limitations that should be considered. The results of qualitative research can give indications as to the why, how and when, and gain familiarity of the research problem for further experimentation and hypothesis development, but generalizations cannot be made based on a case study and caution must be exercised when interpreting qualitative data from the literature review and the interviews.

As NIPT is in its early stages of clinical integration into prenatal care, the responses of participants may change once the screen becomes more widely available. Further studies will be needed to examine the findings among larger and more diverse populations and as the noninvasive platform for prenatal testing evolves. Further studies are also warranted regarding the diffusion of potentially disruptive genomic innovations in other healthcare areas. Although the findings may be limited to our sample population, the data provide important insight into the educational, management and decision-making components necessary for informed uptake of this new technology.

# The impact of service robotics on service work within a healthcare service system

*Michaela Friedrich (née Klemisch), Andrea Rößner<sup>2</sup>,  
Dr. Anne-Sophie Tombeil<sup>3</sup>*

<sup>1</sup>Fraunhofer IAO, <sup>2,3</sup>University of Stuttgart

*Demographic change nowadays has more and more influences on the health care sector. Less nursing staff face more and more patients and elderly people. Those changes on work processes can be observed in the area of prevention but also in the field of medical and elderly care. Technical support in the sense of IT is considered as helpful to support documentation. Nevertheless, support is still required concerning physical interaction in nursing and elderly care. The proposed solution in the paper at hand describes the potentials of service robotics for complex service systems in healthcare, also describing the mutual influences between the possible applications of service robotics and the changes in service work.*

## 1. About the project “SeRoDi”

The staff in the health care system, especially for nurses for the elderly and in hospital, can benefit from modern robotic technologies. Robotics may disburden them from routine jobs and help at physically exhausting tasks. Currently, nursing staff needs about 20 percent of their working time for jobs which are not about care, but about transporting waste or dirty laundry (cf. Simon et al., 2005). This means that the physical and mental stress is high for the nurses. Through service robotics, this stress can be reduced. Patients and residents can benefit from the use of service robotics as the service robotics may help them in their daily life or give cognitive stimulation.

This situation is the initial position for the research project “SeRoDi” which is an acronym for the German expression for “Service robotics for supporting personal services”. The SeRoDi project is funded by the German Federal Ministry of Education and Research (BMBF). Six project partners (four research institutions and universities, a clinic and a retirement home) work on this project, starting in November 2014 until October 2018.

The project focuses on three topics. One focus is the purchase of automated guided vehicles (AGV) which are already in use in big clinics in particular for transporting food, laundry or waste in areas without patients. These AGV will be further developed and be made to assistants for nurses or patients and residents. Another focus in the project is which consequences the use of such technology has on nurses and patients. It is analysed what the technology means for the working conditions, the workload and support opportunities of the nurses, but also for the quality of care and for the acceptance of technology. The next focus is the service research perspective. It is analysed which part of the service system could be supported by service robotics and how service processes will change. The use of service robotics will have consequences for the productivity and the quality of the work.

This last mentioned focus is the topic of the paper at hand. It raises following questions:

- How does the service system change through the development and use of service robotics?
- How does service robotics influence the interaction in the field of medical and elderly care?
- In which parts of the processes in medical and elderly care are potentials for improvements through service robotics?
- Where and how can the productivity and also the quality be raised?
- Which mutual correlations can be observed between the technological development and configuration of the (modular) service robotics, the service work and the design of the overall service system?

These questions should be answered during the project span. This paper deals with a first insight in some of these questions.

## **2. Methodology**

First of all, it had to be decided which kind of service robotics in the form of a mobile care assistant should be tested in the involved clinic and in the retirement home. Additionally, it was important to get first insights in a typical workday, in the service processes and in the use of the originally, non-automated medical trolleys, as these should be transformed to automated guided vehicles. In order to find this out, a three day visit for the research partners in the clinic and the retirement home was organised, followed by feedback workshops.

As a next step, the service robotics are being developed, which will be ready for a first test use in January 2016. In order to be able to compare the work situation and the service processes before and after the use of the service robotics, a set of surveys is necessary. These service instruments are being developed and discussed with the clinic and retirement home. The surveys will be conducted in autumn 2015.

One part of these surveys will be the so called “three component model”, which is a process modelling method developed by the Fraunhofer Institute for Industrial Engineering (Fraunhofer IAO) and the University of Greifswald. This method will help by analysing the service processes and by designing them new.

In the following sub-chapters, the steps are described in detail.

### **2.1. Visits in and workshops with the involved clinic and retirement home**

To get a first insight in the service processes and in the use of the medical trolleys the research partners visited the clinic and the retirement home for three days in spring 2015. In teams of two persons the research partners accompanied the nurse

staff during their shifts. Like this, in the two facilities of the retirement home and in the involved ward in the clinic different shifts (early, late and night shift) were accompanied. The researchers were especially interested in finding out how much time is needed for the care, for administration or documentation, for transport and logistics etc., and which distances the nurses have to go in order to fulfil their jobs. For this purpose, the researchers had tablet PCs with an app (“ATracker”) with categories for different tasks where they could indicate the duration and the kind of tasks and add additional notes if necessary. This kind of documentation was not systematically and stringent, but should just be an assistance to note the first impressions. The tasks which were installed in the app belonged to different categories:

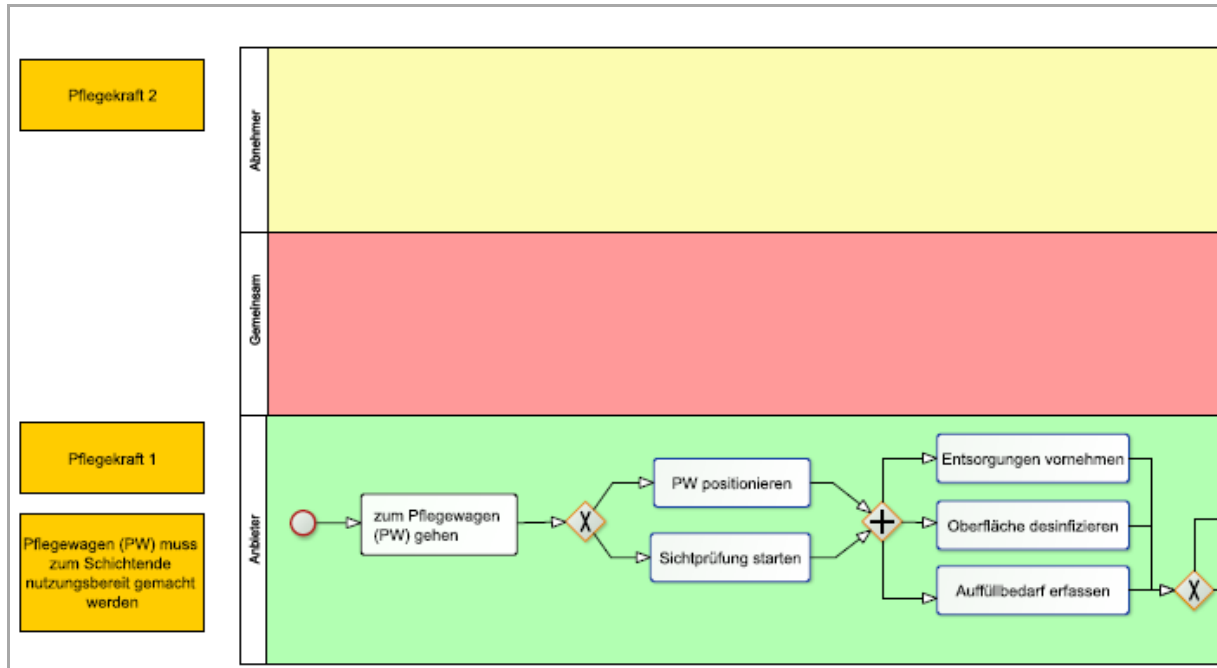

- Autonomous tasks: Tasks which are done by the service giver (here: the nurse), e.g.:
  - Documentation
  - Communication to other persons
  - Giving medicine
  - Cleaning up
  - Transport of goods
- Relational tasks: Tasks which are done in interaction between the service giver (here: the nurse) and the service receiver (here: the patient or the resident), e.g.:
  - Basic care
  - Curative care
  - Emergency care
  - Transport of patients
  - Ward round
  - Direct communication to patients and residents
- Heteronomous tasks: Tasks which prepare the service receiver (here: the patient or the resident) for an active collaboration, e.g.:
  - Information for patients and residents

Additionally, there were categories for other tasks which do not fit in the available categories, and for nonworking time.

Directly after the three days in the clinic and the retirement home, the project partners had short workshops with the nurses they had accompanied in the clinic and the retirement home. The aim of these workshops was to exchange the experiences from the nurses and researchers made in these three days. The researchers reported what they had noticed about the processes (what seems to work well, where could the nurses need support), and the nurses commented on it. Although these workshops were quite unstructured and without preparation (as they were conducted in-

stantaneous after the three days), first opportunities for the use of an automated guided medical trolley turned out.

In the weeks after this visit and first workshops, the researchers developed a first rough process model for typical service processes in the clinic and in the retirement home, based on the information from the visit. The processes are defined with the “three component model”, which will be explained in chapter 2.3., and visualised with “yEd Graph Editor”.

**Figure 1: Extract from process model**

For the clinic, two processes were visualised. Both of them are about the use of the medical trolley. The first process is how the nurses check the content of the trolley at the end of their shift, refill it and prepare it for the next shift. The other process is about the use of the medical trolley when they care for the patients during their shift. The process which was visualised for the retirement home was about how the trolleys with the laundry are used in case that a resident has to be changed and the bed has to be made up with fresh sheets.

For the clinic, it was soon clear, that the medical trolley will be automated and that the process from filling, using and refilling the trolley will be focused. In the retirement home, the decision was more difficult, as there exist many different trolleys which could be automated, e.g. for clean laundry, for dirty laundry, for dishes, for waste.

The researchers prepared additional workshops, one with experts from the clinic, and one with experts from the retirement home. For these workshops, they further developed the focused process for the clinic and suggested three processes for the retirement home. The processes for the retirement home were the following: The use and refilling of the trolley with the clean laundry, the use of the trolley for the dirty laundry and the disposal, the use of a new trolley which contains a basic accoutrement with laundry and offers enough space for the medicine which is needed in a ward round.

In the first workshop, the researchers and the experts from the clinic discussed the idea and the requirements of the clinic for an automated trolley. In the second workshop, the researchers and the experts from the retirement home discussed which trolley from the three ideas is the most useful if it is automated. The experts favoured the third idea with an automated trolley which the nursing staff can take with them when they care for the residents and distribute the medicine.

## **2.2. Development of survey instruments**

After the processes were defined in which automated trolleys shall be tested, the technical partners started with the development and construction of the trolleys under consideration of the requirements from the clinic and retirement home.

The other research partners started the development of the survey instruments. The aim of the surveys is to record the service processes before and after the use of automated trolleys in order to be able to redesign service processes later on. As it is likely that the use of automated trolleys changes the daily work of the nursing staff, changes in the service processes concerning quality and productivity are possible.

In a first step, survey instruments for the analysis of the current situation without automated trolleys are developed. The surveys shall be conducted between October and December 2015, as the test of the automated trolleys will in January 2016.

For the following process steps in the clinic, survey instruments are needed:

- (1) The allocation of care materials at the ward
- (2) Filling the medical trolley with material at the beginning of the shift
- (3) Using the trolley
- (4) Checking the stock of materials and order

At the current stage of the project, the survey instruments are being planned and developed by the research partners and will then be discussed with the participating clinic and retirement home in a workshop. For this reason, at this point of time, the paper can only give a rough idea about the planned survey instruments.

For the first process step “the allocation of care materials at the ward”, it will be observed several times how the care material which is delivered once a week through the automated goods transport system is put away and ranged in the different stores at the ward. It should be found out how much different material is currently stored, how big the packaging units are and which material is ranged in which of the stores and why. These questions are crucial in order to find out how the filling of the medical trolley could be improved in the future, e.g. by ordering smaller packages which fit better in the trolley or by a modified storing which reduces the ways between different stores.

For the second process step “filling the medical trolley with material at the beginning of the shift”, there will also be observations. At the end of the shifts the trolley is re-filled with the material which has been used and expended. These situations will be observed several times and it will be recorded which materials must be refilled and

from which store it is taken. Additionally, in a workshop with a couple of nurses or in individual interviews the nurses will be asked about typical problems and incidents at the refilling process and about ideas for improvement.

For the third process step “using the trolley”, a couple of methods is planned. First of all, the use of the medical trolley is observed. For this purpose, the trolley and/or the nurse is fit with electronic devices which record for example the length of distances, the time needed, the distance between nurse and trolley or the pulse. Additionally, a structured questionnaire is to be filled in by the nurses about the stress and strain at the workplace and about the acceptance of automated systems in the health care system. Then another questionnaire is filled in by the head nurse about the organisation of the ward (cf. Hasselhorn, Müller, 2005). The aim is to analyse and evaluate the organisation of the ward in order to find out how the organisation could change through the use of automated trolleys and how this would be accepted.

For the last and forth process step “checking the stock of materials and order”, documents about the orders of material from the last twelve months will be analysed in order to find out which material is needed in which amount over a period of time. This could give hints how the storage could be reduced and which material is currently not stored in the trolley although it is constantly needed. Additionally, the person in charge for the orders (normally the head nurse) is interviewed about the characteristics, routines and possible changes in checking and ordering materials.

From all these analyses and data, process models will be developed for the four different processes. These models will be created with the three component model, which is explained in 2.3. The process models are discussed in a workshop with responsible persons from the clinic (e.g. head nurse, health care leader) to check if the processes are correctly represented and to change them where necessary. In a second part of the workshop, the processes are discussed with regard to possible improvements regarding quality and productivity, especially, but not only, through the use of automated medical trolleys.

For the processes in the retirement home, similar survey instruments should be applied, although the process steps differ somewhat. In the retirement home, the trolley which will be automated in future is currently used only for the transport of laundry. It is planned to automate it and to make it to a trolley which contains additionally basic care materials and, if possible, medicine. Thus the current processes which are object of the analyses are the following:

- (1) Taking the laundry from the basement to the storage in the residential area
- (2) Filling the trolley with the laundry
- (3) Using the trolley
- (4) Taking the used laundry into the basement where it is collected and brought to the washhouse

Like in the clinic, the instruments will be observations, interviews and workshops. At the current stage of the project, the detailed planning about the instruments is not as advanced as for the clinic.

These surveys aim at the representation of the current processes without automated trolleys. The surveys will be conducted between October and December 2015. At the

beginning of 2016, the automated trolleys, which are being developed, will be experimentally implemented in the clinic and in the retirement home for a couple of weeks. While and after this experimental use, the next survey unit will be conducted in order to record the future processes. The survey instruments will be developed in the further course of the project.

### 2.3. The three component model

The three component model is a process modelling method which subdivides different process parts into three components.

In the service process, the provider and the customer refer to each other. They mutually control their constructive action. For service providers, it is characteristic that they need to integrate the customer. They are reliant on the cooperation of the customers. To be able to offer the service, it is for example necessary that the customer is present at a specific place to a specific time, or that he gives certain information (cf. Bornewasser et al.; 2014).

Every service process consists of sub-steps, which are corporately generated by provider and customer. Some sub-steps are generated by the provider, some by the customer and some by both together. Consequently, three different components of the service work can be distinguished: activities, which conduct the provider, activities, which conduct the provider together with the customer and activities, for which the provider gives instructions to the customer (cf. Bornewasser et al., 2015).

The first mentioned activities are the **autonomous** component of the model. The second mentioned activities are the **relational** component. And the last activities are the **heteronomous** component.

The provider is in an autonomous position, and the customer temporarily resigns his right of proposal because he expects to satisfy his needs in this way. There are never two autonomous partners in a service situation. It is always one autonomous partner who gives specifications and, relational to this partner, a heteronomous partner, who is integrated into the service. He can participate, he can disturb or he can quit the system. Concerning these decisions he is quite autonomously, but as soon as he engages in the service, he is heteronomously governed by the other partner (cf. Bornewasser et al., 2015).

This approach leads to a structured representation or model of service processes. The model contains three stripes. In the green stripe, all the process steps which the provider conducts autonomously, are recorded, in the red stripe, all the collective made steps, which are coordinated by the provider, are recorded, and in the yellow stripe the heteronomous process steps, which are conducted by the customer, are recorded (see figure 2).

|           |  |
|-----------|--|
| Abnehmer  |  |
| Gemeinsam |  |
| Anbieter  |  |

**Figure 2: Empty pattern for three component model (cf. Bornewasser et al., 2015)**

In this model, all process steps should be registered in chronological order and categorized in the three stripes.

The aim is now to improve service processes, which means to increase the productivity without downgrading quality. Originally, productivity means the proportion between output and input (cf. Ganz et al., 2013). The productivity could be increased in different ways: the same result could be achieved in less time or with fewer resources or with less process steps (cf. Bornewasser et al., 2015). But a process oriented productivity definition focuses on the analysis of the service process with all its steps and the question, if the current arrangement should be kept or changed, in other words, if the process should be reorganised. For the three component model, it is also important to decide how the process steps should be distributed in the different components (stripes) (cf. Bornewasser et al., 2015).

For those service steps which are conducted only by the provider and which the customer does not notice, many productivity rules from the industry can be adopted. But if the provider acts together with a customer or if the provider delegates process steps to the customer, the customer needs, customer wishes and the customer contact must be considered. This means that in services the relational parts should be as little as possible, as far as it does not impair the customer wishes. The steps in the relational component (the red stripe) should be changed and made to heteronomous steps (which requires good and precise instructions from the provider to the customer) or to autonomous steps.

In summary, productivity of services results from three aspects (cf. Bornewasser et al., 2015):

- Service providers improve or automate components which they can design on their own.
- Service providers explain the customers how the service process works and navigate the customer through the process.
- Service providers design all the cooperative and interactive service steps in a professional way and replace the direct parts with indirect parts (for example information via electronic devices or guide signs instead of personal communication).

The three component model will be used for the visualisation of the processes in the clinic and in the retirement home. With the rules for productivity and quality in mind, suggestions for further improvements of the processes and a reasonable implementation of the automated trolleys are made.

### **3. Summary and conclusion**

The experience in the project so far showed that it is important to get a first impression of the processes in the facilities in question before starting with concrete and structured surveys and that the technical possibilities and the needs of the facilities have to be balanced permanently.

This is why the research partners first of all visited the clinic and the retirement home impartial and then identified together with the experts from the facilities the processes which should be further analysed and in which an automated trolley could be integrated. The functions which shall have the automated trolley are developed in the field of the technical possibilities and the requirements of the facilities.

With the three component model, a suitable method is found to visualise the current processes and to find point where the process could be improved by automated trolleys or just by the change of service steps.

It elaborates and makes the learning process explicit based on theory of expansive learning.*

## 1. Introduction

The digital era revolutionizes traditional hierarchical and sector-specific service provision: roles of professionals and employees, organizations and managerial practices are changed. Digitalization calls for *new forms of institutional change and learning*. View of single organization, service or profession does not make sense anymore. Social, economic and environmental challenges demand co-creation between service providers. There is a critical lack of research attention on management of digital disruptions in political, organizational, and professional levels.

Emergence of digitalization and mobile applications accelerates scale-up process of services and service systems, but complex relationships in the value network obfuscate the wider purpose of the services and their influence on everyday life of citizens. Who is in charge of potential negative effects and risks? Who should learn from impact of system innovations? Where is the locus of learning for complex value networks aiming at solutions for societal level problems? We claim that the development of new organizational and institutional forms in the digital era *needs new methods, models and arenas for collective, intentional learning and collaborative experimentation* in and between value networks.

The aim of the paper is to outline an intervention method for enhancing inter-organizational learning. The paper explores how organizational learning theories have been present in discussion on co-creation of value networks and ecosystem management so far. Potential risks as impediments and motivational factors as opportunities for learning are identified and weighed up based on previous literature. Ways of tackling the risks and preparing the arena ready for co-creative encounters and learning between value creators are discussed. Then, it elaborates and makes the learning process in a value network explicit with theory of expansive learning.

## 2. Everyday life of the citizen as a basis for digitalized service innovations

As service dominant (SD) logic becomes the prevailing way of organizing offerings, customers are considered as active co-creators of value adapting the service to their individual needs. Service suppliers' motivation is to understand and improve customers' mundane practices in order to create value for the customer. This means not only getting feedback from customers during the service, but even gaining understanding of where and how supplier's offerings fit customer's overall activities. Co-creation opportunities are integrated into the service itself, in supplier's encounters with the customers. Mobile services are designed to engage customers to co-create innovative goods, services and experiences. In certain industries, parts of the services are shifted to be the customers' own responsibility by re-distributing activities of the traditional value chain, such as in IKEA concept the customer is expected to do most of the assembly of the furniture. (Payne; Storbacka; Frow, 2008.)

The firm-centric view of constructing services is challenged by communities of connected, informed, empowered and active consumers. The quality of customer experience becomes dependent on how interactions for co-creation of value have been facilitated. Individual consumers need to have access to firm's knowledge. Co-creation needs transparency of processes and continuous dialog, this even leading into personalized understanding of the risk-benefits of different alternatives of the services. (Prahalad; Ramaswamy, 2004.)

Although this promise of co-creation within a single service is huge, we still have some doubts on how mundane needs of citizens guide service integrations. When we think new digital service innovations from the point of view of everyday life of the citizen and a potential user, we should even go further than SD and ask how digitalized services change the everyday life of the customer in the first place. Can the citizens really influence on offerings of the suppliers based on their needs or are they first offered a service which they then start to modify, although this is called a co-creation opportunity?

Understanding citizens' life in a holistic way, not only as a service user, may open a new perspective to innovating new services. For example understanding continuities, disruptions, rhythm and routines in everyday life of the elderly people could contribute to designing new service offerings for the elderly (Kivilehto; Ritala, 2014). Research on what kind of everyday life produces wellbeing of the citizen (Korvela; Tuomi-Gröhn, 2014) may draft another kind of 'big picture' on how and what services should be digitalized or what kind of services should be integrated.

The frontline employee's role representing dyadic customer-employee interactions is in transition in the complex and digitalized service environment. As service employees' role may seemingly fade away as a face-to-face servant when the technological interface pushes them into the back offices, they may adopt new roles as *innovators* of new services, *enablers*, helping customers using the technology or *coordinators*, taking care of the integration and bridge-building between different offerings. (Ostrom & al, 2015.) However, the focus of research and intervention efforts on frontline employees as service innovators has been scarce (Hasu; Saari; Mattelmäki, 2011; Saari; Lehtonen; Toivonen, 2015). Case studies so far indicate that empowering and allowing employees bring their customer knowhow and ideas into service innovating

increase preconditions for development, improve services and have positive influence on their wellbeing (Hasu & al., 2014; Honkaniemi; Lehtonen; Hasu, 2015). Employee's participation to learning between organisations in value networks could bring a significant breath of everyday life of themselves and their customers into interventions. Focus in *customers' mundane life* and how to provide customers and employees support to enable mutual learning processes is *the first challenge* for the intervention.

### **3. Trust and distrust in creation of new relationships**

In the digitalized world, integration and knowledge sharing between service providers may be accelerated. Liquefying information resources enables novel integration of service offerings and changes the dynamics between organisations. ICT becomes like a nerve system enabling learning in the value network. Intermediaries turn into infomediaries, which support the value network and connect the provider organizations and thus bring all the resources available for the customer. However, supplier organization needs a new kind of strategy, including arguments with whom to network with. Both service research and innovation studies have identified trust between partners an avenue for shared efforts. Lack of trust in sharing critical information between partners may take place as a fundamental impediment to collaboration and systemic innovations. (Lusch; Vargo; Tanniru, 2010.) According to service innovation studies (Fuglsang, 2013), development of trust is a critical factor to determining whether actors begin and continue to collaborate with each other to accomplish an innovation.

How to build *trust and openness* in a value network is *the second challenge* for the learning intervention. Trust refers to "willingness of a party to be vulnerable to the actions of another party based on the expectation that the other will perform a particular action important to the trustor, irrespective of the ability to monitor or control that other party." (Mayer; Davies; Schoorman, 1995, 712). In other words, when you trust someone, you are willing to take a risk, but you assume the intentions of the other party to be good. Since value networks are complex constellations of organisations, trust between parties make collaboration between them less formal. Formal agreements can be simpler, shorter and less specific. The focus of working together may be focused on acting more than monitoring the actions.

According to recent research on trust, it is not considered as a unidimensional construct. Instead trust and distrust can be seen to exist simultaneously. Trust contains a feeling of hope and willingness to become vulnerable to the trustee. While distrust contains fear and actions to buffer oneself from the conduct of the other party. In multiplex working relationships in modern organisations it might be most prevalent that collaborative parties have both sustained trust and distrust attitudes. Distrust allows us to set boundaries around another's behavior yet permitting the functional interaction. Scholars (Lewicki; McAllister; Bies, 1998) even think that healthy dose of both trust and distrust forms a productive tension between the collaborators leading into high performance.

While communication is increasingly becoming electronic in modern working life, we may ask is it possible that trust between parties emerges without face-to-face interaction? Research on comparison between electronic online negotiations and face-to

face communication prove that trust becomes milder and parties become less satisfied with their negotiation outcome in online negotiations (Naquin; Paulson, 2003). We may draw a conclusion from that creating a shared idea of a new service demands a chance of face-to-face communication between value creators. However, paradoxically, prospects of digitalized services rely often to an expectation that everything can be digitalized, even services traditionally based on human face-to-face interaction such as care, teaching or managing.

Trust can also be seen as an evolving phenomena in dyadic relationships. Study on network dyads in entrepreneurial settings has analysed the formation of a productive and successful alliance to be developing in three phases. In the first phase preconditions for exchange are established. Knowing each other from previous working history and knowing each other's reputation and competences reduces uncertainties and enhances early cooperation. In phase two conditions for mutual trust increase in safe spirit if partners move to developmental trial period in which the new idea or business is experimented in incremental way. One firm has to be the initiator, but the other must be willing to respond to the requests for gaining mutual engagement and trust. Mutual economic advantage is necessary but not sufficient rationales. In the third phase integration occurs in operational, strategic and social control levels. The partners become interdependent from each other. Strategic integration extends the collaboration from routine coordination to new joint projects to improve old or develop new products or services. (Larson, 1992.)

In the early development of a value network it may benefit from a presence of facilitators who help the participants generate new ideas and value (Fuglsang, 2013). Facilitators may provide a trust bridge between parties before they know or trust each other (Manring; Moore, 2006). Trust between parties could be an issue which could be worth of bringing into the consideration before starting the collaborative effort. However, as observations of evolution of the dyadic entrepreneurial relationship indicated, trust is something which will grow along the shared effort.

#### **4. Societal problem as a motive for intentional network learning**

Many social, economic and environmental challenges are too big to be solved by individual product or service innovation created in individual organisations. Service research is currently facing the challenge of how to examine and develop innovations at the systemic level (Ostrom and al., 2015; Toivonen, 2015). Inter-organizational learning is needed when the problems to be solved are so complex and multifaceted that pre-existing power relations are not able to solve them. Although scholars of service research have recently used the concept of learning (e.g. Lusch; Vargo; Tanniru, 2010) in their texts, it has mainly referred to how firms could learn to serve a customer or how a firm could learn to become vital and sustaining part of the value network. Learning has been described as an adaptation process to customers' needs, which liquefying information resources via digital communication and computation has accelerated and shifted into macroscale without pondering whose intentions and motives are guiding the overall development of the service system. In service research, learning in the level of entire value network related to a societal problem is still waiting to be elaborated.

In the ecosystem management literature, in the area of sustainable development and nature ecosystems we may find studies dealing with inter-organisational learning and learning in networks (e.g. Manring, 2007; Mandell; Steelman, 2003; Manring; Moore, 2006). This literature points out that a transcendent vision and a unifying purpose among stakeholders is needed for generative learning. Previous power-relations between stakeholders may be re-formed by constructing a new sustained culture of decision making through consensus. In addition, a growing spiral of trust and nonhierarchical integration between stakeholders are important for promoting systemic change. (Manring, 2007.)

These empirical analyses of long term projects have used organisational learning theories to identify and outline the dynamics of their success. They have referred to organizational learning scholars such as Chris Argyris and Donald Schön (1978), Mark Easterby-Smith and Marjorie Lyles (2003) and Peter Senge (1990), who are concerned on explanatory mechanisms for success and failure in organizational renewal from the managerial perspective. However, this literature does not guide what kind of method or facilitation could lead into inter-organisational learning and productive co-creation between stakeholders.

Theory of expansive learning derived from cultural-historical activity theory provides an avenue for the interventionist framework. In activity theory, the concept of object is central (Leont'ev, 1978). The object embodies the meaning, the motive and the purpose of a collective activity system or even systems. Different participants take different partial perspectives on the object, it is internally contradictory and constantly changing. In network context we may say that the concept of object is resembling the notion of shared vision, but the notion of object is theoretically more grounded (Miettinen, 2005).

Expansive learning in a community begins when, during the course of activity, some individuals begin to question the current goals, patterns and norms, even the basic motive/need of the activity, and search for new practices. In some cases, this escalates into collaborative envisioning and a deliberate collective change effort at grass-roots level (Engeström 1999, 2001a, 2001b), after which a new motive and expansive cycle follows. Engeström (1987) proposed this as a new form of learning: *expansive learning* of cultural patterns of activity that do not yet exist, and which therefore involves *horizontal or sideways* learning and development (Engeström 2001a, 2001b). Individuals' and groups' transformative agency, their intentions to make a change, are at the core of expansive learning even in multilevel inter-organisational innovation processes (e.g. Toiviainen, 2007) and in new forms of collaboration (Engeström; Kajamaa; Lahtinen; Sannino 2015).

The third challenge for the intervention is to persuade and stimulate potential actors *to co-create/ find an ambitious shared vision or object that potentially solves a societal level problem*. To make the vision or shared object doable we should define an experiment of the new activity to test it in a concrete way.

## 5. Learning in value networks as a new method

### 5.1 The learning process as an intervention in a value network

Interventions enhancing employee-driven innovating from bottom-up in a service organization based on practice-based learning (Ellström, 2010) activity theory and human-centred service design (Hasu and al. 2014) pave the way for learning in a multi-actor-network inside an organisation. However, an intervention between different organisations as value creators expands the focus into inter-organisational and societal level, without excluding the meaningful principles needed in learning in employee-driven innovation.

In the following, we present a method for learning in value networks, based on how to tackle the three previous challenges concerning including needs and holistic understanding of the users, trust between value creators and forming an ambitious shared object. Theoretical principles for the method derive from the expansive learning theory, but we aim to its novel practical solution. We describe first the methodological principles and then the phases of the intervention process.

#### *Bringing the everyday life of citizens as a motive for change*

This principle relies on the expectation that frontline employees and citizens using existing services bring an important perspective for altering the services both in incremental or radical way. Employees have often an in-depth understanding of the service from the user's perspective. Workshops are an arena for making this hidden knowledge explicit by letting employees play with different user roles. Human-centred design methods (e.g. Brown, 2009) offer many practical means for this. On the other hand, the everyday life of the citizens should be studied as such and used as a leverage for learning. Research interviews exploring the everyday life of e.g. young or elderly could provide a resource for opening needs of users from a more holistic perspective, not just as users of a single service. Learning in value network should include possibilities for users to become as co-innovators of their own services.

#### *Investing on trustful relationships*

As value networks tend to evolve more and more complex constellations of organisations, which have different mechanisms of making profit, building trust between them becomes critical. Hectic working life and digitalization has changed communication between organisations increasingly electronic (Naquin; Paulson, 2003), which may not be suitable and sufficient media for co-innovating, elaborating long term visions or building trust. Learning in a value network requires a chance to face-to-face interaction, time for encounters and reflecting different alternatives between value creators. Based on research of strategic alliances (Larson, 1992), there may be a tendency that a value network evolves around people who have a common working history or previous acquaintance. Facilitators should act as a trust bridge and bring also new value creators to the network.

#### *Expanding the object of activity to system level*

Persuading and stimulating potential actors to co-create/ find an ambitious shared vision or object that potentially solves a societal level problem is probably the most difficult challenge for the intervention. It may be triggered with the help of indicating

existing ruptures, disturbances and troubles leading into questioning of the present service, as suggested in developmental work research. Learning from more advanced examples or with more knowledgeable partners is another strategy. In the workshops, examples from other service contexts could be used as a leverage for collective insights. Policy-level actor who is concerned of national level impact of different developments should become a mentor for the entire value network for keeping the focus in wide perspective.

### *Reflexive learning through tool use and collective evaluation*

Learning in a value network is enhanced by activity-theoretical classic principle of double stimulation (Vygotsky, 1978). The participants are offered practical but inherently conceptual tools for analysing and making sense their shared activity and for making intentional decisions how to proceed in their “zone of proximal development”. Developmental impact evaluation for innovation networks (Saari; Kallio, 2011) offers practical guidelines how to learn and evaluate in a network between researchers, users and policy actors. Collective evaluation of impact of services as well as evaluation of experiments representing future services serve as arenas for reflexive learning for the value networks.

The phases for learning in value networks are:

- 1) *Constructing the value networks*: In this phase researchers meet and interview potential value creators in each organization and discuss their current routinized work and horizons for change. Although a shared vision or object is not yet formed, the facilitators may involve unfamiliar value creators to the discussion. The aim of the first workshop, which is organized for each value network, is to build trust between potentially innovative value creators and play with alternative visions.
- 2) *Visioning for all the value networks*: Basis for visionary service integrations are searched in a workshop from mundane needs of the citizens. Service integration and digitalized service models are used to expand the horizon of the value networks. Each value network is guided to form a shared vision and become inspired by each other's aims. Each value network nominates and is provided with a societal actor as a mentor to guide the new digitalized service integration to become societally relevant, feasible and impactful.
- 3) *Learning between value networks*: In this phase researchers organize workshops between two local value networks which may learn ideas, ways of managing, ways of relating etc. from each other.
- 4) *Defining the innovative experiment by the value network*: In this phase each value network defines an experiment which implements the shared vision. Researchers help to explain the experiment in a form of a model, concept or prototype, in order to be able to gain support and wide understanding.
- 5) *Experimenting novel service integration*: In this phase each value network conducts a small-scale experiment, which may take 3-6 months. The experiment is realized together with the users of the service or services. The researchers follow the process and collect data on impact of the pilots in each value network.
- 6) *Developmental evaluation and scale up*: After the experiments have been finished, all the value networks are gathered to a workshop to reflect on what has been generated and to design how the scale-up of the novelty could be

organized. Societal level actors have a role in evaluating the potential wider impact of the novelties.

The learning process could be depicted as a cycle, in which learning between value creators and value networks is taking place. Experimenting phase focus more in learning with the users (Kallio; Lappalainen, 2014).

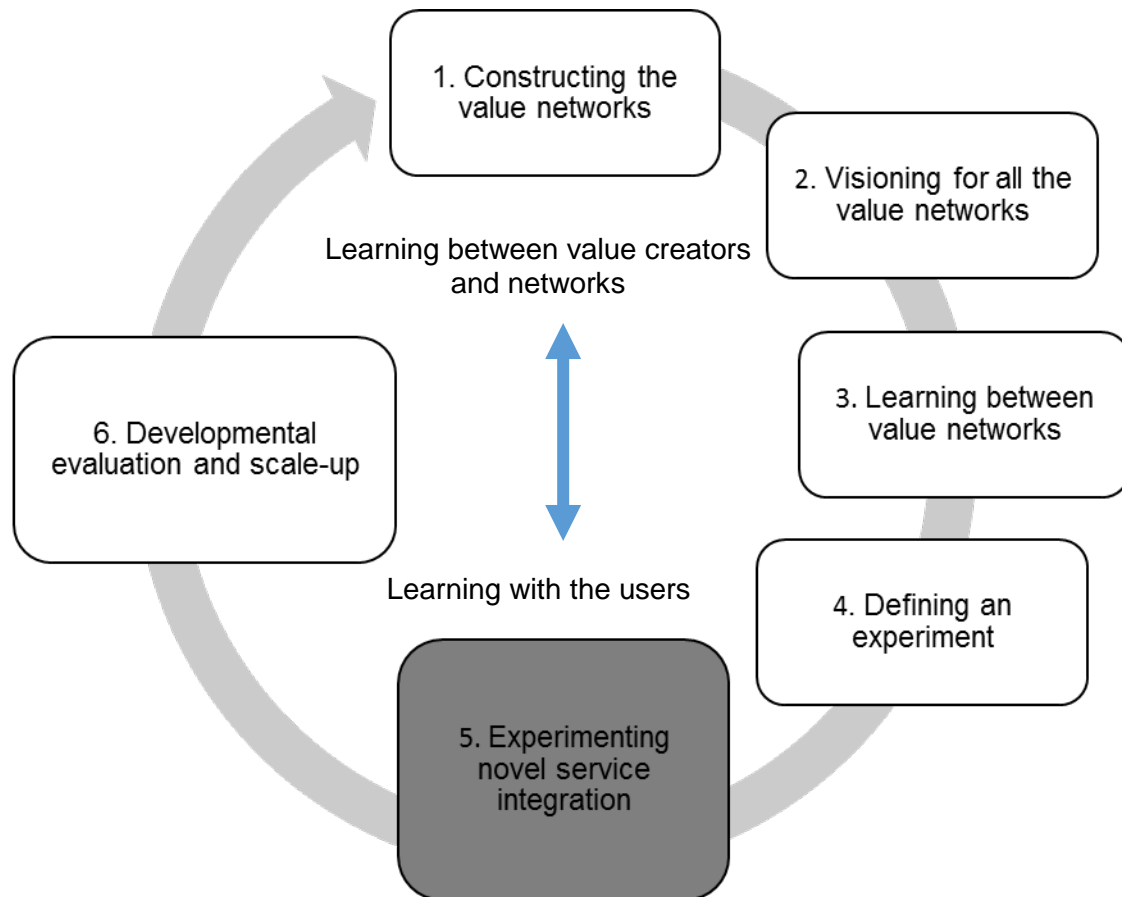

Figure 1: Learning in value networks as an intervention

## 5.2. Cases of complex value network as a locus of learning

In the project of the Revolution of Service Economy – Human Being at the Core of Digitalization (2015-2018), we will organize a learning process between 3-4 value networks. Value networks will co-create innovative experiments in 2016, within three domains; digitalized support services in health care, integrated wellbeing services for the citizens and digitalized learning at primary schools. In the following table we draft what are these value networks about and based on the preliminary interviews of the value creators how could we define their premises according to elements highlighted in the paper.

| Value network                                      | Whose needs in focus?   | Value creators  | Trust/ Distrust (in the beginning)  | Potential societal value  | Experiment of the new activity  |
|--|---|---|---|---|---|
| <b>Digitalized support services in health care</b> | Medical doctors' need for quick online transcripts of diagnosis saving their time for saving lives<br><br>Patients' need for understanding their own health records | -HUS Servis (support services),<br>-HUS Servis in-house IT<br>-HUS, Hospital district of Helsinki and Uusimaa<br>-CGI (IT infrastructure)<br>-Lingsoft (language model)<br>-Arcusys (integration solutions)<br>-ManPowerGroup (staffing in periods of overload)   | Previous pilot project have created a feeling of trust between dyad HUS Servis-CGI  | Transparent, quick, high quality on-line medical records between professionals and patients saving time, improving service and health   | Digitalised medical records pilot 2 managed by HUS ?<br><br>New expert role of the transcriber between MD and patients?                       |
| <b>Integrated wellbeing center</b>                 | Citizens, particularly elderly people's need for active, social and healthy everyday life   | -Public primary health care<br>-Public welfare services<br>-Third sector associations providing recreational voluntary services<br>-Security services<br>-Housing and cleaning services for the elderly<br>-CGI<br>-In-house IT of public services<br>-Peer guides to support learning to use mobile services | On-going integration development in single municipalities has constructed trust between professionals of primary health care and welfare services.<br><br>Third sector still searching its way of acting.<br><br>Peer guides have some feelings of distrust for the digitalization trend. | Saving taxpayers' money in organizing health care and welfare services.<br><br>More holistic and proactive wellbeing services for the citizens<br><br>Orienting elderly people for active and healthy life. | Wellbeing center pilots with mobile services in South Karelia Social and Health Care District   |
| <b>Digitalized primary school</b>                  | Pupils' and families' need for actual, creative way of learning<br><br>Teachers' need for new (digitalized) tools for teaching                                      | -Pupils and families<br>-Public primary school, nursery school, physical education<br>-Edupoli (education services for adults and organisations)<br>- Third sector services e.g. family care and sports<br><br>- Digital platforms to enhance collaboration in networks                                       | Previous pilot project has enhanced collaboration and trust across sectors,<br><br>Ongoing renewals are based on collaboration and trust between municipality, pupils and families,<br><br>Third sector searching its way of acting.  | Educated children to become creative, critical and active knowledge creators for the future knowledge society,<br><br>To enhance equality between citizens and prevent social exclusion                     | Integration of formal and informal education to support the learning in city of Vantaa<br><br>Enhance the learning by novel digital platforms |

Table 1: Critical elements for learning in a value network – preliminary expectations from the interviews

Value networks are constructed between partners who already know each other from previous project history or subcontracting relationships. Each value network becomes

a complex constellation in which trust is not divided evenly, but evolving along their collaboration as the table could be interpreted. In the intervention process, it could be revealing to make the relationships between value creators visible by analysing in depth what part of service is conducted with whom. In each of these cases the public service organization is the most dominating value creator and manager of the network. However, the entire network would benefit from opening up what is the potential societal value of the entire network, and how the future experiments implement it. In the table, the descriptions are researchers' constructions based on interviews of the parties. This kind of a table could work as a preliminary orienting tool for the emerging value networks to ponder together relevant elements for their learning and co-creation.

## **6. Conclusions**

The paper explored how learning approach could support co-creation and novel service innovations in complex and emerging value networks in the era of digitalisation of services. We outlined three challenges for learning and intervention based on previous literature on value networks and inter-organisational learning.

First, a holistic understanding of everyday life of the citizens should guide innovating new digitalised and integrated services instead of reducing the idea of human needs only as users of a single services. Frontline employees' knowledge on customer-employee interactions should be included in innovating new service offerings. Second, building trust and managing distrust between value creators should be secured when constructing complex value networks. Co-innovating between value creators requires openness and transparency between partners. Third challenge for the value network is to create a shared vision or common object which potentially solves a societal level problem.

We proposed an intervention method based on expansive learning theory for learning in and between value networks. Since value networks often form around partners who already know each other, facilitators may work as a trust bridge for including unfamiliar value creators to co-innovating. Expanding the horizon to see what is not yet there, as an intentional collective learning effort of the entire value network may be leveraged by a facilitator and supported by a societal level policy maker. New tools for defining what a value network is and what it should aim at are needed. The paper developed a tool for intentional learning and orienting to the future.

# XXV. International RESER Conference:

## KIBS and the Dynamics of Industrial Clusters: a Complex Adaptive Systems Approach

*B. Desmarchelier\**, *F. Djellal\*\**, *F. Gallouj\*\**

\* Xi'An Jiaotong-Liverpool University, China

\*\* University Lille 1, Clersé-CNRS

### Abstract

*An important and highly debated question in economic geography is how to explain the dynamics of industrial clusters, i.e. their emergence and evolution through time. Two main theories are generally explored, without being confronted: the cluster life cycle theory - which mainly adopts an aggregate point of view - and the network-based approach. Although KIBS are an important actor of industrial clusters, these two theories pay little attention to them as a potential driver of clusters' dynamics.*

*We show in this paper that properly taking KIBS into account requires considering an alternative and integrative approach that conciliates these two theories. In particular, we argue that complex adaptive systems (CAS) constitute a promising basis for such a synthesis. We then operationalize the CAS approach by studying an existing industrial cluster - Skywin (aeronautics in Wallonia region, Belgium) - within this framework. For this purpose, we use an exhaustive list of the innovation projects undertaken within this cluster between 2006 and 2014 and we build temporal innovation networks linking the agents of the cluster. It appears that Skywin's innovation networks exhibit a small-world effect. This implies that any agent who takes part into an innovation project of this cluster can easily benefit from knowledge and information generated within another ongoing project. We argue that this effect is an interesting proxy of a cluster's attractiveness and an appropriate aggregate variable for studying clusters' dynamics as it shows cluster's potential for further growth. We also demonstrate that KIBS are the main responsible for the emergence of this small-world effect in Skywin's innovation networks.*

### Introduction

This paper aims at intertwining – in a theoretical and operational way – three strands of literature: (i) innovation through knowledge intensive business services (KIBS thereafter), (ii) industrial clusters' dynamics, and (iii) complex adaptive systems.

KIBS are services which are processing, generating, and diffusing knowledge within the economy, and as such they are largely regarded as important (co-)producers of innovations (Miles et al., 1995; Gadrey and Gallouj, 1998; Den Hertog, 2000; 2002; Gallouj, 2002), as well as a promising engine for economic growth (Desmarchelier et al., 2013a) and a key component of regional and national innovation systems (Muller and Zenker, 2001) and of technological and sectoral systems of innovation alike. Typical activities are training services, R&D, engineering services and consultancy in its various forms (technical or not). KIBS include both traditional professional services (such as legal services, audit and accountancy, market research, personnel services, management consultancy, etc.) and new technology based services. According to Miles et al. (1995), regarding “*their relation to new technology*”, compared to the latter, the former are “*users rather than agents in development and diffusion*” (p. 27) of new technologies. Universities are often not included into the broad category of KIBS (ex. Muller and Zenker, 2001; Miles et al., 1995). They have indeed many functions (e.g. teaching and fundamental/academic research), which are not directly oriented towards businesses’ technological (and non-technological) needs. However, some of their functions clearly fit into KIBS purposes, especially but not exclusively new technology based KIBS (ex. technical training, technical consultancy, business funded R-D, establishment of research centers in partnership with businesses) and industrial clusters’ studies very often highlight their central role in explaining clusters emergence (Saxenian, 1994; Audretsch and Feldman, 1996a; 1996b). The present study itself also underlines universities’ role in favoring the emergence of new technologies within an industrial cluster. In this paper we therefore include universities and research bodies within the KIBS category and the empirical part is mainly focused on such types of KIBS.

More generally, KIBS’ central role within successful industrial clusters has been emphasized since the birth of this latter concept. Indeed, in Porter’s words “*clusters are geographic concentrations of interconnected companies, specialized suppliers, service providers, firms in related industries, and associated institutions (e.g. universities, standard agencies, trade associations) in a particular field that compete but also cooperate*” (Porter, 2000, p.15). In this definition, KIBS enter mainly into the “*associated institutions*” category, as it includes “*universities, think-tanks, vocational training providers*” (p.17).

An important and highly debated question in economic geography is how to explain the dynamics of these clusters, i.e. their emergence and evolution through time (Frenken et al., 2015; Boschma and Fornhal, 2011). Two main theories are generally explored, without being confronted<sup>1</sup>: the cluster life cycle theory (Menzel and Fornahl, 2010; Shin and Hassink, 2011; Audretsch and Feldman, 1996) - which adopts mainly

---

<sup>1</sup> A notable exception is to be found in Martin and Sunley (2011), whose contribution will be discussed in this paper.

an aggregate<sup>2</sup> point of view - and a network-based approach (Saxenian, 1994). Surprisingly, these two theories pay little attention to KIBS as a potential driver of clusters' dynamics.

We show in this paper that taking KIBS into account requires considering an alternative and integrative approach that conciliates these two theories. In particular, we argue that complex adaptive systems – or CAS - (Martin and Sunley, 2011; Holland, 2012) constitute a promising candidate for such a synthesis. Since these systems are mainly encountered into the theoretical literature (Dilaver et al., 2014; Albino et al., 2003; Squazzoni and Boero, 2002; Boero et al., 2004), we choose to justify our theoretical stance by studying KIBS' leading role within an existing industrial cluster, conceived as a CAS: Skywin (aeronautics in Wallonia region, Belgium).

The remaining of the paper is organized in two parts: we begin by discussing about the competing theories of clusters dynamics and we advocate for the CAS approach, then we conduct our empirical analysis in order to illustrate the usefulness of this theoretical stance.

## **1. Life Cycle Theory vs. Network-Based Approach: the need for a synthesis**

### **a. From product and industry life cycles to cluster life cycle**

The life cycle hypothesis in economics and management literature is, in its original form, a descriptive model aiming at synthesizing in a coherent manner a wide variety of stylized facts about the evolution through time of the marketed products.

Pioneers of the Product Life Cycle (PLC) theory, Utterback and Abernathy (1975) portray product evolution in three successive steps: (i) the “uncoordinated process”, within which firms undertake mainly product innovations aiming at improving their technical performance, (ii) the “segmental process”, where firms modify minor characteristics for increasing product variety and earning market shares, then (iii) the ‘systemic process’ where innovation efforts focus on reducing production costs. These three phases are also and more often labeled: “fluid”, “transition” and “specific” phases (Abernathy and Utterback, 1978). Even though authors claim that *“there is reason to believe that in any cases the progression may stop for long periods, or even reverse”* (Utterback, and Abernathy, p. 645), they insist on the high degree of predictability/determinism in the way products evolve through time. Klepper (1996, 1997) systematizes this PLC into a model of Industry Life Cycle within which firms'

---

<sup>2</sup> This means that the age of the cluster is proxied by just one (or a limited number of) variable(s), which can be for example the number of employees or the number of firms, etc.

entries, exit, growth and innovations in “*technologically progressive industries*” (p. 564) are the driving forces behind the PLC.

The general character of this theory has been challenged by the advent of service economies. In particular, Barras (1986) points out the existence of a “reverse product cycle” (RPC) within service sectors. In this view, service firms acquire innovations (mainly information technologies) coming from manufacturing sectors firstly for improving the efficiency of service operations. Then comes the stage of service quality improvement, and eventually the production of totally new services. The PLC is supposed to be reversed as far as process innovations precede product innovation in the cycle. Likewise, this life cycle theory of the innovation dynamics in services proved to be incomplete. Gallouj (1998) argues that it reflects a “*technological bias*” (p. 128): indeed in Barras model (1986), services cannot innovate by themselves as their innovations mainly come from the use of the so-called “enabling technologies”, i.e. information technologies. Non-technological forms of innovation which are important in services and which concern not only the organization and the process but also the product are not taken into account by the RPC theory. In contrast, Gallouj (1998) finds that many KIBS perform several types of non-technological innovation including “ad hoc” innovations, i.e. custom made innovations adapted to their clients’ needs.

Gallouj and Weinstein (1997) proposed a more complete view of firms’ innovations (whether they originate from industry or services). Adopting a characteristics-based approach of the product – good or service – conceived as a set of technical and service characteristics<sup>3</sup>, they identify six different modes of innovation: radical, improvement, incremental, ad hoc, recombinative and formalization (see Gallouj and Weinstein, 1997 for details). These six modes are not exclusive to each other nor a priori ordered in a pre-determined sequence. Another important point as regards the life cycle theory is that, according to the authors, the PLC encompasses only “one point of entry” for innovations: the technical characteristics of the product. It follows that the Life Cycle conception offers a limited and deterministic view of innovation dynamics. Nevertheless, it is a popular metaphor for reporting industrial clusters’ evolutions.

A first exploration of the Life Cycle theory applied to industrial clusters is undertaken by Audretsch and Feldman (1996a; 1996b). According to them, the main driver of firms’ agglomeration is the low transferability of tacit knowledge through long distances. Following Klepper’s Industry Life cycle, they postulate that tacit/ localized knowledge is important in early developments of a given industry, fostering a certain degree of firms’ agglomeration. However, as the industry becomes mature, a dominant design emerges and the product becomes standardized. Firms thus mainly rely on codified knowledge and information, which are easy to share in long

---

<sup>3</sup> In the Lancasterian tradition (Lancaster, 1966, Saviotti and Metcalfe, 1984)

distances. The initial clustering is thus replaced by a movement of firms' dispersion when the industry reaches maturity.

Even though KIBS are not explicitly mentioned by Audretsch and Feldman (1996a; 1996b), universities are seen by these authors as an important source of tacit knowledge and are thus a key focal point for early clusters' developments. Moreover, knowledge codification process appears to be the driving force of the life cycle. Arguably, services and KIBS in particular are major actors in knowledge processing (Gallouj, 2002) and transmission (Miles et al., 1995; Lau and Lo, 2015) and should thus be regarded as key actors in explaining clusters' evolution. This service-friendly theory is questioned by Klepper (2010), who rather emphasizes the role of a "spinoff process", that is of the emergence of "*firms with one or more founders that previously worked at another firm*" (p. 16).

Menzel and Fornahl (2010) for their part also propose a knowledge-driven clusters' life cycle theory, summarized in Figure 1. Two dimensions of the cluster are considered: the number of employees and the heterogeneity of "accessible knowledge". The main driver of the cluster life cycle, addressed in terms of number of employees, is a gradual process of knowledge homogenization among the members of the cluster. Although similar to Audretsch and Feldman's approach (1996a; 1996b) by the role it attributes to the nature of knowledge in the dynamics of the cluster, this theory has the advantage to avoid too deterministic evolutions from emergence to death, since clusters can always enter into loops of self-sustainment, successive cycles of growth and decline, or even re-orient themselves through a process of "transformation". This adaptability is determined by the degree of knowledge heterogeneity and by the openness to new comers of incumbent firms' networks.

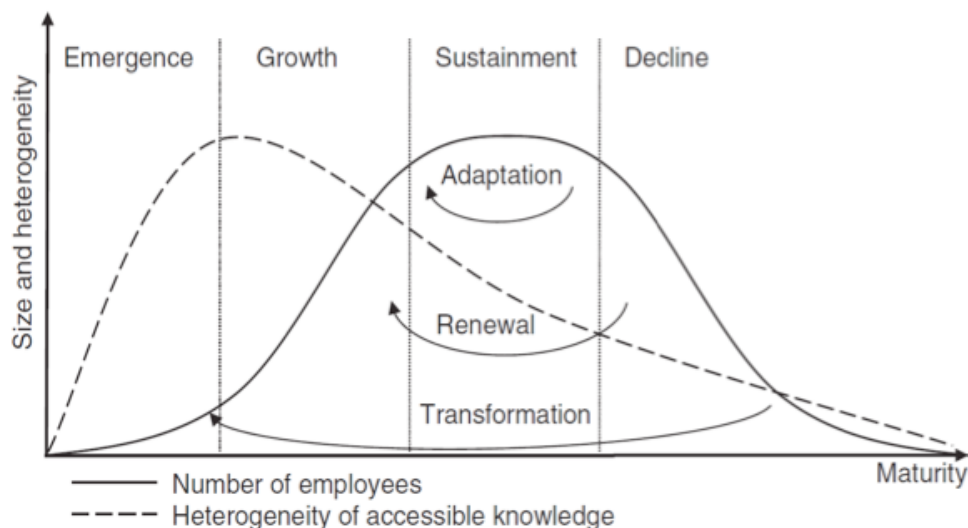

Figure 1: Knowledge-based cluster life cycle (from Menzel and Fornahl, 2010 p. 218)

Interestingly, cluster life cycle theory has moved away from the original product and industry life cycles, as it becomes less deterministic and more influenced by local

drivers, notably clusters' ability to maintain a healthy degree of knowledge heterogeneity (especially through new entrant firms or new "imported" technologies). At the opposite of Audretsch and Feldman (1996a; 1996b), for whom clusters' life cycles are "shaped" by the industries that they belong to, Menzel and Fornahl (2010) consider clusters as more independent entities. However, we argue that this approach remains too restrictive and deterministic since, at least for incumbent cluster agents, it considers only one kind of innovation trajectory, i.e. only one kind of knowledge processing mode, namely: formalization (Gallouj, 2002). Actually, "renewal", "adaptation" and "transformation", i.e. the reverse innovation trajectory or knowledge processing mode (namely differentiation/localization) (Figure 1) are only possible through "external knowledge" (Menzel and Fornahl, 2010 p. 229), thus through exogenous/unexplained factors.

More generally (and beyond Menzel and Fornahl's contribution) another point of criticism towards the life cycle theory is that it gives too few importance to cluster's actors in explaining aggregate dynamics. Indeed, this approach generally considers the cluster – i.e. an aggregation of heterogeneous actors – as a relevant decision maker. Following Martin and Sunley (2011), one can wonder whether "products, technologies, industries and clusters [can] be treated as if they are the economic equivalent of biological organisms" (p. 1301). Besides, even though universities are sometimes cited in early clusters' dynamics (Audretsch and Feldman, 1996a; 1996b), the main actors mentioned are very often the "firms", but we neither know which primary sector of activity they belong to (or whether they all belong to the same sector) nor the nature of the interactions they entertain between each other. Klepper (2010) "spinoff process" is clearer on this point, since spinoffs generally belong to the same sector as the original company – or as the research team in the case of university spin-offs - and are, at first, of smaller size. The exclusive focus on firms is not satisfactory for addressing the clusters dynamics. Indeed, according to Porter (2000), firms are also supported by a number of "*associated institutions*" within clusters, mainly "*universities, think-tanks, vocational training providers*" (p. 17). Regarding the account for the diversity of the actors involved, the network-based approaches are obviously more appropriate.

## **b. Networks and clusters dynamics**

An alternative explanation of clusters' dynamics is focusing on their internal organization in the form of networks of interacting entities. According to Newman (2003, p. 2), "a network is a set of items [called] vertices or sometimes nodes, with connections between them, called edges. Systems taking the form of networks abound in the world". Within clusters, nodes are companies and supporting institutions and the edges are all kind of relations between these actors: common investments in R&D, involvements in the same production processes, common patents or shared resources, etc. However, the network is not only a structure, it is also a mode of coordination that fits between market and hierarchy. From an innovation perspective, the network is considered as a coordination mode that is

more effective than both market and hierarchy. Indeed resorting to the market assumes the establishment of explicit contracts, while in the field of research and innovation, projects are highly complex and uncertain. This makes it difficult to establish explicit contracts, which furthermore raise the risk that strategic secrets might be divulged (Hakansson, 1989; Callon, 1991; Hakansson and Johansson, 1993). The hierarchy for its part reduces transaction costs but involves the risk of bureaucratisation, which (as already foreseen by Schumpeter) may be prejudicial to innovation. In this network tradition, one can mention here Saxenian's (1994) seminal work, comparing the "*network*" or system-based Silicon Valley and the "*independent firms-based*" Route 128. Saxenian argues that this is the prevalence of horizontal networks between firms and research institutions (e.g. Stanford) in Silicon Valley that allowed this cluster to successfully switch from semiconductors to microcomputers during the 1980s, whereas independent firms in Route 128 failed to adapt to the new technological conditions of that time. An horizontal network is in Saxenian's words a set of actors who "*deepen their own capabilities by specializing*" (p. 4), thus whose links are different from just input-output flows.

An interesting observation here is that, in a network perspective, clusters exist and develop because of a specialization process, which is the opposite of the knowledge homogenization generally invoked by the Life cycle literature. However, KIBS can be drivers of both dynamics: formalization of existing tacit knowledge or generation of custom-made (specialized) knowledge (Gallouj, 2002). It follows that if we recognize that KIBS are active members of industrial clusters, we have to acknowledge that both dynamics are possible. This remark about KIBS advocates for an integrative approach recognizing the influence of actors' interactions on the direction taken over time by the cluster as a whole. We argue in the following that Complex Adaptive Systems (CAS) allows integrating, within a single framework, both the aggregate perspective of the life cycle theory and the micro (or multi-agents based) perspective of the network-based approach, without falling into deterministic predictions.

### **c. Complex Adaptive Systems: towards and integration of network and life cycle perspectives**

Martin and Sunley (2011) recently proposed to consider industrial clusters as a particular type of CAS. According to them, a CAS is a system "*made up of numerous components with functions and inter-relationships that imbue the system as a whole with a particular identity and a degree of connectivity or connectedness*" (p. 1303). Furthermore, a CAS is "characterized by non-linear dynamics because of various feedbacks and self-reinforcing interactions amongst component (...). It is also characterized by emergence and self-organization". However, reading from these authors, it is not clear what improvements these CAS bring to Saxenian's network-based framework (Saxenian, 1994) nor to the Life Cycle theory discussed above. Indeed, Martin and Sunley (2011) use a typology of "*meta-models*" covering the various forms of CAS dynamics (inspired by Cumming and Collier, 2005). These meta-models range from deterministic (traditional) life cycles to totally random walks.

Life cycle trajectories are envisaged as special case of CAS among others<sup>4</sup>. Among the proposed models, Martin and Sunley argue that clusters dynamics are well depicted by the so-called “*adaptive life-cycle model*”<sup>5</sup> and they try to adapt it to the cluster dynamics. The resulting “*modified cluster adaptive cycle*” that they propose is reproduced in Figure 2. Arguably, this “*meta-model*” is very similar to the knowledge-based life cycle proposed by Menzel and Fornahl (2010), as we can easily draw a parallel between their respective alternative trajectories: “*constant cluster mutation*” in Martin and Sunley (2011) stands for “*adaptation*” in Menzel and Fornahl (2010), similarly “*cluster stabilization*” stands for “*renewal*”, and “*cluster re-orientation*” stands for “*transformation*”. However, the two cycles are not equivalent: in Menzel and Fornahl (2010), knowledge heterogeneity between firms and other actors explains the emergence of a cluster, and the process of knowledge homogenization drives cluster’s evolution. In Martin and Sunley (2011), there is no general mechanism of evolution, since there is no general principle explaining why a cluster shifts from one phase to another. Instead, these authors propose a descriptive list of potential drivers. For instance, cluster re-emergence is possible thanks to “sufficient resources, inherited capabilities and competencies” (p. 1313) left after a phase of decline, or a constant mutation comes from “high rates of spin-offs” (p. 1313). Apart from a chance factor, there is no explanation of why the rate of spin-offs is high or why the remaining capabilities are enough and up-to-date. Another weakness of their model is that, despite their definition of a CAS, they do not precisely ground clusters’ dynamics in a network-based view of the actors, and the actors are not considered as heterogeneous entities.

Figure 2: Martin and Sunley (2011) “modified cluster adaptive cycle” (p. 1312)

<sup>4</sup> The typology of meta-models of CAS includes the following meta-models (types of complex systems): life cycle, random walk, replacement, limitation, succession, adaptive cycle, evolutionary.

<sup>5</sup> The “adaptive cycle model of the evolution of a complex system” (Martin and Sunley, 2011 p.1307) is similar to the “modified adaptive cycle” represented in Figure 2, minus the alternative trajectories of “failure”, “constant cluster mutation”, “cluster disappearance”, “cluster stabilization” and “cluster re-orientation”.

Although we point out limitations of Martin and Sunley's (2011) adaptive cycle, we find very relevant their proposition to rely on CAS for conceptualizing clusters' functioning and dynamics. Rather than trying to classify such systems, we consider that a general definition and a list of properties can justify this point of view.

According to Holland (2012) a CAS *"consists of a multitude of interacting components called agents [...]. The agents are diverse rather than standardized, and both their behavior and their structure change as they interact"* (p. 57). Furthermore CAS display the following three main features:

1. *"There is no universal competitor or global optimum in a CAS"* (p. 58).
2. *"Innovation is a regular feature of CAS"* (p. 58).
3. *"In a CAS, anticipations change the course of the system"* (p. 60).

Clusters' network structure has already been documented by many authors, including Porter (1998; 2000) and Saxenian (1994). All of them focus on the diversities of the "agents" involved: firms, universities, think-tanks, etc. It might thus be argued that, as structures, clusters are examples of CAS. But do they share CAS properties?

Applied to clusters, the first characteristic mentioned above implies (i) that networks of agents can be found in many technological or market niches, and (ii) that cooperation between specialized agents can always allow for improvements. The remark about niches is particularly relevant for clusters, since the clustering phenomenon reflects a tendency towards regional specializations in very distinctive activities including vine production, sportswear, semiconductors, etc.

Regarding the second characteristic, evidence shows that, within clusters, agents are specialized and that they cooperate in order to be more innovative (Porter, 1998; 2000; Saxenian, 1994). Innovations can take various forms, without following any pre-determined sequence (Gallouj and Weinstein, 1997).

Finally with regards to the third characteristics, it can be underlined that within a cluster, every agent can anticipate/forecast new technological or market opportunities, although their anticipation is imperfect because of bounded rationality (Frenken, 2006; Desmarchelier et al., 2013b). This characteristic is important, because it contradicts the very conception of a from birth to death pre-determined cluster cycle. In addition, unlike Menzel and Fornahl (2010), who introduce exogenous factors as the main drivers likely to change the course of a system, in a CAS approach, clusters adapt because of their agents' individual anticipations.

In conclusion, and as we will try to confirm it in the empirical part of this work, these characteristics seem to fit well with what is known about clusters functioning. Then, how does the conception of clusters as CAS change the way we understand their dynamics?

Our literature review identified the very reason of clusters' existence: the knowledge-seeking behavior of the firms. They seek knowledge from other firms or from other

types of agents – notably KIBS, including universities. But we also identified an important difference between Life Cycle theory and network-based theory, regarding the way they address the knowledge dynamics within clusters: the life cycle theory postulates a knowledge homogenization process, whereas the network-based approach postulates a specialization process. The first CAS property (i.e. no global optimum) fits well with the idea of specialized agents, but the “anticipation” and “innovation” properties are not imposing any type of pre-determined process. Agents are heterogeneous, and KIBS may allow for both homogenization and specialization trajectories, admitting that a general/cluster-level trajectory can be found. The two other CAS properties (i.e. innovation and anticipation) indicate that the alternative routes in Menzel and Fornahl (2011) (i.e. adaptation, renewal and transformation) are the rule rather than the exception in CAS dynamics. It follows that a proper deterministic life cycle is likely to be the reflect of a degenerative cluster (ex. Route 128 in Saxenian, 1994).

Clusters have already been modelled as CAS thanks to agent-based modelling<sup>6</sup> (Dilaver et al., 2014; Boero et al., 2004; Squazzoni and Boero, 2002; Albino et al., 2003). Important question to tackle within this perspective are how specialized agents tie to each other and then how these ties evolve. In this respect, Boero et al. (2004) propose various matching strategies. As an example – for a specific agent – the strategy could be: *“look at the first agent with different technology/techno-organizational asset you meet”* (p. 12). These theoretical efforts are welcome, but the building of relevant models has to rely on a set of well-established stylized facts (Borrill and Tesfatsion, 2011). Discussing about clusters’ dynamics and their main drivers supposes to decide in a first step which aggregate indicators/variables (number of actors, quantity produced, number of patents, R&D expenditures, etc.) and which underlying networks to consider. Unfortunately, to our knowledge, there is still no such empirical study within a CAS framework. Indeed, although theoretically appealing, the CAS approach remains hard to put into practice. We thus propose, in the remaining of the paper, a strategy for operationalizing the CAS framework.

## **2. Clusters as CAS: empirical example and insights about clusters dynamics**

In order to conduct an empirical investigation, we have to make several choices: (a) which industry to study? (b) Which cluster to focus on within this industry? (c) What kind of networks are we looking at? After making our choices, we explore the dynamics of the selected empirical network of agents and we draw general conclusions about clusters dynamics.

---

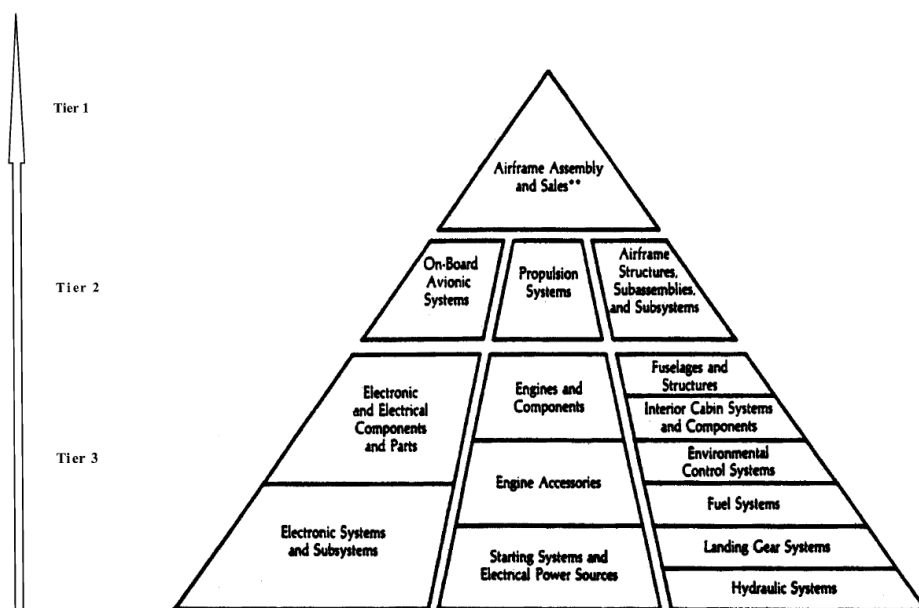

<sup>6</sup> Applied to economics, agent-based modelling is “a computational approach that aims to explain economic systems by modeling them as societies of intelligent software agents. The individual agents make autonomous decisions, but their actual behaviors are constrained by available resources, other individuals’ behaviors, and institutions” (Osinga et al., 2011).

## a. Which industry to study?

The “*non-universal competitor*” principle (Holland, 2012) advocates for the study of sectors with complex technology landscapes<sup>7</sup>, because they are the most likely to offer many niches and thus many opportunities for clusters to emerge. According to Arthur (2009), all products display a tree-like recursiveness: “*the technology is the trunk, the main assemblies the main branches, their subassemblies the sub-branches, and so on, with the elemental parts the furthest twigs ... The depth of this hierarchy is the number of branches from trunk to some representative twigs*” (p. 38). The more complex a product is, the more it relies on a complex technology – i.e. a technology with a high depth. Arthur (2009), among others (Frenken, 2006; Niosi and Zhegu, 2005), argues that the aircraft industry relies on very complex technologies, composed of many subparts.

The resulting hierarchy between producers of various airplanes’ subparts is represented in Figure 3, from Niosi and Zhegu (2005). Following the CAS approach, clusters can be found in any layer of this hierarchy. The biggest clusters include agents involved in top layers, and more particularly the “prime contractors” or “airframe assemblers”: Bombardier in Montréal, Airbus in Toulouse, Boeing in Seattle (Niosi and Zhegu, 2005) or Lockheed Martin in Los Angeles (Scott, 1990).

<sup>7</sup> Kauffman et al (2000) define a technology landscape as a set of values attributed to all the various possible “production recipes” (p. 8), which are represented as vertices of a “directed graph”. A production recipe “encompasses all the deliberate organizational and technical practices which, when performed together, result in the production of a specific good” (p. 4).

Technology landscape is a metaphor originated from biology (Kauffman, 1993) for representing the choice of economic agents when they have to decide what to produce and how to produce it. It states that agents’ initial choice has long term incidence on their adaptability since it constraints their innovation capabilities, this is the reason why production recipes are embedded into a directed graph: it is not possible to switch easily from a recipe to another.

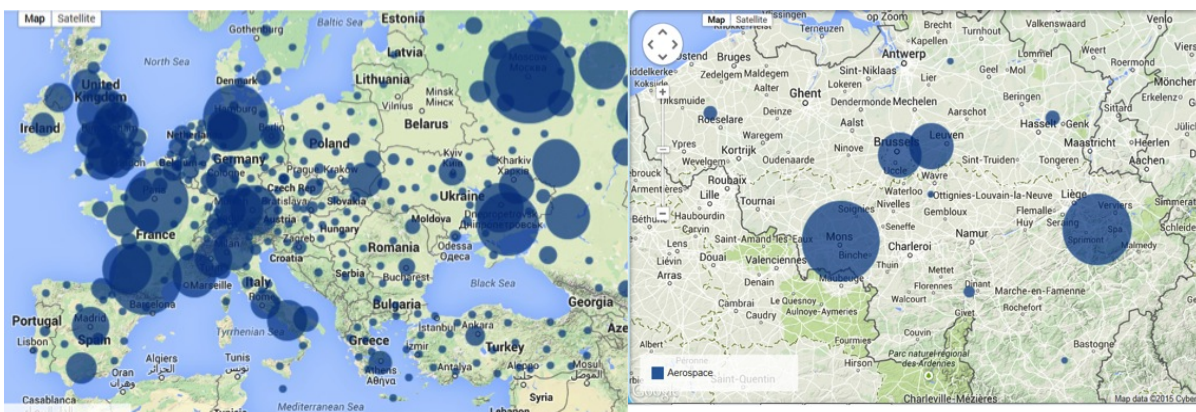

Figure 3: Aircraft producers' pyramid (from Niosi and Zhegu, 2005 p.8)

## b. Which cluster to study?

For every sector, it is common to find contributions focusing on successful/first class clusters: Route 128, Silicon Valley, Detroit, Los Angeles (Saxenian, 1994; Klepper, 2010; Scott, 1990). The most important ones for the aircraft industry have already been mentioned (Montréal, Toulouse, Seattle, Los Angeles) and won't be considered for the present study. Indeed, we rather choose to focus on a niche cluster, for highlighting the difference between the CAS and the more traditional/aggregate (or life cycle) approach of the clustering phenomenon.

In the traditional approach, authors generally study the geographical concentration of employment or companies by industry (Shin and Hassink, 2011; Niosi and Zhegu, 2005; Scott, 1990), or the geographical concentration of production (Shin and Hassink, 2011) or of the innovation activity (Audretsch and Feldman, 1996a; 1996b) for a given industry. Interestingly, there are very few accounts of the actual linkages between these actors, although Saxenian (1994) reported – with the example of the Route 128 – that spatial proximity does not necessarily imply strong cooperation. One can also highlight a very limited account for actors' diversity within this aggregate approach, since only “firms” are generally mentioned.

Figure 4 (left) displays the most recent account for the number of employees in aerospace industry within all European regions. We observe that aerospace employment is widespread, although quite concentrated in Western Europe and Russia. This dispersion is higher than what is observed in the United States and is generally explained by political reasons, notably the need to ensure countries independence (Niosi and Zhegu, 2005). In an aggregate view, we would consider studying the Southwest of France, Northern Germany or South England. However as far as we favor the CAS approach, we rather choose a small cluster. Figure 4 (right) displays a map of Belgium and the regional concentration of employment in aerospace. We distinguish two relatively major poles within the southern regions - surrounding the cities of Mons and Liège – and two smaller poles near Brussels and Leuven. In 2006, all the actors from these 4 poles joined to create an official association called Skywin.<sup>8</sup> We propose to study this cluster.

<sup>8</sup> <http://www.skywin.be/?q=en> (last access: 10 Feb. 2015)

Figure 4: Number of employees in the aerospace industry in Europe (left) and in Belgium (right) in 2011<sup>9</sup>

### c. What kind of networks are we looking at?

As we have already pointed out, a CAS is primarily a network of heterogeneous and specialized agents, which can be described in the following terms: (i) it emerges within (technological or market) niches, (ii) it is strongly oriented towards innovation and (iii) it is quick to adapt to changes in its environment thanks to its agents' anticipations and innovations (Holland, 2012). Skywin is presented as *"a group of companies, training centers and research units engaged in public and private partnership and building synergies around common and innovative projects"*.<sup>10</sup> These projects fit into six main axes that the agents anticipate to be of strategic importance for their future development<sup>11</sup>:

1. Composite materials and processes
2. Metallic materials and processes
3. Embedded systems
4. Airport services
5. Space applications and systems
6. Modelling and simulation

These six themes reflect the niche position of Skywin within the aircraft producers' pyramid (Figure 3), as they mainly fit into some of the third tier activities: fuselage and structure for the first two axes and the electronic systems for the third axe. Interestingly, the fourth one - airport services - is not part of the aircraft production process and it responds to a potential market in developing countries.<sup>12</sup> This exemplifies clusters ability to re-orient their activity through time. The sixth axe – "modeling and simulation" – arguably applies in every parts of the pyramid (Figure 3) since simulation is generally involved in the conception phase of any airplane components. Finally, the fifth axe on "space applications and systems" reveals a specialization relevant for the space industry (not considered in the present work).

Skywin is thus a group of heterogeneous agents, and the main interactions we should look at are those taking place within these "common and innovative projects". An exhaustive list is provided by the cluster website<sup>13</sup>, which covers 46 common projects undertaken collectively between 2006 and 2014. The following informations are provided for every project: the agents involved - classified into two categories

<sup>9</sup> [www.clusterobservatory.eu](http://www.clusterobservatory.eu) (last access: 10 Feb. 2015, the numbers are for 2011)

<sup>10</sup> [http://www.skywin.be/?q=en/mission\\_and\\_strategy](http://www.skywin.be/?q=en/mission_and_strategy) (last access: 10 Feb. 2015)

<sup>11</sup> [http://www.skywin.be/?q=en/mission\\_and\\_strategy](http://www.skywin.be/?q=en/mission_and_strategy) (last access: 10 Feb. 2015)

<sup>12</sup> As an example, it has been reported that 25.2% of flights in Mainland China have been delayed in 2012, 14.9% of them for an "unidentified reason".

(“industries” and “research bodies”<sup>14</sup>) – as well as the total budget (in millions of Euros) and the duration of the project (start and end years).

These informations allow for the building of a bi-partite relational database linking two sets of nodes (cf. the definition of a network): the agents and the projects in which they are involved. This database makes it possible to draw Figure 5. In this figure, red ellipses represent the projects and the blue ones represent the agents, whether they are “industries” or “research bodies”. Links represent somehow the involvement within a project or more exactly the level of expected involvement, as it may be expressed by the budget allocated to the project<sup>15</sup>. The thicker and darker they are, the higher the project’s financial value (and the expected involvement) is. This Figure does not distinguish between time periods: it summarizes all the interactions that took part within Skywin from 2006 to 2014.

Figure 5: Skywin bi-partite innovation network (blue vertices = Agents; red vertices = projects)

#### d. Studying clusters dynamics through innovation networks

In Figure 5, the agents are not directly linked, that’s why we modify the network on the basis of the hypothesis that agents who are participating to the same project are in fact directly linked. We also consider the time dimension and obtain as a result the 9 configurations of the network for each year from 2006 to 2014 displayed in Annex 1. Table 1 summarizes some descriptive statistics of these configurations.

<sup>14</sup> These “research bodies” include universities, training centers and private research institutions. We thus assimilate them to KIBS.

<sup>15</sup> It should be noted that as far as there is no information on how the budget is allocated between the different partners of a given project, the whole budget is associated with each of them.

|             | Number of Actors | Av. Degree <sup>16</sup> | Density (No Loops allowed) <sup>17</sup> | Av. Path Length <sup>18</sup> among reachable pairs |
|-------------|------------------|--------------------------|--|---|

**Table 1: Properties of Skywin temporal networks**

In a traditional – aggregate – perspective, authors focus on the number of actors within a given geographical area. In table 1, we rather report the actors who actively cooperate on a set of common projects. Looking at first at the number of these actors – and abstracting from the European economic crisis during the period - we may consider that Skywin enters into a phase of decline starting from 2010. This general movement goes hand in hand with a decrease in the average degree and networks' densities, which means that the agents who take part to innovation projects are more and more loosely connected. In other words, the cluster loses its attractiveness for potential newcomers: knowledge-seeking agents cannot find enough useful knowledge for exploring their technological or market landscapes, or simply the niches within which Skywin is evolving are not promising enough. Overall, these evolutions are consistent with the life-cycle theory.

However, several elements contradict this pessimistic and deterministic conclusion. (i) The configurations of the network displayed in Annex 1 are particularly dynamic throughout the considered time span. From year to year actors are leaving and others are entering into the network, following projects life cycles. Active actors are thus changing: looking at the network's configurations, we count in total 92 different active agents from 2006 to 2014, although no more than 67 were operating at the same time. This suggests a positive rate of turnover among these agents. (ii) There remain plenty of opportunities for partnerships, as innovation networks' densities always evolve within a range comprised between 17 % and 31 %.<sup>19</sup> In this respect,

<sup>16</sup> The average degree of a network gives the average number of links per agent within the network. For instance, the agents taking part to innovation projects in 2008 were, on average, linked to 13.57 agents.

<sup>17</sup> Network density is the ratio between the actual number of links and the maximum possible in a hypothetical situation where each agent is connected to all the others. For instance, a density equal to 0.52 means that 52 % of the connection possibilities are exploited by the agents.

<sup>18</sup> The path length between two agents *i* and *j* is the shortest distance between them (i.e. the shortest sequence of vertices). The average path length of a network is obtained by averaging all the path length between all the reachable agents of this network. Isolated agents are thus not taken into account.

<sup>19</sup> We omit the density of the network configuration in 2006 (date of the creation of the cluster) because its relatively high value is explained by the fact that the cluster included only one project with several actors..

Skywin accounts for a total of 117 members.<sup>20</sup> Considering the 92 active agents, this highlights both a high rate of cooperation between Skywin members and the existence of unused opportunities. (iii) The path length values in table 1 are always much smaller than the number of agents within the network. This reveals the presence of a small-world effect (Newman, 2003): because of a high rate of overlap between the members of different projects, it becomes easy for any agent – even for a newcomer – to obtain information or knowledge coming from other projects. These short path lengths can thus be considered as a good proxy for evaluating the advantages of taking part in this cluster. Considering the relative stability of this measure in Table 1, we cannot sustain the declining hypothesis that results from the sole observation of the number of active agents.

We argue that, in a knowledge-seeking perspective, agents benefit from the existence of a small-world effect, which itself emerges from a certain degree of overlap between the various projects. It follows that the core agents of a given cluster are those who allow for overlaps to occur. A good way to identify them is to compute agents' degree centralities, i.e. for a given agent  $i$ , to count the number of links he/she has with the other agents in the network. We can also take into account the fact that different links are not equivalent, in the sense that – at least for our current networks – the financial values of the various projects are different. In order to take these links' values into account, we compute the weighted degree of centrality measure proposed by Opsahl et al. (2010).

Be  $\alpha \in [0; 1]$  a tuning parameter,  $k_i$  the number of links connected to the agent  $i$  and  $s_i$  the average weight (or value) of these links, then  $C_D^{W\alpha}(i)$ , the weighted degree centrality of the agent  $i$  is given by the following equation:

$$C_D^{W\alpha}(i) = k_i^{1-\alpha} \times s_i^\alpha$$

The more  $\alpha$  is important, the more we attribute importance to links' values in computing agents' centralities. Top 10 weighted degree centralities for every year and for various  $\alpha$  values are reported in Annex 2. We observe that, in virtually all cases, the two most central actors belong to the “research bodies” category. The University of Liège and the Catholic University of Leuven are particularly central. Industrial firms are also well represented in these rankings and, even though we observe the recurrence of national leaders in the aerospace industry (e.g. Sonaca), they are much more “volatile” than universities in the sense that their relative positions are less stable and that there is a much higher rate of turnover among firms within the top 10.

These results give interesting insights about the drivers of clusters' attractiveness – measured in our case by a small-world effect within clusters' innovation networks. We show that this attractiveness relies on the presence of a stable core of highly

<sup>20</sup> <http://www.skywin.be/?q=en/members>

connected knowledge intensive business services (universities or research bodies in general). Arguably, what determines if a cluster is declining is not the age of the cluster as a whole, nor the number of the (active) agents it includes, but the quality and connectivity of the knowledge intensive business services in its core part. When looking at the number of innovation-active agents, we could say that Skywin is entering into a phase of decline, but a closer look to its innovation networks' properties reveals an attractive cluster and thus show potential for new phases of growth.

## Conclusion

Clusters' dynamics are generally understood as the evolution of an aggregate indicator, like the number of firms operating in a given geographical area. Two competing theories aim at explaining the dynamics of this indicator: the life cycle theory and the network-based approach. Both consider knowledge processing as the main driver but in an opposite way. For the tenants of the life cycle, clusters evolve through a process of knowledge homogenization among their members, whereas the network-based approach considers that knowledge becomes more and more specialized. We argue that KIBS play a major role in both of these directions, and we thus advocate for an alternative/ synthesizing approach.

Such synthesis should combine the aggregate point of view of the life cycle theory with the actor-centered network-based approach, while avoiding their deterministic predictions. Complex adaptive systems are a promising candidate for such a purpose. In order to consider their implications for clusters' dynamics, we conducted within this framework an empirical analysis on a given industrial cluster (the aeronautics cluster in Belgium).

We discovered that this cluster's innovation networks exhibit a small-world effect. This implies that any agent who takes part into an innovation project of this cluster can easily benefit from knowledge and information generated in another ongoing project. We argue that this effect is an interesting proxy of a cluster's attractiveness and an appropriate aggregate variable for studying clusters' dynamics as it shows cluster's potential for further growth. We also demonstrate that KIBS are the main responsible for the emergence of this small-world effect in innovation networks.

## Annex 1: Skywin's innovation networks from 2006 to 2014

These networks have been obtained by formulating the hypothesis that agents' participating to the same project are linked together. All nodes thus represent firms or research centers. Isolated agents are those who are taking part in projects in which they are the only actor involved. In a given graph, darker and thicker links represent partnerships in projects with relatively higher financial values.

*University campus management organizations are challenged by digitalization, decreasing public funding, and low utilization rates of physical premises. In the network of increasingly complex service offerings, taking underutilized operand resources into more efficient uses is a strategy applied by novel service providers such as Hoffice, Uber and LiquidSpace. Hence, this paper explores such services as potential solutions for supporting mobile knowledge workers of university communities and beyond. As a result, a set of service clusters is drawn to help academics and practitioners understand services on offer and their potential implications for the university campus management organisations.*

*Keywords: Service management, Service logic, Utilization, Access, University campus management*

## 1. Introduction

University campuses are focal attractors of global talents and hubs for knowledge creation and exchange. They are globally competing (Barnett 2013, Drori 2013, Poon and Brownlow 2015), monetarily struggling (Van Damme 2012, OECD 2012, Maassen and Stensaker 2015, Kamarazaly et al. 2013), digitally challenged (Carr 2012) and extravagantly utilized (Den Heijer 2011, Den Heijer and Zovlas 2014, Harrison and Les Hutton 2014, Hietanen 2014, Neary et al 2010, University Herald 2013).

When observed through service-dominant logic (Vargo and Lusch 2004), campuses are operand resources that exist to enable exchange and creation of operand resources – education, research and societal impact. The main challenges do not seem to be in limited operand resources per se but rather in an extravagant use of vast operand resources. They are inefficiently used and accumulate costs rather than optimally support operand resource creation and exchange.

Service-dominant logic suggests that services rather than goods should be seen as fundamental basis for value creation (Vargo and Lusch 2004, 2008). The value is seen to be co-created only by interactions of social and economic actors - resource integrators (Vargo and Lusch 2008). Furthermore, the roles of the suppliers are increasingly shifting towards supporters of proposed values that are then created through interactions with the value users, meaning customers. Building on the service-dominant logic, Grönroos and Ravald (2011) argue for service logic suggesting that value is even increasingly controlled by the customers, demand-side resource integrators, in their own processes.

These changes among others widen the engineering and cost-driven approaches traditionally applied in the field of Facilities Management (FM). Coenen and Von Fel-

ten (2012) argue that FM today has to overcome management challenges that go beyond the engineering and cost-driven approach. They suggest a service management approach to be applied in the context of FM.

Therefore, this paper aims to identify potential services that utilize access to underutilized operand resources as a key strategy to support mobile workers of a university community and beyond as resource integrators of campus services. It does so by first pinpointing the research gap through a literature overview of university campuses in spatial transformation, and second, analysing business models of services which, through providing access, are designed to support mobile knowledge workers. The primary data is collected on the internet sites of the services.

The paper is structured as follows: First, it links service theories with literature of university campus utilization. Second, it analyses access-based services by exploring the internet sites of the services through the lenses of the business model canvas (Osterwalder et al 2010). Third, it presents the main findings, and finally, it discusses the implications and limitations, which are followed by concluding remarks.

## **2. Literature**

The service-dominant logic (Vargo and Lusch 2008) suggests that resources can be divided to operand, referring to physical goods, and operant, referring to non-physical resources such as knowledge or skills. Vargo and Lusch (2008) define that all economic and social actors are resource integrators. Kleinaltenkamp et al. (2012) perceive resource integration as means through which resource integrators co-create value which is determined phenomenologically.

Based on the service logic (Grönroos and Ravald 2011), value creation is increasingly controlled by the customers as resource integrators. Hence, Hibbert et al (2012) suggest that customers must acquire the necessary skills and knowledge to be effective resource integrators as they engage in activities that facilitate or create value. This is why organizations have a role in supporting customer learning. Therefore, supplying organizations can be seen as facilitators and co-creators that engage themselves in the customers' processes (Ojasalo & Ojasalo 2015).

University campuses can be seen in very essence as operand resources that exist to facilitate operant resource exchange including knowledge, learning, research and societal impact. The resource integrators can be thus seen in the university campus context to include but not necessarily be limited to students, staff members, entrepreneurs, researchers and the public. Their working and learning activities are increasingly mobile and disseminated around city structures (Laing 2014, Lindsay 2014, Waber et al 2014).

The demand-side resource integrators are also offered multiple services and alternatives for executing their daily routines and tasks individually, and in collaboration with each other (Laing 2014, Digitalworkhub 2013, Lindsay 2014, Waber et al 2014). Consequently, organizations decreasingly dictate the location of workplace, and knowledge workers as space users are provided with more freedom and responsibility of choosing where, how and when to work from (Termaat et al. 2014, Brinko et al. 2014).

University campus utilization is affected by digitalization in forms of Massive Open Online Courses (MOOCs) and totally virtual universities (Carr 2012). At the same time, campuses are struggling monetarily (Van Damme 2012, OECD 2012, Maassen and Stensaker 2015, Kamarazaly et al. 2013) and have low utilization rates globally (Den Heijer 2011, Den Heijer and Zovlas 2014, Harrison and Les Hutton 2014, Hietanen 2014, Neary et al 2010, University Herald 2013). They used to be funded by large with public funds which in general have been decreasing steadily with the tuition fees increasing in the systems where tuition fees are applied (Levy 2013, Bernasconi 2013, Fincher and Shaw 2009, Marginson 2007, Den Heijer 2011, Van Damme 2012, Maassen and Stensaker 2015).

Hanmer (2015) counted that an average square meter of usable floor area in an Australian university costs 350\$ AUD annually. This implies that each student would pay on average 4000\$ per annum of the university facilities in the most appreciated Group of 8 (Go8) universities which is 1500\$ more than a student studying in more efficient Australian institutions. In Finland, during a major university reform in 2009, the government handed majority of the university facilities to companies owned mainly by the universities. A study suggested that there was 12-20% too much space in the university facilities – instead of accommodating a population of 5,3 million, there was enough space for needs of 8 million inhabitants (Sievänen 2014).

Multiple studies have indicated university facility utilization rates as low as 20-40% in the normal office hours (University Herald 2013, Hietanen 2014, Neary et al. 2010, Den Heijer and Zovlas 2014, Harrison and Les Hutton 2014). Due to the periodic nature of the educational and research activities, the usage is even lower between the lecturing periods. From facility lifecycle perspective, on the one hand, large investments are needed to maintain and renovate the buildings that are mainly built in the 1960s or the 1970s in Europe with outdated pedagogical designs and poor in technical condition (Den Heijer and Zovlas 2014). On the other hand, universities are eager to experiment with totally new solutions because the old facilities designs do not adapt to the new demands.

In practice, majority of universities are struggling with similar challenges. Large investments are made in spaces with low utilization rates, high lifecycle costs and maintenance fees which does not create value for the university core businesses – education, research and societal impact. Empty spaces rather accumulate costs that could be invested in the university core businesses. The largest challenges seem to lie in economical paucity and institutional sharing – how to get the best out of narrow resources and how to facilitate sharing of them in massive traditional organizations.

In addition to the obvious digitalization of education and research itself, there is an increasing amount of services that provide access to pools of virtual information and underutilized operand resources (Eckhardt and Bardhi, 2015) such as Airbnb, Hof-fice, Uber and Liquidspace. Their logic is ground breaking but rather simple - they connect the ones that own or have the right to use underutilized operand resources to the ones in need of them, and take a provision from each connected provider and demander. As it seems, that the role of university campus is increasingly to connect multiple stakeholders with one another, these sorts of services combined with location-based technologies might help in overcoming the challenges that university campus managers are facing.

### 3. Method

This study follows a single case study with embedded units methodology as described by Yin (2003). It constitutes part of a project that was set up to understand and develop services that are challenging – even replacing – traditional workplace. The case services were hand-picked and the evidence was let to emerge from the data through constant cross-case comparison.

The data collection was done in two phases: first, market level data collection aimed to create a holistic understanding of the service branches that support multi-locational work in the market, and second, the service level data collection aimed to identify differences between services in service branches through cross-case comparisons. The initial sample that was explored on the market level consisted of a hundred services that support multi-locational workers. For the second data collection phase, the sample was narrowed down to eight service examples. The selection was made based on four criteria - they: represent different service segments, link multiple traditional service segments, improve utilization of underutilized resources and have potential of supporting university communities.

The data in the first phase was collected on the internet sites of the services based on the Business Model Canvas (Osterwalder et al. 2010) tool. It is described as “a shared language for describing, visualizing, assessing and changing business models” (Osterwalder et al. 2010, 12) and designed to help entrepreneurs and managers in modelling the playground of their business and communicating it throughout the organization (Osterwalder 2012). It consists of nine building blocks: Value proposition, Customer segments, Channels, Customer relationships, Revenue Streams, Key Resources, Key Activities, Key Partnerships and Cost Structure.

The second phase data was also collected on the internet sites of the chosen service examples but deepened in terms of building blocks and narrowed down in terms of service numbers through applying the service logic business model canvas as suggested by Ojala and Ojala (2015). It differs from the business model canvas approach in that it highlights the role of a customer as a value creator by approaching each building block from both the customer and the service provider perspectives.

#### 3.1. Analyses

Throughout the first data collection phase, the case services were analyzed within and across cases in three levels: *framework*, *pattern* and *component*. First, an initial *framework* emerged from identifying key elements of the canvas that differentiate the services from one another: Offering, Main User Segment, Revenue Streams, Resources, Cost Structure, Service providers.

Thereafter, emerging *patterns* were identified. Offering was identified to be space, community, technology or logistics –driven. Main User Segments were divided into three consumer personas: Molly the Mover, Felix the executor and Sally the socializer. Revenue streams consisted of eight patterns: membership, usage subscription, lease/rent, asset sale, free, licensing, ads and other. The resources were clustered into four patterns: Community presence, location, network and other. Cost structure was divided into two patterns: cost-driven and value-driven. And the service provid-

ers were categorized into seven according to their main businesses: Tech developers, Landlords, Community operators, Tech lords, Community developers, Community lords and Community lord developers.

The recently emerged services that support multi-locational work were noticed to have common characteristics in that they connect four major business fields of space, community, technology and logistics. The services can be seen as components that constitute a service offering that connect:

- 1) spaces and community, catering for people to meet face-to-face (MEET 'EM),
- 2) community and technology, catering for people to collaborate by means of technology (TECH 'EM),
- 3) technology and logistics, facilitating real time tracking of locations of objects, people and spaces (TRACK 'EM),
- 4) logistics and space, delivering objects, people and spaces from place to another (TRANSPORT 'EM).

After the analyses of the data collected in the first phase, for the purposes of this research and context of the university campuses, two examples of each service component was decided to be included in the second phase data collection and analyses. The services are exemplary and only serve to illuminate the case better. As the reviewed literature highlighted the increasing role of customer in value creation, we decided to deepen the analyses by taking the service logic business model canvas suggested by Ojala and Ojala (2015) as our tool to explore these services in more detail. The framework and the chosen cases under the service components are illustrated in Figure 1.

**Figure 1 The framework and the chosen service examples**

## 4. Results

The results indicate that all of the eight chosen services included in the final analyses function on a double-sided market where both the community of users and the community of service providers as demand-side resource integrators are equally important. As there are only eight services, we are not aiming for highly generalizable results but rather an illumination of types of services on offer.

In each analyzed service, the demand-side resource integrators, namely clients and users, play roles of Customers, Key resources and Key partners at the same time. Therefore, the argument of Grönroos and Ravald (2011) for service logic, where customers increasingly determine and control value creation, seems solid.

Each service utilizes a strategy of connecting operand resources in an attempt to create more value of operand resources through connecting demand-side resource integrators - service providers as clients and users as customers - together. However, four major clusters that base on different tactics related to operand resources were identified from service provider aspect: Inviting to, Facilitating sharing of, Providing access to; and Integrating use of a variety of accessible operand resources.

The major differentiators between the clusters are in the revenue logic and the offerings which indicates a similar trend as the arguments of Eckhardt and Bardhi (2015). The clusters are illustrated in Figure 2.

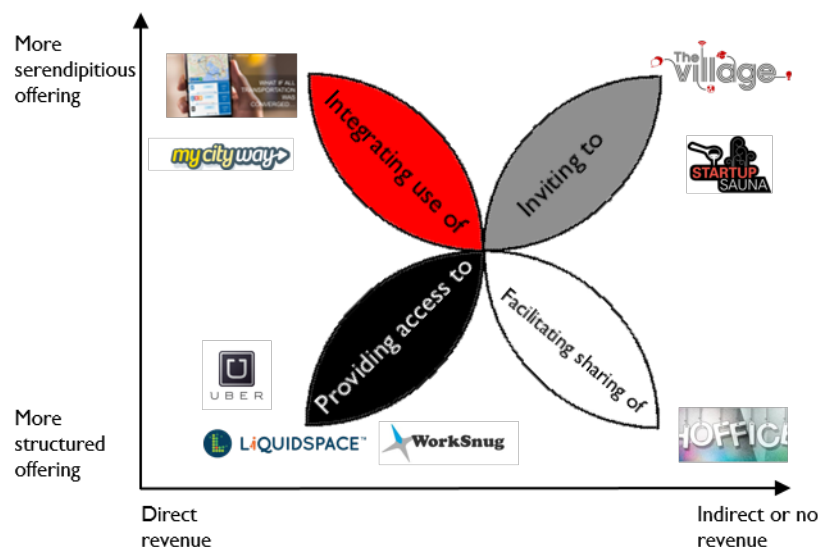

Figure 2 Identified service clusters

In *Providing access to* cluster, revenues are the most direct, and the offering is the most structured. The service provider as a client gets a certain part of the revenues per transaction gained from the user as a customer and the explored service offers a platform that facilitates the link between these two. The user as a customer is in control of the offering, knows what to look for and knows what to expect rather than looking for serendipitous encounters.

In *Integrating use of* cluster, the revenues are direct from the service providers as clients, the users as customers or both. The offering is more serendipitous and per-

sonalized, meaning that the user might get something even better than what expected resulting in loss of some control over the offering from the user perspective. The value is created by collecting personal data of users as customers, integrating offerings of clients as service providers, and facilitating the connections in between in real time.

In *Facilitating sharing of* cluster, no money is transferred. The offering from the user point of view is more structured than in the *Inviting to* cluster, as the community is more closed and personal - one can not just pop in when passing. The value is wholly created through facilitating individuals as peers who are sharing their own operand resources to exchange operand resources.

In the cluster of *Inviting to*, the service provider does not get direct revenue through the service it provides but uses the service provision as means of marketing, as an attractor or gains revenue indirectly through donations or funds. The offering is more serendipitous from the user point of view. The value is created to a large extent by the resource integrator community which exchanges operand resources in the physical premises and has the potential of attracting more similar-minded users.

## **5. Discussion**

The role of university campuses seem to increasingly be facilitation of collaboration between people and organizations, and laboratory and forge works experiments, because majority of individual knowledge-intensive tasks can be done from a distance with a wifi connection. In general, the existing campuses are extravagantly utilized as each institution, faculty and industry firm tends to have a building and a specialized laboratory of their own.

### **5.1. Practical and research implications**

Multiple services that aim to take operand resources in more efficient uses can be identified. Utilizing those services as a basis for improving the use of facilities on campus seems worth experimenting.

In practice, the results imply to university campus management organisations that multiple means of conducting businesses, that aim to take underutilized operand resources to better uses, exist. The model that functions best for each project or case depends on how structured offerings and how direct incomes each project aims to deliver. All the models compliment each other, and it is a matter of finding the right balance between them in supporting university core tasks - education, research and societal impact. Both ends of the spectrum are needed in lifelong learning, and require attraction and engagement from the service providers as clients and proactivity from the users as customers of the campus.

For example, if the purpose is to cater for very focused discipline-specific research and the user knows what to expect, the offering is very structured, and the revenue very direct. In this case, the user is in control and finds a way to execute the required tasks. Whereas if the purpose is to support innovative actions, and the user is looking for pleasant surprises - serendipity - then more flexibility is required from both the

offering and the revenue. In the latter case, the service needs to make assumptions based on behavioral data collected earlier of individuals and communities on campus and suggest ways forward in time and in location.

As there are multiple sorts of communities that utilize university campuses for a variety of uses and in a variety of manners, these kinds of services could increase transparency and thus help in making the most out of the available resources. The university facilities today are utilized in an extravagant way because the data of the usage nor the availability of the resources is not communicated nor showed transparently. Through the analyzed types of services it would be possible to provide access to, invite people to, integrate use of and facilitate sharing of facilities which could potentially help in cutting costs of university facilities, diminishing needed amount of space, maximizing serendipitous encounters and improving sustainability of university institutions.

## 5.2. Limitations

This paper is qualitative and thus limited to analyses of literature and business models of a hundred services, and thereafter eight services in more detail based on their Internet sites. These results are not thus highly generalizable but rather provide an idea of available services that could potentially be tested in the future.

The validity of the results can hence be criticized. No service providers, users, customers, nor clients were interviewed for the purposes of this study which would have provided more realistic insights to how the services function. However, it provides an initial framework with help of which university campus management organizations could improve the efficiency and effectiveness of their campuses by making their operand resources more attractive and accessible.

As the initial framework emerged from the data, and the services were not monetarily nor otherwise quantitatively assessed nor evaluated, the reliability of the results can be criticized. However, due to collaboration of multiple researchers and a large amount of services analyzed, the results indicate weak signals of strategies applied in services that aim to take extravagantly utilized operand resources into better uses.

The initial framework can be furthermore tested and re-iterated in a case where university campus is developed.

## 6. Conclusions

Due to increasing digitalization, university campuses should be increasingly able to attract people and provide serendipitous encounters and focus less on facilitating individual executive work. With low facilities utilization rates, increasing global competition and scarce monetary resources, university campus management organizations are challenged to come up with more effective solutions to cater for education, research and societal impact. This study suggests that experimenting with business strategies applied in the service clusters of *Inviting to*, *Facilitating sharing of*, *Providing access to* and *Integrating use of* operand resources, could be a potential way forward.

# **XXV. International RESER Conference: Building documentation for building operation – A study based on the theory of planned behavior**

*Torben Bernhold, Jana Koers, Vanessa Platner, David Serbin*

*University of Applied Sciences Muenster*

*The paper presents an overview of the documentation status quo within the real estate and construction branches and the motivation of planning participants to document their results with regards to building operation. Based on the Theory of Planned Behavior, an extensive online survey and problem-centered interviews with experts were carried out. The results highlight the reasons for insufficient building documentation and show factors and conditions, which could influence the motivation and behavior of the participants.*

## **1. Introduction**

A main part of construction projects is the documentation of significant processes and building information. Nevertheless, the documentation is still considered as an annoyance and its importance is underestimated. This is the reason why the documentation is often provided just rudimentarily. That entails that famous and complex buildings fail and produce additional costs, because decisive and important steps are not documented adequately. The integral documentation goes one step further. In this case, cooperation and planning participants are considered. Consequently not one stakeholder is responsible for the whole documentation, but every planning participant contributes to the integral documentation. This minimizes the error rate enormously.

## **2. Integral Documentation**

In the construction and real estate branch, the focus is transferred more to sustainable and lifecycle comprehensive designing. This is also called “integral” project planning and refers to all lifecycle phases of a building from the initiation to the demolition. In traditional planning, the building itself is the focus of consideration. Within the service oriented planning, the objective lies in an optimal satisfaction of the customer demands while using the building (König et al., 2009). To achieve ambitious, functional, technical, economic, social and ecological objectives, the variegated parties have to coordinate their contribution for achievement in a new way along the lifecycle of a real estate (Schäfermeyer et al., 2008; Pfnür, 2011). In comparison to the traditional project planning, this is much more complex because of the increased coop-

eration demand between the planning participants involved and the higher data volume (Both et al., 2013; Kalusche, 2012).

The early designing of building running requires the patency of information, data and documents (IFMA, 2014). Therefore an integral documentation is needed. Here, the various participants of designing, construction, and operation processes are involved to guarantee that the right information in every point of time is delivered and stored

- to the right addressee,
- at the right time,
- in the right format,
- in the right quality,
- in the right place.

Documentation includes the long-dated safeguarding of main information of a project, which is important for later operations (Kalusche, 2012). At the end of the building construction, the documentation has to be complete (GEFMA 198-1, 2012). That means that the planning and construction participants should document the results of their work continuously. But in practice, a large part of project ends with massive information deficits. One well-known reason is that the planning participants understand the documentations just as a sampling of documents, which are produced anyway. Moreover, there is no time to collect the relevant information and data continuously. Another problem is the large amount of involved participants (Kalusche, 2012; GEFMA 198-1, 2012). The broad variety of participants entails a broad variety of transfer and data formats, interpretations of information, and understanding of terms (König et al., 2009). That leads to frictional losses and high costs for additional assessment (Möller et al., 2013; GEFMA 198-1, 2012).

The Theory of Planned Behavior could explain this suboptimal situation, which leads to the necessity of investigation into the present status quo of documentation.

### **3. Theory of Planned Behavior**

Applied to the background of integral documentation, the decision was to use the Theory of Planned Behavior as a basis for the study to analyze how the different stakeholders, who are part of the lifecycle of properties, are dealing with this topic of the documentation and how their attitudes and future behavior intentions are. Moreover we were interested in the motives to perform or not to perform an integral documentation.

Research question:

How is the topic integral documentation in Germany currently being managed and how are the attitudes and future behavior intentions of the different stakeholders, who are part of the lifecycle of properties?

The Theory of Planned Behavior (Ajzen und Madden, 1986) is one of the approaches most frequently used for social-psychological research and has arrested attention

and confirmation by different applications (Armitage and Conner, 2001). The particularity of the Theory of Planned Behavior is that the focus of research is the individual attitude of human beings, in contrast to other exclusively economic theories.

The theory started with the core statement that the behavior of humans is not necessarily connected to their attitudes (Eagly and Chaiken, 1993; Zanna and Fazio, 1982). Based on this phenomenon, Ajzen developed the theory of reasoned action (Ajzen and Fishbein, 1977), on which the Theory of Planned Behavior grounded (Ajzen and Madden, 1986). According to this model, behavior is particularly determined by a concrete behavioral intention. This central factor of behavioral intention is affected by three conceptually independent determinants of intention (Ajzen and Madden, 1986).

The first determinant conducts the attitude toward the behavior and refers to the degree to which a person has an advantageous or disadvantageous evaluation of the behavior. The second predictor is a social factor named subjective norm. This predictor refers to the perceived social pressure of the society to execute or not to execute a specific behavior. The third antecedent of intention is the degree of perceived behavioral control, which refers to the expectation of the level of difficulty the performance of behavior is. Related to this, past experiences serve as references and are compared to the current situation (Aronson et al., 2008).

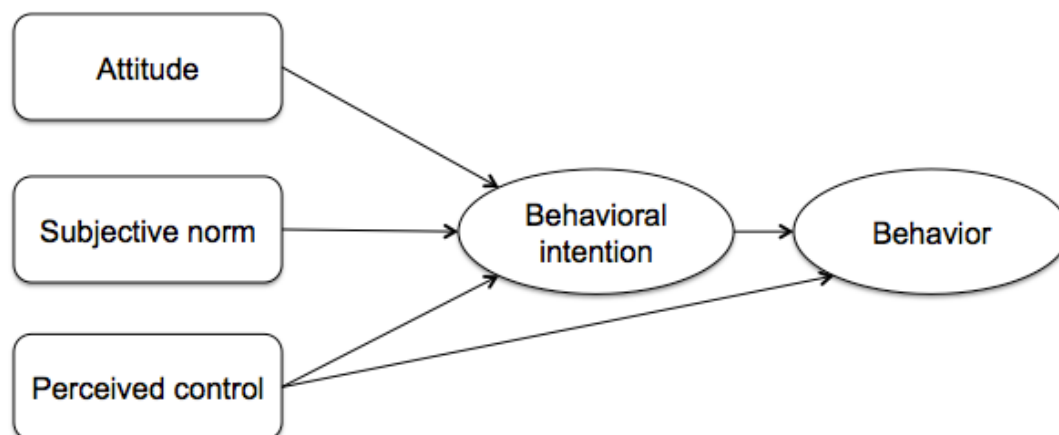

Fig. 1: Ajzen and Madden's model (1991)

The main statement of the theory is, the more favorable the attitude and the subjective norm are regarding a behavior, and the majority of the perceived behavioral control, the more likely an individual's intention will be to perform the behavior under consideration (Kanning et al., 2008).

The predictor Attitude describes the attitude of a person towards determined circumstances. The more distinct this attitude is, the stronger the behavioral intention and the higher the probability to show a specific behavior. The attitude of a person is influenced by the potential consequences of his/her behavior. As a general rule, persons strive for a determined behavior if their personal evaluations of this behavior are positive (Brandt, 2010).

The Subjective norm is defined as “the perceived social pressure to perform or not perform the behavior” (Ajzen, 1991). The behavior of a person is influenced by normative beliefs which are concerned with the likelihood that important referent individuals or groups approve or disapprove of performing a given behavior. Consequently the subjective norm refers to an individual perception of the social environment to perform or not perform a behavior. If a person has the impression, that a determined behavior is common or desirable, it will have a strong influence to the behavioral intention (Brandt, 2010).

The Perceived control as the third determinant of behavioral intention describes how a person feels to realize a successful planned behavior. It is possible that the realization of a determined behavior is easy or it is necessary to spend a lot of effort and resources. At this connection, the control is influenced by external factors or by the missing trust in the own capability (Brandt, 2010). At the same time, perceived controllability also exerts a direct influence on behavior realization. In this case the Perceived control depends not on the other determinants, Attitude and Subjective norm (Ajzen, 1991).

For the analysis of the behavior and behavior intention regarding to the integral documentation in the lifecycle of properties, we had to formulate focused hypotheses according to the theory.

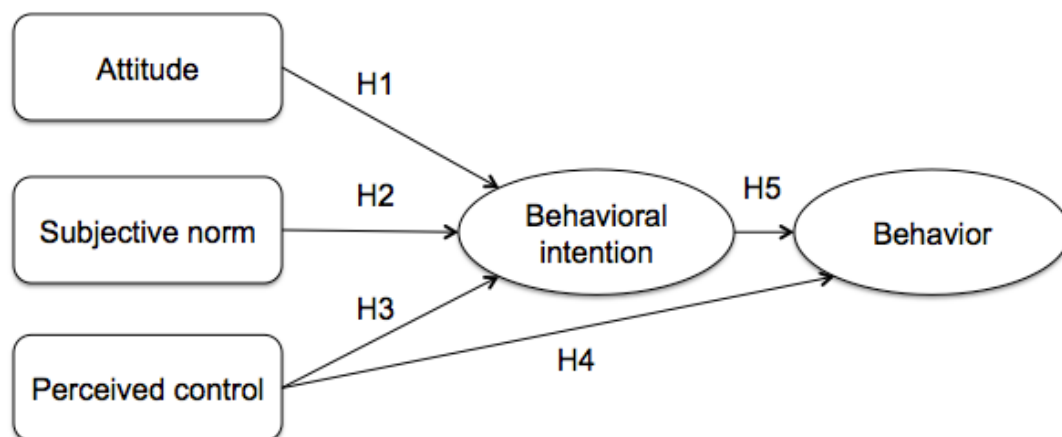

Fig. 2: Ajzen and Madden's model with hypotheses

#### Hypothesis 1:

The more positive one's attitude towards integral documentation, the more strengthened the behavioral intention in accordance with the integral documentation is to act.

#### Hypothesis 2:

The higher the perceived pressure of the social environment for the implementation of integral documentation, the stronger the behavioral intention is to act accordingly.

#### Hypothesis 3:

The higher the perceived control is designed in terms of integral documentation, the stronger the behavioral intention is to act according to the documentation.

Hypothesis 4:

If the perceived control of integral documentation is clearly defined, then the behavior is influenced to documentation.

Hypothesis 5:

The stronger the behavioral intention is to act in accordance with the integral documentation, the more likely the behavior is to carry out the integral documentation.

## **4. Methodical Approach**

In the beginning of the students research project, the definition of the academic void and the description of the research guiding question were pointed out, which leads to the research design. On the basis of the existing survey and the preponderant on practice focused literature, the following question was formulated: "How is the issue of integral documentation currently handled in Germany, and how are the attitudes and future behavioral intentions of the participants of the buildings lifecycle pronounced?" For deep insights into the structure of integral documentation, the survey took a deductive and inductive approach. Though, the stated objective was to understand and use both approaches as complementary elements and two different perspectives on one and the same object of research. The formal deductive approach along the Theory of Planned Behavior (Ajzen und Madden, 1986, Ajzen, 1991) should generate a tentative verification respectively falsification of the hypothesis's (Kromrey, 2006). For the case study method, problem centered interviews (Mayring, 2002; Lamnek, 2005) were performed to understand the research object in more depth and to support and concretize the results of the quantitative survey within the scope of the multiple case study (Yin, 1984). Particularly through this method mix, a transparent and complete picture of the reality could be given. This also serves as the argumentative interpretation safeguard.

To achieve the comparability of the results and a similar interpretation of the respondent (questionnaires) and the interviewee (interviews), a general definition of integral documentation was produced: "In integral documentation, the different participants of designing, construction, and operation processes are engaged lifecycle across. This ensures that the right information in every point of time is delivered and stored to the right addressee, at the right time, in the right format, in the right quality, in the right place." The survey techniques refer to this definition.

In the quantitative approach, a questionnaire was carried out, which was based on the hypothesis and the formulation of the appendant variables along the theoretical and hypothetical construct. Finally, the measurement model was displayed formatively.

Fig. 3: Hypothesis and model based on Ajzen and Madden

According to the definition of the integral documentation, related variables were derived based on the theory (see table 1). In this connection the answers have been carried out by means of closed questions on a six-point scale.

Table 1: Variables and items in the questionnaire

| No. | Dimension       | Scale | Question   |
|-----|-----------------|-------|--|
| 1   | Behavior        | a     | To what extent is an integral documentation implemented in your company already?   |
| 2   | Attitude        | a     | In my estimation, the integral documentation is an essential part of the implementation of the life cycle concept of real estate.  |
| 3   | Subjective norm | a     | In my estimation, the vast majority of my clients is the assessment that an integral documentation is an essential performance component of the implementation of the life cycle concept of real estate. |
| 4   | Subjective      | a     | In my estimation, the vast majority of my employees is   |

|    |                   |   |  |
|----|-------------------|---|--|
|    | norm              |   | the assessment that an integral documentation is an essential performance component of the implementation of the life cycle concept of real estate.  |
| 5  | Subjective norm   | a | In my estimation, the vast majority of my competitors is the assessment that an integral documentation is an essential performance component of the implementation of the life cycle concept of real estate. |
| 6  | Perceived Control | a | To what extent are you estimating that an integral documentation (e.g., consulting, etc.) can be implemented by an additional remuneration of participants readily?  |
| 7  | Perceived Control | a | To what extent are you estimating that an integral documentation can be implemented by normative standards (eg. DIN, GEFMA, gif, etc.) readily?  |
| 8  | Perceived Control | a | To what extent are you estimating that an integral documentation can be implemented by the expertise of the staff readily?   |
| 9  | Perceived Control | a | To what extent are you estimating that an integral documentation can be implemented by the additional support of IT (e.g. BIM, CAFM, etc.) readily?  |
| 10 | Perceived Control | a | To what extent are you estimating that an integral documentation can be implemented by a documentation agent for the overall project readily?  |
| 11 | Intention         | b | How strong is your intention to develop your business significantly in the next 6 months in terms of integral documentation?   |

Notes: with all questions "not specified" is also offered as an option; Scale a) 1 = completely to 6 = not at all, scale b) 1 = very strongly to 6 = not; no answer = missing value

The questionnaire was applied on personal contacts and social networks, which mainly deal in practice with these technical contents. The focus was on groups within the scopes of project development, architecture, construction/ project managers and real estate consulting firms.

Fig. 4: Group orientated records in the questionnaire

To achieve the highest possible validity of the evaluation, only the records were incorporated into the analysis, which have been completely filled regarding the variables v1 - v11 by the people interviewed. Dropouts of the questionnaire have not been studied in detail with respect to the response behavior and also not considered in the analysis. In addition, the remaining records (45) were subjected to a detailed analysis in terms of the response behavior. Anomalies and abnormalities in the response behavior were found in three more records, which were excluded from the close consideration and evaluation. Due to the not normally distributed data and the small number of cases, a bootstrapping at 95% confidence interval was carried out with 1.000 bootstrap samples, which enable a further classification of the data and the results. Through this proceeding, the particular correlations could be verified. In this context, the degree of (relative) influence can be determined by the method of squared correlation coefficients (Homburg und Klarmann, 2012).

In the context of the qualitative study, the collection of data was carried out on the basis of problem-centered interviews and qualitative content analysis along the multiple case study plan (Mayring, 2002). Due to the different participants in the integrated planning process of a property, the multiple case study (multiple case with embedded cases) was selected as the research method (Yin, 1984). It has the objective to examine several cases and to derive laws, observations, comparisons, and generalization from the experiences of individual interviewees.

Fig. 5: Structure of the multiple case study

Notes: PM = Project Manager / End User Client, AR = Architect, PD = Project Developer, FC = Facility Consultants

With all of the companies involved in these cases, analogous problem-centered interviews were conducted. The conversations were recorded with the consent of the parties and transcribed in the further course. The transcript was made available to the interviewees in understanding the communicative validation available again. After, all text components were disassembled, paraphrased and assigned to qualitative content analysis to make them accessible to a detailed evaluation and representation. The key questions within the interviews were closely modelled on the existing questionnaire for the quantitative study group in order to precisely explicate these arguments and interpretations. As part of the within-case analysis, the statements of this group were shown and described. Then, they were compared again at a higher level of abstraction in the context of cross-case analysis with the other groups (cases).

## 5. Results and Findings

In the context of the Theory of Planned Behavior, the hypotheses H1 and H5 are assumed in alternative hypotheses. For the hypotheses H2, H3 and H4 the respective null hypotheses had to be maintained.

Notes: \*p<0,05; \*\* p<0,01

Fig. 6: Results for Integral Documentation

Away from all limitations of the study performed and the current state of interim results, initial estimates and indicators for the additional scientific and practical connectivity can be derived, especially in combination with the qualitative results of the content analysis. On one hand, it becomes obvious that a positive attitude to the integral documentation affects the general behavior. In relation to the other constructs, approximately 85% of the content of the declaration of behavioral intention (intention) refers to the construct “positive attitude” towards integral documentation<sup>1</sup>. This behavior intention also correlates positively with the belonging behavior.

According to the qualitative content analysis the stakeholder interviewed are of the opinion that integral documentation is a significant part of the lifecycle orientation. Nevertheless, the integral documentation is used in different contexts because of the disagreement regarding the conceptuality. Architects and specialist planner belong to

<sup>1</sup> Normalized squared correlation coefficient. To process of the squared correlation coefficient see Homburg and Klarmann (2013).

the group with the most analog understanding of the term. According to the opinion of the different stakeholder interviewed, the integral documentation does not follow this comprehensive knowledge. Rather, the documentation depends on specific construction projects, but has less universal and generic character. Individual groups built their own standards of documentation and archiving, which they used in their projects; other alternative systems are regarded as time consuming and maintenance-intensive. In this context, it is important to mention that the documentation not only integrates building components and elements. Rather, the holistic and sustainable view of processes and the results are focused to create the hybrid product more efficient along the entire lifecycle. Nevertheless, this is more likely a sequential planning and perspective. Particularly, the maintenance effort of data and the assurance of the necessary actuality still present a big challenge for the participants. Regarding the integral documentation, the FM-consulter have a comprehensive and diversified understanding, but are generally not those who must also implement it. They are of the opinion that professional and temporal barriers between the participants of the lifecycle constitute an obstacle of the holistic implementation.

In this context, it becomes obvious how closely product and service are woven together in the hybrid value added. But how the specific service is planned, performed and monitored, remains uncertain, if necessary input factors of the property are not or not actually documented. These circumstances are reflected by the most projects in practice. Particularly, frequent changes of ownership or fast project development apply very often in practice before the general process of documentation starts. Almost every stakeholder interviewed confirms that there is a significant connection between the documentation of products (building/real-estate) and of operational performance processes (building management).

25 of 42 study participants were of the opinion that the integral documentation could contribute to eliminate planning errors by regular information exchange.

Fig. 7: Opportunities for ensuring a better planning and design process

The conclusion is that the majority of the participants agree to an integral documentation, because the benefit along the lifecycle is clearly evident. Nevertheless, just a small part of stakeholders adheres to these guidelines or the way of documentation; integral documentation is important, but in some cases a bothersome duty.

Regarding to the subjective norm (the noticed pressure to change the behavior or the intention), the employees are decisive. In the opinion of the respondents, additional fees and / or other normative standards (VDI, GEFMA, gif, etc.) will not be necessary to implement an integral documentation. Here, the qualitative study supplies comparable results. Especially in the area of staff, a differentiated picture is emerging. While especially consultancies and architects/specialist planners represented the view that employees are a major reason to implement the integral documentation, mainly builders/project manager and project developer cannot completely agree.

Furthermore, some participants of the quantitative study and some interviewed people are of the opinion that additional norms and standards for the implementation of the integral documentation are required. This presentation and evaluation is of considerable interest, just facing the formation of the documentation using BIM. Ultimately, however, a binding documentation standard with the exchanged documents would possibly also replace project- and customer-specific solution alternatives. According to the documentation standards and the timeliness and completeness of the information, this real estate projects would be clearly comparable, as it is the case at the present time. Especially the group of architects and planners relies on normative guidelines like the designation of the HOAI. The HOAI gives only rudimentary information on standardized implementation regarding the lifecycle. Especially the future will show how BIM can map the required documentation uniformly, or if not procedural documentation standards are needed to reduce information asymmetries between the stakeholders in order to create the hybrid product as efficiently as possible.

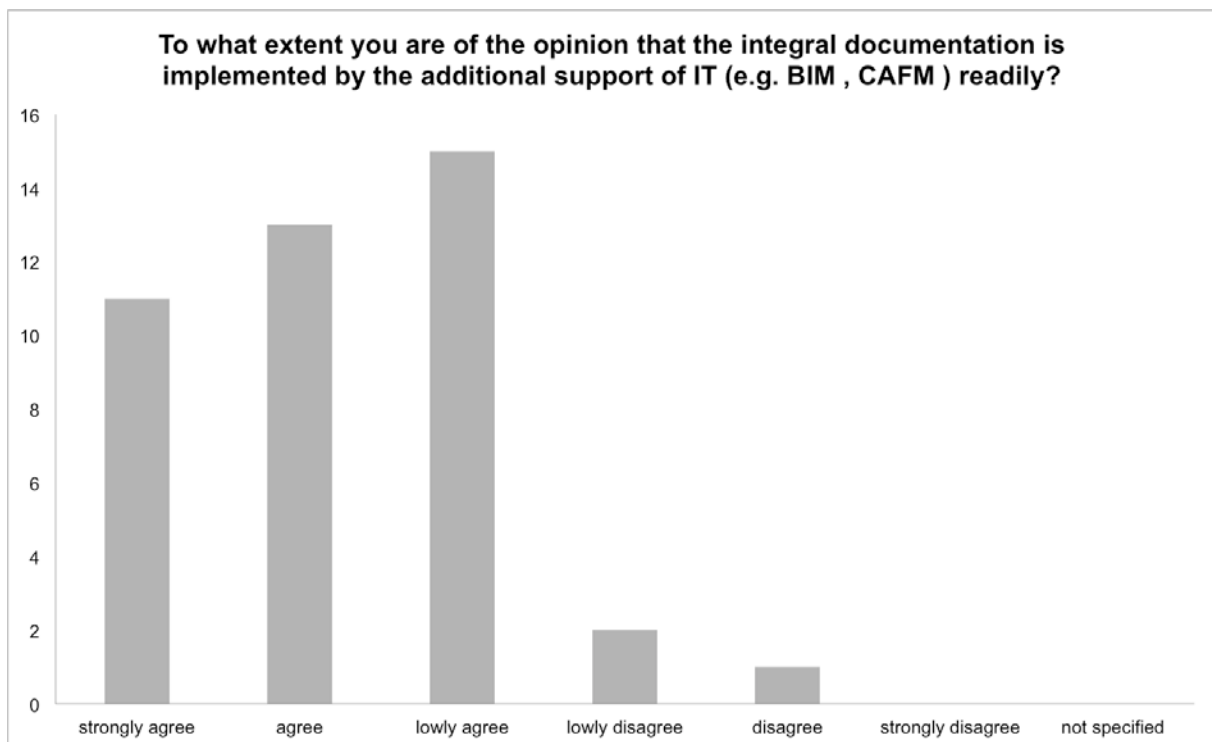

Fig. 8. Implementation of BIM (Building Information Modeling)

Although not significant, especially the competitors could represent an important role in the future. The more companies forge ahead and implement this holistic form of support for the real estate project, the higher could be the perceived pressure to change the own behavior in the future. Especially the project developers interviewed do not see a significant competitive advantage by an integral documentation on the currently market. At this connection, other topics with clearer relevance seem to be in the main focus. Moreover, also the question rises whether a customer would pay a pricing supplement for a property with integral documentation, or whether better credit conditions by the financing bank are provided as a result of an optionally lower risk. In this context, a need for further research can be formulated.

However, customers seem to have no significant influence on the behavioral intention. Sometimes, it can be presumed that the customers and their documentation structure in practice are so fragmented and heterogeneous that there is no uniform and contractually secure base of understanding about the nature and the scope of the integral documentation. Also as part of the qualitative study, corresponding content were recorded. Therefore, customers seem to have such a sophisticated idea of what needs to be documentation, so that the customer also determines the contents and consequently the project-related standard. According to the participants interviewed, it is primarily the customer who determines the relevant conditions and also the used standards, contents and formats. The stakeholders which are involved in the planning process of the hybrid product would especially follow and implement this customer request.

In this connection, the quantitative evaluation showed that the use of BIM is not the complete remedy of choice and does not pick up all the challenges of the practice to solve the problem. In that regard, BIM can be associated with the supporting area in the context of information logistics as a tool for implementation; its use alone will not improve any project documentation. Apparently, the value-added partnership and cross-stakeholder information exchange needs to be rethought and formulated. The participants interviewed indicate that currently online platforms are available for data exchange. The architects and planners just sometimes consider BIM-tools critically, because these solutions are not yet fully developed from the perspective of the respondents to satisfy the practical requirements.

Due to the currently very heterogeneous implementation and perception of integral documentation on the market, the question was asked whether a separate documentary representative in the lifecycle could dominate the control over the processes better. Although, in the quantitative study cannot derive any significance, just the interviews reflect a heterogeneous impression. It became clear that in particular the determination of responsibility in the lifecycle is critical and is assessed differently by many respondents. On one hand, some participants interviewed represented the view that the responsibilities over the lifecycle phases should change (e.g. by architect to FM service), others are of the opinion that there should be a charge on the phases. Similarly inconsistent presents the image of who is the best stakeholder to implement the integral documentation. In many cases, the responsibility is at least seen in a respective other group.

## **6. Conclusion**

The integral documentation – combined with the design of integrated planning – is a currently significant addressed issue in Germany. In particular, the number and the extent of failed major construction projects force to implement new forms of collaboration and cooperation, and not to remain in the status quo. The present study makes a significant contribution to the fundamental understanding of integral documentation and to possibilities of successful implementation. It was found that BIM for example, is not alone in the position to take up the multifaceted challenges in the planning process exhaustive and all encompassing. According to the authors, the starting point of data, the objectives of the project, and of the documentation as well as the value-added partnership of cooperation partners have to be at the center of considerations in Germany. A purely technocratic regulation of an instrument will ultimately remain in the case status without any change in the core. Against this background, the formation, structuring and maintenance of a functional cooperation for the creation and operation of real estate (understood as a value-added partnership of the hybrid product) should be given more attention than before. Only if the procedural sequence of tasks is matched transparent connected with the documents and information required the responsibilities between the participants are present.

## **7. Limitation**

The conducted quantitative study must be considered against the background of the rather small number of the existing case. In that regard, the statements should investigate once again in a major, also international study. Although the quantitative and the qualitative statements generally correspond in many respects, the application of structural equation model for confirming the statements should be required to interpret the present interim results mainly as preliminary results. In particular, the complexity of the model as well as the formulation of the variables (formulation of the items) should be reviewed in a further study.

### **Abstract:**

The literature on the internationalization of firms has traditionally been applied to goods, since they have been more subject to international transactions. This is due to services having had some features very different to those of goods, which have prevented them, in some cases, from adopting certain forms of internationalization. However, in recent decades there have been some changes in the nature of services that, alongside the emergence of new information technologies and new contractual arrangements for accessing other countries, etc., have permitted their foreign expansion. In this context, the objective of this work is to analyse the extent to which some of the traditional theories on the internationalization of services have been adapted and what changes should be considered in order to justify the adaptability of such theories to services and, in particular, to knowledge-intensive services.

**Key words:** Services, Knowledge-Intensive Services, Internationalization

**JEL:** F21, F10, L80, L90.

**Thematic Area:** FDI and multinational companies

## 1. Introduction

In recent decades there has been a great international expansion in services. In particular, said growth has been influenced, according to Muñoz-Guarasa (2001, 125-126), firstly, by the growth in the consumption of services for families in the domestic economy, which has generated great expectations for business and for profits in firms, leading to the firms wanting to use these advantages not only in their local markets, but also beyond their national borders. Secondly, the organizational changes in firms have given rise to the outsourcing of some phases of the production process, such that firms outsource certain services (advertising, accounting services, etc.) to other independent firms in other countries. Thirdly, the process of deregulation in national economies have allowed the liberalization of markets by facilitating easier access for firms, not only resident ones but also foreign, to these markets (telecommunications, personal services, financial services, insurance, etc.). Fourthly, advances in information technology and telecommunications, as well as the emergence of new services based on the use of information and knowledge, and innovations in transportation, have encouraged the increase in trade in services that were not being traded before. The latter two factors have also been identified by Miozzo; Miles (2002, 24). Thus, all these reasons have led to some changes in the nature of services and more specialization in services being produced, as well as a great development of knowledge-intensive services and a significant increase in their capacity to internationalize.

The process of internationalization of service firms may be driven by the same variables that affect manufacturing firms. However, the intensity and direction of some key relationships require consideration of the specific characteristics of services (Patterson *et al.*, 1999). These distinguishing features of services influence their mode of internationalization and have raised significant doubts regarding the appropriateness of applying internationalization theories for manufacturing firms to those businesses that provide services.

Therefore, the objective of our analysis will be to analyse the applicability of some theories of internationalization on imperfect competition to services, in general, and to knowledge-intensive services, in particular, starting from the theoretical and empirical literature. In addition, we will raise possible changes that would have to be included to improve such applicability. Therefore, first, we analyse the Theory of Industrial Organization, second, Transaction Cost Theory and Internalisation and, third, the Eclectic Paradigm Theory. We finish by providing a set of conclusions and we propose future research.

## 2. Characteristics of Services and KIS

Over time, services have evolved and have gained in importance. Specifically, their traditional features (intangibility, heterogeneity, inseparability and non-durability) have been questioned by various authors, among which are found Beaven; Scotti (1990), Wright (1995), Winsted; Patterson (1998), Grönroos (2000), Loveloch; Wright (2001), Miozzo; Soete (2001), Johnson; Gustafsson (2003), Vargo; Lusch (2004), Edvardsson *et al.* (2005) and Moeller (2010). First, the intangible nature has been criticized because this feature of the transformation process is not the specific service, but the intangibility of its offer (Moeller, 2010, 362); even if the client possesses nothing tangible when the service has been produced, generally, there are many objects that do have that feature and that participate in its activities. Second, the heterogeneity feature has been little questioned since it can be caused by human interaction in goods as well as in services (Zeithaml *et al.*, 1985; Gummesson, 2000; Vargo; Lusch, 2004; Moeller, 2010) as they all include customer engagement. Third, the inseparable feature has been criticized because many services can be separated in time and place between the production and the consumption using new technologies of information and communication, allowing its internationalization. Finally, the non-durability feature has changed since services can be stored in systems, buildings, machinery, knowledge

and people (Moeller, 2010, 364). For example, software systems can be stored in the computer system or education services in the knowledge acquired by the people who receive them.

Of the various activities that make up the service sector, it is the knowledge-intensive services that have achieved the greatest growth and importance in recent years. Knowledge-intensive services (KIS) are characterized by having a set of own intangible resources such as human capital, knowledge, innovation, network relationships, among others, and thanks to their organizational resources and learning are able to transform them into dynamic capabilities<sup>i</sup> of networking, of knowledge and of innovation that allow them to better adapt to the international market opting for strategies of following the customer. In general, although KIS are characterized by their orientation to the market<sup>ii</sup>, location<sup>iii</sup> and for their human capital<sup>iv</sup>, they can develop the following capabilities, differentiating them from other services:

- The ability to create knowledge<sup>v</sup>: KIS, through their organizational resources, have the ability to transform all the information acquired from the different agents of the knowledge market and, in this way, provide personalized services with high added value for the customer.
- The capacity for innovation<sup>vi</sup>: KIS participate in the innovation process and develop such capacity through three functions. First, as facilitators, since they help customers develop their own products or processes. Second, as carriers, transferring the developed innovations elsewhere and, finally, as sources of innovation to meet the needs of customers (Smedlund; Toivonen, 2007, 197). Therefore, innovation and KIS are especially linked (Strambach, 1998, 5-9). The capacity for innovation is transferred to the organization, to the extent that they are able to offer new services with high added value for the customer.
- The ability to create networks<sup>vii</sup>: KIS have the capability to create networks both in the exchange of information between customers and suppliers, as well as between the employees and the organization itself as a whole, because both the founders as well as the employees need to acquire knowledge from all the market players.
- The ability to learn: KIS are able to assimilate the new knowledge acquired from the internationalization process and from the networks themselves and partnerships with market agents, and transform them into the very organizational know-how of the firm<sup>viii</sup>. This capacity to learn from the organization itself influences the service provided to customers by providing them with high value added and personalized services.
- The ability to internationalize: this capability is found in harmony with the dynamic capabilities that KIS firms possess, since they have intangible resources that enable them to learn from the market, from their networks and alliances and from the organization itself (Nelson; Winter, 1982; Dosi, 1988; Lado *et al.*, 1992; Teece *et al.*, 1997), thus the internationalization of KIS is favoured by the high degree of acquired knowledge.

### 3. Empirical and theoretical literature referring to some theories of internationalization

Now we will look at the applicability of some Theories of Internationalization of Imperfect Competition<sup>ix</sup> (Theory of Industrial Organization, Transaction Cost Theory, Internationalization Theory and Eclectic Paradigm Theory) to services and, especially, to KIS, from the empirical literature (Table 1) and the theoretical.

### 3.1. Theory of Industrial Organization

The Theory of Industrial Organization according to Hymer (1960)<sup>x</sup> focuses on explaining the reasons why firms may be interested in investing abroad to have ownership advantages, regardless of the innate advantages that other firms in the host country possess (economy, language, law, politics, etc.). Principally, Hymer (1960) highlighted three types of ownership advantages. First, the economy of scale benefits derived, mainly, from technology, from marketing or from management of the organization, which allow the firm to reduce its average costs. Second, the advantages of product differentiation, which consist in the differentiation of the design or the physical quality of the competing products, of the brands, of their advertising efforts, etc. Third, the absolute cost advantages such as the control of superior production techniques, imperfections in the market of the factors of production, etc. Thus, the possibility of obtaining such advantages enables the firm to set prices below competitors. Later, Johnson (1970)<sup>xi</sup>, on the base established by Hymer (1960), introduced as a key factor in the development of his analysis, the feature of public good in innovations. The author deals with exploiting the same technology and innovation initially developed in other countries. Furthermore, the firm could exploit and obtain monopoly rents with a very low marginal cost.

The authors Katrishen; Scordis (1998) and Bhagwati *et al.* (2004)<sup>xii</sup> consider that the Theory of Industrial Organization would be applicable to services in general, as they are characterized by achieving

large economies of scale (Markusen, 1989; Von Marrewijk *et al.*, 1997). Thus, the increase in their specialization and differentiation of knowledge enables them to provide services with predictable and quality features, granting them economies of scale and scope and improved delivery times (Miozzo; Soete, 2001, 163-166). However, Boddewyn *et al.* (1986) and Buckley *et al.* (1992) show that this theory could be relatively well accommodated through simple modifications and re-workings, given that the internationalization process may differ between manufacturing and services (Majkgard *et al.*, 1998), mainly due to the nature and features of services, especially KIS.

Lommelen *et al.* (2005) arrived at a specific model for service firms in which they concluded that the factors that influence the choice of the mode of entry are different for goods firms than for those of services, although both have ownership advantages to exploit. In this model, the factors of production of the target market are eliminated. Furthermore, the factors of the mode of entry and those of management behaviour are also added. As well, they concluded that internal factors could be influenced by the organization. Subsequently, Javalgi *et al.* (2007), based on Lommelen *et al.* (2005), proposed a model called "Framework for internationalization", which deals with the factors that influence the strategy of entering the international market, since the internal factors are different for firms providing services and those selling goods (Zeithaml *et al.*, 1987; Regan, 1963; Rathmall, 1974; Bateson, 1989; Majkgard *et al.*, 1998). Specifically, the know-how, the cultural and regulatory knowledge of the company itself or the knowledge derived from the experience of the founder, among others, are more important for service firms because due to the characteristic of inseparability between production and consumption, what is needed is continuous interaction with the customer and, in this way, personnel that convert the tacit knowledge obtained from the customer into explicit knowledge (Nonaka; Takeuchi, 1995), thereby facilitating the learning process within the company. Therefore, the capacities of human capital are more important for the development of the internal factors of service firms than for businesses providing goods. Owing to the scarcity of empirical studies devoted to the applicability of said model of industrial organization to services, we highlight the study of Williamson; Shaw (2001) referring to the tourism sector, which adapts the Theory of Industrial Organization to this sector, using as advantages the ownership of innovation.

Therefore, although the Theory of Industrial Organization would generally be applicable to services, since any firm in the tertiary sector with ownership advantages in economies of scale, differentiation or absolute cost advantages could choose to exploit them in foreign markets, reducing the prices and obtaining higher profits than firms previously located in that country, some modifications to the theory should be introduced. Firstly, the flexible nature of services to adapt to changes more easily, the differentiation of services and the intensity of human capital should all gain in importance, since these theories mainly focus on firms in the capital-intensive secondary sector. In this way, Contractor *et al.* (2003), in their study of the service sector, rely on economies and then on diseconomies followed by diminishing returns, which are associated with very internationalized firms, dispersed markets, areas with large cultural distances and high costs of coordination. That is why one might think that the benefit of having ownership advantages for service firms is reduced in a short period of time due to their peculiarities. In other words, most of the services are consumed at the time at they are provided. Thus, it is necessary to have the maximum market information to determine the degree of customer satisfaction due to the heterogeneity of the tertiary activity. Secondly, we believe that, in order to be better adapted to the service industry, one must include, in addition to the said ownership advantages, the factors of the market of the destination country itself, since they relate to the nature and characteristics of the services (Boddewyn; Perry, 1986; Bhagwati, 1988; Erramilli, 1990)<sup>xiii</sup>. Finally, one must include the extension of the period of investment in innovation, not only as an initial situation, as it was shown in Johanson (1970), but it should be constant, principally because some features of services have direct implications for innovation, such as the close relationship between production and consumption, the high content of intangible information in services and in the process, the important role played by human resources as a key competitive factor and the importance of organizational factors in the performance of firms (Sirilli;

Evangelista, 1998, 884). Especially, KIS are market-oriented services (Liesh; Knight, 2007, 296) since they provide personalized services with high added value for customers, implying that they develop innovations more easily than other services.

One must also reflect on the need to further adapt the Theory of Industrial Organization for KIS than for the other services. In this way, KIS need to plan their relationships with clients and ensure excellent communication in order to achieve an increase in the personalization of service and the creation of value added (Amaro *et al.*, 2008, 1532). In addition, we should introduce the importance of networks in the said Theory of Industrial Organization to tailor it to KIS, as they are characterized by establishing networks and partnerships to transfer and accumulate knowledge in the organization in order to raise the overall level of business innovation. As well, one should consider the idea of also incorporating multidirectional learning, which is produced through the establishment of networks in the earlier phases of internationalization (Morgan, 2001, 122).

In short, the Theory of Industrial Organization is well suited to services and KIS. However, one might reflect on the feature of inseparability between the production and consumption of services, which causes them to be intensive in human capital. Thus, the development of ownership advantages such as innovation, knowledge, expertise, etc., depend on the ability of the personnel of the firm to transform all the information obtained from the market into organizational learning and in developing their skills (Hamel; Prahalad, 1994; Nonaka; Takeuchi, 1995). Specifically, KIS need greater adaptation than other services because they are services that are intensive in knowledge and human capital, which allow them to be very different from other tertiary activities. It would be necessary to orient the Theory of Industrial Organization towards the perspective of resources and capabilities<sup>xiv</sup>, since KIS are characterized by having their own intangible and organizational resources, which allow them to develop the specific advantages of economies of scale, differentiation of the service or absolute cost advantages in their own organizational know-how and, in this way, the benefits in the destination country would last longer. In spite of this, this theory forgets how external factors could affect the learning of the company and thus the process of internationalization.

### **3.2.Transaction Cost Theory and the Theory of Internalization**

Transaction Cost Theory (Coase, 1937; Williamson, 1975, 1985) tries to explain the reasons why a firm finds it more beneficial to directly exploit their ownership advantages through, fundamentally, Foreign Direct Investment (FDI) that transfer them to others, since in that case these firms could incur the costs derived from market imperfections. These costs will depend on the costs associated with the specificity of the assets of the firm. For example, a technology and knowledge-intensive firm has to bear additional costs to prevent its differentiated assets from falling into the hands of competitors. In addition, the agents who work abroad may not work well and these can produce additional costs (Erramilli; Rao, 1993; Klein *et al.*, 1993; McNaughton; Bell, 2001) as well as costs associated with the uncertainty of knowledge in predicting the behaviour of individuals in a foreign country (Williamson, 1985; Gatignon; Anderson, 1988; Rindfleisch; Heide, 1997). This uncertainty could lead to opportunistic behaviour, cheating, misrepresentation of information, lack of accountability and other forms of indecent behaviour (Williamson, 1985). Finally, these costs will depend on the related environmental uncertainty, which are created by the environment of the target market (Brouthers; Nakos, 2004). It refers to the risks associated with the host country, for example, the type of political and legal risk (Williamson, 1985; Erramilli; Rao, 1993; Gatignon; Anderson, 1988). Thus Williamson (1975, 1985) points out that in negotiating an agreement in the market between two parties, the transaction costs would increase in the following circumstances: first, when the qualities of the goods and services involved in the transaction costs are difficult to measure, second, the greater the uncertainty of the environment in which the transaction takes place and, finally, the greater the specificity of the assets involved in the transaction.

With the objective of reducing these costs, the Theory of Internalization then arises (Buckley; Casson, 1976; Casson, 1979; 1982; Rugman, 1981; 1983), which argues that the activities resulting from the intangible assets of the organization, such as knowledge, innovation or the qualifications of personnel, among others, must be internalized, as it ends up being more advantageous to exercise them within the common property of the firm (Teece, 1981; 1982; 1985; Hennart, 1982; Rialp, 1997; Pla-Barber, 2001) than transferring them to another. Rugman (1981; 1982) states that the assignment of ownership rights of the firm to another and the use, by the latter, of an internal market to monitor and control the exploitation of the knowledge as a specific advantage constitutes the fundamental principle of the theory of internalization. A similar argument is that offered by Magee (1977), who argues that the more sophisticated the know-how of the firm is, the more likely is its internalization as a means of appropriating the benefits at the highest level. Thus, the supply of the market by means of internalization makes sense if the benefits, derived from internalizing the activities of the ownership advantages, are greater than transferring said activities to other firms.

Brouther; Brouther (2003, 1196) empirically analysed the influence of transaction costs between manufacturing and services. These authors concluded that Transaction Cost Theory would be applicable to both services and manufacturers, since both sectors seem to react to the different conditions of uncertainty based on transaction costs. However, Erramilli; Rao (1993) indicate, essentially, that the analytical framework of transaction costs is likely to expand in order to develop better-defined models that more accurately explain the behaviour of the election of mode of entry into the foreign country. In addition, besides reducing transaction costs, there may also be other reasons for integration into the international market. Kim; Hwang (1992) support the need to incorporate strategic objectives of the firm globally. Fladmoe-Lindquist; Jacque (1995) explain what types of controls are chosen by service firms in their foreign operations under a conceptual framework that includes aspects related to transaction cost analysis. The conclusion suggests a direct relationship between cultural distance and the international experience of the founder, as well as the uncertainty of the destination country, but is inversely related to the specificity its image presents<sup>xv</sup>.

The study of Murray; Kotabe (1999) proposes a modification to the model of Williamson (1985) to capture the supply of services, which may be different from goods. Thus they question the internal consistency of Transaction Cost Theory and propose a modification to apply it to services. It involves, first, capital intensity factors in which the greater capital, the harder it is for the service firm to use the internal supply through vertical integration. Second, the inseparability of services, since the greater such inseparability is, the more pronounced is the use of inseparable internal services sources for services that have a high specificity of assets. As services require large investments in training employees in skills and knowledge to provide the services, the supply is limited and the terms to ensure the supply of these services are unfavourable (Williamson, 1985). Therefore, the higher the inseparability of services, the higher the level of domestic supply. For Williamson (1979), the firms that find themselves with uncertainty are able to organize new services. However, Murray; Kotabe (1999) find that for service firms with very specific assets, the high level of uncertainty poses a special risk for them. Third, it involves the frequency of the operations in which transactions involving services are repeated due to the characteristics of inseparability and heterogeneity. Thus, it is more appropriate for firms of specific assets and low standardization, such as knowledge-intensive services, to provide internal services when the frequency of operations is carried out under the following conditions of uncertainty:

- When the quality of services is assessed by a third party.
- When incentives to the supplier to invest in specific assets is required, if they are to provide the service infrequently and the deployment of specialized assets are not being used elsewhere.

- By internalizing infrequent transactions involving a high level of specificity of assets, firms can potentially prolong their sustainable competitive advantage and provide the same service without resorting to modifying the service continuously to obtain a differential advantage.

Therefore, Transaction Cost Theory and the Theory of Internalisation would be well adapted to services in general, although some modifications should be raised. On the one hand, they adapt well, since services contain very specific assets that are not very standardized and are characterized by a high degree of inseparability of production and consumption, which could aid them to internalize their business activities and exploit their own ownership advantages in the international market, because the associated costs of transferring said ownership advantages to other companies could be very high. Furthermore, the heterogeneous and non-enduring nature of the services would entail high transaction costs if the company decides to transfer its ownership advantages to another, since they would have to pass on the knowledge acquired by the human capital and organizational learning, know-how and the organizational culture of the firm, among others. Therefore, the internalization of their activities would create a more beneficial situation. As well, although internalizing activities in order to reduce transaction costs would be a favourable solution for services in general, one must think about the value of certain factors that decrease the degree of uncertainty so that, even though the firm opts for FDI, internalizing their activities allows them to adapt more dynamically to the international market. That is why we think it is appropriate for the importance of the external factors to be valued, for example, the culture of the destination country. Also, cultural incompatibility poses a greater risk for service firms than for goods firms, because they are people-intensive (Samiee, 1999) <sup>xvi</sup>. Therefore, the success of service firms focuses primarily on the individual's ability to adapt to the foreign culture in which the business operates.

Regarding KIS, Poppo; Zenger (1998) empirically studied software services, which discussed internalizing all services related to it, such as software applications, end-user support, data network design, assessment decisions, among others. In the research is proposed a logical reasoning based on knowledge, to the extent that co-specialization generates its own know-how and organizational culture which impedes the acquisition of new sources of knowledge, the internalization of activities can reduce value for the company. Therefore, the knowledge predicts the benefits of co-specialization arising from the specificity of the assets focused on the internal culture of the company and on its routines. That is why, when the valuable knowledge is generated by the formation of specific routines and by the know-how of the company, it will prefer to internalize the activities, opting for FDI. However, when the routines and the specific language of the company create obstacles to the creation of valuable knowledge, the ownership advantages are transferred to other companies. These authors, together with Masten *et al.* (1991) and Walker; Poppo (1991), find a positive relationship between asset specificity and internalization. The studies focus on environments where technological change is less frequent and, therefore, the value of the specific language of the company and the routines are more durable.

In short, there exist important doubts about the applicability of Transaction Cost Theory and Internalization Theory to KIS, as neither of the two theories predicts the way in which a firm, from its own resources, can obtain more market information through the establishment of networks and alliances and thus reduce the level of uncertainty. In this regard, it is necessary to introduce some details and modifications to these theories to be able to further adapt them to the characteristics and specificities of the knowledge-intensive services. Thus, it becomes necessary to include:

- The importance of knowledge: knowledge-intensive services are able to develop dynamic capabilities from information obtained from the market and transform it into knowledge and know-how of the firm, making it easier to reduce the level of market uncertainty and quickly adapt to the international framework. Therefore, the associated costs are reduced and it would not be beneficial to transfer such dynamic capabilities to other companies. Thus, exploiting its capabilities would be best for the firm.

- The qualified human capital: which performs the function of feedback between external factors (customers, other service providers, other firms in the same industry, etc.) and the firm itself, developing its own learning and organizational culture. In this way, they represent the fundamental part of reducing the maximum costs of uncertainty associated with international transactions.
- The experience of the founder: KIS are characterized by the previous experience of the founder in the international market, which motivates the strategic environment of their own firms where they acquire the knowledge that results in organizational learning and in the development of their skills (Nonaka; Takeuchi, 1995; Hamel; Prahalad, 1994).
- Networks: the creation of networks facilitates adaptation and dynamism in the international market. In particular, relations between the different international actors (customers, other service providers, other firms in the same tertiary activity, etc.) are important determinants of the transfer of knowledge (Windrum; Tomlinson, 1999) and the development of skills and of the perceived service quality, and enable the sharing of resources, including technical and functional resources. In short, the buyer and seller adapt to each other through the relational processes (Eriksson *et al.*, 1999)<sup>xvii</sup>.

In general, the theory does not predict how one could reduce costs in terms of the management capacity of the firm, nor the benefit that would accrue with regard to competitors. For example, an ICT-intensive firm could decide to exploit its own ownership advantages instead of transferring technology to other firms out of fear of possible imitations. However, full market knowledge obtained prior to being internationalized through the experience of the founder or the establishment of networks and partnerships would permit it to adapt to market changes and thus achieve greater dynamism and flexibility in terms of the overall picture. Therefore, its capacities are those that allow it to reduce the costs associated with market uncertainty.

In short, Transaction Cost Theory and Internalization Theory, on the one hand, would be well adapted to services, although some modifications may be needed in order to include the features of inseparability, heterogeneity, intangibility and non-durability possessed by service companies. For this, it is essential to include factors that are outside the firm and are important, with the objective of reducing the costs associated with uncertainty, such as the country's culture or the characteristics of the market and human capital, which causes the transaction costs to affect services from a different perspective than goods and, on the other hand, so that these theories are well adapted to KIS, a set of variables should be included that are consistent with the specificity of knowledge-intensive services. As well, this also permits them to reduce the costs associated with market uncertainty and to adapt themselves to the global framework more easily. Overall, the Theory of Internalization has been characterized as being excessively general and for presenting empirical problems (Muñoz-Guarasa, 1999, 67).

### **3.3.The Eclectic Paradigm Theory**

The Eclectic Paradigm Theory tries to offer a more comprehensive and complete perspective from the above theories of imperfect competition. Thus, Dunning (1977, 1988) configures the OLI framework<sup>xviii</sup> based on ownership, internationalization and localization advantages. First, the ownership advantages refer to the strengths of the firm that is internationalized with respect to competitors in the foreign country, such as advanced technology, economies of scale, better knowledge of marketing techniques, etc. Second, the locational advantages deal with the attractions of the location of countries with respect to the country of origin, which will bring greater value added to the firms, for example, the economies of agglomeration, among others. Finally, there are the advantages of internalization, which consist in reducing the costs associated with market transactions. Therefore, a firm is internationalized in terms of the OLI framework if it has competitive advantages over companies in the destination country.

There are two seemingly contradictory points of view concerning the applicability of the Eclectic Paradigm Theory to services. On the one hand, several authors such as Weinstein (1977); Yanopoulos (1983); Terpstra; Yu (1988); Agarwall; Ramaswami (1992); Miller; Parker (1998); Dicken (2003); Cole *et al.* (2007) have argued that the eclectic paradigm is applicable to services, since there should be no distinction from manufacturing because the FDI would be the preferred route for both. However, on the other hand, there are those authors who say that the crucial differences between goods and services make it difficult to generalize the Eclectic Paradigm Theory for services and, therefore, the paradigm should be applied starting from the unique characteristics of services (inseparability, heterogeneity, non-permanence and intangibility), or with some modifications or adaptations to said model (Carman; Langeard 1980; Boddewyn *et al.*, 1986; Sharma; Johanson, 1987; Li; Guisinger, 1992; Erramilli; Rao, 1993; Dunnig 1993; Campbell; Verbeke, 1994; Gronroos, 1999; Bouquet *et al.*, 2004; Bryson *et al.*, 2004; Ekeledo; Sivakumar, 2004; Rugman; Verbeke, 2008; Abdelzaher, 2012). Both perspectives are developed below.

Argawall; Ramaswami (1992) studied the choice of the mode of entry of equipment leasing service firms versus goods manufacturers and found no differences, although they expressed doubt with respect to this type of service not requiring a permanent local presence in a foreign market. Cole *et al.* (2007), in their study of insurance companies, try to prove the Eclectic Paradigm Theory for services. The results indicate that this paradigm provides a general framework for investigating the internationalization of services. Dicken (2003)<sup>xix</sup> proposes the OLI advantages in order to understand the internationalization of business services, which suggests that the said tertiary activity will internationalize by FDI if it has competitive advantages over other companies with respect to assets and OLI competences.

Several authors have emphasized the important differences between firms of goods and of services, from which there were serious doubts regarding the applicability of the Eclectic Paradigm Theory. First, Rugman; Verbeke (2004, 403) accepted the limitation of the location of service firms with respect to manufacturing firms. Second, Abdelzaher (2012, 1725) raised doubts that, while the entry to the market of manufacturers can be driven by a combination of reasons (the pursuit of the market, the search for efficiency to access lower resource costs or the increase in the quest for strategic assets) (Dunning, 1988), the expansion of service companies is motivated primarily by the access of services to a bigger market and by following the customer (Li; Guisinger, 1992). Third, Bouquet *et al.*, (2004, 35-37) asserted that services rarely require large-scale investments in physical assets, such as equipment goods or manufacturing facilities. Therefore, the creation of asset value in a service firm relies more on human capital than on physical infrastructure (Erramilli; Rao, 1993; Campbell; Verbeke, 1994). Conversely, investments in services focus on training programs, expert visits, employment, etc. (Grosse, 1996, 796). Consequently, the distinct nature of services exerts tension on the choice of the mode of entry and the use of human capital. As well, given that for many services the production and consumption are inseparable, it is necessary to invest in human capital and take their own workers to local company in the destination country. Thus, these workers represent an effective strategy to help foreign affiliates to meet the objectives (Edstran; Galbraith, 1977; Kobrin, 1988; Mayrhofer; Brewster, 1996).

Tallman (1991) says that the eclectic model does not provide a unified perspective to explain and predict the choice of modes of entry. Thus, this does not explain why two service companies in the same line of business with similar OLI advantages, necessarily, do not choose the same entry mode. Li; Guisinger (1992, 677), starting from the following empirical research (Aharoni, 1966; Horst, 1972; Dunning, 1973; Root; Ahmad, 1978 and Davidson, 1980), introduce a set of characteristics that affect the international behaviour of services, such as the way to expand the FDI to services, the greater adaptability to the culture and language of service companies than manufacturers and, finally, the need for subsidiaries due to the simultaneity of production and consumption.

Dunning (1993) analyses changing the general paradigm, adapting it to the characteristics of services because of their intensity in FDI and the importance of cross-border alliances. To do this, he

establishes that the tertiary activity is less geographically concentrated than for goods, that services do not need to be global to be competitive (more goods have to be produced in order to reduce fixed costs and increase innovation to be more competitive), that investment in the tertiary sector is lower than in manufacturing, that services are more specialized than goods, that some of their activities precede the goods, which is why services increase in foreign subsidiaries and in the location of the sales generated, and that many services are employment intensive and not capital intensive. The research concludes that the Eclectic Paradigm Theory is an appropriate analytical framework for examining all types of multinational service companies and that the modifications or adaptations of the paradigm to services are a strategic response. In short, it adds a set of ownership advantages (consistency of quality, reputation, economies of scope, of scale, specialization, etc.), locational advantages (availability of services, research and development, job training, etc.) and internalization advantages (human element, information, tacit knowledge, etc.), which turn out to be essential factors in adapting said eclectic model to services.

On one hand, the empirical analysis of Bryson *et al.* (2004) should be highlighted, which develops new OLI advantages to apply them to services. First, the ownership advantages are based on the firm's reputation and knowledge of the workforce. Second, the locational advantages focus on the importance of the knowledge of local markets and providing face to face services to customers in that place. Third, the internalization advantages focus on the ability to exploit specific knowledge of the firm without the risk of giving that knowledge away to competitors. On the other hand, Ekeledo; Sivakumar (2004) conclude that the eclectic model ignores the characteristics of goods and services and, therefore, variables must be included that are based on the perspective of resources, such as the specific skills of the firm, the tacit knowledge, the experience of the firm, the specialization of services, firm size, organizational culture, firm reputation, resources and the complementary nature of the services. Finally, Faulconbridge; Beaverstock (2007) state that the OLI advantages can be improved by the internationalization of services, given that the firms of the tertiary sector internationalize not only to exploit advantages of ownership, location and internalization, but also to create spatial advantages.

In short, we believe that it is necessary to reflect on adapting the OLI advantages, generally, to the features of services. First, to inseparability given that, because of this feature, service companies will need to have their own personnel abroad. Therefore, FDI will be a perfect solution for many of them. Second, to heterogeneity, as two services are often not identical because if the delivery of the service involves various factors of interaction between the employees and their customers, they will need more knowledge concerning the factors of location than will manufacturers. Third, to non-permanence and inviolability, given that the reputation or brand image is necessary, since the quality of services is very difficult to prove. Therefore, we should think about the importance of including variables such as market knowledge, preferences and tastes of customers from the home destination, the learning of human capital and the organizational culture itself. Furthermore, the OLI advantages should be adapted to the special features of each type of service, which causes the eclectic model to be modified. For example, for an insurance firm it will be very important to include market knowledge as a locational advantage. However, for an ICT business it will be to exploit its advantages to avoid possible imitations.

Concerning knowledge-intensive services, Narula (2014) attempts to approach the changes in the international arena based on the general paradigm of Dunning. The research also highlights the duality between the co-evolution of the assets of the firm as a function of the factor endowments of the country, including knowledge-intensive services like those that are located in advanced economies. Therefore, it is worth mentioning that the locational advantages are not very relevant for KIS, as they usually have knowledge of the market and establish prior networks and partnerships in foreign markets. Therefore, KIS generally do not seek to be located in advanced countries for the factor endowments of the country, but rather for the pursuit of opportunities and following the customer. In particular, we believe it appropriate to make some modifications to the locational advantages proposed by Dunning (1997, 219)<sup>xx</sup>, which are focused on (1) the search for natural resources (physical and human resources), (2) finding markets

(domestic market and access to regional markets), (3) the pursuit of efficiency, particularly in the rationalization of production to exploit economies of scale (specialization of products and processes), and (4) the search for strategic assets with a lead in the regional or global strategy (technology, organizational capabilities and markets). To do this, we believe that importance should be given, as factors of location, to the search for opportunities, following the customer, the establishment of networks and alliances and the previous experience of human capital. In addition, the co-evolution of the assets of KIS firms is often not based on the endowments of the country, but rather is a function of the feedback between human capital and the customer. In general, we think that in order for the Dunning paradigm to be able to adapt well to KIS, the importance of the perspective of the dynamic capabilities of the firm should be increased, which allows them to exploit their ownership advantages without the need to have locational advantages based on the factor endowments of the countries. Thus, the framework of globalization will depend, to a greater extent, on the internal capabilities of the firm, which would increase the information thereby reducing market uncertainty.

#### **4. Conclusions**

##### **The Theoretical Contributions**

This paper has tried to adapt some traditional theories of internationalization, mainly those based on market imperfections, such as the Theory of Industrial Organization, Transaction Cost Theory, Internalization Theory and the Eclectic Paradigm Theory, to services and, especially, to knowledge-intensive services, given that their features and their wide variety of activities make it necessary to differentiate them by sectors with their features and nature being the most common classification criteria for their applicability.

On the one hand, it can be seen from the analysis of the theoretical and empirical literature of cases of services and KIS, that the theory that best fits the behaviour that services and KIS often show in the modes of entry to the international markets is the Eclectic Paradigm Theory. Thus this was an attempt to avoid the shortcomings and lack of clarity of the Theory of Industrial Organization, Transaction Cost Theory and Internalization Theory on the internationalization of service companies, since, although in principle they help to explain their international behaviour in general, they subsequently turn out to be very static and need some development and modifications to be better suited to the conditions experienced by service firms. We also believe it appropriate to introduce a flexible nature, differentiation of services, intensity of human capital, continued investment in innovation or market factors in order for the Theory of Industrial Organization to be better tailored to the service sector and, for KIS, qualified human capital and the perspective of resources and capabilities. Furthermore, for Transaction Cost Theory and Internalization Theory to have greater adaptability, we propose that importance should be given to the external factors of the firm and, for KIS, knowledge, qualified human capital, the experience of the founder and networks or international alliances. In summary, we consider the theory that is best adapted to the service sector and to KIS, despite the modifications that have been raised in this work, is the Eclectic Paradigm Theory.

On the other hand, thought should be given to making modifications to Dunning's eclectic paradigm in order to tailor it better to the characteristics of services, especially KIS. Thus, in order that the general paradigm is applied well to services, the importance of human capital should be introduced as a proprietary advantage, as it is essential in the carrying out of their characteristics, allowing more flexibility in the face of the global dynamism. Particularly, the Eclectic Paradigm Theory needs more introductions and developments to properly adapt it to knowledge-intensive services than to the other service activities. We especially think it very relevant that, on one hand, the paradigm include the perspective based on the dynamic capabilities of the firm to promote the process of internationalization,

because they allow them to be more competitive in the international market and, on the other hand, the locational advantages should undergo a change of criteria, which focus more on the customer and on the search for opportunities than on the factor endowments in the country.

### **Future Research Suggestions**

In accordance with the above, in future research we will try to empirically investigate the following proposals. First, if including the modified variables to better tailor the Theory of Industrial Organization and Transaction Cost Theory and Internalization Theory to the service sector, would improve the applicability of the Eclectic Paradigm Theory to said sector. Second, analyse whether including the importance of human capital and inseparability or not of services in the OLI advantages would better adapt said paradigm to services. Third, modify these OLI advantages to enhance their applicability to KIS, on the one hand, by introducing variables related to the dynamic capabilities of the firm and, on the other hand, by reorienting the locational advantages in the search for market opportunities and in following the customer. In short, it is proposed to empirically investigate whether, based on what we have been able to show through the theoretical and empirical literature of cases on some theories of internationalization, the development and modification of the proposed variables would improve the applicability of the Theory of Industrial Organization, Transaction Cost Theory, Internalization Theory and Eclectic Paradigm Theory to services and, especially, to KIS.

---

<sup>i</sup> Teece *et al.* (1997, 516) define Dynamic Capabilities as “the firm’s ability to integrate, build, and reconfigure internal and external competences to address rapidly changing environments.”

<sup>ii</sup> Market orientation: KIS are characterized by being market-oriented because they provide personalized services with high added value to the customer (Werawardena *et al.*, 2007, 296). Being market-oriented implies knowing the needs of the customer, the influence of technology, competition and other environmental forces and acting with this knowledge in order to be competitive (Slater; Narver, 1995, 67). Therefore, it becomes essential for KIS to plan their relationships with customers and ensure excellent communication in order to increase the degree of adaptation of the service and the creation of added value (Amaro *et al.*, 2008, 1531).

<sup>iii</sup> Location: KIS typically focus on areas where the majority of service providers are found (Bettiol *et al.*, 2013, 4). It is for this reason that, in some cases, they pursue strategies of following the customer in their internationalization. The main factors explaining the location of KIS is

---

the formation of knowledge, the innovative potential and the economic possibilities of agglomeration (Alcocer; Maroto Martin-Sanchez, 2010, 85). Thus, KIS focus on highly innovative environments, so that information and knowledge can spread efficiently in terms of population density levels, production and economic development.

<sup>iv</sup> Employees: Employees of KIS firms are characterized by being highly qualified, by their training, professional experience and for their high degree of autonomy. The autonomy can include greater decentralization of decision making to employees and/or increased participation by them at the firm level (Von Nordenflycht, 2010, 155). The personnel of KIS firms employ specialized knowledge to solve customer problems (Lowendahl *et al.*, 2001, 915), as well as representing an intellectually qualified workforce (Von Nordenflycht, 2010, 159).

<sup>v</sup> See Spender (1996), Petrash (1996), Holsapple & Singh (2001), Scarso & Bolisani (2010). As well, empirical studies dedicated to services (Erramilli, 1991; Mattsson, 2000; Lindsay *et al.*, 2003) and to KIS (Malkgård, 1998; Saarenketo *et al.*, 2004; Strambach, 2008; Scott-Kennel & von Batenburg, 2012; McQuillan *et al.*, 2013).

<sup>vi</sup> See Barras (1990), Gallouj; Weinstein (1997), Windrum; García-Goñi (2008), Gallouj; Savona (2009), Maglio; Sphrer (2013). As well, the following studies decided to services and KIS: O'Farrell *et al.* (1998), Cavusgil *et al.* (2003), Dib *et al.* (2010) and O'Cass; Sock (2013).

<sup>vii</sup> The ability of the firm to create networks is derived from Johanson; Mattson (1988). See the following empirical research: on services (Zain ; Ng, 2006), on software services, knowledge-intensive services and businesses and high-tech services (Bryson *et al.*, 1993; Moen *et al.*, 2004; Mort; Weerawardena, 2006; Strambach, 2008; and Scarso; Bolisani, 2011).

<sup>viii</sup> Organizational learning is the process of the assimilation of new knowledge in the knowledge base of the organization (Autio *et al.*, 2000, 911).

<sup>ix</sup> Based on the classification of Muñoz-Guarasa (1999, 56-67).

<sup>x</sup> Taken from Martínez Mora (1997, 53-58).

<sup>xi</sup> Taken from Martínez Mora (1997, 53-58).

<sup>xii</sup> Taken from Breinlich; Criscuolo (2011).

<sup>xiii</sup> Taken from Muñoz-Guarasa (2005, 593).

<sup>xiv</sup> The Theory of Resources and Capacities proposed by Penrose (1959, 25) suggests that resources are fundamental for providing future services. According to Barney (1991, 105) three types of resources exist: physical, human and organisational. As well, they establish that in order to achieve a sustainable competitive advantage for resources, they must be valuable, rare and perfectly inimitable, having a low degree of substitutability. Thus, so that resources generate competitive capacity for the company, it is necessary to differentiate between resources and capacities.

# Current State and Perspectives of 3PL Outsourcing by SMEs

*Laurențiu Tăchiciu, Vasile Dinu*

Bucharest University of Economic Studies

*Outsourcing knowledge intensive services is a solution for SMEs to reduce the competitiveness gap in relation with larger companies. However, the number of SMEs who resort to outsourcing of knowledge intensive services is still limited. In the present paper we explore SMEs understanding of logistic challenges and the determinants of their choices between integration and outsourcing of logistic processes, barriers which slow market expansion of 3PL services outsourcing by the SME sector.*

## 1. Introduction

The present paper explores the desirability and feasibility of third party logistics (3PL) services outsourcing by SMEs in the Romanian context.

The interest for this issue came from a number of real life stories.

A micro-enterprise is a supplier of customised cardboard packaging and display stands. They are not a traditional manufacturer, but more an integrator, as they subcontract the majority of manufacturing activities, performing in-house mostly the design, and some finishing tasks. They perform a critical role within their informal network, as they get the contracts and take the responsibility for their execution. The owner of the company explains that they can compete with larger and better endowed companies only by flexibility. For instance, he says, nobody else will accept an order Friday to be fulfilled until Monday afternoon. About one third of the production is sold abroad. Under such circumstances he faces problems with the delivery. Once, they arranged transportation with an independent truck owner. The load was not secured as it should and the goods delivered were damaged during transportation, with multiple bad consequences for the firm.

Another case is that of a medium-size company distributing assembly elements for constructions, furniture manufacturing, DIY retail etc. They work with tens of thousands of individual items which are also grouped in various selling “units” or articles (box, blister, set etc.). They invest heavily in warehousing technology, including the acquisition of a warehouse management system (SAP). The implementing of the system took about five years, with assistance from a specialised consultant firm. The most challenging was to develop an internal competency related to the implementing and maintenance of the system. Now, when the system became operational, they take into consideration to extend services to other companies, either consultancy, or even warehousing related services, in order to better exploit the acquired competency.

Each case is particular, and the behaviour of each firm was dictated by individual sets of motivations. Nevertheless, both cases (along with several other similar ones)

raise a question about the state and the future of the 3PL market, from the SME sector perspective in particular. One may also have in mind an analogy with other outsourcing industries which appeared as practices of large corporations, but then expanded to the SME market, like accounting and IT services. Additionally, in the case of Romania, there is little information about the logistics services industry, so any investigation in this field will contribute to a better understanding of the situation.

We consider that it worth exploring the subject because, in contradiction with the very rich literature on logistics and supply chain management (SCM) on one side, and on SME logistics performance on another, the research regarding the outsourcing of logistic activities by SMEs is very scarce. There is little interest for the topic because for the moment it is a very rare practice but the situation will probably change in few years if we consider an analogy with other outsourcing industries which appeared as practices of large corporations, but then expanded to the SME market, like accounting, IT services or consulting. Additionally, in the case of Romania, there is little information about the logistics performance, so any investigation in this field will contribute to a better understanding of the situation.

The present paper starts by several theoretical considerations, and then we give an overview of the logistics industry in Romania. Next, we present the methodology and the results of a qualitative survey among Romanian SMEs about the way in which they are fulfilling their logistics activities and about their propensity to outsource some of these activities. Finally, we discuss the findings and suggest directions for further research.

## **2. Theoretical considerations**

Introduced first in relation with military deployments, in the 19<sup>th</sup> century<sup>1</sup>, logistics was defined as a “science” or an “art” of making resources (people, equipment and material) available in good conditions, at a certain (different) place and at a certain time, where and when they are required. It is concerned with ensuring performance of operations (efficacy, economicity and efficiency) and relies heavily on methods derived from the Management science (operations research).

Applied to business, logistics is commonly understood as a function of the enterprise, a set of interconnected activities leading to an intended result, a critical component of the ‘value creation chain’ (Porter, 1985) at the level of an enterprise, or “value creation system” when several enterprises contribute at creating a single end value added. Porter’s concept “value system” is now named supply chain.

Logistics and supply chain management enjoyed increasing interest from scholars, being considered as “an evolving, expanding academic discipline that does not appear to be approaching full maturity in the near term” (Maloni, Carter and Carr, 2009, 264; cited by Karatas-Cetin and Denktas-Sakar, 2013). These authors - last cited here - have indeed demonstrated the interdisciplinary character of logistics identifying

<sup>1</sup> Dictionary.com, “logistics,” in Online Etymology Dictionary. Source location: Douglas Harper, Historian. <http://dictionary.reference.com/browse/logistics>. Available: <http://dictionary.reference.com>.

17 disciplines and 18 theories which contributed at addressing logistics research questions during the last two decades.

However, it seems that nowadays developments in the field of logistics and supply chain management are led by industry professionals, organised within such bodies as the Council of Supply Chain Management Professionals (CSCMP), the European Logistics Association (ELA), or APICS –SCC. Such organizations have developed Dictionaries and Glossaries, benchmarking standards, reference frameworks and standards of professional competencies in the field.

CSCMP glossary defines logistics as:

“The process of planning, implementing, and controlling procedures for the efficient and effective transportation and storage of goods including services, and related information from the point of origin to the point of consumption for the purpose of conforming to customer requirements. This definition includes inbound, outbound, internal, and external movements” (CSCMP, 2013).

A more detailed understanding of the content of such process may be acquired from ELA Standards of Competence for logistics supervisors, mid-level and strategic level managers.

Within this professional milieu, with the increasing specialization, and outsourcing expansion, a new industry of logistics services is developing and new distinctions appear to be necessary. Third party logistics has appeared when logistics service providers undertook some of the tactical decision making tasks from their customers (choice of other service providers, coordination among different activities like warehousing, multimodal transportation) as well as the provision of some value adding activities. Then, the specialists providing the customer support in making strategic decisions regarding the design and setup of a supply chain framework received the name of Fourth-Party Logistics or Lead Logistics Partner (4PL or LLP). While it seems to be an agreement about the difference between 3PL and 4PL in the level (tactic vs. strategic) where the interaction with the customer occurs, there is a controversy about whether or not 4PLs may be concomitantly providers of asset dependent services (transportation, warehousing etc). In this respect, some argue that it might be a case of conflict of interest, and we tend to agree.

Anyhow, 3PL can be considered as an already established (sub)industry, while 4PL looks (at least in Romania) more like a desiderate. Not only many companies define themselves as being 3PL service providers, but also this segmentation is largely recognised in the academic literature. Alexandra Marasco has analysed and classified more than 150 scholarly articles on 3PL. She found a need for a more solid conceptual basis as “research relating to specific TPL issues has been conducted from various perspectives and is often based on different definitions or interpretations of what is meant by TPL”, which limits the possibilities for sharing and comparing research results. (Marasco, 2007, 142). Interestingly, Yang, finds a possible explanation for why the definition of third party logistics is still blurred: “From the provider's point of view, their business covers a great number of relationships involving everything from simple logistical activities to advanced logistical solutions; from the customer's point of view, the degree of outsourcing varies and the outsourced logistics activities differ greatly” (Yang, 2014, 18) The missing link unifying the provider and the customer perspectives is also emphasised by Soinio, Tanskanen and Finne (2012).

We agree with the fact that there is room for conceptual clarifications but addressing this issue falls outside the scope of our paper. Anyhow, from what we could see, practitioners do not have a concern about it.

For us it is important to note that the specialization has provided 3PL companies with the opportunity to develop superior competencies and to make use of sophisticated technologies which brings sizable efficiencies in the supply chain. Expanding the use of these capabilities to the entire economy will raise the overall economic performance. The problem is that a large part of the economy, consisting of SMEs, doesn't seem to be part of the game yet. Still, analogies with other outsourcing industries suggest that this will happen sooner or later. Here we share the views and concerns of Soinio, Tanskanen and Finne. They addressed the same kind of issues and they found that in Finland SMEs have little interest to none for improving logistics performance, either through outsourcing logistics activities or through other means. We also noted a useful elaboration of several service models, and the suggestion that SMEs may need strategic consultancy (4PL) in first place (Soinio, Tanskanen and Finne, 2014). On the other hand, in our opinion, the cited authors fail to consider a number of issues: the structure of the 3PL industry and possible market failures which may limit the providers' interest for the SME market, the state of the technologies and knowledge which may limit the capacity of service providers to meet the needs of SMEs, the interest of the consumer that may justify some kind of public policies supporting the overcoming of the said limits. By difference, we assume a perspective biased toward the public interest.

In Romania, apart from infrastructure, which ranks high in the public debate, the economic role of logistics and the state of the logistics industry is almost ignored by public policies. In other countries the interest is already manifested and raising (Rantasila and Ojala, 2013). At international level, the World Bank has developed a Logistic Performance Index (LPI). This study provides a clear support for making logistics a policy concern:

“Reductions in supply chain trade barriers improve the efficiency of the movement of goods, thus recovering resources otherwise wasted. By contrast, most tariff reductions reallocate resources, capturing only the more modest inefficiency created by the tax”. (World Bank, 2014)

### **3. The logistics industry in Romania**

The most significant and reliable information on the state of logistics in Romania is provided by the World Bank LPI. The overall index is composed in six components

- The efficiency of customs and border clearance (“Customs”).
- The quality of trade and transport infrastructure (“Infrastructure”).
- The ease of arranging competitively priced shipments (“Ease of arranging shipments”).
- The competence and quality of logistics services—trucking, forwarding, and customs brokerage (“Quality of logistics services”).
- The ability to track and trace consignments (“Tracking and tracing”).
- The frequency with which shipments reach consignees within scheduled or expected delivery times (“Timeliness”).

The first three components measure inputs from policies and regulation and the last three the outcomes in terms of logistics performance (time, cost and reliability). Between 2010 and 2014 Romania has improved its relative position with 19 places in respect to the overall index and has made progress on almost all the dimensions. The fastest improvements, as well as the best relative ranks, were realized in terms of Timeliness and Tracking and tracing. It is obvious that the performance of the Romanian logistics industry surpassed the policy improvements.

Table 1. Evolution of Romania LPI ranks 2010 – 2014

|                               | <b>2010</b> | <b>2012</b> | <b>2014</b> | <b>+/-</b> |
|-------------------------------|-------------|-------------|-------------|------------|
| Overall LPI                   | 59          | 54          | 40          | + 19       |
| Customs                       | 85          | 61          | 59          | +26        |
| Infrastructure                | 99          | 87          | 64          | +25        |
| Ease of arranging shipments   | 34          | 53          | 36          | -2         |
| Quality of logistics services | 66          | 64          | 43          | +23        |
| Tracking and tracing          | 66          | 53          | 34          | +32        |
| Timeliness                    | 73          | 29          | 27          | +46        |

Source: World Bank

Despite the overall positive evolution, Romania remains on the second lowest position among EU member states, being considered as a partial performer, a category of countries for which the World Bank report recommends addressing with priority the lagging behind in the fields of services reform, integration of border management, regional facilitation and corridors, transport infrastructure.

We could not identify any reasonably credible study regarding the logistic industry in Romania providing aggregate information at national level, apart from a recently announced research done by Ken Research. This one could not be consulted because of the prohibitive price. However, from the listing of the companies covered by this research we find that a large number of European major logistics firms have established subsidiaries in the country: GSK Europharm Distributie, Macromex, DB Schenker, H.Essers, HAVI, Dumagas, Tibbett Logistics, GEFCO, Dunca Expeditii, Kühne & Nagel, Aquila, Delamode, Gebrüder Weiss, DSV, OTZ, FM Romania, KLG, Cargo-Partner, Frigoexpres, Geodis Calberson. While by volume the transportation market is dominated by domestic companies, warehousing and third party logistics services are dominated by multinationals. It means that even if the Romanian logistics market is far from maturity, knowledge and experience from best performers are available.

The first international logistics companies came to Romania following their international customers, but during the last years, logistics companies are attracted in the country because of different reasons. Many come not only for the Romanian demand for services, but also to establish regional operations, taking into account the access to Constanta Port and to Danube, the relatively low price of real estate and the availability of well educated, foreign languages speaking personnel. Together with domestic companies which develop competencies in providing integrated services, the offer of 3PL services will increase and the need to address smaller size customers will become more pressing.

#### **4. SMEs propensity to outsource 3PL services**

We are looking to find out an indication about the presence of a latent demand for 3PL services among Romanian SMEs, as a recognized need for improving existent processes. We designed the investigation as an exploratory survey supported by an on-line questionnaire addressed to a convenience sample<sup>2</sup> of about 500 SME owners or managers from manufacturing and commerce sectors. We chose to keep the questionnaire simple in order to improve the answer rate. We also took into consideration that the subject or terminology may be unfamiliar for many respondents. In this respect we avoided to use terms and expressions like logistics, supply chain, or outsourcing. We did not neglected the possibility to encounter cases of on-going solution implementation, either in the form of investments in improving in-house capabilities, or in form of quest or even negotiations with external service providers. However, this last case – otherwise fruitful for market and transaction characterization - is considered to be outside the scope of the present paper. The questionnaire has been launched in March 2015 and until the end of June we got 114 valid answers. We consider that the answers' rate is very low, which given the circumstances, indicate – referring to the non-respondents - either a total lack of interest for the subject or a lack of readiness to address this kind of aspects (like "I am not prepared to answer these kind of questions yet").

The questionnaire is structured in several sections, each of them aiming to support collection of specific sets of information:

- Information on the type of business activity, allowing a categorization of respondents in line with suitable criteria;
- Information regarding problems faced in running the business, possibly generated by a dysfunctional logistics; these questions have an important role in the survey, not only because we expect a disclosure of a latent need for more advanced or better adapted logistics solutions, but also for their potential to raise the involvement of the respondent in relation with the aspects under investigation;

<sup>2</sup> The sample consisted of enterprise owners or managers that have already participated in a survey, who were personally invited to answer the new questionnaire.

- Information about the importance given by respondents to the different components of the logistics function in present, and about respondents' anticipations regarding a change in the future;
- Information about the extent to which respondents take into consideration as a possibility to outsource logistics services in present, in the near future or on longer run;
- Information about the using or intention to implement in future enterprise resource planning (ERP) systems

It is worth mentioning that the questions have been formulated in Romanian, in a somehow colloquial manner, using a terminology which is common in daily business activities, and avoiding the logistics specialised jargon. We made any effort to ensure the best semantic match, but fine differences cannot be entirely eliminated.

In addition to the general interpretation of the survey – which is further presented here – each respondents answers will be analysed in order to identify situations that can be latter analysed more in depth, through case studies.

*The first set of questions* aimed at segmenting respondents by type of business represented. Respondents were categorized following two sets of criteria: business model and degree of involvement in foreign trade<sup>3</sup>. The resulting categories and number of respondents in each category are presented in Table 2.

Table 2 The survey sample by category of enterprises

|  | High degree of foreign trade participation | Low degree of foreign trade participation | No participation to foreign trade | Total |
|--|--|---|-----------------------------------|-------|
| Consumer goods manufacturer (CGM)            | 4  | 5   | 9                                 | 18    |
| Make-to-Order intermediate goods manuf.(MTO) | 2  | 2   | 9                                 | 13    |
| Make-to-Stock Intermediate goods manuf.(MTS) | 1  | 2   | 7                                 | 10    |
| Consumer goods wholesaler (CGW)              | 3  | 8   | 13                                | 24    |
| Intermediate goods wholesaler (IGW)          | 4  | 4   | 3                                 | 11    |
| Retailer (RET)                               |  |   | 38                                | 38    |
| TOTAL  | 14   | 21  | 79                                | 114   |

When deciding on the classification criteria we overlooked<sup>4</sup> an important distinction discussed by Soinio, Taskanen and Finne. They remarked that SMEs affiliated to an existing supply chain managed elsewhere (usually by their powerful customers) have little room for logistics decisions (Soinio, Taskanen and Finne, 2012). We suspect

<sup>3</sup> The questions were of type: "Which of the following describe best the activity of your company?"

<sup>4</sup> We deliberately overlooked this aspect, in order to avoid excessive complication of the questionnaire and may be suspicion of respondents, potentially reducing the answering rate.

that many enterprises in our sample might be in such a situation, but we did not control this feature and this is a limitation for the present paper.

We must also mention that it would have been probably a better idea to consider separate questionnaires for manufacturing and commerce as in the current framework a series of particularities could not be clearly addressed.

*The second set of questions* was about problems faced by companies, possibly caused by logistics system dysfunctions, separately for inbound and outbound logistics. We listed 20 possible problems and asked respondents to estimate the impact on business operations (high, moderate, minor or none) of each, by combining frequency of occurrence with the gravity of consequences. The problems taken into consideration were referring to inadequacy of assets (insufficient warehouse area), administrative and information flow problems (errors), operational problems (mishandling, damage) and the consequences in terms of time, cost, overstock or stock-outs, demand or customer loss.

Almost all the respondents – exception being those representing retail companies – tended to give higher impact estimates to the problems related to the outbound logistics. Understandably, issues that can lead to customer dissatisfaction are a major concern for companies' leaders. In the case of retail companies, they are at the bottom of the logistics chain, they have little outbound logistics concerns, except when they also offer a home delivery service (some restaurants, supermarkets and durable goods retailers). Many "brick-and-mortar" retailers take orders by telephone or internet and organise the home delivery in house as a non-core activity which sub-optimal performance creates no concern. In contrast E-Commerce retailers outsource the outbound logistics to carrier companies. We could not identify any e-commerce company within our sample.

The highest bad impact score tended to be attributed to outbound inventory (overstock or stock outs), this time the sizeable difference being made by retailers and MTOs. Second, came administrative and information system shortcomings: slow processing, data missing, and errors. This finding should be noted, as this is exactly the area where the superior competency of 3PLs can make substantial difference.

*The third set of questions* addressed the perceived importance for the business of different logistics sub-functions or activities. The respondents were asked to make an opinion about the importance of each item (very important, important, not so important, not at all important) for the success of their company. They have been asked to consider the importance in present and in 5 years from now. The items displayed by the questionnaire are: planning, inventory management and control, warehouse management and operation, organizing transport, processing of orders and invoices, performance assessment and reporting. All the items were considered as important to very important, but the highest score was given to planning. We wouldn't guess this result, being the stereotype that practitioners are less sensitive to 'soft' inputs and more concerned about "hard results". In our opinion ranking planning high as importance comes partly from education, to some degree from the perceived need of information and mostly from the risk pressure. One should not forget that many of the respondents are enterprise owners. Probably, for them it is important to reduce at least the risk sentiment.

There are almost no variations between the importance attributed to each item in present and after five years. This can be verified not only by aggregated scores but

also for each respondent. We have already met during previous studies this incapacity to figure what changes will appear in the future. In general it is a symptom of the lack of strategic thinking. In this case we don't have elements in support of the same conclusion.

*Fourth query* is about the intention to outsource logistics services. In brief: "taking into consideration the problems related to logistics that affect your business, how likely is your company to ..." The respondents were asked to assess various scenarios with the following options: already done, in the pipeline, most likely in five years, in five years maybe, I don't know, probably not, absolutely not. The scenarios presented included:

- Acquisition of new assets (real estate, trucks etc.)
- Acquisition of IT (software, scanners, etc)
- Staff training (in logistics related matters)
- Hiring qualified personnel
- Contracting a master logistician (4PL)
- Outsource logistics activities with asset based service providers (3PL) including planning
- Outsource logistics activities with asset based service providers (3PL) excluding planning

The respondents were encouraged to leave aside the financial constraints and to presume that the cost associated with alternative choices is equivalent.

Overall, the companies in our sample display a preference for developing in-house competencies. Answers indicating likelihood of some measures in the near future were far more frequent in relation to in-house developments. The most popular scenarios are related to technology and knowledge acquisition. We could not see any relevant difference between categories of enterprises. On the other hand, the possibility of arrangements with 3PL or 4PL service providers is not excluded in an absolute manner; it is only treated as less likely by the large majority of respondents. Only 2 respondents representing CGM said they have outsourcing arrangements in the pipeline, while 21 respondents said that such arrangements is most likely to occur in five years. When it comes to likelihood of outsourcing, the majority of respondents (69) were undecided, choosing among the answers: "in five years maybe" and "I don't know".

The scenarios presented in the questionnaire are not mutually exclusive. One may take action to develop the company's asset and human related capabilities, and still consider the possibility to outsource the majority or the most critical logistics activities in five years. Yet, such behaviour has little sense.

In general, we guess that the attitude of respondents toward outsourcing is motivated by a combination of fear to lose control over the business and lack of information about the way in which outsourcing works.

*The last query* was about the IT capabilities in place. We received information, but finally we consider the result as being inconclusive. We do not have enough information to distinguish among in-house developed IT solutions, inexpensive-poorly adapted and poorly integrated solutions, or the degree to which companies owning sophisticated ERP solutions exploit the full potential of the technology. While IT talent

is not scarce in Romania, there is penury of sophisticated business knowledge, deep understanding and ability to use business phenomena modelling techniques.

## **5. Conclusions**

The main conclusion of our study is that among Romanian SMEs there is awareness about the weaknesses of the logistics system and preoccupation for improving its performance. The perceived need for improvement act as a latent demand for solutions, but outsourcing activities toward external service providers is regarded with justifiable reserve, motivated by lack of information and fear to lose control over the business, in principal (adequacy of financial resources being let aside).

We have taken a non-conformist approach in designing the survey, and we believe that the solutions adopted in this case can be further refined and exploited for deepening the investigations.

Mass outsourcing of logistics services is considered to be a mark of a mature and sophisticated market. This is clearly not the case in Romania where the 3PL industry is in its nascent phase, characterized by lack of authentic rivalry among service providers, lack of transaction transparency, and deep information asymmetry between 3PL providers and their customers.

Our study support the conclusions from Finland of Soinio, Taskanen and Finne that perhaps, SMEs pass toward outsourcing 3PL should start with 4PL, as a source of more confidence and control over the subject. Additionally, if we accept a public interest in accelerating SMEs outsourcing of logistics activities, there a scope for public contribution to removing identified barriers. The priority should be to make available market information and industry benchmarking studies, and next, to disseminate success stories and best practices.

# **Which Factors Influence Formalization in New Services Development Processes? Empirical Findings from European and Mexican Service Firms**

*Ilyas Khan<sup>1</sup>, Thomas Meiren<sup>2</sup>*

<sup>1</sup>Heilbronn University, <sup>2</sup>Fraunhofer Institute for Industrial Engineering

*Current literature revealed that formalization in New Service Development (NSD) processes contribute significantly to the NSD success. If this is true, then why companies are not tending to implement formalized NSD processes? At the same time a review of the current literature shows that formalization in NSD processes are rare in most service firms. This study is aiming to investigate which factors influence the degree of formalization in NSD processes? A mail survey was conducted in seven European countries and in Mexico. In total 1333 companies participated in the study from a wide range of service industries. Multiple linear regression model was estimated and its assumptions were tested. The model predicted that explicit service strategy, type of service, type of innovation, and customer integration are positively influencing the degree of NSD process formalization.*

# 1. Introduction

In increasingly dynamic competitive environments, cost, quality and technology leadership are no longer sufficient for service enterprises to secure crucial advantages. Instead, growing importance is nowadays attached to more subtle differentiations in the form of innovative services, which in many branches are rapidly developing into the unique selling propositions of each firm. The principal challenge facing companies is the need to offer the marketplace continuously improved, if not new, services, while keeping one step ahead of their competitors and at the same time fulfilling the needs and expectations of their customers.

Many service providers are however hindered by the fact that their present corporate structures and processes are not designed to enable services to be efficiently developed and launched on the market. Difficulties are frequently encountered because the new services created by firms are not clearly defined, there are no unequivocal descriptions of the service contents, the relevant processes, the customer interfaces and the necessary resources. As a result, efficient and successful implementation of these new services is considerably impeded by an absence of transparency as well as by interface and quality problems (Spath and Fähnrich, 2007).

Those companies that develop new services regularly are compelled to search for ways of avoiding the described difficulties, to prevent repetitions of past mistakes and to enable existing know-how to be reused. In order to accomplish this objective, they generally begin by describing their development processes and by standardising individual development steps to a certain degree. This *formalization* extends from predefined, rigid development process on the one hand to flexible, situation-specific procedures on the other. Where the term formalization is used in the following, it is thus in no way intended to imply that development processes are constrained inside an absolutely tight straitjacket. On the contrary, it means that these processes are no longer always arbitrary, but that there are defined guidelines according to which the services are supposed to be developed (Bullinger et al., 2003). In literature, the formalization of development processes is often seen as a success factor for new services (e.g. Meiren, 2006; Horne, 1993; Cooper and de Brentani, 1991), but there are as well research results claiming that formalization limits development speed and creativity and therefore could have a negative impact. Both positions have in common, that they refer on studies that are limited on low populations, on only a few industries and on generalizing research approaches. With the data of an extensive survey among service providers we now have the opportunity, to investigate formalization in new service development in detail.

## 2. Literature review and hypotheses

### 2.1. New service development strategy

“Service development strategy set goals, provide available resources and market window for which to aim” (Edvardsson et al., 2013). It is substantially revealed from the current literature that strategy is one of the key contributors to the success of new service projects (see, for instance, Gebauer et al., 2008; Jin et al., 2014; Posselt and Förstl, 2011). Particularly, Edvardsson et al. (2013), found that strategy contributes significantly to the NSD success and was the most influential factor. NPD literature shows that strategy is positively related to the new product development process. For example, Moore (1987), observed that most successful companies are more likely to tie new product development into their strategic plan. In the context of NSD, Fischer et al., argued that service innovation should be aligned with the service strategy, which should include determination of responsibilities within the innovation process, division of the innovation process into sub phases, contextual design of every step along the innovation process and customer integration into the individual steps of the innovation process. Moreover, Cooper and Brentani (1991) highlighted that strategic focus not only provides guidelines for resource allocation but also “*keeps a service firm from considering innovation as an ad hoc process*”. In addition, Horne’s (1993) study of 16 different US firms including consulting, information processing, retailing, financial services and hospitality suggests that some form of strategic planning exists for most service firms and the majority of successful firms shows great commitment to the strategic planning for new services development. Based on the above discussion we propose the following hypothesis.

*H1: Service development strategy positively influence NSD process formalization*

### 2.2. Customer integration into NSD

It is well established in the literature that customer integration in NSD is crucial and play an important role to develop services more successfully (see, e.g, Edvardsson et al., 2013; Polonsky et al., 2005; Posselt and Förstl, 2011; Tajeddini, 2011). Edvardsson et al. (2007), described customer knowledge as a key term in NSD and emphasized that new service development process and structure should be capable to accommodate different changing customer preferences. (Baron et al. 2009) argued that there is a need for NSD to be customer-intensive in order to integrate customer to a greater extent throughout the development process unlike traditional NSD process. Alam and Perry (2002), observed customers contribution in all phases of NSD process and at least one activity in every NSD step was performed. They proposed an NSD model which incorporates customer into various stages during the development process. This shows that customer’s integration is vital in NSD process and every step in the development process requires unique input from customers. This further suggests that new services development process should be more systematic and should include all important development stages in order to integrate customers in the NSD process to a larger extent. Besides the importance of customer integration, the method to integrate customers is of great concern. Edvardsson et al. (2007), explained that the extent and method of customer integration into NSD is dependent on the NSD type. Moreover, “In some cases it is enough to simply ask

customers what they want and then design and offer what they require. In many cases, however, customers have a hard-time verbalizing what they want in a way that gives sufficient information to direct the service development processes” (Edvardsson et al., 2007). The authors aimed for multi-method approach in order to fully understand customers. In their opinion simple surveys and verbal-based customer satisfaction studies are not sufficient. It leads us to our second hypothesis.

*H2: Intensive customer integration has positive influence on NSD process formalization*

### **2.3. Service typology**

A review of the current literature suggests that heterogeneity in services influence the NSD process in particular formalization. For instance, financial services are developed more rigorously compared to other services. Crevani et al. (2009), observed that educational services are developed in more formalized way than logistic services and those companies have developed some standard modules for new service development. Recently, Meiren et al. (2015), derived a service typology which consists of four heterogeneous clusters of services. Namely knowledge-intensive, technology-intensive, routine-intensive and contact-intensive services. The results revealed that the degree of formalization in NSD process is different across these four groups. Knowledge intensity and technological intensity in services are significantly influencing the degree of formalization in NSD process positively. In other words, processes are more formalized for knowledge-intensive and technology-intensive services compared to contact-intensive and routine-intensive services. Examples of knowledge-intensive services are consulting, software development, medical, and coordination services. Technology-intensive services include engineering, IT, maintenance, repair, technical support, and energy management services. They argued that in these types of services technology complexity plays an important role and high risk in terms of cost and time convinces service companies to develop new services in more formalized way which include detailed principles.

*H3: Type of service influence the degree of NSD process formalization*

### **2.4. Types of innovations**

For assessing the causes of success and failure it is crucial to consider the degree of innovativeness in a service because the level of uncertainty associated with new services is high compared to incremental services (Avlonitis et al., 2001). Available literature shows that classification of innovation varies across studies. For instance, Galoulj and Weinstein (1997) introduced six types of service innovations: 1) radical innovations, 2) incremental innovations, 3) improvement innovations, 4) combinatory innovations 5) formalization innovations, and 6) ad hoc innovations. However, Avlonitis et al. (2001) used a different classification: new to the market, new to the company service, new delivery process, service modification, services line extension, and service repositioning. Furthermore, Oke (2007), used three types of innovations: incremental innovation, me-too innovation, and radical innovations. Avlonitis et al. (2001) found that types of innovations have a relationship with the NSD process and different types of innovations require different development process. To investigate

these differences systematic behaviour, documentation and assignment of responsibilities were used in the study. Results revealed that systematic behaviour is correlated with “new to the company service”, and documentation is correlated with “service modification”. Furthermore, differences were also observed in the NSD stages across different types of innovation. For example, new to the market services have given strong consideration on idea generation and screening, business analysis and market strategy. Furthermore, moderate focus was given to the development and launch stages. Test phase however received little attention (Avlonnitis et al., 2001). Similar indication has given by Goudarzi and Alam (2011), in a comparative study of Indian and Australian financial sector. Australian firms considered most of the development stages during NSD projects especially more market test and service test were performed by Australian firms. It was argued that Australian firms develop more innovative services than Indians. Oke (2007) used “implementation” to assess the NSD activities across three types of service innovations (radical, me-too, and incremental). Implementation consists of multifunctional teams, formal procedures, and stage-gate systems. Findings revealed that implementation is only significantly correlated with radical innovation. Reasons were given that the development process is mostly built to poster radical innovation and incremental innovations are considered as a continuous improvement activity. Based on the above evidences we develop the following hypothesis and sub hypotheses.

*H4: The degree of NSD process formalization is varying for different types of innovation in services*

Furthermore, we assume the following hypotheses.

*H4.a: New service offer does not has an influence on NSD process formalization*

*H4.b: New customer encounter interface has positive impact on NSD process formalization*

*H4.c: New operating structure does not have a relationship with NSD process formalization*

*H4.d: Service delivery processes have a positive correlation with NSD process formalization*

*H4.e: Adding new service attributes to the existing service offer does not have an influence on the NSD process formalization*

*H4.f: Developing new business models have an influence on NSD process formalization*

*H4.g: Service development process is positively influencing the NSD process formalization*

## **2.5. Cross-functional teams**

It is substantially revealed in the literature that cross-functional teams in NSD projects have yielded positive results (see for instance, Edvardsson et al., 2013; Polonsky et al., 2005; Froehle et al., 2000; Edvardsson et al., 2007; Gebauer et al., 2008; Posselt and Förstl, 2011). Edvardsson (2013), suggested that “An integrated

development team captures the skills and capabilities of the employees, and the team should be comprised of individuals representing a diverse set of skills". He argued that close and working cooperation between functions, professional groups and customers within firms are the key success factors to develop services successfully (Edvardsson et al., 2013). Furthermore, Johnes and Storey (1998) highlighted that teamwork in cross-functional fashion is extremely important throughout the entire development process. In organizational studies, rules and procedures have shown positive impact on cross-functional coordination. For instance, in the study of Reukert and Walker (1987), positive relationships were found between rules and procedures and perceived effectiveness of interdepartmental relations. Similar results were reported by Pinto et al., (1993) from the healthcare industry. Rules and procedures were described as "the degree to which activities or tasks on the project team were mandated or controlled". The study found that rules and procedures have a positive correlation with cross-functional teams. Furthermore, Crevani et al. (2009), observed that bureaucratic characteristics were assumed by some firms during the NSD process and it could harm innovativeness in many different ways. Among others, co-workers contributions to innovations initiatives will possibly be constrained and it will limit individual creativity. However, in those organizations where processes are formalized, he noticed that co-workers participation and commitment is of high interest for the management. The managers are however convinced for change and believe that innovation and improvement initiatives should happen in a bottom-up manner (Crevani et al., 2009). Based on the above studies and observations we propose our 5th hypothesis.

*H5: Multidisciplinary team has a positive influence on the NSD process formalization*

### 3. Research Methods

#### 3.1. Data collection and sample

The data was collected in seven European countries (Germany, Switzerland, Austria, Italy, Sweden and Finland) and Mexico by a consortium (Fraunhofer Institute for Industrial Engineering, Hochschule Luzern, Service Research Center, Karlstad University, University of Turku, Campus 2 University of Applied Sciences, cfmt Milano, and Tecnológico de Monterrey, Mexico). In total 1333 companies participated in the survey. The data collection took place in 2014. The sample covers a wide range of service industries including finance and banking, health care, hotel, sport and amusement, retail, logistic, rental accommodation, construction, business and social services.

**Table: 1 Sample characteristics**

| Country     | No of responses | Percentage |
|-------------|-----------------|------------|
| Germany     | 186             | 14         |
| Austria     | 72              | 5.4        |
| Switzerland | 202             | 15.2       |

|                 |     |      |
|-----------------|-----|------|
| Italy           | 211 | 15.8 |
| Sweden          | 251 | 18.8 |

| 250-999         | 270 | 20.3 |
| 1000+           | 169 | 12.7 |

### 3.2. Questionnaire

The questionnaire was developed based on both academic and practitioner-oriented literature review and discussions with experienced practitioners in the field of services. The questionnaire consists of several questions and constructs which covers different NSD aspects such as organization of NSD, customer integration, NSD process, NSD performance, and upcoming new trends in services. The questionnaire was developed in English, translated into five European languages (German, Italian, Swedish, Finnish and Spanish) and compared to check the meaning of each question in the above five languages. Mail surveys were carried out in each country. In addition to the mail survey, an online survey was launched in Germany by Heilbronn University and EvaSys tool was used. To assess the quality of the questionnaire a pre-test was performed with five companies. Most of the questions in each construct was measured on Likert scale from 1 to 10 (1: strongly disagree and 10: strongly agree).

## 4. Analysis

IBM SPSS (version 22) was used for statistical analysis. Specific questions were selected from the questionnaire for the repurpose of this study. Factor analysis was carried out to operationalize the construct of NSD process formalization. Principal component analysis was used as a method to extract components. Components were selected based on Eigen value criteria. In the construct of NSD process formalization only one factor had Eigen value greater than one. Varimax method was used for rotation. To measure the internal consistency of the construct Cronbach's Alpha was calculated ( $\alpha = .87$ ). Kaiser-Meyer-Olkin Measure of sampling Adequacy test (KMO = .797) was carried out in order to assess the sample adequacy. For the types of innovations in NSD the whole construct was selected to assess the influence of each type of innovation on dependent variable (NSD process formalization). The construct consists of seven variables (new service offer, new customer encounter interface, new operating structure, service delivery process, adding attributes to the existing service, new business model, and service development process). Strategy and cross functional teams are dichotomous variables. Customer integration is a single variable measured on Likert scale from one to ten (to co-create value with customers we use methods beyond interviews and focus group). Factor and cluster analysis were carried out to derive the service typology variable from the construct of service types for the subsequent analysis. The cluster analysis yielded four different clusters of services: knowledge-intensive services, technology-intensive services, contact-intensive service and routine-intensive services. For hypotheses testing, a multiple linear regression model was estimated. NSD process formalization was used as a dependent variable. NSD strategy, cross-functional teams, customer integration, and types of innovations (new service offerings, new customer encounter interface, new operating structure, new service delivery process, adding service attributes, new business model, and new NSD process) were analysed as independent variables. The model R square is 25.2% and Adjusted R square is 24% which is adequate for this study. This shows that there is no irrelevant variables in the model. Variance inflation factor was used to detect the existence of multicollinearity. If VIF of a variable is below 10 then multicollinearity is not a problem (Myers, 1990). In our model no variable has VIF greater than 10. Regression standardized predicted value and residual were plotted to check if there is any sign of heteroscedasticity. The plotting shows no evidence of heteroscedasticity.

## 5. Results and discussion

### 5.1. Descriptive statistics

Descriptive analysis shows that 59.6% companies have explicit strategy for new services development and the rest don't have strategy for NSD. Regarding the organization of new service development, 67.8% companies use cross-functional project teams for new services development and 32.2% do not. Concerning special organizational units for NSD, 20.4% firms answered with "yes" and 79.6% with "no". Furthermore, 36.5% have other organizational units such as marketing department for NSD and 17% outsource NSD. These questions were asked as multiple choice questions. On average 7.03 new services development projects were conducted by the

respondents companies in the last three years. Of which only 4.81 were launched in the market and 4.17 survived the first year after launch.

**Figure 1: NSD process formalization and service typology**

**Figure 2: Strategy and NSD process formalization**

## 5.2. Hypotheses testing

Results from the regression model (table 2) shows that new service development strategy is highly significant and positively influencing the degree of NSD process formalization. It gives us a clear indication that strategy play an important role to develop new services in a formalized fashion. This finding is also depicted from figure 2

and shows that those companies who have an explicit strategy for new service development, develop services in a formal manner compared to companies having no NSD strategy. Moreover, the model confirmed that formalization in NSD projects varies across different types of service innovations. NSD process formalization is positively influenced by new customer encounter interface, new service delivery process and new service development process for a new service. It means if a new service project involve the development of one of these types of innovations: new customer encounter interface, new service delivery process, and new service development process, requires high degree of formalization in NSD process. These results are somehow in line with the findings of Brentani (2001), that successful companies install a formal "stage gate" NSD system for the development of low innovative service projects. In case of new offerings alternative process and service patterns are mapped by these firms.

New service offer, new operating structure, and adding attributes to the existing service however is not statistically significant at all. Interestingly new service offer is not correlated with NSD process formalization. It could be explained by the fact that the development staff have limited knowledge and experience about the new service offer especially when a service is new to a company. Johnes and Storey (1998), pointed out that high quality and experienced development staff are required in order to develop new services through a formalized NSD program proactively and structurally. The model predicts that the type of service has a strong relationship with NSD process formalization. It means the degree of NSD process formalization varies among different types of services. The types of service were classified into four different clusters namely knowledge-intensive services, technology-intensive services, contact-intensive services, and routine-intensive services. Figure 1 provides a detailed picture and indicates that NSD process formalization is relatively high in knowledge-intensive and technology-intensive services. NSD process formalization has been discussed and investigated in several studies. However, the role of service typology was ignored during the assessment of the NSD process formalization. Most of the studies are carried out in the financial or other single specific service industry. Findings from multiple services sectors regarding NSD process formalization did not make typological distinction among services. For example, Crevani et al. (2009), claimed that process formalization is not that common during new services development. It was observed that only half of the interviewed companies could refer to an example of formalization in their companies during the NSD process. Similar results were revealed from a study by Kelly and Storey (2000), in various service industries in the UK. Furthermore, Chan et al. (1998), investigated innovation in retail/wholesale, financial services, hotel/restaurant, and tourism in Hong Kong, found that most of the service firms do not have proper system to control the NSD process even though they were engaged in some kind of innovation.

No significant relationship was found between cross-functional teams and NSD process formalization. The issue of formalization and innovation is still debatable in the literature. High degree of NSD process formalization may put constrain on innovation, especially when innovation initiatives coming from co-workers (Crevani et al., 2009). Customer integration by using methods beyond interviews and focus group is highly significant and has positive influence on the NSD process formalization. As noted by several authors that customer integration is of high importance in every phase of NSD processes. If only traditional method i.e. interviews and focus groups are practised, then value co-creation will be limited. Therefore, to integrate customer extensively, requires high degree of NSD process formalizations.

## 6. Conclusion

The aim of this paper was to investigate which factors influence the degree of formalization in new service development processes? Data from 1333 service companies was obtained in six European countries (Germany, Austria, Switzerland, Italy, Sweden, and Finland) and in Mexico from a wide range of service industries. A multiple linear regression model was analysed. The results revealed that NSD strategy, service typology, types of innovations, and customers integration beyond traditional

methods have positive impact on the degree of formalization in NSD process. Companies having explicit NSD strategy follow more formalized approaches in order to develop new services which leads to success. The degree of NSD process formalization varies across different types of services. This study revealed that knowledge-intensive and technology-intensive services demand high degree of formalization in the NSD process, compared to routine-intensive and contact-intensive services. Furthermore, NSD process formalization varies for different types of innovations. For instance, the results show that new service offer, new operating structure, adding attributes to the existing service, and the development of new business model are not correlated with NSD process formalization. On the contrary, new customers encounter interface, new delivery process and new service development process have positive impact on the degree of NSD process formalization. In addition, customer integration beyond interview and focus group play a crucial role in the context of process formalization.

# The impact of regulation of network and professional services on competition and trade

*Peter M. Smith*

KU Leuven

*Using data from Belgium over the period 1997-2005 and taking the perspective of the domestic policy maker, this paper looks at how regulation of network and professional services affects competition on the domestic market as well as imports and affiliates of foreign companies. The impact of regulation on the wider domestic economy is looked at first in terms of forward and backward linkages using input-output tables, second in terms of the impact of imports on manufacturing productivity and third that of foreign investment on productivity of the services themselves. Policy should look beyond the immediate impact of a regulation on the sector concerned to take into consideration the wider effects on the economy as a whole.*

## 1. Introduction

There has been increasing interest in the way regulation affects key economic outcomes and in particular the way in which regulation can affect trade either internationally or within the European Single Market. However attempts to open up services to trade will likely fail if the domestic imperatives for regulation remain strong. In the first instance domestic regulation must be addressed through the interests of policy makers in the country concerned. In turn this warrants attention on the domestic effects of regulation, both on the services concerned and more widely on the rest of the economy through the linkages between regulated services and other sectors.

This paper therefore looks at the way in which regulation of certain types of services affects the domestic economy in terms of competition as well as trade. It looks first at the impact on network and professional services themselves. Then it looks at how these services impact the wider economy. The paper applies to Belgium over the period 1997 to 2005, a period when many regulatory changes were being made to this small open economy using micro data on more or less all enterprises in Belgium.

The paper innovates first in using micro data covering nearly all of the economy and not only large companies. Second it innovates in looking at forward linkages between these services and the rest of the economy and the impact on costs of user sectors both manufacturing and other service sectors. Third it extends the analysis to providers of services as a source of demand, particularly for manufacturing industry. Fourth it goes beyond intermediate inputs to look also at the effect of regulation on demand for machinery and equipment and other forms of capital investment.

## 2. Literature Review

Interest in opening up previously protected services to competition largely dates back to the 1980s, when such services as air transport and telecommunications began to be affected first in the United States and then in other English speaking and Nordic countries. The OECD has provided a significant boost to the study of the process of liberalisation of services through a series of product market indicators for services dating back to the late 1990s and sometimes earlier using a comparable methodology and applying to a large number of countries (Conway & Nicoletti, 2006; Koske; Wanner; Bitetti; Barbiero, 2015). The indicators have been criticised (Pelkmans, 2010) but they nevertheless constitute a very rich source of information. The possibility to use low level and intermediate levels of aggregation to verify the effect of different kinds of product market regulation on economic performance represents a key advantage of the OECD product market indicators for services and one that is exploited in this paper. A limitation acknowledged by the OECD is the fact that the indicators make no attempt to measure the stance of regulation with respect to public policy goals other than promoting competition. While this makes the process of constructing indicators less subjective, policy makers must always take into consideration the balance between efficiency gains from greater competition with the adequate protection of public policy goals. Enforcement is another important issue which the indicators have not been able to deal with satisfactorily.

A large number of macro-and micro-economic studies have applied the indicators to test the impact of regulation on a wide variety of different dimensions of economic performance including domestic and foreign direct investment, productivity, employment and wages, markups and firm entry rates. These studies use different techniques and types of data from economy wide to sectoral to micro data on individual enterprises. From the beginning a dual impact of services' regulation has been identified, that on the sector concerned and that on the rest of the economy, in particular manufacturing industry. These "knock on" effects depend on the extent of anti-competitive regulation in non-manufacturing sectors and the importance of services as suppliers of intermediate inputs. The importance of services as a source of demand for, often high technology, investment goods supplied by the manufacturing sector appears to have been largely overlooked, but an issue explored in this paper.

A number of studies look at the level of competition in services measured by markups or price cost margins. Høj et al. (2007), Bouis and Klein (2008) and Christopoulou and Vermeulen (2008) use sectoral level data. Nguyen-Hong (2000), Dihel and Shepherd (2007) and Bottini and Molná (2010) use individual company data. Christopoulou and Vermeulen and Bottini and Molná limit themselves to estimating markups, while Bouis and Klein further look at the effect of markups on productivity. Høj et al., Nguyen-Hong and Dihel and Shepherd all relate the degree of product market regulation to the level of competition, the latter two extending the analysis to the impact on trade by calculating tax equivalents.

These studies all find that the level of competition in services is generally lower than in manufacturing, but can differ on which services and which countries record the lowest levels of competition. The most recent study using micro data (Bottini; Molná, 2010) concluded that estimated markups were high for services where a high degree of information asymmetry prevails and products are customer specific, such as real estate, renting and utilities and professional services. Markups tend to be substantial-

ly lower for traded services and industries that produce more standardised products such as construction, computer services, distribution and catering.

In the light of the conclusion of the Uruguay Round when services entered for the first time the multi-lateral framework for trade and efforts to complete the EU's Single Market for services, the impact of domestic regulation became an important topic. Molinuevo and Sáez (2014) describe the different approaches to measuring the impact of regulation on trade along with an extensive discussion of the literature. They include measuring the impact of regulation on markups or price-cost margins discussed above and a number of indirect methods including gravity equations and CGE models. Less frequent are studies of the impact on (inward) FDI, which is a major lacunae since most trade in services takes place through permanent presence rather than through cross-border trade (Smith, 2015).

Three studies cover the interaction between manufacturing and services (Pilat; Wölfl, 2005; Faini; Haskel; Navaretti; Scarpa;Wey, 2006; ECSIP, 2014). Pilat et al show that the link can be measured in various ways. First the contribution of intermediate inputs and value added in the growth of gross output can be used to calculate rising dependency on bought in goods and services. Second occupational data can be used to show how service functions increase in manufacturing industry. Third input-output tables can be used to show how services are “embodied” directly and indirectly in manufacturing production. In the mid-1990s, the beginning of the period examined in this paper, services accounted directly or indirectly on average for about 22% of OECD manufacturing production. Backward linkages measure a sector's dependence on other sectors which supply it with intermediate products. However as mentioned some of the impact of greater demand for manufacturing occurs through demand for investment goods, which is included as a component of final demand in the input-output tables rather than intermediate consumption. Pilat et al do not mention the possibility of also measuring forward linkages using input-output tables. Forward linkages measure a sector's dependence upon other sectors as buyers of its output.

A study by Dietzenbacher (2002) addresses both of these issues by taking into account final output coefficients of consumption, exports and investment and by measuring both backward and forward linkages and then applying them to the case of an intercountry input-output table for six European Union countries. He found that the three smaller countries (Netherlands, Belgium and Denmark) have smaller backward and forward multipliers than the larger countries (Germany, France and Italy) indicating that their production processes depend more on external sources such as imports and exports and that small countries also have significantly larger import and export multipliers than large countries. Manufacturing sectors have larger backward output multipliers than services, larger import multipliers and larger intercountry spillover effects. For forward effects, the major distinction is between sectors that produce for final demand, which have small output multipliers, and those that produce for intermediate consumption which usually exhibit large output multipliers, among which are to be found services such as transport and communications.

As pointed out by Faini et al, aggregate productivity analyses exclude input-output linkages by definition while sectoral or firm-level analysis typically focus exclusively on variables that are related to the sector of interest. Both Faini et al and ECSIP look at the impact of services on growth in manufacturing productivity, with the first using OECD regulatory restrictiveness indices for network and professional services weighted by the direct and indirect contribution of these services to goods producing

industries, finding a negative effect of regulation on productivity. ECSIP looks at how domestic and foreign linkages affect manufacturing productivity growth and find that domestic linkages play the major role for large European countries and foreign linkages for the small ones like Belgium.

In addition to their work on manufacturing productivity, Faini et al also show that regulation of network and professional services negatively affects inward FDI in manufacturing industries that use these services heavily and because foreign affiliates have higher productivity than domestic firms this also affects negatively levels of productivity. Their work is in line with that of the OECD where Nicoletti et al. (2003) show that regulatory policies that restrict market access or reduce the potential returns to foreign investment negatively influence the share of foreign direct investment in OECD countries. Conway et al. (2006) regress the share of employment by foreign affiliates in total employment at the sectoral level on the regulation impact indicators and a number of control variables. They find that regulatory restrictions to domestic competition and FDI both have a significant negative effect on the employment share of foreign affiliates across model specifications.

Input-output models can be used alongside other models to assess the impact of a change in policy or the threat posed by an exogenous change in the economic environment on output, employment or other variables of interest. Studies by Susuki and Uchiyama (2010) and by Kerschner et al (2013) for example look at the impact of a rise in the price of oil on respectively the Japanese and US economies and identify vulnerable sectors based on the energy dependence and location within the production chain. Kveiborg et al. (2006) evaluated regional economic impacts from heavy vehicle fees comparing input-output based models with system dynamic and computable general equilibrium models (CGE). Input-output models do not often look at how demand side can react to changes in prices. Price increases will affect both intermediate and final demand leading to further declines in demand. CGE models are typically comparative static equilibrium models with substitution between inputs. They are capable of taking into consideration different types of interaction. However it is usually difficult to distinguish what is driving the results and because the adjustment path is instantaneous the time dimension is absent. System dynamic models can take into consideration different types of effect and are better able to take into consideration the dynamic aspect of a policy change but the models have not been very consistent.

Ogarenko and Hubacek (2013) made a study of the effect of eliminating energy subsidies in Ukraine that from a methodological point of view most resembles the approach adopted in this paper. First a price model is utilized to estimate price changes resulting from subsidy elimination and then a demand driven input-output model is adopted for estimation of associated changes of environmental and social variables. Their approach uses own price elasticities of demand to establish the link between price changes estimated by the price model with changes in final demand.

### **3. Methodology**

Measurement of the effect of regulation proceeds in two stages. First the effect of regulation on competition and trade on enterprises in Belgium is measured econometrically. The econometric results are then used to evaluate the impact of such regulation on the wider economy, including the manufacturing sector.

#### **3.1. The impact of regulation on competition and trade for individual enterprises**

OECD sector specific regulatory indices are used to measure types of regulation separately for network industries and for professional services. The indices are constructed on the basis of very detailed questionnaires, the results of which are then weighted and combined into sub-indices and an aggregate index for each sector with values varying between 0 for no regulation and 6 for the most restrictive regulation (Conway; Nicoletti, 2006). From a policy point of view and also to avoid the need for weighting, the most detailed level of regulation proves the most useful. Rather than measuring whether regulation per se has an impact on a particular variable, it is much more interesting to be able to distinguish which particular type of regulation is affecting competition or alternatively trade. However, at a disaggregated level, indices for the same sector for the same country tend to be highly related and to pose a problem of multi-collinearity in the estimation procedure. Regulations that weigh heavily in the overall result will likely have a high explanatory power when taken individually, and a comparison between the adjusted  $r^2$ s of the overall regression with those of regressions on the underlying individual regulations can help to identify which these are.

For network industries, the questions on entry relate to the legal conditions by which domestic or foreign suppliers may enter the market. Additional questions relevant to the particular market may be added to the basic questions on market access such as participation in open skies agreements, third party access to the grid, consumption thresholds to be able to choose a supplier. Because the underlying questions differ from one sector to another for network industries, only sub-indices can be used to compare the effects of entry regulation across sectors. The indicator on public ownership relates to the percentage share in the largest firm(s) in the sector and is highly comparable across the different network industries.

Since the underlying questionnaires for the four professional services are the same, comparability of the results can be assured. The indicators on entry concern the exclusive right to provide certain services (for instance to plead in court or to audit publicly quoted companies), educational and training requirements to be admitted to the profession and restrictions on the number of firms that may practise a profession. Indicators on conduct relate to the legal form that is permitted to practice, limitations on cooperation between professionals, price regulations and restrictions on the ability to advertise. It should be noted that in Belgium none of the professions had restrictions on the number of foreign professionals/ firms permitted to practice by quo-

tas or economic needs tests so that this type of regulation could not be tested. These restrictions would have needed to be abolished subsequently under the Services Directive, which applies also to professional services, had they existed.

The regulatory indices used for the estimation phrase are limited to the period 1996 to 2004 for network industries and to the years 1996 and 2003 for professional services owing to limitations in the availability of Belgian micro data (see section on data) and in the case of professional services to the collection periods for the OECD exercise. The OECD overall product market regulatory indicator for Belgium declined from 2.3 in 1998 to 1.64 in 2003 and then to 1.52 in 2008 and 1.39 in 2013. It can be of interest to see how regulation has developed since 2004 also for the network industries covered (electricity generation and distribution, postal and telecommunications services, air and rail transport) and professional services (lawyers, accountants, architects and engineers) (Table 1).

| year | Electricity |       |                  | Telecom |       |                  | Post    |       |                  | Rail    |       |                  | Airlines |                |                  |
|------|-------------|-------|------------------|---------|-------|------------------|---------|-------|------------------|---------|-------|------------------|----------|----------------|------------------|
|      | Overall     | Entry | Public Ownership | Overall | Entry | Public Ownership | Overall | Entry | Public Ownership | Overall | Entry | Public Ownership | Overall  | Entry Barriers | Public Ownership |
| 1996 | 4.68        | 5.00  | 1.73             | 4.62    | 5.00  | 3.01             | 4.33    | 2.00  | 5.00             | 5.63    | 6.00  | 6.00             | 1.53     | 0.00           | 3.06             |

Table 1b: OECD Regulatory Indices for Professional Services

While the OECD regulatory indicators measure domestic regulation, the main impetus for liberalisation of network industries in Belgium has come from European Union legislation to open up such industries to competition in the context of completion of the Single Market for Services. The major legislation affecting professional services has been the Directive on Mutual Recognition of Qualifications, which has a much wider coverage than the four professions covered here.

Electricity and Telecommunications undertook the major process of market liberalisation during the period covered. Entry regulation diminished gradually for postal services before during and after the period covered while public ownership only began to fall from 2006. Entry for rail services remained heavily regulated until 2006 and public ownership remains high today, while entry barriers for airlines had already been eliminated prior to 1996. Public ownership of airlines fell markedly in 2001 with the bankruptcy of the national flag carrier SABENA. Therefore it is possible to exploit differences in changes over time as well as differences in the initial level of regulation between network sectors. For professional services there has been no clear pattern of liberalisation either during or after the period covered. The major difference con-

cerns regulation across sectors with accounting and legal services highly regulated, architects less regulated and engineers not regulated at all.

As indicated in the previous section, the OECD regulatory indices have been used in the past to measure tax equivalents for trade in services. The potential gains from trade are then assumed to flow from the total elimination of regulatory barriers. However, this approach inherently lacks realism. Services are regulated for a purpose and will continue to be regulated in future. Rather at issue is the form that regulation takes and whether regulation adequately meets the public interest that prompted the introduction of regulation in a way that minimises the adverse impact on competition and trade. For this reason it is more realistic to begin from the identification of those regulations that adversely affect competition and trade most severely and from there to try and devise alternatives that minimise these adverse effects.

This paper continues to use price-cost margins as a measure of competition on the domestic market. Price-cost margins have the advantage that data on an individual firm level can be calculated from balance sheet data while prices and quantities are not directly observable. Greater competition should lead to lower margins and ceteris paribus lower prices for users. A key assumption has been that the fall in price-cost margins from a one point decrease in regulation will lead to an equivalent fall in prices of the service in question. While questionable, it should be understood that the impact assessments are presented as an exercise in possible outcomes and that another price assumption can easily be substituted for the one employed here.

The basic regressions are a reduced form similar to that in Nihel and Shepherd (2007) using a pooled OLS with robust standard errors clustered on the firm for competition and cross-border trade and a logit regression for measuring the probability of permanent presence.

For competition:

$$(1) \quad \log(PCM_{ij}) = c + B[controls_{ij}] + X.TRI_j + \varepsilon_{ij}$$

where the price cost margin (PCM) for firm  $i$  in sector  $j$  is “explained” by a constant, a set of sector and firm level control variables, the regulatory indices  $X.TRI$  and a white noise error term.

For cross-border trade:

$$(2) \quad \log(imports_{ij}) = c + B[controls_{ij}] + X.TRI_j + \varepsilon_{ij}$$

where imports are measured as the world wide imports of firm  $i$  for services  $j$ .

For permanent presence:

$$(3) \quad \log \frac{p_i}{1-p_i} = c + B[controls_{ij}] + X.TRI_j + \varepsilon_{ij}$$

where foreign affiliate takes a value of 1 if the firm  $i$  in sector  $j$  is the affiliate of a foreign company and 0 otherwise and  $p_i = P\{y_i=1/x_i\}$  is the probability of observing outcome 1.

In the case of the regressions on price-cost margins and on imports of services, the log-linear form constitutes a semi-elasticity which implies that a coefficient  $\beta_j$  measures the proportionate change in the expected value of the dependent variable as the explanatory variable changes. In the case of competition, this can be seen as the proportionate change in price-cost margins,  $PCM_j$ , for each one unit change in regulation,  $X.TRI_j$ . This feature of the regressions proves very useful for subsequent work on the impact of changes in regulation on manufacturing and the rest of the economy and is preferred to the tax equivalents approach. Similarly, for cross-border trade the coefficient  $\beta_j$  provides an estimate of the proportionate change in imports of services for each one unit change in regulation. In the case of FDI which uses a logit form of regression the coefficient cannot be interpreted in this way.

While offering the virtue of simplicity, the reduced form regression must be subject to a number of caveats. As is standard in an OLS regression, problems of endogeneity and of omitted variable bias are to be expected. To control partially for endogeneity, the regulatory indicators are lagged one period with regard to the dependent variables. Control variables for both sectoral and firm specific characteristics pose a particular problem for regressions on price-cost margins because the denominator for the margins is turnover. A great many of the common standardised variables such as capital intensity or labour costs also use turnover as the denominator leading to the same variable on both sides of the regression. For that reason, control variables have been limited to the Herfindahl index to control for sector specific characteristics influencing competition and labour productivity to control for firm specific characteristics. Year dummies control for business cycle effects. First a regression is run using sectoral dummies in the place of the indices of regulation and then the same regression is run replacing the dummies with the regulation indices and the results compared in terms of their explanatory power. Indirectly, it is hypothesised that the regulatory indices represent the major influence on the observed differences in outcomes due to the different sectors.

Because service characteristics and regulation are related, observed differences in regulation could potentially be ascribed to inherent characteristics rather than regulation itself (Smith, 2014). To mitigate this source of error, services with similar inherent characteristics have been selected. Correlation coefficients for the different services have been calculated based on nine questions relating to physical and mental intangibility, five questions related to the search-experience-credence framework and one variable measuring whether cross-border trade takes place through the need for both the provider and the user to be physically present for a transaction to take place. The results are presented in Tables 2a and b.

| <i>Electricity</i>                | 0.25                              | 0.44                            | 0.37                   | 0.30                    | 0.76                      | 0.09                     | 0.23                   | 1                  |

**Table 2a: Degree of Similarity in Service Characteristics between Network Services**

|   | <i>Legal services</i> | <i>Accounting, auditing, book-keeping and tax consulting services</i> | <i>Architectural, engineering and other technical consultancy</i> |
|---|-----------------------|---|---|
| <i>Legal services</i>   | 1                     |   |   |
| <i>Accounting, auditing, book-keeping and tax consulting services</i> | 0.71                  | 1   |   |
| <i>Architectural, engineering and other technical consultancy</i>     | 0.56                  | 0.69  | 1   |

**Table 2b: Degree of Similarity in Service Characteristics between Professional Services**

Transport, postal and courier services share similar characteristics while telecommunications and electricity are more similar to each other than they are to other network services. Electricity in particular, which has highly intangible characteristics, displays least similarity with the other network services. Among professional services accounting services are most similar to both legal services and architectural and engineering services.

### 3.2. The impact of regulation of service industries on manufacturing and the economy

Backward and forward linkages in the economy form the basis for measuring the extent to which regulation of competition can affect the rest of the economy and in particular manufacturing. The coefficients on price-cost margins can be used to estimate the value of a reduction in price for user industries (forward linkages). It can be considered as a measure of improved competitiveness for the rest of the economy and therefore excludes the price effect on the own consumption of the regulated service itself. Backward linkages are estimated through the effect of the price reduction on demand for the service considered. The impact of regulation on trade is evaluated here in terms of the effect on the productivity of manufacturing industry in the case of imports of services or on productivity of the sector concerned in the case of foreign direct investment.

Since estimates for the effect of regulation on competition relate to Belgium, 2005 national input-output tables produced jointly by the Federal Planning Bureau and the National Bank of Belgium are the primary source for the impact assessment of domestic regulation on competition (Federal Planning Bureau, 2010; Eurostat, 2008). They are used to calculate forward and backward linkages of network and profes-

sional services. Understandably, domestic policy makers are most interested in the impact on the domestic economy rather than spillover effects on the rest of the EU or third countries. Coefficients for the domestic economy therefore are the basis for the impact assessment.

The basic approach to impact assessment using input-output tables is set out by Miller & Blair (2009) and the necessary matrix algebra summarised in the methodological appendix. A symmetric input-output table has the use for each product or sector as row while the column represents all the inputs that are required to produce a given output. The Leontief model is usually used to calculate the effects of a change in demand on upstream inputs (backward linkages). Here the quantities change but prices remain the same. In order to calculate the impact of a change in regulation on backward linkages a further assumption has to be made concerning the impact of a fall in prices on demand for the services in question. Estimating own price elasticities of demand represents a major undertaking in itself and existing studies have been used to derive a range of plausible elasticities to apply to final demand. For meta studies in which both an average and standard deviation of values are provided, the low and high elasticities have been calculated as plus or minus one standard deviation from the average. A list of the studies consulted is provided in Annexe 2. While there are a large number of studies on price elasticities for network industries, only one study has been found for professional services and that relates to the US, which may well not be representative of Belgium or the EU generally.

|                             | Total demand elasticities |         |      |
|-----------------------------|---------------------------|---------|------|
|                             | Low                       | Average | High |
| Electricity                 | -0.2                      | -0.4    | -0.6 |
| Telecommunications          | -0.3                      | -0.5    | -0.7 |
| Postal                      | -0.3                      | -0.6    | -0.9 |
| Air Transport               | -0.8                      | -1.3    | -1.8 |
| Postal + Telecommunications | -0.3                      | -0.5    | -0.8 |
| Professional Services       | -0.4                      | -0.6    | -0.8 |

Table 3: Own price elasticities for network and professional services

Since elasticities vary according to different types of product or according to different types of users, elasticities have to be weighted appropriately to arrive at an overall price elasticity of demand. The estimated impact on total initial demand (both final demand and demand for intermediate inputs) is then calculated as a combination of the own price elasticity and the fall in price for a one unit change in regulation estimated econometrically. The production of this additional demand in turn requires the production of more inputs to the sectors whose demand has increased. This indirect output is estimated using the input coefficients required for one unit of output of the service in question.

A particular problem arises with regard to the impact on purchases by network and professional services on machinery and equipment. These are treated as outputs of manufacturing industry to gross fixed capital formation and final demand rather than as sales to other sectors. For the total, including imports, the Belgian input-output tables provide an estimate for GFCF by ownership branch which enables an investment rate to be calculated, but there is no breakdown by type of investment. To arrive at a figure for the impact on manufacturing industry, the share of machinery and equipment in total GFCF by network and professional services is calculated.

It should be emphasised that the estimates are made for network and professional services as groups and are not valid for individual services since the econometric coefficients are for the groups of services. In order to avoid aggregation bias, forward and backward linkages for network services are estimated using the most detailed level of input-output tables available (60 by 60 products) and then aggregated into a group, rather than first aggregating the products. Professional services are all part of the group “other business services” and it is impossible to differentiate the coefficients of that group further so that it has been necessary to apply those coefficients to the share of professional services in the total output of that group (28%). Combined with the poor quality of price elasticity information all the linkage effects for professional services need to be treated with particular caution. With the exception of air transport, estimated own price elasticities of demand for these services are quite low and below unity, meaning that a fall in price does not lead to an equivalent increase in the volume of the service demanded.

Similar to the Leontief model for backward linkages, the Ghosh model can be used to calculate the effects of an increase in supply on the rest of the economy. Following Dietzenbacher (1997), the Ghosh model can be interpreted as a price model. The coefficients can then be viewed as the effect of a change in one euro in the costs of industry  $i$  on the total value of production with quantities unchanged.

A number of limitations to the approach should be pointed out. In reality, lower prices for network and professional services would result in consumption of more services per unit of output and more service intensive intermediate inputs, which in turn would increase prices. The input-output price model sets the upper margins to price changes which would eventually occur and thus it is suitable for short term impact rather than long term analysis and that the impacts of regulatory reform are estimated before the economy has adjusted for price changes assuming that there is no time for structural changes and substitution of labour and capital for bought in services as well as cross-substitution between services.

A different approach has been taken with regard to impact of trade, in particular of the effect of regulation on imports of the relevant services. While the econometric procedure for estimation is the same as for price-cost margins the coefficients are used to assess the impact of more imports on manufacturing productivity in line with the results of the recent study by ECSIP for the European Commission on the relation between industry and services in terms of productivity and value creation. Although covering a somewhat different list of services than this paper, that study found that for small open economies like Belgium only linkages for foreign services had a positive effect on manufacturing productivity. Their estimate of a significant and positive effect of 0.264 on labour productivity growth rates appears plausible and will be used here as a basis for the impact of lower regulation on imports of services. Surprisingly, the study did not find evidence of positive effects of foreign direct investment in business services on manufacturing productivity. Instead the impact of foreign direct investment on the productivity of firms in the sector will be examined.

Dependent variable: Labour productivity growth rates (VA-based)

|                                     | Membership status    |                     |                      | Country size         |                      | Technology intensity |                      |                     |

Table 4: Impact of service linkages on manufacturing productivity

## 4. Data

Panel data on individual firms for the period 1997 to 2005 held by the National Bank of Belgium is drawn from different sets linked by the basic business repertoire. For this paper data on balance sheets, on cross-border trade in services and on inwards foreign direct investment has been used. From these different data sets the relevant variables identified in the previous section are extracted and combined. Firms are selected on the basis of their principal activity for the regressions on price-cost margins and foreign direct investment. Unlike goods, where imports are concentrated within either the manufacturing sector or the distribution sector, a wide variety of user sectors import services. For this reason, the impact of regulation is measured on all imports irrespective of whether the service itself is the importer in question.

All firms in Belgium with a limited liability legal form are obliged to file balance sheet data with the National Bank of Belgium (NBB). Most economically active firms in Belgium choose to incorporate in order to benefit from limited liability. The exception are some of the self-employed who may choose to incorporate or not. Balance sheet data served to calculate price-cost margins on an individual firm basis from accounting data and to select firms on the basis of their principle activity.

There are two major problems with the balance sheet data. Small firms are not required to file data on turnover in their balance sheets. In fact only 40% did so in 1997 declining to 25% in 2005. Since turnover is required as the denominator to calculate price-cost margins, it was imperative to solve this problem by combining data from the VAT authorities with that from the National Bank. In this way it was possible to achieve an overall coverage of turnover of 84.2% of all firms for which there is balance sheet data. These firms however represent 97.5% of value added, 98.4% of employees, 99.1% of imports of services, 98.7% of exports of services and all imports and exports of goods.

The second major problem encountered is that only employees are covered in the balance sheet data while 52% of all firms in the NBB balance sheet data had no employees, which falls to 48% if only those firms for which there is data on turnover are considered. On the one hand this makes the coverage of the data very interesting

because it covers service firms that are excluded in most data sets, including micro enterprises which are very common particularly in professional services. On the other hand the absence of any employment data for these firms makes any calculation of labour productivity problematic because we lack a suitable denominator. The work around employed following that of Eurostat (2010) is to make a statistical adjustment to the figures on paid employees by adding a constant representing unpaid employment of one. However very small enterprises may have more than one non-salaried worker and this biases the labour productivity upwards. For that reason a quadratic form of labour productivity has been added to the variables in order to control for possible non-linearities.

Another important issue concerns the coverage of the data on cross-border trade in services. Data on cross-border trade in services is collected by the National Bank of Belgium as part of the statistics on balance of payments but the level of detail is quite limited and this poses a problem of matching between the regulatory indices and the trade data. Imports of both electricity and rail transport are englobed within broader categories (other business services and land transport respectively) which means that the effect of regulation on trade cannot be isolated for these two network industries. For professional services the situation is equally problematic. One category englobes imports of legal services, accountancy with management consultancy. Another category englobes both architectural and engineering services. The solution adopted was to weight the regulatory indices by the share of each profession in value added for the relevant category, putting all the indicators for management consultancy at zero since this is essentially an unregulated profession.

Further difficulties have been encountered with the impact assessments of the second stage. As with imports, input-output tables for rail transport englobe also road transport, which is both a much bigger sector and one that sells mainly to other enterprises contrary to rail transport, which supplies predominantly individual consumers. Coefficients for land transport are unlikely therefore to be valid for rail transport alone and therefore rail transport has had to be excluded from evaluations of the impact on the rest of the economy. As indicated previously, the only way impact assessments can be made for professional services using input-output tables is to use the coefficients for other business services and apply them to the share of output of professional services. The investment rate for air transport in 2005 poses a particular problem. Prior to bankruptcy the national carrier made substantial investments in aircraft which were acquired by the successor airline, which made few further investments with the result that the observed investment rate in 2005 was particularly low at 1%. Instead an investment rate of 9% for air transport has been assumed in line with that for other transport services.

## **5. Results**

### **5.1. The impact of regulation on service sectors**

Regressions on price cost margins for network and professional services are presented in table 5. For both network and professional services, the coefficients for entry regulation are positive and significant implying that regulation acts to increase margins and depress competition on those markets. For network services the impact

of public ownership is both significant and negative while for professional services conduct regulation is both significant and positive, indicating a supplementary effect to entry regulation on competition. The regressions illustrate the value of more disaggregated measures of regulation, particularly for network services where only entry regulation is seen to depress competition.

When interpreting these results, the purpose of regulation needs to be borne in mind. For network regulation, where issues of security of supply and safety are important, it is not clear why entry regulation should be required. Public interest requirements can be met in other ways than limiting entry. For professional services the situation is not so clear cut. It is more difficult to regulate the service so that regulation of providers has been the preferred form of regulation to protect users. Regressions on individual types of regulation can help to clarify the issue.

| Network Services                      |            |            |            |            |            | Professional Services                 |            |            |            |            |            |

Table 5: Regressions on price-cost margins

One way to look at the impact of individual service regulations is to compare their explanatory power with that of the overall regression on entry and conduct regulation (Table 6). Three of the individual regressions have explanatory power equal to or higher than the adjusted  $r^2$  of the overall regression, compulsory practice, professional exams and legal form indicating that these regulations weigh particularly heavily on the overall result. Since compulsory practice and the need to pass professional exams are required to validate the competence of the professional supplying the service, it is unlikely that these requirements will be relaxed for professions such as lawyers or auditors. The entry barrier that would appear least possible to justify concerns the restriction of the number of professionals allowed to practise, but as

indicated previously such restrictions do not apply in Belgium to the four professions considered here (although such restrictions do apply to pharmacies). Less justifiable also are restrictions to the possibility of offering services beyond those required to protect the public. In the case of Belgium, the coefficient on the exclusive right of a profession to provide a service is negative, not significant and the overall explanatory power low. Even if an individual coefficient that is not significant can become significant alongside other variables, the negative sign should indicate that this seemingly strong barrier to entry does not have the expected effect on competition. While therefore some entry barriers for professional services do restrict competition, public interest requirements are likely to maintain such barriers for the foreseeable future. This should be borne in mind when interpreting the results for the impact of entry barriers to professional services on the rest of the economy.

Even though regulation on conduct appears to increase price-cost margins less than entry regulation it is much more difficult to justify on public interest grounds. Since the explanatory power on restrictions on the legal form under which a business can operate (for instance partnerships) is high, this restriction would appear as a prime candidate for future action to increase competition for professional services.

Table 6: Regressions on price-cost margins for individual forms of professional regulation

The coefficients for the impact of a one unit change in regulation on the value of imports are very high and often highly significant (Table 7). In the case of network services both entry and public ownership depress imports of these services highly significantly while for professional services it is only entry regulations that depress imports when both entry and conduct regulations are taken together. The rationale for restrictions on imports appear much weaker than for the regulation of domestic markets. It is not obvious for example why a profession that is regulated in a similar way to a similar level in another member state of the EU should be less proficient in providing a service than a domestic supplier. The highest explanatory power of the specific types of regulation for professional services taken individually are for duration of education and forms of cooperation. Duration of education and compulsory practice are in fact highly correlated and that between legal form and possibilities for

cooperation between professions is also quite high so that we have a similar pattern for the effects of individual regulations on imports as for competition. In itself this is an important finding since it shows that regulation can have multiple types of effect.

Table 7: Regressions on imports of services

The situation with regard to the impact of regulation on inward direct investment is not so clear cut. On the one hand, the negative effect on imports may induce foreign suppliers to enter the market via permanent presence rather than through exporting to Belgium. On the other hand, entry regulations that apply to domestic firms will also apply to firms from other EU member countries under the principle of non-discrimination. They will therefore have to overcome similar types of barrier although if the foreign firms are better resourced they may be in a better position to do so. For network services, public ownership seems to be a greater barrier to inward FDI than entry regulations although the coefficient is no longer significant when taken together with entry regulation. In highly concentrated industries public ownership of the major player(s) affects the potential for entry through acquisition or the form by which entry takes place (joint venture between Vodafone and Belgian Telecoms for mobile telephony as opposed to local subsidiary).

For professional services, it is only entry regulation that appears to depress inward FDI. These results need to be interpreted with great caution. There are very few legal and accounting affiliates of foreign firms established in Belgium in the FDI data and none for architects. Essentially the comparison made in the regression on FDI for professionals is between unregulated engineering services and regulated professions. This may be because the legal form for other professions are often partnerships and sole practitioners, which after establishment may be treated as domestic firms or too small to be reported under the surveys for foreign direct investment. However when it is the professional association itself that assesses the equivalence

of foreign diplomas under the European Professional Qualification Directives as appears to be the case for architects, this can lead to protectionist outcomes unfavourable to local establishment by suitably qualified professionals.

Table 8: Regressions on inward foreign direct investment

## 5.2. The impact of regulation of services on manufacturing and the rest of the economy

Linkages between the major sectors of the economy are illustrated in Fig.1 adapted from the Eurostat EU-27 input-output tables for 2007. The area of the rectangles is proportionate to the share of the sector in total value added. The value of sales to or purchases from each sector is proportionate to the width of the arrows: forward linkages are in red and backward linkages in blue. Producer services use their own primary inputs (labour and capital) to provide services to the rest of the economy. Their linkages are mainly forward but they also have sizable purchases from the goods producing sectors as well as very sizable sales among producer services. Goods producing sectors (including agriculture, mining and construction) act to transform brought in goods and services and then to sell them on to other sectors, thus exhibiting both very strong forward and backward linkages. The trade and distribution sector acts as a conduit for enabling goods and some service producing sectors to reach the final consumer and is characterised by strong forward linkages. Services to households use their own primary inputs to provide services to the final consumer and unlike the other three major sectors are very little integrated with the rest of the economy. Services therefore are situated either at the beginning of the flow of goods and services through the economy or at the end with goods producing sectors in the middle.

Fig. 1:

## The Flow of Goods and Services through the Economy

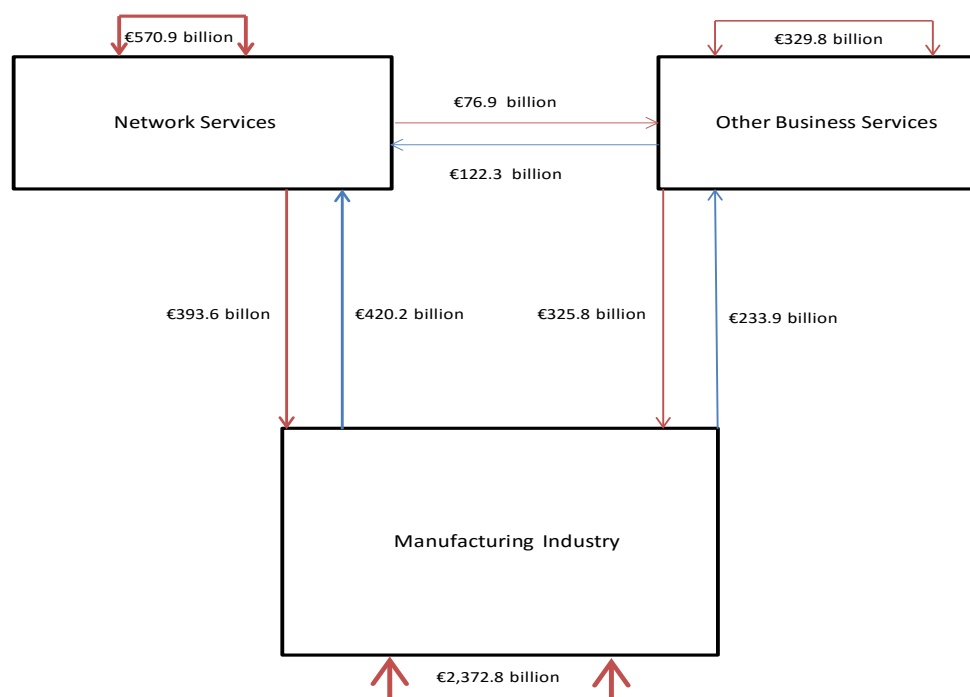

Source: Eurostat 2007 input-output tables EU-27

Within this general schema, this paper looks more particularly at the relationship between certain types of producer service (network services and other business services) and manufacturing industry. Network services cover energy, transport and post and telecommunications. Other business services comprise professional services and administrative and support services. The EU combined value added of network and other business services in 2007 was of a comparable size to manufacturing industry (€2 trillion against €1.9 trillion). Services for which econometric estimation was conducted comprise 59% of production of network services and 36% of other business services in the EU. The equivalent figures for Belgium are 57% and 28%.

Figure 2 examines these relationships for the EU in more detail. Of note are the very large intra-group exchanges, particularly for manufacturing (€2.4 trillion). Rather balanced flows characterise sales to and purchases from network services, business services and manufacturing. Sales of network and other business services constitute essentially intermediate consumption of user industries but purchases can be composed either of intermediate consumption or of machinery and equipment in the form of gross fixed capital formation by these services. An estimated 54% of manufacturing sales to network services and 60% of sales to other business services are constituted by sales of transport and other machinery and equipment, often with a high technological content. By contrast, these purchases are estimated to make up only 8% of purchases by manufacturing industry from itself essentially because of very large purchases of intermediate inputs within manufacturing industry. Measurement of intangible investments in gross fixed capital formation continues to lag that of

goods so that it is difficult to distinguish from these figures the important role of business services as a leading supplier of such investments.

Fig. 2: Network services, business services and manufacturing industry: flows within and between sectors

Source: Eurostat 2007 input-output tables and own calculations

Applying the methodology outlined in section 3.2, the effect of a 6.57% reduction in price of selected network services from a one unit reduction in entry regulation on the rest of the economy via forward linkages can be estimated in 2005 for Belgium as a cost reduction of 1,311 million euros of which 359 million euros for manufacturing industry and 952 million for all other sectors of the economy apart from network services themselves. For professional services a price reduction of 7.24% as a result of entry barriers could be estimated as a cost saving of 1,314 million euros of which 342 for manufacturing industry and 972 for all other sectors of the economy apart from professional services themselves. For the reasons indicated previously, it is probably not reasonable to expect that such a reduction would in fact be achieved. A reduction of 3.68% as a result of a one point reduction in conduct regulation appears more realistic. This can be estimated as equivalent to a cost reduction of 668 million euros of which 174 million for manufacturing industry and 494 million for all other sectors of the economy. Likely gains from reducing entry regulation of selected network services would therefore be roughly double those from reducing conduct regulation of professional services. These estimates represent the possible impact on the competitiveness of user sectors from regulatory reform.

Applying an estimate of the own price elasticities on overall demand to the projected fall in price from a one unit change in regulation of network services generates a total increase in output of 768 million euros under the low elasticity assumption, 1,378 million under the average assumption and 2,005 million under the high assumption. 68% of this increase can be attributed directly to the increase in demand for network services and the rest, between 247 and 632 million euros, indirectly from the additional output required to meet that demand from sectors that supply intermediate in-

puts to network services (backward linkages). The equivalent figures for professional services from the reduction of entry regulation would be respectively 642 million, 962 million and 1,283 million, of which 78% from professional services themselves and between 143 and 285 million euros from additional output in supplier sectors. More realistically, those for a one unit reduction in conduct regulation would be 326 million, 489 million and 652 million euros (between 72 and 145 million in supplier sectors). The impact on total output for a reduction of entry regulation for network industries is therefore estimated to be between 2.4 and 3.1 times that of a reduction of conduct regulation for professional services. Since network services depend more on inputs from other sectors than professional services, the relative impact on the output of other sectors from a reduction of regulation in network services is greater at between 3.4 and 4.4 times that of a reduction of conduct regulation for professional services.

In view of the strong links between producer services and manufacturing industry for often industry specific capital equipment, it can be interesting to evaluate the impact of an increase in demand as a result of lower regulation also on gross fixed capital formation and in particular that of purchases of machinery and equipment in addition to the impact on intermediate consumption. Again, increases in both of these items can be attributed directly by increased demand in the services for which prices are reduced or indirectly through increased demand in the industries serving the services in question.

By applying an overall investment rate in the sector in question to the estimate of increased output for that sector from the reduction in price of network or professional services, an estimate of increased gross fixed capital formation can be derived. Taking the share of machinery in equipment in total gross fixed capital formation, a further estimate of the impact on manufacturing industry can be made (most of the rest of GFCF is in construction and public works). In this way a reduction of entry regulation for network industries can be estimated according to the demand elasticity chosen as producing an increase of 77 million, 138 million or 201 million euros in gross fixed capital formation of which around two thirds by the network services themselves and the rest from increased demand in sectors supplying inputs. Of these respectively 38 million, 71 million and 105 million euros are expected to go to the manufacturing sector in the form of increased demand for machinery and equipment, three quarters of which by the network industries themselves. It should be noted that unlike the other figures quoted, this increased demand can be supplied either by domestic or by foreign firms in the form of imports.

Similar estimations can be made for professional services bearing in mind that both their overall investment rate and the share of machinery are lower than for network services. Taking also the lower estimate for the impact of conduct rather than entry regulation, professional services are estimated to contribute respectively 24 million, 37 million and 49 million additional demand for gross fixed capital formation under the different elasticity assumptions, 60% in professional services and the rest in supplier sectors. Respectively 13 million, 19 million and 25 million euros are for equipment and machinery of which 64% would be in professional services.

Bearing in mind that in 2005 Belgian gross output totalled 629,713 million euros, the figures quoted above may seem small (less than 1% of total gross output) but they are not insignificant in absolute terms. They are based on the hypothesis of a one unit decrease in regulation and more extensive market liberalisation can then be expected to produce greater benefits. The effect of a price reduction with unchanged

technical coefficients can be considered as a short term indicator of improvements in cost competitiveness of users. The impact on demand would be of a longer term nature. Measuring adjustments in terms of relative labour and capital inputs and of technical coefficients require the use of CGE models and are beyond the scope of this paper. They have been used extensively for example in ex ante and ex post evaluations of the effect of European integration but have been shown to be widely implausible in their results. The advantage of the procedure employed here is that it can be related directly to actual flows of goods and services in the economy and identifies different ways in which a change in regulation can affect the economy. The extent of linkages within the economy, the share of a sector in gross output, own price elasticities of demand and the semi-elasticity of a change in regulation on price are the four elements that together condition potential effects on the economy.

A different type of impact can be expected in terms of how imports of services affect the economy. Traditionally impacts in terms of greater competition for domestic suppliers as well as more choice for users have been highlighted as gains from trade. Here the impact on manufacturing productivity of more imports have been looked at more narrowly. The 0.264 coefficient for the effect of foreign business service linkage on labour productivity for small countries from the ECSIP study for the European Commission is quite high. In line with the conservative estimates made for the impact of greater competition, a lower coefficient of 0.200 would probably be more appropriate. Combined with a semi-elasticity of -.306 for entry regulation for network services and an even higher -0.452 for public ownership a combined effect of 0.15% on the growth rate of labour productivity in manufacturing from a one point decrease in regulation of selected network services should probably be taken as an upper bound. Professional services represent only 2% of imports of business services in the study and it is not considered realistic here to make an estimate of the effect of an increase in imports on manufacturing productivity.

The impact of greater access for foreign firms on the domestic market is expected to result first of all in an increase in labour productivity since the affiliates of foreign firms may displace or take over domestic firms rather than adding to competition on the domestic market (Smith, 2015). With the significant exception of electricity foreign firms have higher labour productivity than domestic firms (Table 9; numbers of observations in brackets). The difference can be substantial in other network industries than electricity or negligible in the case of legal and accountancy services. There are no foreign affiliates in the data for rail transport or architectural services so it is not possible to compare productivities for these services. The high domestic labour productivity for electricity can stem from a combination of high capital intensity and a dominant supplier in the period under consideration (even though Electrabel was already majority controlled by Suez during this period and presumably should have been classified as an affiliate of a foreign company). It should be mentioned that there are very few affiliates of foreign firms among legal services (9) or accountancy firms (3). Limitations on the legal form under which professional firms can operate alongside limitations on several professions operating together may be particularly burdensome for foreign firms.

| <b>Network</b>                     | <b>Overall</b>    | <b>Electricity</b> | <b>Air Transport</b> | <b>Postal &amp; Courier Services</b> | <b>Telecommunications</b> |

Table 9: Labour Productivity in Network and Professional Services, 2005

## 6. Policy Implications

The previous sections have illustrated the strong interactions between upstream and downstream service activities and goods producing, particularly manufacturing industry. Certain of these relations have been explored in more detail from the viewpoint of the effect of changes in regulation for services on competition and trade both on the sectors themselves and with regard to their impact on the rest of the economy. Two major types of policy conclusion can be deduced, one concerning the appropriate way to look at the impact of changes on the services concerned, the other on how to view and develop policy towards both industry and services in the context of today's economy.

It is not sufficient to demonstrate that there is a connection between the regulation of a service and some variable of interest. The exact regulation or failing that the type of regulation must be identified since individual regulations may have very different effects than those for regulation overall and it is important to be able to identify which particular regulations are causing the most negative effects on growth, employment or in the cases studied here on competition on the domestic market and trade. Ideally the specific channels through which a regulation affects outcomes should be specified. Even then it may be that a regulation that is burdensome may be required for public interest purposes when there is no other effective way of regulating the service.

While an econometric approach can be useful, knowledge of how the markets for specific services operate in practice will often be required. This can provide insights into which particular obstacles form a binding constraint on activity and help to narrow down the area of concern. The workshops organised by the author in the European Commission in 2007 were an example of how policy makers can obtain information easily and at low cost (Smith, 2007). The econometric analysis presented previously of conduct regulations, specifically restrictions on the permissible legal form for professions and the ability to cooperate between professions, has confirmed the insights previously garnered from the workshops that these restrictions are particularly burdensome for the ability to enter markets effectively. “Softer” forms of information and “harder” forms such as those presented here are indeed complementary.

The identification of particularly burdensome forms of regulation helps to go beyond the generic policy of more or less regulation to concentrate on the individual changes that are required. Many services will continue to be regulated in future, sometimes regulation of incumbents is even required to open up markets to competition as has been seen in numerous cases for network services. The term “de-regulation” is therefore inappropriate as a term for policy towards services and should be replaced by that of “appropriate regulation” by which is meant the regulation that achieves public policy aims with the minimum adverse effects.

Arguments about the nature of industrial policy, whether it should be so-called “vertical” or “horizontal” by which is usually meant “interventionist” or “non-interventionist” have largely been laid to rest although they resurface occasionally. It can be shown that framework conditions that apply to the economy as a whole can have very different effects on individual sectors whether manufacturing or services. Intellectual property rights provide an example. For pharmaceutical firms patent protection represents an indispensable part of their competitiveness. For information technologies it is the danger of being locked out of key technologies through patent thickets that represents the main issue for intellectual property. Other sectors may not patent because speed to market is more important than the time consuming procedure for obtaining a patent or because other forms of intellectual property are more important for that sector (trade marks for luxury goods or copyright for services). The fact that a policy which applies to the economy as a whole may have very different impacts on different sectors pleads in favour of examining more closely those impacts when formulating the policy in question not in favour of more targeted policies towards individual sectors.

The revival of interest in manufacturing industry in advanced industrial countries of western Europe has been driven partly by fear that these countries will no longer be able to maintain a strong manufacturing sector in the face of strong competition from China and other emerging markets and by the re-composition of supply chains around foreign direct investment in lower cost locations nearer home, particularly new members of the EU in central Europe. It has also been driven by the search for secure, well-paying jobs for those without advanced skills that manufacturing used to provide. While ultimately innovation, the provision of ever higher quality products and control of costs are the principle ways to maintain competitiveness in high cost locations such as Belgium, the overall environment for doing business and the very specific ways in which manufacturing interacts with services both upstream and downstream should not be neglected. Competitive suppliers of services constitute themselves an important competitive advantage for manufacturing industry – and one

that is relatively hard to replicate since it is built around intangibles and tacit knowledge. Nor should the importance of a competitive distribution sector be neglected because high mark ups dampen demand for goods and create rents between the consumer and the producer to the detriment of both a situation that has for instance been observed in southern Europe for a lack of pass through to final consumers of opening up the market for apparel under the Uruguay Round of trade negotiations.

The very strong linkages between upstream and downstream services and goods producing industries illustrated in figure 1 and explored in more detail in this paper would indicate that no policy towards manufacturing can be effective if it ignores the conditions under which such services are provided. The concept of “industrial policy” would then need to be broadened to include the relevant services so that it becomes a policy towards the productive sector in the sense of “standortspolitiek”. While this concept of policy may be considered too broad, it retains a sense of focus if the emphasis is placed on the interaction between different actors and different sectors rather than on each one taken individually. It ought also to be mentioned that certain very important services (public administration, non-market services and market services to households other than trade and distribution) are not in the first instance concerned by such an approach since the linkages with the rest of the economy are much less developed.

## **7. Conclusion and Further Work**

This paper has set out a way to measure the impact of regulation of a service on both the service itself and the wider impact on the rest of the economy for a single country, Belgium. The information requirements particularly for the first stage of the procedure are high. It would of course be desirable to have such evaluations for a wider array of countries and also to be able to see how the impact of regulation changes over time.

Often it is the impact of regulation on the dynamics of an economy that are of interest. Here many other types of factors than regulation specific to a sector come into play. A dynamic model of entry, exit and growth using panel data and constraints in the form of different types of regulation including those that affect an economy as a whole, such as labour market regulation or ease of doing business, along with other important explanatory variables would be a more suitable approach to evaluating the effect of service specific regulation on growth of turnover, value added or employment. Since these areas are those of the most of interest to policy makers, such an approach marks a logical extension to the procedure outlined here, but the information requirements are even more demanding.
