## Appendix 1

### ***Methodological approach***

To start with, we shall use the following notation:

**Z** = domestic intermediate input-output matrix

**I** = identity matrix

**x** = output column vector

Backward linkages are derived directly from the technical coefficient  $a_{ij}$  calculated as the ratio between the purchased input  $i$  in sector  $j$  and the output of sector  $j$  derived from the values in **Z**.

*Input-coefficients*

$$A = \mathbf{Z} * \text{diagonal}(\mathbf{x})^{-1}$$

In order to take into account the indirect value of inputs  $i$  present in other purchased inputs by sector  $j$  it is necessary to calculate the Leontief inverse or total requirements matrix given by:

*Leontief inverse of input-coefficients*

$$L = (\mathbf{I} - \mathbf{A})^{-1}$$

An equivalent matrix for forward linkages, the Ghosh matrix **G**, can be calculated from the direct output coefficients  $b_{ij}$  or the distribution of sector  $i$ 's outputs across sectors  $j$  that purchase inter-industry inputs from  $i$ .

*Output-coefficients*

$$B = \text{diagonal}(\mathbf{x})^{-1} * \mathbf{Z}$$

*Ghosh inverse of delivery-coefficients*

$$G = (\mathbf{I} - \mathbf{B})^{-1}$$

## Appendix 2

### Studies on price elasticities for network industries

| Sector      | Segment            | Sub-segment             | Period    | Country       | Source                   | Elasticity Low | Elasticity Average | Elasticity High |

# **XXV. International RESER Conference: Governance for collaborative development of service and system innovations**

*Kirsi Hyytinen<sup>1</sup>*

<sup>1</sup>VTT Technical research Centre of Finland

This paper studies the multi-actor collaboration in the service innovation using the concept of ServPPINs. We concretize forms of such new governance mechanisms in which the solutions to societal problems are based on the integration of technological and service based novelties, and which appreciate partnerships, negotiation and trust between multiple kinds of actors. The study focuses on service innovation in the environmental sector.

## **1. Introduction**

The objective in this paper is firstly to study the collaborative forms of system and service innovations and secondly to illustrate how the collaboration in innovation can be supported with the mechanisms of network governance (e.g. Lévesque, 2013; Hartley, 2005; Moore & Hartley, 2008). The focus is specifically on *service and system innovations in the environmental sector*.

Environmental sustainability is one of the so called “grand societal challenges” referring to extremely complex global societal problems that are systemic by nature and cannot be solved via individual product or service innovations created in individual organisations. Conversely, the challenges require the combination of various innovations and their effective dissemination on the basis of continuous interaction and dynamic between different organisations and parts of society (Toivonen, 2015; Geels, 2002; Rubalcaba et al., 2013; Gadrey, 2010; 2004; 2010). Thus, besides the combination of technological and service innovations, system and social innovations are required. *System innovation* refers to a renewal of whole set of networked supply chains, patterns of use and consumption, infrastructure, regulations etc. that constitute the socio-technical system providing basic services such as energy provision (Smith et al., 2010). To develop system innovations new operational model based on the simultaneous development of organisations, technologies, services and multiple network relationships (Gallouj, 1994; 2002; Windrum and García Goñi, 2008; Harrison et al., 2010; Rubalcaba et al., 2012) are required.

A prerequisite for the realisation of these system level challenges is the active engagement of various actors in the creation, implementation and diffusion of innovations. Thus, system innovations are interlinked with *social innovations*, characterised in the recent literature by the two different aspects of social: it is social by its ends and by its means. First ‘social’ refers to the societal challenges (e.g. environmental sustainability) innovations are aiming to solve and the second aspect of ‘social’ refers to participatory and networked processes without which it is not possible to create innovation in a multi-actor environment (Toivonen, 2015; Harrison 2011).

However, in the literature the networked structure of innovation has been understood only partially. Large amount of literature is focused to analyse innovations from the organisational perspective (Moore & Hartley, 2008) and typically private and public innovations have been studied in isolation (Rubalcaba et al., 2013). In addition, understanding the different logics and drivers of innovations in private and public sectors is insufficient. That may produce a partial and incomplete understanding of the drivers, dynamics and impacts of innovations and services (Levesque, 2013; Moore & Hartley, 2008; Hartley, 2005; Rubalcaba et al., 2013). What is needed in the comprehensive understanding of the collaborative development processes providing societally important innovations and how it can be supported from the perspective of broader social decision-making system (Moore & Hartley, 2008.)

Recently introduced network concept ServPPIN (Public-private innovation networks in services; Gallouj et al., 2013) aims to bridge this gap and focuses to the complementarities and synergies between public and private service providers (Rubalcaba et al., 2013). ServPPINs have been developed as a mode for organising diverse actors, competences and knowledge in complex service innovation processes and thus for driving the systemic change in flexible, cooperative and interconnected way (di Meglio, 2013). They can be seen as a practical way to create cooperative and interactive arenas to tackle the growing complexity. These new mixed organisational arrangements have mainly emerged as a result of the modernisation and reform trends in the public sector reflecting a change in focus in public service provision: from cost-efficiency, markets and consumers towards complexity, co-production and public value (Rubalcaba et al., 2013; Levesqué 2013). This development manifests the broader paradigmatic change gaining ground in the governance system. Instead of hierarchical top-down coordination (e.g. new public management), there is a tendency towards non-hierarchical, de-centred governance mechanisms (Lévesque, 2013; Hartley, 2005; Sorensen & Torfing, 2007). The new networked way of governance is seen as a possible answer to the challenges posed by increasing societal fragmentation, complexity and dynamism (Sorensen & Torfing, 2007).

This paper studies the multi-actor collaboration in the environmental services using the concept of ServPPINs (Gallouj et al., 2013). We concretize forms of such new governance mechanisms in which the solutions to societal problems are based on the integration of technological and service based novelties, and which appreciate partnerships, negotiation and trust between multiple kinds of actors (Hartley, 2005; Voss et al., 2007; Moore & Hartley, 2008; Levesqué, 2013.)

Empirical data of the study is collected in Finland and describes on a new policy instrument SHOK (Strategic Centers for Science, Technology and Innovation) accelerating service, system and social innovations in the area of environmental sustainability. Data has been gathered from face-to-face interviews (35 in total), observations of six collaborative workshops, program documents and other strategy material.

The paper is structured in five sections. The second section after this introduction presents the central literature focusing on system and service innovation, new governance mechanisms to support the innovation development in the complex and system context and ServPPIN as a manifestation of novel networked based governance. The third section presents the case context in energy and environment sector and research methodology we have applied in data gathering and analysis. In the fifth section we describe our results and the final section sums up the study, provides some managerial and policy implications and gives ideas for further studies.

## **2. Theoretical background**

### **2.1. System change through social innovation**

Today the challenge of sustainable development is increasingly understood as a transition towards more sustainable socio-technical systems (Elzen et al., 2004; Geels, 2010). The perspective of socio-technical systems acknowledges difficulty in studying the sustainability of isolated technologies and services, if not analysed as embedded in a broader context. It points out strong interdependencies between various elements of the systems which impede new ways of organising the provision of renewable energy, for instance. The analytical challenge is to understand these interdependencies in a dynamic system, and then to identify how innovation can induce a transition to other, potentially more sustainable, systems. (Geels, 2005; Smith et al., 2010.) Sustainable systems innovation implies that major changes are required along the entire production-consumption chain, its flows, its multi-level architecture, its institutions and structures including policy and governance processes, and – not least – the behaviour of the actors involved in it, from resource extraction to the final consumption of goods and services (Weber and Hemmelskamp, 2005; Smith et al., 2010).

However, the current literature on systemic change concentrates relatively much to the introduction of new technologies and obscures the discussion and questions how to intervene in ordinary practices and dynamics to accelerate the systemic change (Showe and Walker, 2010). The perspective of social innovation is needed to create understanding of the participatory and networked processes without which it is not possible to create innovation in a multi-actor environment (Toivonen, 2015; Harrison, 2011).

This paper studies the social innovation as participatory and collaborative processes which are necessary for the emergence and implementation of innovations in a multi-actor environment. Also in the novelties created, new ways of interacting is an important ingredient. Thus, the activities and actors involved have often been highlighted as the most distinctive feature of social innovations. Social innovations may emerge at the grassroots level among users and employees; they may be produced in the collaboration of private, public and third sector organisations; or they may be initiated by policy makers and regulatory bodies. In all cases, integration of bottom-up and top-down processes is essential (Rubalcaba et al., 2013).

Bottom-up grassroots activities are seen as an ‘engine of social innovations’. The process of creation and implementation of social innovations highlights empowerment: the role of citizens is an active co-developer. The importance of bottom-up processes is clearly observable in the sustainability context. The behaviour of consumers has a crucial impact on the achievement of the goals set. A change in user preferences is necessary in order to avoid undermining the improvements in the production and delivery of energy by consumption patterns (Weber and Hemmelskamp, 2005).

Equally important are the top-down processes which translate the general objectives into concrete policies and practices in circumstances characterised by societal and political dispute (Meadowcroft, 2009). They are needed for the materialisation and dissemination of social innovations. Community decision makers and company ma-

nagers have to support, recognise and organise bottom-up processes in order to make ideas implementable and scalable (Høyrup, 2010). Policy actors have to enhance society's innovation capacity by revitalising innovation institutions and by fostering the innovation activities of public, private and third sector organisations (Rubalcaba et al., 2013).

## **2.2. Governance mechanisms to accelerate systemic change**

Above described developments have significant implications to public policies and create need for new governance approaches that support the collaborative and dynamic development and implementation of social and system innovations. In addition, the future of services are seen to shaped through new type of governance mechanisms which includes the rise of networks and partnerships, innovations as democratic practice, the development of "choise" and co-production of service models (Langergaard, 2011; Newman & Clarke, 2009).

Even the tendency in the literature is towards networked forms of governance (Levesqué, 2013; Moore & Hartley 2008) there is no agreement that in practically network governance is currently the dominant steering mechanism in public sector. More likely the public sector steering and decision making is still organised based on bureaucratic and new public management (NPM) (Levesqué, 2013; Moore & Hartley, 2008) that focuses on economic and technologist views of innovation and service and does not take into account their collaborative, interactive and dynamic nature. Therefore governance may be seen rather a problem producer than a problem solver (Voss et al., 2006) which may hinder the innovation activities in complex and continuously evolving society.

This critique reflects the broader paradigm change gaining ground in the governance system (Newman and Clarke, 2009). Although the benefits of hierarchical new public management based coordination are indisputable compared to the earlier bureaucratic view (Hartley, 2005; Moore & Hartley 2008; Levesqué, 2013) the limits of NPM have become apparent along with the development towards increasingly complex issues, involvement of multiple actors and need for open dialogue (Sørensen, 2002). The shift from hierarchical top-down "government" to more horizontally organised self-regulating networks of governance (Sørensen & Torfing, 2007) has been seen as a possible answer to the challenges posed by increasing societal fragmentation, complexity and dynamism (e.g. Levesqué, 2013; Moore & Hartley, 2008, Voss et al., 2007; Sorensen & Torfing, 2007; Hartley, 2005; Rhodes, 1997) and useful mechanism that supports the innovation development frequently along the continuously changing societal conditions (Voss et al., 2006).

However, because of the comprehensiveness of changes in governance it is not simple and immediately clear how to apply these transitions in practice (Shove and Walker, 2010). Recent literature have analysed the central aspects from the practical point of view to identify the factors which challenge the application of new governance culture (Shove and Walker, 2010; Moore & Hartley, 2008). According to the literature, fundamental problem lies in understanding the interaction between top-down and bottom –up approaches and co-creation with different actors and actor groups including the public private and third sector organisation not forgetting the central role of citizens in “doing” the change.

### **2.3. Public-private innovation networks (ServPPINs) in conducting the change**

ServPPINs (Gallouj et al., 2013) have emerged as a result of the above described modernisation trends in the public sector (Di Meglio, 2013). They are reflections of novel forms of governance which focuses to the rise of networks and partnerships, innovations as a democratic practice, the development of “choice” and co-production of services and innovation (Langergaard, 2011; Newman & Clarke, 2009). ServPPINs embody flat and flexible types of organisations which aim to develop synergies between different knowledge, competences, interests, objectives and services that different partners bring in to the network (Gallouj et al., 2013; Di Meglio, 2013; Rubalcaba et al., 2013).

In the heart of the ServPPIN is the collaborative relationship between public and private sector partners. Compared to the traditional innovation networks, ServPPINs highlight the equal role of public sector service providers and manufacturing firms. Instead of having limited role in providing infrastructure, financing and institutional framework public organisations may be real co-producer of service innovation by initiating, organising and propagating new ideas (Di Meglio, 2013). Moreover to facilitate better matches between technology and demand ServPPINs involve consumers, intermediate users and third sector organisations to be active collaborators (Rubalcaba et al., 2013). Based on the empirical studies on ServPPINs (eg. Rubalcaba et al., 2013) their potential is in credibility, dissemination, speeding up the process of agenda setting and decision making, provision a more comprehensive view of the problems, legitimacy, resources and efficiency, learning capacity and knowledge transfer.

There are some key features which help to understand how ServPPINs operate. *Firstly*, they are grounded on a *broad concept of innovation* brought about by evolutionary economics (Nelson and Winter, 1982; Kline & Rosenberg, 1986; Dosi et al., 1988; Dosi, 1999) that highlights the dynamic nature and integrative perspective of innovations in which both technological and non-technological aspects have a crucial role. *Secondly*, they are formed as multi-agent frameworks (Windrum & Garcia-Coñi, 2008; Windrum, 2013) in which the variety of actors from the public private and third sectors is involved both in the innovation process and delivery of final service and in which each of the actors incorporate their specific competencies and interests into the innovation process. By engaging various actors in the different phases of innovation they may promote systemic change in sectors concerned (Weber & Heller-Schuh, 2013). *Third* aspect relates to the life –cycle perspective referring to the evolution of ServPPIN through different phases. Phases are design (1), pilot and imple-

mentation (2) and consolidation (3) which may affect to the dynamic and composition of ServPPIN. *Fourthly*, they are characterised by the open, complex, uncertain and interactive trust based (Fuglsang, 2013) process in which the several driving forces influence to the final outcome. The level of “formality” and structuring of relationships may vary, but typically certain degree of formalization is usually required (e.g. exploitation of intellectual property rights).

Djellal and Gallouj (2013) propose a typology of ServPPINs. The criteria used for the typology pays attention to the nature of innovation (e.g. tangible and intangible nature of innovation) and the characteristics in its’ development process (planned and unplanned nature of development).

Table 1. ServPPINs according to their complexity (modified by author from Djellal & Gallouj, 2013)

| Analytical dimensions               | ServPPINs according to their complexity           |  |  |  |
|-------------------------------------|---|--|--|--|
| Type of ServPPIN                    | Simple ServPPIN to adopt technological innovation | Simple ServPPIN to co-produce technological innovation | Simple ServPPIN to co-produce non-technical innovation | Complex ServPPINs to adopt, produce and enhance implementation of complex architectural innovation |
| Type of innovation                  | Technological innovation                          |  | Non-technological innovation                           | Broad based, complex innovation including various technological and non-technological innovations  |
| Dominant type of innovation process | Planned innovation                                |  | Unplanned innovation                                   | Planned/unplanned innovation including both bottom up and top down innovations                     |
| Theoretical perspective             | Assimilation                                      |  | Demarcation  | Integration  |

As set out in the table 1 four types of ServPPINs are identified: 1) simple ServPPINs set up to adopt a technology; 2) simple ServPPINs set up to produce technological innovation; 3) simple ServPPINs set up to produce non-technological innovation; 4) complex or architectural ServPPINs. These ServPPIN types are also related to traditional service innovation perspectives: assimilative (or technologicistic), demarcative (or service-oriented), and Integrative (Gallouj and Weinstein, 1997).

### 3. Research context and methodology

#### 3.1. Case context

The focus in the selected case-study is to provide information how recently established Finnish policy instrument SHOK – Strategic Center for Science, Technology and Innovation – operating in the area of environment and energy, promotes the systemic change and industrial renewal in energy and environment sector. Centres operate as not-for profit limited companies build on public-private partnership aiming to enhance collaboration and interaction between business life and academia over the traditional industrial sectors. Their main goal is to renew industry clusters and to create system innovations to meet the needs of Finnish industry and society within five-to-ten-year period.

In this case study our focus is in Cleen-SHOK (later Cleen) which aims renew the energy and environment cluster and to promote industry's competitiveness in the area. Cleen has currently 44 shareholders including companies (28 in total) and universities and public research organisations (16 in total). The focus areas and operational activities are based on a strategic research agenda (SRA) jointly defined by the partners. The targets of the research agenda are operationalized through long-term research programs carried out in collaboration of research organisations, universities, companies and other actors. Funding for the programs is coming from multiple sources. An average forty per cent is co-funded by partner firms involved in it, ten per cent by public research organization and the rest is coming from public funding providers such as Finnish Funding Agency for Innovation (Tekes) and the Academy of Finland. The SHOKs also apply to EU research programs for funding.

We examine specifically three ongoing research programmes and the preparation of two “second generation” programmes. The ongoing programmes are 1) *‘Distributed Energy Systems’* (DESY) aiming to increase the production of renewable energy and the promotion the use of hybrid energy technologies, 2) *‘Smart Grids and Energy Markets’* (SGEM) aiming to develop smart grid architectures and, intelligent management and solutions for smart consumption and customer interface. Interaction between ICT systems and energy systems is a central innovation behind the advancements in this area and 3) *‘Measurement, Monitoring and Environmental Assessment’* (MMEA) that aims to develop an environmental information systems to monitor and evaluate the environmental efficiency of various industrial processes, products and infrastructures. Two programmes in preparation relates to the development of *‘architecture of sustainable energy systems’* and *‘healthy urban living’*. The former aims to provide holistic view needed for the energy system revolution towards sustainable and flexible system. Programme focus is on optimal integration of centralised and decentralised energy resources and production on system level as well as flexible use of various energy carriers (electrical networks, gas, heat, cool). The latter programme “healthy urban living” aims to increase urban resilience and well-being of citizens. It focuses on the interaction and interlinkages in urban system taking into account the energy chain, human behaviour, environmental and meteorological data, air quality and its effect on human well-being. It engages the citizens and enhances the co-production of urban system between different societal actors.

Cleen can be characterized as ServPPINs generating complex and architectural innovations (Djellal & Gallouj, 2013). Following table 2 describes our case context in the analytical dimensions of ServPPIN.

Table 2. Cleen SHOK as a ServPPIN

| Analytical dimensions                               | Description   | Cleen as a ServPPIN  |
|---|---|--|
| <b>Goal, type of innovation</b>                     | Broad perspective to innovation; complex, architectural innovation including various forms of technological and non- technological innovations  | Complex innovation to promote the systemic change and industrial renewal in energy and environment sector and to define e.g. “the new architecture of the future energy system”.<br><br>System renewal requires variety of technological and non-technological innovations; e.g. new patterns in production and consumption of energy.   |
| <b>Type of ServPPIN</b>                             | Complex ServPPINs to adopt, produce and enhance implementation of complex architectural innovation<br><br>Multi-actor network   | Co-production of various forms of technological and non-technological innovations<br><br>44 shareholders representing private and public organisations and different parts of the system<br><br>Multi-actor collaboration essential to co-develop new competences, to promote the creation of new business and industrial competitiveness and to enhance the implementation of complex innovations in the area of energy and environment |
| <b>Dominant type of innovation process/ dynamic</b> | Planned/unplanned innovation requires both bottom up and top down innovations developed both within formalized models and various informal models (e.g. bricolage & rapid application models) | Systemic change in energy end environment sector requires innovations in every level of society and is based on top down strategies and activities as well as bottom up activities and experiments. The systemic change is promoted by both by formalized and informal models of innovation.   |
| <b>Theoretical perspective</b>                      | Integrative   | Renewal of energy and environment sector is based on the collaboration of multiple actors representing the different sectors of society and on the integrative solutions combining multiple types of technological and non-technological innovations.  |

Regarding to the goals Cleen aims to tackle with prominent societal challenges, among which the environmental sustainability is primary. It accelerates new system level innovations and industrial renewal through new type of interaction and co-creation. The innovations developed in the network can be characterized as complex combinatory innovations encompassing both technological and non-technological ingredients and are developed in the collaboration between multiple actors.

### 3.2. Data collection and analysis

In order to gain an in-depth understanding of the governance in the case organisation, we gathered data from four types of sources. *The primary* instrument for data collection was face-to-face interviews (35 in total). The interviews were gathered between February and June 2013. Some complementary interviews were done in

spring 2015. We applied snowball sampling in the identification of interviewees: the first respondents were Managing Director of Cleen Ltd and the Programme Managers. Based on their suggestions, we thereafter selected the other interviewees among the members of the programme consortiums. The final sample represented actors in the area of sustainable energy and environmental measurement in a versatile way. It consisted of representatives of small and medium size companies (SME's) and large companies in the field of environmental measurement and sustainable energy. In addition the experts representing universities and other public research organisations in the same fields were interviewed. All interviewees were managers or senior experts in their background organisations and they had a significant role in the preparation and implementation of research programmes. Typically they were acting as program managers, work package leaders or they were leading the service demonstration development as a part of the programme implementation. Interviews were complemented during the spring 2015 by the interviews of technological and development managers of Cleen.

We applied a semi-structured interview method: the topics were decided beforehand but within them the respondents were given a great deal of freedom (Bryman and Bell, 2011). We structured the topics on the basis of our theoretical analyses in the areas of the systemic change and innovation in the area of energy and environment, governance and management of the innovation process in ServPPINs and roles and responsibilities of network actors in the innovation process. The duration of the interviews ranged from one and half to three hours. All interviews were recorded and transcribed.

*Second* source of material gathered were observations of new programme preparation process. We took part in six collaborative workshops which were directed to company, university and research organisation participants to work on new research programmes. Workshops took place during the spring 2014 (February-May). During the meetings we wrote up field notes based on the discussions. To complement the field notes we had access to the official minutes of meetings, which were provided by the case organisation.

*Third* source of information is the material provided during the preparation phase of the new programmes. Thanks to our access to the digital working space we were able to follow the programme documents and other material provided in the course of programme preparation. *Fourth* information source we have utilized is the strategic documentary material provided by the case organisation. These include, for example, the strategic research agendas, guidelines and criteria for the programme preparation, annual reports and programme result material.

## **4. Research results**

### **4.1. Tackling the societal challenges in the collaboration of multiple partners**

Based on our data, Cleen Shok is one of the central actors in the Finnish innovation system to tackle the above described environmental challenges and enhance a systemic change in the energy and environment sector. The role of research pro-

grammes has perceived to be especially important in the creation the comprehensive picture of the required transition, in the definition of strategic research questions and in the identification the central actors who are needed to solve the identified problems and thus to enhance system level change.

According to our interviews the empowerment of multiple actors representing variety of sectors, competences and world views is in essential role both in creating holistic understanding of the requirements of system level change and in developing solutions that correspond with these comprehensive needs. They highlighted that the novel programs have accelerated the network generation over the traditional organisational borders and have thus enabled the generation of strategic understanding and development of completely new competences required for the systemic change. For example in the SGEM programme interaction between energy and ICT systems is in central innovation behind the advancement of novel smart energy infrastructure. Like revealed in interviews in face of complex and systemic problems actors are running out of competence and are not capable of handling systemic problems without the support of broad based network:

*“Understanding the ongoing change is anything but a linear process. To create general understanding we need multiple organisations, multiple actors, multiple backgrounds. One actor understands this and other actors that and together we are able to create a holistic view of the ongoing changes. Without the collaboration of many actors the creation of strategic view is no possible. For that reason we did not have strategic understanding of the ongoing changes in energy sector before the first SHOKprogramme period”. (Representative of university A)*

*“We are running out of competence alone regarding the systemic transition in the energy and environment sector. Thus we need to have variety of playmates who have different types of competences required for the creation of holistic understanding of the ongoing change” (Representative of large company A)*

However, compared to traditional research and development programs collaboration between multiple partners and over traditional sectoral borders also complicates the structure of networks. For example in the SGEM encompasses in total 21 industrial partners from energy sector including for example energy technology providers, power production companies, energy distributors, energy sector service providers and from ICT sector including for example software developers, network providers and network safety consultants. In addition eight partners representing universities and public research organisations are in the core of the network. And in the first preparatory workshops of new ‘healthy urban living’ -programme approximately hundred participants representing variety of public, private and third sector organisations took part. Although the structure is complicated, the interviews revealed that extensive participation ensures both the system level problem solving and real co-creation.

*“On the one hand traditional research programs are more clear and simple in their structure, but on the other hand they have not managed to incorporate all the actors needed for the system level problem solving. In addition traditional research programmes lack of real will and capacity of co-creation. By empowering all the central national partners SHOK programmes have man-*

*aged to create a forum for real collaborative innovation ” (Representative of public research organisation A)*

Although in all the interviews multi-actor collaboration was commended the central notions regarding the participating actors is the abundance of research and company actors and absence of other public sector authorities, municipalities and citizens. Interviewees agreed that in the first generation programs the focus has primarily been in development of new technologies and solutions. Instead the broader understanding of citizens' needs and societal aspects has been lacking. They admitted that to create comprehensive understanding of the healthy urban living conditions or the requirements of novel comprehensive energy architecture, new actors and competences need to be incorporated in the programs networks. Like revealed in interviews understanding the function of political and social systems including the power relations and consumer needs and behaviour are in crucial role in order to support acceptance of novel solutions and enhance the systemic change.

*“To tackle the ongoing transition in energy sector we need to incorporate the competences and perspectives of multiple actors. Technology is the easiest part of the transition. To really be able to tackle the complex needs of system change we need to incorporate new actors and competences into our network. We need to have understanding of the energy as a political issue. In addition we need to understand what customers really need and how do they behave. When we have comprehension of these societal aspects of energy and their dynamic interaction in the system we may be able to develop viable and comprehensive service solutions and novel business concepts. (Representative of university A)*

Interviewees admitted that the program actors are just awakening to the need of sociological competences and that in the next generation programmes new competences need to be incorporated to broaden the perspective to systemic change. Based on our observations in the preparation of the “second generation” programs the centrality of citizen centric approaches and participation of public authorities have been taken into account. For example in the currently ongoing preparation of healthy urban living –program the behavior and need of citizens and role of municipalities as service development “platform” have been taken into account in strategic research agenda and attendees of the programme.

Like highlighted in interviews broadening the collaboration is crucial not only for the development but also for the implementation of better and viable solutions. The most of the actors were confident that the active participation of companies and complete value chains in the programs supports the practical implementation of the results, which is required for the systemic change. The actors believed that the evidence gained through pilots and demonstrations carried out in ongoing programs manifests also successfulness of the programs and support the systemic change. Like the citation below illustrates specially the co-development with large companies was seen crucial because of the ability to enhance the change also through companies strategies.

*“To really make systemic change happen it is important to have large companies in these networks. They are also capable of enhancing the transition through their organisational strategies and programs” (Representative of large company A)*

However, the success on SHOK-programs is manifested only if the new knowledge and innovations developed in the programs can be executed as nationwide decisions and implemented for example as new structures for energy production system and healthier urban architectures. Like some of the interviewees regretted currently the application of the research results in real life situations is too slow. One reason given is the above described insufficient collaboration with users. Besides an inadequate communication with decision-makers was seen as a bottleneck for insufficient implementation of the results. Although, several program actors were active in collaborating with national and local policymakers and some of the actors were participating in EU and national working groups, the interviewees called for more systematic collaboration with decision makers. Like interviewees revealed, to really enhance the systemic change more influence on decision-making and more systematic collaboration with the policymakers and other interest groups are needed.

*"Currently the actors have produced lot of paper. But nothing is really happening if we don't have courage to implement the results. Now the research is going round in circles. Instead we should be thinking how and with whom we implement the results as practical and concrete solutions and changes" (Representative of a small company A)*

*"We should be more active in communicating our research results to decision-makers. Single actors have been active in contacting national decision-makers and politicians. This is are very important if we want to have an influence and impact in society. However, we should be much more active in national and EU-level vision work to really have influence on the future developments." (Representative of large company B)*

#### **4.2. Creating new competences and business solutions in a trust-based collaboration**

As shown above, programs have managed to create a model for a network type of collaboration which integrates variety of competences and actors needed for the enhancement of systemic change. According to our empirical data the innovative network structure and its ability to create novel competences is based, on the one hand, on the formal contracts and partnerships and on the other hand on the deep-going trust based collaboration which has been systematically facilitated by the Cleen and programme personnel. According to the interviews partners' role as formal shareholders is a good way to ensure the commitment and success of network collaboration. In addition the collaboration is regulated by formal contracts and intellectual property rights. However, their role in collaboration is reported to be less meaningful than the role of informal trust, which was highlighted in all interviews in attaining open and profound collaboration. Like one interviewed representative of university B pointed out *"without trust the collaboration is limited only to the change of information"*.

Informal trustbuilding has been systematically facilitated from the beginning of programme planning. According to our observations, Cleen has an active role in the matchmaking new partnerships and in the creation the forum for open and trust-based discussion. They organise an open call for multiple stakeholders to take part into the creation of research agenda in the series of workshops. By organising the workshops aim is to give voice to multiple partners' needs and to match companies

and research actors over traditional sectoral borders. According to our data, setting the common targets and planning the practical implementation in the interactive and collaborative process, weld the partners together from the beginning.

The operational principle of Cleen defines that programmes are industry driven meaning that the industry needs are high on the research agenda and the targets are mainly set by the stakeholder companies. Like one large company (B) representative revealed *“thanks to the novel programmes company targets are high on the agenda, whereas in the traditional research programs funding is directed to research done in ivory towers”*. Our informants considered that the companies’ will and ability to sit on “a driver seat” commit them into the network and is a core issue when aiming for a profound collaboration. However, interviewees also highlighted the centrality of research partners in balancing the longer term strategic research competences and shorter term business opportunities. Like the following situations demonstrate the combination of different type of targets enhances the understanding the other parties’ objectives and thus benefits the collaboration.

*“This new instrument has created condition for true and open collaboration over company borders. Partners sit in the same meetings to set targets for the common development and they implement targets collaboratively. Companies are actually affecting the target setting and thus the company and user needs are taken into account in research and development work. Also our research partners have benefitted from the collaboration – they have said that now they understands better what are company needs and what are the challenges that need to be solved. In the best case this operational model generates an innovative platform for variety of organisations willing to tackle collaboratively our common societal problems.” (Representative of large company A)*

*“Programme instrument includes variety of actors from research and industry and it have managed to combine the long term visionary research work and concrete short term business objectives. The combination of different types of targets is essential for good trustbased collaboration and relevant to tackle system level problems.” (Representative of large company B)*

According to interviews profound and trust based collaboration has been a stone base leading to new combinatory competences and the creation of integrative service solutions. Programs have for example generated the new type of coproduction between experts from energy and ICT sectors and thus facilitated the generation of comprehensive energy architecture. New combinatory competences have for example made possible the coexistence of centralised and distributed energy systems and guaranteed the safe energy flow in the system. In addition, by combining ICT in the energy system, programs are making possible to multiple actors to design, construct, steer and use the smart and flexible energy system in future. Like one large company (A) representative illustrates novel combination of competences and helps in tackling the challenges in the energy and environment sector. *“We have generated completely new competences with completely new partners. This creates a ground for a completely new industrial sector”*.

Novel combination of competences generates new strategic partnerships and gives a room for practical pilots and demonstrations. It benefits both companies and research partners. For example actors who develop platform for sharing environmental data

experience that the program has given rise to new knowledge cluster which has both ameliorated the scientific base in the area and supported the development of concrete business solutions. Like citations below illustrates close collaboration has led to the interdependence between partners. It has changed the way of thinking and doing business and has given rise to novel ecosystems. In addition it has is seen to be in strategic importance in ensuring the long-term business opportunities, in strengthening companies competitiveness and in facilitating their entrance into the international markets.

*“Shok programmes have generated new type of collaboration between company partners. We have learned to collaborate fluently and openly with other companies which is not typical way of action in business. It has strategic importance for us and gives us a competitive advantage in markets five or ten years. In the future the firms who do not have the same capacity stays alone and focuses to the own narrow doings. These company networks are extremely important in the internationalisation of business. We cannot fight Chinese alone, but we can compete with them in the well-functioning company networks. Collaboration strengthens our competitiveness domestically and internationally” (Representative of large company A)*

*“For our company this programmes has been extremely important. It has especially supported our internationalisation into China. In Europe it is easy to operate for our type of small company. On the contrary it China operating alone is not possible. Without the support we get from this public-private innovation network it would be impossible to create business in China.” (Representative of small company B)*

Building a trust based relationship and creating completely new collaborative ways of working is essential but not a simple issue. On the contrary it is time consuming work which is based on systematic and open interaction, recognition of common interest and value added of each party in the development. Learning to speak common language and having the shared working methods cannot be adopted immediately into the organisations. On the contrary it requires changes in mindset and ways of working. Single organisations need for example to adopt the idea of shared value which again affects the operational model and business logic in entire organisations and business networks. Although the needs for change were ambitious interviewees underlined, that the first generation programs managed to generate shared working methods and to increase understanding of the co-production of value when tackling the complex societal challenges.

#### **4.3. Supporting the multi-actor collaboration by steering and governance mechanisms**

Programmes are steered by multiple mechanisms and in different phases of their implementation. The most part of funding is coming from Tekes, who is both setting the criteria for funding and following the success of programs based on continuous reporting and evaluation. In addition Cleen is monitoring the success of the programs. According to interviews the double steering only increases bureaucracy and does not improve the program results. However it was seen as a small and bureaucratic snag: the bigger problem according to our empirical data is the governance criteria and

mechanisms of funding organisation which do not take into account the systemic nature of the programmes. The problem manifests as contradictory and mechanistic targets of evaluation, bureaucratic preparation process and restricting consortium rules.

Like discussed above, programmes aim to find solutions to complex environmental problems. A paradox when setting programme targets is to match them up to funding criteria which do not take into account the complex and systemic nature of the programmes. Criteria set by funding organisation are based on the linear view of innovation which emphasises the short term results such as publications, patents, computer softwares and new products. Long term systematic changes emerging in the collaboration of variety of actors are not taken into account. Like interviewees highlighted the problem in steering reflects the absence of good measures capable of capturing the integrative nature of solutions and their dynamic development process.

*“The traditional evaluation and steering is based on concrete outputs of programs such as publications, softwares. But what we are actually developing is comprehensive and holistic understanding to support the societal transition in energy sector. Programs support the new ways of thinking and new societal structure, but how to measure these types of changes. It is paradoxal that there are no good measures for these systemic innovations. At the same time it is understandable that good measures do not exist yet. The changes would not be innovative and revolutionary if there were already measures for these changes”. (Representative of University representative B)*

*“Problem in steering of the programs is the traditional measures and indicators. Funding organisation is still focusing for example on the numbers of developed products or reviewed articles. We should report how many new products we have launched during the programs period and how many articles we have written. But the answer is none. Because this was not set as target. The targets for the programs are something completely different but the current measures are not able to capture the program targets which are much more holistic than these current measures. (Representative of large company C)*

Problems in understanding the systemic nature of the development and challenges in finding good criteria are seen, from the viewpoint of programme participants as contradictory targets. On the one hand programs are supposed to be risk taking and renew industrial structures in a long term but on the other hand the indicators to measure their success remains rather concrete and highlights mechanical outputs. In concrete terms funding organisation for example expects short term readiness to launch new products and services into markets. However, according to the criteria concrete service and technology development in the programmes is denied. Like citations below illustrate the conflicting criteria make the preparation of the programmes schizophrenic and causes uncertainty about the role of different actors in governance of network.

*“Problem is the contradictory funding criteria set by Tekes. On the one hand we are expected to promote export activities but on the other hand we are not allowed to do any service or project development. Steering is schizophrenic because of contradictory and too mechanistic targets (Representative of small company C).”*

*"Current steering is based on contradictory targets. On the one hand the programs need to be long term and risk taking and on the other hand programs should provide concrete short term results. I don't know if I should laugh or cry when thinking which targets to follow. Funny thing is that Tekes has denied us to develop concrete products, anyhow they are having it as a success indicator because they do not have any better indicators. But how can you get something which has not been set as target? Furthermore the steering culture is very much dependent on the personal opinions of person in charge in funding organisation. During our programme preparation the person has changed for three times and every time that has affected to the emphasis of our program. The former stressed completely different things than the current." (Representative of university A)*

Also the timescale in steering was criticised by programs actors. Enhancement of systemic changes such as the emergence of user communities to support the acquisition of real time environmental data and developing concrete business solutions for environmental reporting standards is a complex and long term process. The timeline for these changes is much longer which can be captured by the current evaluation and steering mechanisms. Therefore the reported results do not tell the truth of the attained results. Like revealed in interviews current steering may direct to wrong conclusion of success of the programmes:

*"Current indicator in steering may lead to the completely wrong conclusion of the success of the programs. They may even show that companies have not achieved anything in these programs. The reason for the wrong conclusion relates to the different time scales of steering and productisation in companies. Launching the new products is a long term process. Companies publish the information of new solutions when launching them. Problematic thing is that steering in funding organisation is based on targets which do not take into account different timescales. We have, for example, started several the product development processes based on the program results, but we won't tell about these results in public before we are launching the new products." (Representative of a large company D)*

Current criteria are set top-down by funding organisation. Instead of top-down target setting programme actors are begging for better interaction with funders during the programme preparation and implementation. According to them it would be essential to have a shared vision created in the dialogue between top down and bottom up processes. In addition the operational environment is continuously evolving thus the targets and operations of the programs need to be adapted into the changes in operational environment. That also highlights the need for continuous interaction. Role of funders in the process should be a supportive and collaborative partner, not a controlling administrator. Like revealed in interviews, aspects to be considered in the vision building are the holistic understanding of the forthcoming environmental challenges and users' needs. Equally important is to identify both the most relevant actors and the central milestones required to realise the vision.

*"Funding decisions are made currently in a very bureaucratic process and the selection of programs is based on completely wrong criteria. They are focusing too much formal structure of the proposal although the focus should be in visi-*

*onary targets: how we aim to enhance societal change in collaboration. The bureaucracy and control not enhance the good quality research, business impacts or industrial renewal in this country. On the contrary when we are aiming at radical and long term change the objectives should be defined in the collaboration of multiple actors including funding organisation. Together we should set targets and identify the steps to reach targets.” (Representative of large company E)*

Interviewees believed that open interaction with funders would improve the program preparation. Currently the preparation processes are typically prolonged because of the bureaucracy, lasting in some programs even for five years. Un-effective preparation has led to fatigue of company partners and some of them have decided to opt out from the consortium. Loss of the central partners has led, like illustrated in citation below, to the absence of required competences:

*“Preparation process of new programs is untenable. Long and hard preparation has led to the situation in which the company partners have decided to opt out of the project. Instead of refining the proposal in details the focus should absolutely be in setting long term visionary target and ensuring that we have the best actors in our partnership network” (Representative of University C)*

Not only the poor evaluation criteria and interaction in governance, but also the consortium rules are limiting the agile collaboration and network formation. Current rules are inflexible and do not correspond with the modern way of development which is based on continuously evolving networks. However, current consortium rules necessities permanent participation and do not allow the evolvement of networks which may congeal programs activities. For example programs actors perceived the need to empower the citizens and residents’ associations into the development of energy solutions in ongoing programmes. However, integration of new actors during the programme period was not possible which complicated the program implementation and prevented the empowerment of citizens. In addition, in some companies, for example in start-ups and high growth companies the operations are fast and cycle, which are not recognized in the consortium rules. Thus their participation in the programs may be prevented by too strict consortium rules. Like the citation illustrates our interviews assume that more flexible consortium rules would facilitate company entry and participation in the programs.

*“Consortium rules in programmes are problematic and prevent the flexible entry into and exit from the programs. More flexible rules would facilitate the small companies’ participation. Now the rules are old-fashioned and they do not support the cyclic and fast operations of start-ups and high growth enterprises in which the phases of research and commercialisation alternate flexible in the course of development process.” (Large company representative D)*

Current consortium rules also constrain partners collaborate within national borders and hinders the collaboration with the foreign actors whose competences would be relevant in providing high level research and completely new solutions. Like interviews revealed the consortium rules should be renewed to support the collaboration with the relevant partners instead of being restricted on national borders:

*“China has changed the criteria of innovation activities and they allow the R&D funding abroad. We should also renew our rules in Finland. The current rules restrict the collaboration with international partners which prevents the collaboration and co-production with the world leading partners and stagnates the national competence development. It is impossible to imagine that in Finland you can continuously find partners who are the world’s best in everything. When you try to collaborate in these programs with foreign researcher funding organisation says that we cannot pay the salary for researchers in Chinese universities. I do see why it is difficult to renew the rules; they are only afraid of nasty headings in newspapers that Finland is funding the R&D in China.” (Representative of small company B)*

## **5. Concluding discussion**

In this paper we have examined the collaborative forms of service innovations to tackle the system level challenges in environmental sector. To describe multi-actor collaboration we have applied the concept of ServPPIN (Gallouj et al, 2013). It concretize forms of such new governance approach in which the solutions to complex societal problems are based on the integration of technological and service based novelties, and which appreciate innovation as a democratic practice as well as partnerships, co-production and trust between multiple kinds of actors.

Innovation dynamics within an ServPPIN are result of complex interactions between various actors having heterogeneous competences and goals (Djellal and Gallouj, 2013). The perspective of social innovation is applied to create understanding of the participatory and networked processes without which it is not possible to create innovation in a multi-actor environment (see. Toivonen, 2015; Harrisson, 2011).

Our case study reflects in many ways the complex ServPPINs aiming to enhance systemic change in the area of energy and environment. It developes complex, architectural innovations (see Djellal & Gallouj, 2013) to promote the systemic change and industrial renewal in the sector for example by defining the “new architecture of the future energy system”. System renewal requires variety of technological and non-technological innovations; e.g. new patterns in production and consumption of energy. Besides new technologies, new services, business models and processes (in and between different levels of society) are developed.

Renewal and system level change is accelerated through new type of interaction and co-creation within multiple network partners. According to our results the empowerment of multiple actors representing variety of sectors, competences and world views is in essential role both in creating holistic understanding of the requirements of system level change and in developing solutions that correspond with these comprehensive needs. However in the collaboration the representatives of public and private sectors are dominating. Instead the broader understanding of citizens’ needs and societal aspects are lacking. That may hinder the acceptance of novel solutions and hamper the systemic change.

Development process on the complex innovations include formalised top down strategies and regulations. Like the results show the emergence of an open and collaborative culture is crucial to the development of such a network; the core is in informal

models of innovation by giving room systematic procedures of building trust. Organisational boundaries need to be opened up to facilitate the collaboration and integration of various competences and divergent goals. These characteristics of network imply the need for development of a different set of competences, resources, and expertise, as well as different modes of communication, coordination, and governance in the different level of system. Especially the formal steering mechanisms should be developed to understand the dynamic and long-term nature of systemic changes and to enable the complex development processes in networked world.

*The sectoral composition of an economy matters for growth and development since sectors have different capabilities to induce productivity gains, promote the expansion of other sectors or benefit from demand growth. Our research hypothesis regards whether some specific service sectors may be a sectoral engine of growth in developing countries. Therefore, we revisit and re-estimate Kaldor's Growth Laws by taking into account seven economic sectors (including four service sub-sectors) across twenty-nine Asian, Latin American and Sub-Saharan African countries during 1975 and 2005.*

## 1. Introduction

Research on the transformation of the productive structure of economies along the course of development is back in the spotlight. After the pioneer studies by Clark (1957), Kaldor (1966), Kuznets (1966) and Chenery and others (1986), there has been a renewed interest across developed countries (Jorgenson and Timmer, 2011) and, particularly, across developing economies (Timmer and de Vries, 2009; Bah, 2011; MacMillan and Rodrik, 2011; McMillan, et al., 2014; Timmer et al., 2014, Rodrik, 2015). Nevertheless, there is still a need for going deeper into the analysis of the dynamics of heterogeneous productive structures of developing economies and its impact on growth. Recent contributions “should be complemented by old ideas that have received little attention in contemporary debates, including the growth-productivity connections associated, in particular, with the Kaldorian tradition and the linkages among firms and sectors emphasized by Hirschman” (Ocampo, 2005, page 22).

The structure of an economy matters for growth performance and development since sectors have different capabilities to induce productivity gains, promote the expansion of other sectors or benefit from internal and external demand growth (Cimoli et al., 2005; Thirlwall, 2013). In the Kaldorian tradition, the manufacturing industry has traditionally been considered as the main vector of productivity growth over time and, thus, as an “engine of growth” of economies (Thirlwall, 1983). Kaldor (1966, 1967) proposed a set of long-run relationships between manufacturing growth, productivity growth and output growth that are commonly known as Kaldor's Growth Laws (from now on, KGL). In this structural approach there is a need to distinguish between increasing returns activities, on the one hand (associated with manufacturing), and diminishing returns activities with labour surplus, on the other (associated with agriculture). Manufacturing expansion can induce the growth of GDP per worker as a result

of two mechanisms. First, productivity in manufacturing rises with the growth of manufacturing output due to the presence of increasing returns to scale at the sector level. Second, output growth in manufacturing tends to increase the rate of productivity growth in other sectors. Therefore, industrialization has been seen as a pathway to output growth and, ultimately, economic development.

These old ideas on the pivotal role played by manufacturing in growth via productivity are now being challenged by new evidence. First, several developing economies are experiencing “premature deindustrialization” as documented by Palma (2005); Dasgupta and Singh (2005, 2006) and Rodrik (2015). In these countries, the share of manufacturing in employment and value added is shrinking at levels of income per capita that are much lower of those at which the advanced nations historically began to de-industrialize. Thus, many developing countries are becoming service-based societies faster than what are now developed countries did during their transition through development stages (Bah, 2011; Ghani and Kharas, 2010; Ghani et al., 2012; Szirmai, 2012). Second, the tradability of services has progressively increased and value chains of production have now globally expanded. This means that the advantages that manufacturing and agriculture traditionally had on the trade/globalization sphere are now eroding (Dasgupta and Singh, 2005). Moreover, the increased interdependence of countries implies that an integrative and comparative view of structural change is much more relevant than a closed economy view (Matsuyama, 2009). Third, some service sub-sectors have completely broken away old myths and have turned into some of the most innovative and productive activities. Productivity improvements in market services (namely, in financial and computer and related services or business services) are as important as, or even more important than, productivity growth in manufacturing (Timmer and de Vries, 2007; Timmer and de Vries, 2009; Maroto-Sánchez and Cuadrado-Roura, 2009, United Nations, 2009). At the same time, after the financial crisis, the political and academic discussion is going towards the “reindustrialisation” of (developed and developing) countries and the fostering of industrial policies as a means to achieve sustainable growth paths (Tregenna, 2011; Westkämper, 2014).

Facing the old ideas with the new evidence, our research hypothesis regards whether some specific service sectors may be a source of economic growth in developing countries. Potentially, those services embodying knowledge and technology or with strong inter-industry linkages or highly tradable may serve as a means to catching-up with advance economies by complementing/replacing manufacturing as an additional/new engine of growth. This may happen by the same productivity-growth connections that Kaldor uncovered for the manufacturing sector. Therefore, we aim to revisit KGL and econometrically test them in seven economic sectors (including four service sub-sectors) across twenty-nine developing countries from Asia, Latin America and Sub-Saharan Africa during a time span of three decades (1975-2005). Panel data estimations are complemented with a decomposition of labour productivity growth in order to study how resource reallocation during the process of structural change affects economic growth in those developing economies.

We contribute to the literature in this field by taking into account the heterogeneity of services when examining growth across developing economies within a Kaldorian framework. To our knowledge, no study has tested KGL across developing countries and at the (two-digit) disaggregated level of the services sector. Moreover, this research aims to uncover how the heterogeneous productive structures of the different sub-continent have an impact on growth. Furthermore, whether services-led growth

can become a new growth model in the absence of sizable manufacturing industries is a matter of concern (Rodrik, 2015). This timely investigation aims at contributing to this debate.

The paper is structured in the following way. Section 2 explains KGL and summarizes the related literature. Section 3 presents the data used in this research and the empirical strategy followed. The econometric results for the whole sample of countries as well as for the different sub-continent and the decomposition of labour productivity growth are discussed in Section 4. Finally, conclusions and the future research path are presented.

## **2. The Kaldorian Framework**

Nicholas Kaldor (1966, 1967) attempts to explain large growth rates differences between industrialized countries after the postwar by adopting a sectoral approach where dualisms à la Lewis can be found (Lewis, 1954). Unlike the neoclassical theory of economic growth, which is based on a homogeneous product of the economy and is entirely supply-driven, Kaldor argues that both the production and demand characteristics of each sector of the economy (agriculture, industry and services) matter for economic growth. On the demand side, the income elasticity of manufacturing is similar to that of services but higher than that of agriculture. On the supply side, a low productivity agricultural sector with labour surplus subject to diminishing returns coexists with a capital-intensive manufacturing sector characterized by increasing returns and high productivity growth. At the same time, Kaldor considers that the productivity growth in services tended to be considerably lower than that of manufacturing. Manufacturing showed greater potential for productivity growth than other sectors due to the presence of static economies of scale and of dynamic economies of scale in their production. Static economies of scale are mainly technical, internal to the firm and related to mass production. Dynamic economies of scale refer to increasing productivity derived from “learning by doing” (Arrow, 1962) and from the macroeconomic spillover effects of the expansion of manufacturing activities (induced technological change, externalities in the production, etc.), the so-called “macroeconomic of scale” in the sense of Young (1928).

Considering these conditions, the reallocation of labour from unproductive activities (agriculture) to more productive sectors (like manufacturing) fosters productivity growth in both sectors and depends on the demand derived from manufacturing expansion. Unlike neoclassical economist, Kaldor believes that manufacturing growth is not resource-constrained (mainly by labour) but rather demand-determined. While in the first stages of development, the expansion of this key sector is closely related to the demand of the dominant agricultural sector, in later stages is mainly driven by external demand or export growth. This is explained by the higher tradability of manufactures and the higher income elasticity of demand (Dixon and Thirlwall, 1975). In this respect, manufacturing also has greater potential than other sectors for releasing balance of payment constraints. A virtuous circle of cumulative growth can be explained on the basis of external demand evolution (Kaldor, 1970; Dixon and Thirlwall, 1975). As exports grow, output increases lead to fast productivity growth (by the presence of dynamic economies of scale) which induces an increase in competitiveness that leads to an additional increase in exports.

In the view of these stylized facts, Kaldor articulates a set of long run relationships or empirical generalizations concerning the growth of output, employment and productivity at the sectoral level of the economy which latter came to be known as Kaldor's Growth Laws (KGL). According to these laws, there is a close association between the industrial activity of a country (in particular, manufacturing) and overall output growth, and, therefore, manufacturing can be conceived as an "engine of growth" (Thirlwall, 1983).

### 3.1 Kaldor's First Law

The first law states that the faster the growth of manufacturing output ( $q_m$ ) in an economy, the faster the growth of gross domestic product ( $q_{GDP}$ ). Kaldor fundamentally defines a causal relationship running from sectoral growth to overall growth and more precisely from manufacturing growth to the growth rate of GDP per worker (Ros, 2000). This is the result of two mechanisms that are reflected in Kaldor's second and third laws. Following Thirlwall (2013), we can posit the first law as:

$$q_{GDP} = f_1(q_m) \quad f'_1 > 0 \quad (\text{Equation I-A})$$

According to Thirlwall (2003) and Wells and Thirlwall (2003), there are two additional regressions that overcome the problem of spurious correlation that is evidently present in Equation I-A (since by definition total output growth is the weighted sum of sectoral output growth).

$$q_{GDP} = f_1(q_m - q_{nm}) \quad f'_1 > 0 \quad (\text{Equation I-B})$$

$$q_{nm} = f_1(q_m) \quad f'_1 > 0 \quad (\text{Equation I-C})$$

In equation (I-B) the growth of GDP ( $q_{GDP}$ ) is regressed on the excess of the growth of manufacturing production ( $q_m$ ) relative to the growth on non-manufacturing production ( $q_{nm}$ ). In equation (I-C), the growth of non-manufacturing output is regressed on the growth of manufacturing output, and the estimated coefficient would indicate the strength and size of the impact of manufacturing sector growth on the rest of the economy.

In order to consider manufacturing industry as an engine of growth we need to carry out the same exercise for the other sectors of the economy and show that there is no significant relationship between GDP growth and the growth of agriculture or services. While it is hard to find significant relationships between GDP growth and the growth of the agricultural sector, the relationship of the former with services growth is generally strong (Thirlwall, 2003 and 2013). Despite it is likely that for certain service activities such as transport or retailing, depending to a large extent on manufacturing growth, the direction of causality is in the inverse sense; other services (IT related, in particular) seem to be leading the expansion of manufacturing, rather than the other way round (Dasgupta and Sing, 2005). Two questions remain open in this respect: to what extent do services activities have production characteristics (e.g. static and dynamic scale economies) that induce fast growth (Thirlwall, 2003), and to what extent do services have an independent existence apart from manufacturing (Thirlwall, 2013).

### 3.2 Kaldor's Second Law

The second law states that the faster the growth of manufacturing output ( $q_m$ ), the faster will be the growth of productivity in manufacturing ( $p_m$ ) as a result of increasing returns to scale. This first mechanism explaining causality from manufacturing growth to GDP per worker growth is known as the Verdoorn's law –named after the Dutch economist P.J. Verdoorn who found a strong empirical relationship between productivity and output growth in a cross section of countries in the 1940s.

This law can also be interpreted from the perspective of employment growth in manufacturing ( $e_m$ ): the higher the scale economies of the sector, the lower the employment elasticity with respect to output as productivity grows as a result of output expansion. This means that output expansion induces a less than proportional employment creation that causes productivity gains.

$$e_m = f_2(q_m) \quad f'_2 > 0 \quad (\text{Equation II})$$

Kaldor (1966) specified the Verdoorn relation in terms of a linear regression model:  $e_m = \beta_0 + \beta_1 q_m$  with  $\beta_1 > 0$  being an indicator of increasing returns of scale (the Verdoorn coefficient). However, due to the productivity identity, this can be expressed as:  $e_m = -\beta_0 + (1-\beta_1) q_m$  with  $0 < \beta_1 < 1$  being  $(1-\beta_1)$  the elasticity of employment with respect to output growth.

Verdoorn law itself has been subject to extensive debate and thus generated a large body of empirical and theoretical literature. For the purposes of this paper, several issues concerning the specification and interpretation of the law have to be pointed out. In the first place, Kaldor preferred the specification in terms of employment in order to avoid the problem of identification or spurious relation. Secondly, he states that for the existence of static or dynamic economies of scale in industry, "a sufficient condition is the existence of a statistically significant relationship between  $e$  and  $g$ , with a regression coefficient which is significantly less than unity" (Kaldor, 1975, p. 893; emphasis in the original). When analyzing cross-country data at sectoral level for 12 advanced economies between 1950s-1960s, he found a Verdoorn coefficient for manufacturing of 0.5, which has been confirmed by later studies. This coefficient means that 1% increase in output requires a 0.5% raise in labour and is associated with 0.5% increase in the growth rate of productivity. Kaldor's interpretation is that the Verdoorn law is a dynamic relationship based on the learning-by-doing concept: output expansion promotes human capital specialization and technological progress that fosters labour productivity. In the third place, in the Kaldorian tradition economic growth is determined by demand and not constrained by supply and thus it is the manufacturing output growth the exogenous variable determining productivity and employment growth. This is the reason why Kaldor rejected alternative formulations of the Verdoorn law such as the one proposed by Rowthorn (1975) which used employment growth as the regressor on productivity growth. Rowthorn finally accepted the validity of Kaldor's argument in the presence of labour surplus in the economy. For the case of developing economies, the problems of labour shortage pointed out by Rowthorn do not seem to apply due to their large informal sectors and the significant amount of underemployed or unemployed labour force that could be potentially transferred to manufacturing as the sector grows. An additional related issue is that of simultaneity or reverse causation from employment to output which may lead to estimations subject to simultaneous equation bias, as pointed out by McCombie (1983).

Another extensive debate in the literature has concentrated on the fact that the specification of Verdoorn law made by Kaldor does not control for the contribution of the capital stock growth (Bairam, 1987). If some sort of technical progress function underlies the law, as Kaldor suggested, then excluding this variable from estimations is likely to provide a biased coefficient of returns to scale except if a constant capital/output ratio is supposed (McCombie, 1982). In fact, some studies have included a variable accounting for the expansion of capital when estimating the Verdoorn law (León-Ledesma, 2000; Libanio, 2006). However, for the case of developing economies is very difficult to find reliable and consistent data of capital stocks at sectoral level, as also noted by Jaumotte and Spatafora (2007) and Wells and Thirlwall (2003). An additional problem of Kaldor's specification of Verdoorn's law concerns the measurement errors of the exogenous variables, an issue particularly relevant for the case of services output.

Moreover, in order to avoid a spurious estimation of the Verdoorn relation countries included in the sample should have an uniform technical progress diffusion, or the same rate of "exogenous" productivity growth (i.e., not induced by output growth). This imposes an additional challenge in the empirical estimation of the law. If technical progress diffusion varies across countries, then manufacturing productivity increase in laggards' countries may reflect the receipt of technical progress from leading countries, rather than increasing returns of scale. To avoid this problem, different alternatives are proposed in Verdoorn related literature: (i) the use of additional variables to account for the level of technological development, (ii) the analysis of individual countries using time series data, (iii) the use of cross-regional data, assuming that this minimizes the level of disparities in terms of level of technology.

### 3.3 Kaldor's Third Law

The third law states that employment growth in manufacturing tends to increase the rate of productivity in other sectors as a result of diminishing returns to labour in other sectors and the absorption of surplus labour from these sectors. This is the second mechanism explaining causality from manufacturing growth to GDP per worker growth. Unlike neoclassical economist, Kaldor considers there is disguised unemployment in agriculture rather than assuming that all resources are efficiently employed. This is the reason why the reallocation of labour from agriculture into manufacturing does not reduce agricultural output and, as a result of employment withdrawn productivity is increased. In other words, as employment declines in the non-manufacturing sector overall productivity growth raises.

Most empirical studies focusing on developing economies (Hansen and Zhang, 1996, Dasgupta and Singh, 2005 and 2006; Wells and Thirlwall, 2003) estimate this law by regressing overall productivity growth ( $p$ ) on the growth on non-manufacturing employment ( $e_{nm}$ ), controlling for the growth of manufacturing output ( $q_m$ ) which according to Verdoorn's law induces productivity growth. A linear specification would be:

$$p = \beta_0 + \beta_1 e_{nm} + \beta_2 q_m \quad (\text{Equation III}), \text{ with } \beta_1 < 0; \beta_2 > 0$$

However, most empirical estimates of the third law suffer from spurious correlation and identification problems. Alternatively, growth accounting can be a useful approach for analyzing the relationships underlying Kaldor's Third Law. In particular, a

shift-share analysis would allow us to understand the role played by both labour reallocation between industries and by productivity differentials in overall productivity growth (Felipe et al., 2009).

### **3.4 Evidence on KGL: a review of the literature**

Kaldor confirmed that manufacturing was an engine of growth for 12 OECD countries using cross sectional data over 1953 to 1964. Since then several other studies have examined the interpretation and the validity of the different laws across developed countries (Cripps and Tarling, 1973; Rowthorn, 1975; Parikh, 1978; McCombie, 1983; Michl, 1985); across regions within countries (McCombie and de Ridder, 1984, Hansen and Zhang, 1996; León-Ledesma, 2000); for individual countries (Stoneman, 1979; Bairam, 1991; Atesoglu, 1993); across regions across countries (Pons-Novell and Viladecans-Marsal, 1999, for European regions); across industries in the Verdoorn law (McCombie, 1985, Pieper 2003).

Some studies also argue that manufacturing is an engine of growth in developing economies based on estimation of KGL. Table 1 summarizes such studies and details their country sample, their time horizon, the equations estimated in the empirical exercise and the level of sectoral disaggregation adopted. Felipe (1998) finds evidence across five Southeast Asian countries and Wells and Thirlwall (2003) across forty-five African countries. In case of Latin American economies, evidence of increasing returns to scale in industrial sectors are found by Cimoli et al. (2005) and Libano (2006). Pacheco and Thirlwall (2014) consider the role played by exports growth in open developing economies and conclude that there is a strong association between exports and economic growth.

In contrast, very few studies argue that services may also serve as a means for catching-up in developing economies. Dasgupta and Singh (2005; 2006) are the first ones to argue within a Kaldorian framework that although manufacturing continues to be critical for development, services can also be regarded as an additional engine of growth. In particular, they emphasize the role played by ICT related services in the context of India. Services also have productivity growth inducing effects through the exploitations of scale economies in developing Asia -although to a lesser extent than manufacturing- as discussed by Felipe et al. (2009). Notwithstanding the productive heterogeneity of the region, they emphasize that the composition of services matters for determining the sustainability of their contribution to productivity growth.

As shown in Table 1, only half of the studies have carried out estimations of KGL for manufacturing but also for agriculture and services (the one-digit aggregation level of the International Standard Industry Classification, ISIC). However, all the studies have failed to deal with the heterogeneity of the service sectors in developing economies at two-digit level of ISIC. A notable exception is Pieper (2003) who examines the Verdoorn's law across 30 developing economies covering nine sectors. Strong evidence of increasing returns to scale is found for linear and non-linear specification of the law, with manufacturing and public utilities ranking the highest Verdoorn coefficients. This finding is relevant since it suggests that services may be subject to increasing results and that the same Kaldorian mechanisms that make manufacturing the engine of growth may also apply to these activities. Our paper examines this possibility and, therefore, fills a gap in the current literature by exploring the role

played by service subsectors in economic performance across Asian, Latin American and African developing economies.

Table 1. KGL in developing economies: a summary of the literature.

### **3. Data and empirical strategy**

The empirical strategy followed in this research is double. On the one hand, we use panel data analysis to estimate Kaldor's first and second laws (equations I-A, I-B, I-C and II). Regressions are performed by sector panel, first, for the whole sample of developing countries and, then, for the different sub-continent. On the other hand, instead of econometrically estimating Kaldor's third law, we perform a decomposition of labour productivity growth. This is a more successful approach as traditional estimates of this law suffer from spurious correlation and identification problems (Felipe et al., 2009). On the basis of both empirical analyses we would be able to determine whether some specific service sector may be a source of economic growth in developing economies.

The main source of the sectoral evidence applied in this research is the Groningen Growth and Development Centre (GGDC) 10-Sector Database (Timmer and de Vries, 2007) and the Africa Sector Database (de Vries et al., 2013). These are first databases that provide long-term series at the at the two-digit level of the ISIC codes for developing economies. While other data sources also collect sectoral data and make it publicly available (e.g. the World Bank, the United Nations or the International Labour Office), the series provided "are often short (starting only in the 1980s or 90s), not consistent over time and across countries, and have little sectoral detail" (Timmer and de Vries, 2007, page 3). GGDC 10-Sector Database and Africa Sector Database extend over more than five decades and compute yearly data on value added (in current and constant prices - expressed in national currencies), and employment. At this point in time, they probably represent the best time-series data available for developing countries due to its unique sector disaggregation which covers the entire economy.

The econometric analysis of KGL is conducted using a balanced sectoral panel of 29 developing countries with available information for 1975-2005. Our country sample includes nine countries from Latin America (Argentina, Bolivia, Brazil, Chile, Colombia, Costa Rica, Mexico, Peru, and Venezuela), nine countries from Asia (Hong Kong (China), India, Indonesia, Rep. of Korea, Malaysia, Philippines, Singapore, Taiwan, Thailand) and eleven countries from Africa (Botswana, Ethiopia, Ghana, Kenya, Malawi, Mauritius, Nigeria, Senegal, South Africa, Tanzania, Zambia). The econometric estimations are performed, first, for the whole sample of developing countries and, then, for the different sub-continent. In this way, we are able to account for differences across developing regions and to reduce the level of disparities in terms of level of technology.

As regards the time span of the econometric study, the year 1975 was chosen as a starting point for the practical reason that data for the whole sample of countries is available from that time. Moreover, following Pieper (2003) and León-Ledesma (2000), we use a moving average of value added at constant prices, employment and productivity growth rates (taking 5 years averages) to smooth out short-term fluctuations present in the annual data. As a result, we avoid the problem of conflating the long-run Verdoorn law with the short-term cyclical relationships described by Okun's law.

Time series available in the GGDC Database are broken down into the ten main sectors detailed in Table 2. Since for several countries there is no distinction between value added or employment (or both) in the “Producers of Government Services” sector and the “Community, Social, and Personal Services” sector, we aggregate data for these activities into a single sector (as McMillan and Rodrik, 2011 and McMillan et al., 2014). In addition, a series for the value added and employment of the whole services sector (sectors G to Q) are also included in the analysis. All in all, our econometric exercise is performed for seven sectors: 1) manufacturing; 2) agriculture; 3) total services; 4) commerce (distributive trades and tourism); 5) transport and communications, 6) business services (finance, insurance, real estate and business activities); 7) public services (community, social, personal and government Services).

Table 2. Description of sectoral composition of GGDC database

|    |   | ISIC rev. 3<br>SNA 1993 | ISIC rev. 3<br>SNA 1993 |
|----|---|-------------------------|-------------------------|
| 1  | Agriculture, hunting, forestry and fishing            | Division 01-05          | A+B                     |
| 2  | Mining and quarrying                                  | Division 10-14          | C                       |
| 3  | Manufacturing   | Division 15-37          | D                       |
| 4  | Electricity, gas, water                               | Division 40-41          | E                       |
| 5  | Construction  | Division 45             | F                       |
| 6  | Wholesale and retail trade, restaurants and hotels    | Division 50-55          | G+H                     |
| 7  | Transport, storage and communication                  | Division 60-64          | I                       |
| 8  | Finance, insurance, real estate and business services | Division 65-74          | J+K                     |
| 9  | Community, social and personal services (a)           | Division 75-99          | O+P+Q                   |
| 10 | Producers of government services (a)                  | Division 75-99          | L+M+N                   |

Notes: (a) As ISIC is a classification according to kind of economic activity, and does not draw distinctions according to kind of ownership, type of legal organisation or mode of operation, no clear distinction in terms of divisions can be made for these sectors. Source: Timmer and de Vries (2007, page 3).

In the econometric analysis, data for the seven sectors is pooled, first, for the 29 country time series so that every sector panel ends up having 174 observations based on five-year growth rates. Every sector panel for the nine Asian and Latin American countries included in the sample has 54 observations, while for the eleven Sub-Saharan African economies each sector panel has 66 observations. Outliers are detected and treated using one dummy variable for each . Fix country effects are added in order to deal with omitted heterogeneity. Equations are estimated by OLS with Panel Corrected Standard Error Estimations (PCSE) accounting for groupwise heteroskedasticity, cross sectional dependence and autocorrelation in disturbances within panels .

The following are the linear specifications estimated for examining Kaldor’s First Law at sectoral level:

$$q_{GDP_{it}} = \alpha_{1j} + \beta_{1j} q_{jit} + \varepsilon_{jit}$$

Equation I-A

$$q_{GDP_{it}} = \alpha_{2j} + \beta_{2j}(q_{jit} - q_{njit}) + \varepsilon_{jit} \quad \text{Equation I-B}$$

$$q_{njit} = \alpha_{3j} + \beta_{3j}q_{jit} + \varepsilon_{jit} \quad \text{Equation I-C}$$

where  $j$ ,  $i$ ,  $t$  stand for sector, country and time, respectively, and  $\varepsilon_{jit}$  is assumed to be normally distributed.  $q_{GDP}$  represents total output growth (the growth of total value added in constant prices) and  $q_{jit}$  is the sectoral output growth (the growth sectoral value added in constant prices).

The specification of Kaldor's Second Law is as follows:

$$e_{jit} = \alpha_{1j} + \beta_{1j}q_{jit} + \varepsilon_{jit} \quad \text{Equation II}$$

where  $j$ ,  $i$ ,  $t$  stand for sector, country and time, respectively, and  $\varepsilon_{jit}$  is assumed to be normally distributed.  $e_{jit}$  is the sectoral employment growth and  $q_{jit}$  is the sectoral output growth.

## 4. Empirical findings

### 4.1 Kaldor's First Law: Estimation Results

Our evidence confirms the validity of Kaldor's First Law across the whole sample of developing economies. As in Dasgupta and Singh (2005 and 2006), manufacturing growth seems to be a driving force behind overall growth across developing countries. Table 3 shows that the estimated coefficients are significant and follow the expected sign in equation I-A and the corresponding side tests (equation I-B and I-C). In order to establish that manufacturing is the engine of growth, it is necessary to perform estimations for the agriculture and the service sub-sectors as well and to compare the respective outcomes. Sectoral growth is strongly associated with overall growth, as shown by the estimations of equation I-A. However, spuriousness seems to be a problem in total services, commerce and transport and communications since these sectors do not pass the first side test of the law. When the side test is performed relating overall growth to the excess of agricultural growth over the non-agricultural growth, the regression coefficient is significant but negative. The same result is found for the case of public services. However, one service sub-sectors pass both side tests of the law: business services. This may reflect changes in inter-industry linkages as result of the increase of services as intermediate inputs for the rest of the economy. Business services are generally used as intermediate inputs and thus have important forward and backward inter-industry linkages; apart from embodying and enabling the use of new technology. Including financial services and business activities (R&D, computer services, and other business activities), this sub-sector behaved like manufacturing as an engine of growth in the whole set of developing economies considered in our analysis. Some authors have already argued that

business activities have directly and indirectly contributed economic growth in developed countries, like the European ones (Kox and Rubalcaba, 2007).

Dummy coefficients estimates are available on request. Legend: s.e. for standar deviation; \* p<0.05; \*\* p<0.01; \*\*\* p<0.001

Kaldor's First Law is also confirmed for the sub-continent under analysis, as shown in Tables 4 (i) to (iii). This finding is in line with Wells and Thirlwall (2003) for 45 African economies; Libano (2006) for 7 Latin American economies; and Felipe et al. (2009) for 17 Asian countries. The impact of manufacturing on growth seems to be more important for Latin America than for Asia or Africa. No relationship between the expansion of agriculture and overall growth is found in Asia, whereas in Latin America and Africa the excess of agricultural growth over the non-agricultural growth impacts negatively on overall growth, as in the aggregate country sample. This result is also found for the case of public services in the three different sub-continent. Business services seem to drive overall growth in Asia and Latin America but no evidence is found across African economies. This may be related to the undersized manufacturing basis attained by this region which hampers the development of many related business services. In fact, when the side test is performed relating overall growth to the excess of business services growth over the non-business services growth; the regression coefficient is significant and negative. The impact of business services on growth seems to be more important for Asia than for Latin America. This may reflect that Asian countries have larger participation of manufacturing activities in the economy than their Latin counterparts.

## 4.2 Kaldor's Second Law: Estimation Results

The second law is also confirmed for the whole sample of developing economies: there are increasing returns to scale in manufacturing activities. Table 5 reports panel data estimations for equation II and provides one-tailed test hyphotesis of constant returns to scale ( $\beta_{1j} = 1$ ) and increasing returns to scale ( $\beta_{1j} < 1$ ) at the sector level. All sectors –with the exception of agriculture and commerce– show employment elasticities with respect to output growth that are significantly positively and less than unity. In five out of seven sectors we can reject the constant returns hypothesis at the 10 percent confidence interval for one-tailed tests. Moreover, in these sectors estimates of the employment elasticity with respect to output growth are significantly less than unity. These statistics suggests strong evidence for increasing returns at the sector level of developing economies (as in Pieper, 2003).

There is evidence for IRS in manufacturing in both Asia and Africa. Asian manufacturing output has turned into more technology- and scale-intensive subsectors (Jau-motte and Spatafora, 2007; Felipe and Estrada, 2007; ADB, 2007). But, African manufacturing sectors are characterized by a declining diversity and sophistication (Page, 2011).

We find no evidence for IRS in manufacturing in Latin American economies. Manufacturing output has turned into natural resources intensive sectors (paper, tobacco, etc.) in many Latin American countries (Cimoli et al., 2005).

In Latin America we found no relationship between sectoral output growth and employment growth at the sectoral level, except for business services. In the Kaldorian framework this lack of relationship is explained by the existence of disguised unemployment. This may reflect the high levels of informality in Latin America that hinders productivity growth in services (Pagés, 2012)

There is evidence for IRS in business services in both Asia and Latin America. In Africa we cannot reject the null hypothesis of constant returns to scale at the 5% of significance level.

## 5. Final remarks

Kaldor's old ideas remain valid even now with respect to developing economies: manufacturing has been an engine of growth during the past three decades across Asian, Latin American and African countries. We also find empirical support in favour of some services sub-sector, particularly in Asia and Latin America. Business services seem to allow productivity growth by the same Kaldorian mechanisms that have traditionally made manufacturing the driver of growth. This fact is related with their important (forward and backward) inter-industry linkages and with their use of knowledge and technology. Therefore, this kind of services seems to complement rather than replace manufacturing as an engine of growth in developing countries. This may explain why business services (still) do not play a significant role in African economies with weaker manufacturing basis than many Asian or Latin American countries.

The heterogeneity of the service sectors needs to be taken into account in the debate of how the productive structure of developing countries affects growth. Although being preliminary, our results convey an important policy message: a core manufacturing sector is critical for growth. Yet, there is no need to fear "deindustrialisation" if capabilities are being promoted in some specific service sectors.

The Kaldorian framework relies on an unproblematic take on productivity measurement. Nevertheless, the accurate measurement of services productivity is still an unresolved issue. Moreover, at the time this framework was developed there was a clear-cut distinction between sectors in an economy. At present, the distinction between many service and manufacturing industries is debatable since their boundaries have changed during the course of time.

Some scholars argue that the consolidation and stability of democracies may be hampered by "premature deindustrialization" (Rodrik, 2015). In any case, the political consequences of the surge of services in developing areas are complex and deserve further scrutiny. Other issues still need to be addressed in the context of this investigation and offer a promising future research agenda. First, the estimation of Kaldor's Laws is an econometrical challenge. There is still room for further improvements as regards the use of instrumental variables estimations, non-linear estimations, etc. Moreover, an input-output analysis would allow a better understanding of the relative contribution of final and intermediate demand to changes in the sectoral structure of developing economies. Finally, it would be interesting to take into account the heterogeneity of the manufacturing sector itself as well of business services in order to have further insights of specific sectoral engines of growth in developing economies.

**XXV. International RESER Conference, 2015**  
**INNOVACIÓN, SERVICIOS Y DESARROLLO LOCAL:**  
**EL CASO DE LA ACUACULTURA EN MEXICO**  
Minerva Celaya,<sup>1</sup> Araceli Almaraz,<sup>2</sup> Alfredo Hualde<sup>3</sup>  
El Colegio de la Frontera Norte

**Abstract**

Mexican experiences in fishing farm started early 20<sup>th</sup> Century, on the contrary, the aquaculture activities are significant in last decades. The main area focused on aquaculture activities is located in northwest Mexico. Our hypothesis is that local aquaculture systems linked to external commercial chains can respond more rapidly to global demand if they have capabilities and specialized services. If one location concentrates strategic services, followed by fishing farmers, entrepreneurs, researchers –biologists-, investors, and governmental offices, the system can be growth. To verify the hypothesis we have designed an inductive and comparative methodology. Our interest is focus on aspects controlled by local actors like entrepreneurs or R&D, and what is the government policy pathway. We identified paths of local innovation and key services to it (support biotechnological techniques, services to genetics improvement, nutritional issues and growth process, and biological inputs).

**1. La acuacultura como parte de los sistemas productivos territoriales, alimentarios y de innovación.**

La acuacultura integra un conjunto de actividades que van desde los servicios especializados para el empaque y la venta de especies marinas hasta las actividades y servicios relacionados con la biotecnología, especialmente con lo que se conoce como segunda generación de la industria de la biotecnología y que está relacionada con el uso de células o cultivo de tejidos para el desarrollo acuícola.<sup>4</sup> El Instituto Politécnico Nacional (2010) de México ha identificado cinco tipos de empresas: i) empresas especializadas en innovación en biotecnología, lo que implica actividades relacionadas con el desarrollo y la transferencia de tecnología, así como la generación de conocimiento y desarrollo de patentes;<sup>5</sup> ii) empresas de innovación en ingeniería, las cuales se caracterizan por sus capacidades para la adopción de tecnología o unidades de manufactura, escalar procesos, desarrollo de ingeniería de productos finales, ingeniería básica y de detalle e ingeniería de aplicaciones de procesos y de productos;<sup>6</sup> c) empresas de manufactura de productos biotecnológicos, que dependen de la tecnificación de las unidades de producción;<sup>7</sup> d) empresas de servicios técnicos y analíticos,

<sup>1</sup> Profesora-Investigadora en Estancia Posdoctoral, El Colegio de la Frontera Norte, Departamento de Estudios Sociales.

<sup>2</sup> Profesora-Investigadora, El Colegio de la Frontera Norte, Departamento de Estudios Sociales.

<sup>3</sup> Profesor-Investigador, El Colegio de la Frontera Norte, Departamento de Estudios Sociales.

<sup>4</sup> Véase Celaya, 2014.

<sup>5</sup> Véase IPN, 2010.

<sup>6</sup> Estas empresas no generan conocimiento nuevo, su particularidad radica en su capacidad para adaptar procesos a la realidad reflejados en una aplicación industrial y comercial (IPN, 2010).

<sup>7</sup> Se incluyen en este grupo empresas de nivel básico, tales como plantas productoras de levaduras para la fermentación; empresas de nivel intermedio, como son las empresas productoras de antibióticos; y en un nivel desarrollado a las empresas de manufactura de vacunas (IPN, 2010).

que van desde mediciones físicas y de metrología, hasta mediciones de química fina,<sup>8</sup> y e) empresas consumidoras de productos e ingredientes de origen biotecnológico, las cuales participan en la integración de grandes cadenas de valor y permiten que un proceso o producto alcance la mayor penetración en el mercado (IPN, 2010). Otros estudios clasifican recientemente a la biotecnología por sus aplicaciones, en donde el aprovechamiento de recursos marinos corresponde a la biotecnología azul incluyendo la acuicultura, la química y la farmacéutica (Cuadro 1).

Fuente: DaSilva (2004).

Si consideramos que la acuicultura en su sentido más amplio refiere al manejo biotecnológico de especies marinas entonces estamos hablando de un binomio entre técnicas de manejo y cuidado de especies. En el estudio realizado por Celaya (2015), se señala que los biólogos Aguilera, Noriega y Guzmán (1986), aluden a la acuicultura como aquella práctica que se ha ido tecnificado en sus métodos y técnicas para el manejo y control de los organismos cuyo hábitat es el agua, considerando desde su cosecha hasta su consumo, pasando por el procesamiento y la comercialización. Esta apreciación es consistente con la de las Naciones Unidas a través del organismo para Alimentación y Agricultura (FAO por sus siglas en inglés) quien también considera que la acuicultura representa una alternativa para ampliar la oferta y seguridad alimentaria, así como los encadenamientos productivos para el desarrollo regional (FAO, 2006). Esta perspectiva está relacionada con la identificación de tres tipos de orientación: a) acuicultura para la

<sup>8</sup> Son empresas que fortalecen las unidades de control analítico dentro de las empresas, certifican laboratorios y procedimientos, y orientan a las empresas para que desarrollen y adopten los protocolos más adecuados para calidad y control analíticos de procesos (IPN, 2010).

repoblación,<sup>9</sup> b) acuacultura artesanal o rural,<sup>10</sup> y c) acuacultura comercial o industrial, que pretende alcanzar un incremento en la utilidad a partir de la fertilización y alimentos balanceados, por lo que requiere de instalaciones específicas, uso de tecnologías adecuadas e inversiones estratégicas (FAO, 2006). De acuerdo con la clasificación para México de los sistemas acuícolas podemos destacar tres tipos: i) los extensivos, ii) los semi-intensivos, y iii) los intensivos (cuadro 2).

**Cuadro 2. Sistemas de producción acuícola según SENASICA, México.**

| Características     | Extensivo   | Semi-intensivo                              | Intensivo  |
|---------------------|-------------|---|--|
| Cuerpo de agua      | Grande      | Embalses pequeños o micropresas y estanques | Tanques, jaulas flotantes, cajas y <i>raceways</i> (canales de corriente rápida) |
| Densidad de siembra | Baja        | Moderada                                    | Alta   |
| Base alimentaria    | Natural     | Natural y artificial                        | Artificial   |

Las actividades de innovación y desarrollo de tecnología derivadas de la acuacultura se localizan en las dos primeros eslabones de la cadena productiva de cualquier cultivo, que son: insumo biológico y producción. En cada una de éstas fases es necesario el desarrollo y mejora de técnicas biotecnológicas para la aceleración y optimización de los organismos marinos (cuadro 3).

**Cuadro 3. El binomio biotecnología azul-acuacultura/a**

a/Incluye solo aquellos eslabones donde se utiliza biotecnología.

Algunos sistemas en México han empezado a desarrollar acciones para controlar todo el ciclo biotecnológico y por tanto podría empezar a hablarse de una acuacultura integral, con una orientación a la innovación y a los servicios especializados. Esta hipótesis se sustenta en

<sup>9</sup> Implica la introducción y el control de organismos acuáticos en diversos cuerpos de agua ya existentes, tales como: lagunas, costeras, embalses y ríos.

<sup>10</sup> Se caracteriza por ser de subsistencia, se realiza a pequeña escala en instalaciones que requieren escasa modificación del ambiente natural y bajo nivel de tecnología. Destaca la participación de grupos familiares o cooperativas que tienen su residencia en el medio rural.

los hallazgos de Celaya (2014) quien refiere el alto componente científico – técnico, que se observa en cada una de las etapas que integran los cultivos de vida de especies marinas y que hacen de la actividad acuícola una organización única y no estandarizada, donde la innovación es requerida para acompañar el control de especies. La trayectoria de las actividades acuícolas en los últimos años por los distintos países, ha implicado cambios en las jerarquías de la producción mundial y en los de exportación. A continuación presentamos algunos datos de la última década, que nos llevan a una reflexión sobre los retos de la acuicultura integral, la oferta de servicios especializados, las redes de conocimiento y las cadenas de valor.

### 1.1 La acuicultura en el mundo y en México

En el 2007, de acuerdo con la FAO (2010), el 28% de los bancos de pesca a nivel mundial estaban sobreexplotados o se encontraban en situaciones de agotamiento y de recuperación debido a la excesiva extracción de especies. El 52% de los bancos estaba plenamente explotado y únicamente un 20% moderadamente explotado y con posibilidad de producir más (FAO, 2010). La industria pesquera mundial, dentro de la cual aún se cuantifican las actividades de la acuicultura, generó en el 2000 un total de 131 millones de toneladas. De ellas, el 73% provino de la pesca y el 27% de la acuicultura. Para el 2010, la producción aumentó a 148 millones de las cuales el 60% correspondía a la pesca y el 40% a la acuicultura (FAO, 2012). En el periodo disminuye la contribución promedio en la extracción de peces, y es en el 13% en el que se incrementa el promedio de la contribución de la producción acuícola.<sup>11</sup> Castelló (1993), ha mencionado que acuicultura marina, a diferencia de la continental, presenta mayor dificultad en aspectos biológicos y técnicos para la producción en intensiva de especies. Al respecto se señalan cuestiones ecológicas, pero incluso también de normatividad, relacionadas con áreas protegidas. Ambos aspectos restringen los cultivos en zonas costeras y aguas marinas, limitando con ello un acelerando proceso en las actividades de innovación, como ya se ha visto.

La producción acuícola en el continente americano durante la última década ha sido encabezada por Chile, que en el 2010 alcanzó una producción de 701, 062 toneladas ubicándose en el primer lugar, seguido de Estados Unidos y Brasil. El caso de México resalta porque bajó del cuarto lugar en el 2001 con 197 millones de toneladas, al sexto, siendo superado por Ecuador. En el quinto lugar permanece Canadá (CONAPESCA, 2012 y FAO, 2012). Actualmente otros países han incursionado en la acuicultura y se ubican ya como los principales competidores de México. Entre ellos se encuentra Perú, con una producción acuícola de 89 millones de toneladas en el 2011 seguido de Colombia, Cuba y Honduras con 80, 31 millones y 27 millones de toneladas, respectivamente (FAO, 2012).

Aunque el cultivo de peces en México comenzó a principios del siglo XX, la acuicultura de moluscos bivalvos y crustáceos es una actividad de reciente desarrollo concentrada fundamentalmente en tres estados del Noroeste: Sonora, Sinaloa y Baja California. Actualmente, la relevancia de la acuicultura radica tanto en su crecimiento como en los encadenamientos productivos y el desarrollo regional. En el 2000 la producción **pesquera nacional** fue de 1.4 millones de toneladas de las cuales el 88.5% provino de la pesca y apenas el 11.5 % de la acuicultura. Para el 2010, la tasa anual de crecimiento fue de 1.4%,

<sup>11</sup> De los 35.5 millones de toneladas de productos acuícolas en el 2000, el 60% provino de aguas continentales, mientras que el 40 % de aguas marinas; (FAO, 2005). Para el 2010 el incremento llegó a las 59.9 millones de toneladas, de las cuales el 70% provino de aguas continentales y solo el 30% de aguas marinas.

alcanzando apenas 1.6 millones de toneladas, de las cuales el 83% correspondió a la pesca y el 17% de la acuicultura (CONAPESCA, 2012), mostrando la actividad acuícola una tasa de crecimiento anual del 4.39%. En cuanto a las especies, las 5 principales son el camarón (que en el 2011 concentró el 41.7% de la producción acuícola nacional), la mojarra (27.06%) y el ostión (16.64%). En México la producción acuícola se concentra en tres zonas: a) Océano Pacífico que actualmente representa el 57% de la producción, la zona del Golfo y el Caribe, con cerca del 28% y la zona compuesta por entidades sin litoral con el 14%. En el 2010 la zona del Golfo y el Caribe tuvo una tasa negativa (-0.34%), mientras que las entidades sin litoral lograron un crecimiento del 11.8% (CONAPESCA, 2012).

## **2. El territorio, las cadenas de valor y las redes de conocimiento**

Dos rasgos importantes se destacan recurrentemente en los estudios sobre el desarrollo económico especialmente a partir de la segunda mitad del siglo XX: por un lado, la concentración de espacios competitivos en territorios específicos; por otro, la importancia de formas organizativas como las redes que son complementarias de otras formas tradicionales como las empresas o las instituciones públicas. Sin duda, las empresas siguen siendo la organización central del desarrollo económico, pero actúan cooperando y compitiendo entre sí y con diversos actores de su entorno (Fagerberg, 2005: 12).

Así pues las formulaciones recientes que se apartan de la ortodoxia económica y adoptan una perspectiva territorial destacan la importancia de formas organizativas que interrelacionan las unidades económicas y los actores sociales, en el sentido de las «constelaciones de empresas» de las que habló Becattini (1988) en su descripción del distrito industrial. En la misma sintonía analítica se puede ubicar a Storper (1997), cuando se refiere a las «interdependencias no comerciales», como una forma de entender las relaciones no económicas que sin embargo posibilitan las transacciones económicas en su conceptualización de los *mundos de producción*. Los teóricos de los *clusters* destacan también que la acción conjunta de las empresas y de otras instituciones como centros tecnológicos y universidades, empresas de servicios como los abogados e instituciones financieras, entre otras, contribuyen de manera decisiva al éxito de la actividad económica (Saxenian, 2000; Humphrey y Schmitz, 1995; Pietrobelli y Rabellotti, 2004). Esta característica designada como «acción colectiva» se ha encontrado en los territorios innovadores de ámbito nacional (Lundvall, 2003) y en aquellos que toman a la región como ámbito de desarrollo de los procesos innovadores constituyéndose en Sistemas Regionales de Innovación (Cooke *et al.*, 2003; Fagerberg *et al.*, 2005).

Aunque las teorizaciones mencionadas comparten ciertos rasgos difieren en otros. En los distritos industriales se subraya una organización casi comunitaria en el ámbito local. En contraste las teorías de las cadenas globales de producción se centran en caracterizar y analizar la dinámica y coordinación entre empresas en espacios supranacionales. Autores como Cooke (2004, 2006) introducen matices importantes en la organización espacial de la producción. Desde el punto de vista de la gobernanza se distinguen los territorios que se denominan *grassroots*, de los territorios en red y de los *dirigistas*. En los primeros, el sistema productivo surge desde la sociedad, en los *dirigistas* son las instituciones públicas las que llevan la iniciativa y orientan las políticas regionales (regiones francesas, Eslovenia); finalmente los sistemas en red se constituyen como un tipo intermedio entre los dos anteriores. En lo que se refiere a los sistemas de negocios, se proponen también tres tipos: el sistema localista donde predominan las pequeñas empresas, el sistema interactivo donde existe un núcleo de empresas locales, pero también es importante la presencia de inversionistas medianos y grandes nacionales o extranjeros. Finalmente, el modelo

globalizado es el que surge inserto en redes globales y su dinámica responde a este tipo de lógica. El cruce del sistema de governance y el modelo de negocio dan lugar a distintas combinaciones que Cooke y sus colaboradores identifican para regiones específicas en distintos países y continentes. Sin embargo lo interesante además del predominio de distintos actores y dinámicas en cada tipo propuesto es la evolución que se detectó en un periodo de diez años.<sup>12</sup>

Estas son algunas de las teorías recientes que subrayan la importancia de las redes para el desarrollo, a nivel macro, meso y micro, donde interactúan individuos y organizaciones. Las interpretaciones acerca de algunos aspectos como la importancia de los actores o las secuencias de acciones virtuosas varían; también es cierto que regiones altamente exportadoras como Bangalore en India se apartan de un modelo de redes productivas densas en el territorio; las existentes son sobre de tipo global por las relaciones que los ingenieros de la India mantienen en Estados Unidos (Arora, 2003; Bresnahan y Gambardella, 2004). Sin embargo, ello no resta importancia al enfoque de redes en el desarrollo de software en India pues, como es sabido, muchos de los mercados a los que accedieron las empresas de este país y una parte importante de estas surgieron a raíz de las redes personales y colectivas construidas por los ingenieros hindúes tras su estancia como estudiantes en Estados Unidos.

La constatación de la importancia de las redes en el desarrollo económico no significa que los enfoques acerca de *redes* sean idénticos; por el contrario, entre los estudiosos encontramos distintas perspectivas con énfasis y objetivos diferentes. Ello tiene que ver, en parte, con el hecho de que el tema de las redes se ha abordado desde varias disciplinas como la economía, la antropología, sociología, la ciencia política o la teoría de sistemas. Luna (2003) distingue tres enfoques principales: el análisis de redes, las redes de acción política y las redes como mecanismo de coordinación. Desde una perspectiva económica, las redes han sido caracterizadas como un arreglo organizativo intermedio entre el mercado y las jerarquías. Se trata de estructuras flexibles, de tipo voluntario, en los cuales sus participantes buscan intercambios mutuamente beneficiosos. Se concibe que las redes suelen tener un carácter descentralizado y, para hacerlas eficientes, es necesario llevar a cabo un trabajo importante de coordinación que permita una comunicación fluida entre sus integrantes.

A pesar del carácter descentralizado de las redes y las relaciones relativamente igualitarias que en principio se les suponen, los integrantes de la red no mantienen forzosamente, ni todos tienen el mismo grado de influencia y de poder en la toma de decisiones. En los sistemas de redes, un aspecto fundamental son los nodos que señalan la ubicación de actores u organizaciones importantes dentro de la red. Estos sirven para explicar una parte importante de las dinámicas de las redes, aunque por supuesto no son los únicos actores

<sup>12</sup> La importancia del entorno cobra características particulares cuando el tejido productivo está conformado por pequeñas y medianas empresas. Las pymes suelen tener dificultades para acceder a información necesaria para sobrevivir y para desarrollar innovaciones debido a problemas de costos, escasez de personal calificado, deficiencias organizativas y limitaciones derivadas de su tamaño. Algunas no se plantean innovar sino únicamente sobrevivir, consolidarse como organizaciones, ser rentables y crecer en el mediano o largo plazo. Se consideran agentes débiles por la escasez de recursos humanos y financieros, las ineficiencias asociadas a la escala reducida y el bajo poder de mercado. «Sin embargo, la experiencia demuestra que las pymes que se agrupan en *clusters* pueden tener éxito y competir con las grandes empresas» (Bertini, 2000: 107).

que influyen en ellas. Entre los actores que integran una red, un papel importante lo ocupan los líderes. En la medida en que las redes tienen un carácter voluntario, el líder o los líderes tienen un cierto reconocimiento por parte de los miembros de la red. El reconocimiento surge de determinadas cualidades o atributos: conocimiento acerca del campo de especialización de la red, capacidad de crear consenso o de convencer a los miembros de la red, o bien cualidades de tipo moral, como la honestidad. De lo expuesto hasta ahora se deduce que, en el ámbito productivo y desde la óptica de redes, son importantes tanto los individuos como las organizaciones. La forma de organización de las redes y su inserción territorial son elementos explicativos importantes en el surgimiento de actividades económicas como la acuicultura. Desde esta perspectiva es factible modificar la idea de la frontera norte de México como último territorio parecido a los modelos de enclave y recuperar con ello el papel de los agentes y sus organizaciones.

### **3. Trayectoria de cultivos acuícolas y servicios en el noroeste de México. El caso de Ensenada, Baja California**

Con base en la metodología de análisis propuesta para el estudio productivo-territorial que nos hemos propuesto, son determinantes las redes de conocimiento y las cadenas de valor de la red acuícola para el consumo humano. Nos propusimos identificar aquellos actores y mecanismos que han participado en la generación de proveeduría especializada e innovación para incrementar el valor agregado a los cultivos de ostión japonés y abulón rojo en la región de Ensenada. Los resultados de este trabajo se centran en el papel de los centros de I+D en el marco del extensionismo acuícola en México, el papel que ha tenido el Gobierno Federal desde organismos especializados en la promoción de la acuicultura vía el esquema de extensionismo acuícola <sup>13</sup>; ii) la red de servicios y trayectorias de cultivos de exportación, en donde ciertos actores institucionales y productivos operan mecanismos de interacción y escalamiento de tecnológico; y iii) la recomposición de las cadenas de valor de dos especies marinas de consumo humano que se integran territorialmente en el territorio de Ensenada y se enlazan a mercados internacionales de Asia y Europa.

#### **3.1 El papel de los Centros de I+D y el extensionismo acuícola en México: Trayectorias y red de servicios**

El México el origen y la consolidación de los centros acuícolas impulsado por el Estado mexicano ha tenido un comportamiento errático. Con la finalidad de tener una visión general sobre el desenvolvimiento de la actividad acuícola en el país, se identificaron tres periodos sobre el surgimiento y desarrollo de los Centros Acuícolas Federales,<sup>14</sup> que en su momento han representando el extensionismo acuícola en México (Cuadro 4). Las preguntas que tratamos de responder son: ¿Cuál es la red de servicios que ha venido acompañando el desarrollo de las actividades acuícolas en México? ¿Qué aspectos de la organización territorial están enfocados al desarrollo de servicios especializados y de innovación?

<sup>13</sup> El extensionismo, hace referencia a la propagación o difusión del conocimientos a partir de acciones vinculadas con la gestión y promoción de nuevas tecnológicas así como el desarrollo de servicios de extensión cuyos ejes son la asistencia técnica, la transferencia de tecnología y la capacitación a los productores (Muñoz y Santoyo, 2010), con la finalidad de incrementar la productividad.

<sup>14</sup> Actualmente los centros son operados y administrados por la Secretaría de Agricultura, Ganadería, Pesca y Acuicultura (SAGARPA) (CONAPESCA, 2015).

Veremos cómo estas interrogantes adquieren respuestas diferenciadas en torno al manejo de las especies seleccionados en este trabajo: ostión japonés y abulón.

**Cuadro 4. Los tres grandes períodos de los Centros Acuícolas Federales de México**

| Período                    | Particularidades  | Resultados  |
|----------------------------|---|---|
| Primer período hasta 1970  | - Evolución de la piscicultura extensiva  | - La creación de los primeros centros piscícolas federales para la reproducción de crías, así como el esparcimiento de éstas en cuerpos de agua tanto naturales como artificiales <sup>15</sup> .                                     |
| Segundo período hasta 2005 | - Impulso y desarrollo capacidades territoriales en torno a las actividades acuícolas | - Avances sustantivos en lo que respecta al cultivo de la tilapia y de la trucha arcoíris. <sup>16</sup><br>- Retroceso en el apoyo por parte de los Centros Acuícolas Federales para el desarrollo de moluscos bivalvos y crustáceos |
| Tercer período actualidad  | Baja producción de insumos biológicos de los Centros Acuícolas Federales              | - Reestructuración de los centros acuícolas para modernizar sus instalaciones y optimizar sus operaciones.  |

Fuente: elaboración propia con base en información de FAO (1984), Avilés – Quevedo y Vázquez-Hurtado (2006) CONAPESCA (2015).

**El ostión japonés (*ostra*):** una especie *introducida*. El ostión, es uno de los moluscos comerciales más importantes a nivel mundial, por su gran aceptación en el mercado de alimentos y su rápido crecimiento y adaptabilidad a distintas condiciones ecológicas.<sup>17</sup> Después de analizar el proceso de crecimiento de diversas especies, se optó por impulsar la acuicultura de ostión japonés en Ensenada,<sup>18</sup> ya que el tiempo promedio necesario para producir una pieza de ostión sería de un año.<sup>19</sup>

Con el apoyo del gobierno federal estos trabajos científicos y técnicos, orientados a demostrar el potencial acuícola rindió frutos, ya que de 1976 a 1977 se construyó el primer laboratorio de producción de larvas (Cáceres-Martínez y Vázquez–Yeomans, 2013) en San

<sup>15</sup> Corresponde al desarrollo de la piscicultura y consecutivamente la acuicultura tuvieron su comienzo en las aguas dulces de México (Rojas-Carrillo y Fernández – Méndez, 2006).

<sup>16</sup> Véase Avilés – Quevedo y Vázquez – Hurtado, 2006.

<sup>17</sup> La introducción del ostión japonés, se dio a principios de los setenta como respuesta a las inquietudes de los gobiernos estatal y federal respecto al cumplimiento de los objetivos de investigación científica para los cuales se había creado la Escuela Superior de Ciencias Marinas (ESCM) de Ensenada. En relación con ello un grupo de oceanólogos graduados de la ESCM consideraron que la acuicultura sería una actividad que les permitiría desarrollar y aplicar sus capacidades científicas. Entrevista Dr. Saúl Álvarez Borrego.

<sup>18</sup> La reserva indígena Lummi corresponde a nativos americanos del grupo *Coast Salish* que se localizan en occidente del estado de Washington en Estados Unidos ([www.lummi-nsn.org](http://www.lummi-nsn.org)). En el decenio 1970, la acuicultura emergió como una industria en la costa de Puget Sound, en dicho estado, como resultado del proyecto liderado por los indios para el desarrollo de un criadero y desove de ostras y producción de semilla. Lo cual, dio fin a la dependencia de insumo biológico proveniente de Japón (Clark y Finley, 1971).

<sup>19</sup> Se contactó a la empresa Lummi Indian, que estaba adaptando las técnicas biotecnológicas del ostión del Atlántico al ostión japonés. Tres pasantes de oceanología de la ESCM hicieron una estancia en el verano de 1973, para aprender el desarrollo de biotécnicas, así como las técnicas para el cultivo de microalgas. Unos meses después de la estancia, mandaron la semilla de Seattle a San Diego, y posteriormente a Ensenada; allí se hicieron las sartas y balsas y se cultivaron con gran éxito. Así lo señaló en entrevista el Dr. Saúl Álvarez Borrego, Director de la Unidad de Ciencias Marinas a principios de la década de los setenta.

Quintín (Mapa 1). Sin embargo, debido a la serie de problemas que enfrentaba el sector social en términos de su organización productiva ejidal - pesquera<sup>20</sup>, la academia vio frustrada su intención de impulsar la actividad acuícola en las comunidades ribereñas.<sup>21</sup> Hacia finales de la década de los setenta, se impulsó en la Bahía de San Quintín, de manera independiente de la academia, el cultivo del ostión japonés en la Bahía Falsa, por iniciativa de algunos agricultores y pescadores de la región.<sup>22</sup> Trece años después de haberse formado la cooperativa, concluyó la concesión del cultivo de ostión y los socios de la SCPP Bahía Falsa deciden constituirse en sociedades mercantiles, y para fines del 1994 y principios de 1995 se otorgaron las concesiones de esas nuevas empresas que fueron las primeras.<sup>23</sup> Hoy en día el ostión japonés, de acuerdo con el CONAPESCA (2008) es la principal especie de cultivo en China, Taiwán y Canadá, por su enorme importancia comercial.

**Mapa 1. Ubicación geográfica de las unidades de producción**

Fuente: elaboración propia con base en información del CESAIBC (2014).

En México, tanto en Baja California como Baja California sur se cultiva, para su exportación, el ostión japonés, tanto en áreas de cultivo como en plantas empacadoras certificadas por el Programa Mexicano de Moluscos Bivalvos. Asimismo, y es una de las especies que ya se

<sup>20</sup> Señala el Dr. Álvarez que hacia finales de los setenta, se fomento en algunos estados como Sinaloa el desarrollo de cooperativas ejidales–pesqueras con la finalidad de poner fin a la disputa entre agricultores y pescadores, como resultado de algunas fallas que se presentaron durante el reparto agrario en México. Y es que en el caso de ciudades costeras como San Quintín, algunos campesinos habrían recibido terrenos no aptos para la agricultura como dunas y lagunas costeras, lo que impulsó al agricultor a invadir las playas para recolectar moluscos y venderlos. Un problema fue que las playas estaban concesionadas a las cooperativas pesqueras.

<sup>21</sup> Entrevista, Dr. Saúl Álvarez Borrego.

<sup>22</sup> El proyecto nace en 1977 cuando el Departamento de Pesca promovió un programa social denominado PIDER, Programa Integral de Desarrollo Rural, para el beneficio de las comunidades ribereñas y el maricultivo del ostión japonés (CONAPESCA, 2008). Durante este período, se formó la Sociedad Cooperativa de Producción Pesquera “Chapalita” S.C.L., con la finalidad de acceder a los recursos que ofrecía el PIDER. Mientras conseguían el recurso, se visitaron diversos laboratorios en Estados Unidos y se optó por traer larvas y semillas ya fijadas en concha madre del laboratorio de los Indios Lummi. Sin embargo, era una cooperativa con tintes ejidales por lo que en 1981 se cambia a Sociedad Cooperativa de Producción Pesquera (SCPP) Bahía Falsa, que fue la pionera en el cultivo en la región (entrevista al Dr. Saúl Álvarez Borrego).

<sup>23</sup> A partir del testimonio del Ocean. Carlos Lozoyas.

integra en la Carta Nacional Acuícola 2012. Las fases de desarrollo por las que ha transitado de esta especie son: experimental, en desarrollo y consolidación del cultivo. Lo que es relevante mencionar es la consolidación del ostión japonés debido a la acumulación de conocimiento por parte de los productores en cuestiones relacionadas con las enfermedades y parásitos de los moluscos bivalvos y control sanitario a través de cursos teórico – prácticos con el sector académico.

**El Abulón rojo:** de la pesca al cultivo. En la región, la explotación comercial del abulón rojo a partir exclusivamente de la captura inició por la comunidad de chinos en Baja California (1850 hasta 1900) (Dávalos, 1990) y posteriormente, de 1900 a 1931, por los japoneses quienes controlaban todo el proceso, es decir la captura, comercialización e industrialización desde esta región. La pesca se realizaba de manera sistemática y continua, parando sólo cuando las condiciones climatológicas no lo permitían y con buzos sólo de nacionalidad japonesa.<sup>24</sup> Fue hasta 1937, cuando la explotación y por ende la acuicultura de especies valiosas como el abulón, se convertirían en derecho exclusivo de las cooperativas pesqueras<sup>25</sup>.

El manejo experimental del abulón surge durante la década de 1979 con la construcción de un laboratorio ubicado en la ciudad de Ensenada para la producción de semilla de tipo experimental.<sup>26</sup> Para finales de esta década (1978), el Instituto Nacional de Pesca (INAPESCA) construyó el Centro Acuícola de Eréndira (al sur de la ciudad de Ensenada), con la finalidad de llevar a cabo investigación pesquera y acuícola en la región. Los primeros proyectos en la década de 1980 para la producción de semilla de abulón sucumbieron ante la crisis de 1982 en México. Las instalaciones quedaron casi abandonadas y sin fondos para seguir operando. No obstante, la construcción de este centro acuícola fue una experiencia que dio como resultado el surgimiento de una generación de oceanólogos que empezaron la experimentación de reproducción, producción de larva y producción de huevos de abulón. Estas tareas convergieron algunos experimentos para su siembra en California y en Japón.<sup>27</sup> El gobierno federal, promovió en 1984 un convenio entre la Secretaría de Pesca y la Federación Regional de Sociedades Cooperativas de la Industria Pesquera en Baja California tratando de disminuir las dificultades que presentaba el Centro Acuícola de Eréndira, (como las relacionadas con personal y apoyos económicos ágiles). El objetivo fue la operación conjunta del centro pero el esquema no funcionó en parte por la desorganización de los técnicos cooperativistas asignados al proyecto y dos años más tarde se canceló el convenio (Dávalos, 1990).

En 1984 también se inició un programa de investigación dentro del Instituto de Investigaciones Oceanológicas (IIO) que buscó complementar los esfuerzos en el manejo de

<sup>24</sup> Poco antes de la Segunda Guerra Mundial, se quemaron y abandonaron las instalaciones por parte de este equipo (Dávalos, 1990). De ahí que a los pescadores mexicanos les tomara algunos años aprender las técnicas de pesca y comprender la necesidad de organizarse para poder acceder a apoyos gubernamentales.

<sup>25</sup> Esto prevaleció hasta 1992, cuando cambió la normatividad sobre la actividad pesquera y acuícola en México.

<sup>26</sup> Según Dávalos (1990), la Dirección de Pesca, creó el laboratorio “El Sauzal”, donde se introdujeron de manera experimental semillas de varias especies de abulón. La falta de continuidad en este esfuerzo generó que el laboratorio cayera en desuso antes de 1975 y fuera posteriormente desmantelado. Hasta finales de la década de los setenta (1977), México había obtenido siempre el primer lugar a nivel mundial en producción del abulón por extracción. Sin embargo, a partir de esta fecha, menciona Dávalos (1990), las poblaciones naturales ya no soportaron el ritmo de la sobreexplotación, siendo esto el detonante para retomar los intentos de impulsar la acuicultura (manejo de especies) que se habían iniciado a principios de los setenta.

<sup>27</sup> Así lo indica en entrevista Benito Altamira.

la semilla de abulón a través del desarrollo de tecnología de siembra y engorda de la semilla. El primer obstáculo fue la escasez de semilla en los laboratorios nacionales debido a los bajos niveles de producción que prevalecían; así que se iniciaron estudios con semilla comprada o donada por laboratorios de Estados Unidos (Searcy *et al.* 1988). Al final de la década, los avances científicos en el cultivo de abulón generaron interés en algunos estudiantes de oceanografía de la ESCM quienes, al ver la viabilidad del cultivo, se aventuraron a formar sus propias cooperativas y se asociaron con la principal concesionaria dedicada a la cosecha de sargazo gigante (alga marina) en Baja California. Fue así como surgió a finales del año 1991 la primera sociedad anónima para el cultivo de abulón en el mar: Abulones Cultivados.<sup>28</sup>

En 1992, la empresa firmó su primer convenio de 7 años y posteriormente otro de 15 años con el gobierno federal. El objetivo fue el desarrollo de tecnología para el cultivo del abulón rojo. Con la anuencia de los ejidatarios los oceanólogos tomaron posesión de las instalaciones existentes en el Centro Acuícola de Eréndira en el ejido Eréndira. Para mediados de la década, la empresa desarrolló la tecnología para producir propia semilla propia alcanzando el éxito en 1997. De manera paralela se logró el permiso para importar medio millón de semillas de California acondicionadas para cultivo de abulón, permitiendo que las pruebas en mar se dieron a una escala mayor.<sup>29</sup> Producto de la adaptación de la tecnología utilizada en el estado y con el apoyo de las Universidades en la región también se desarrolló tecnología propia para alimentar a las postlarvas. Debido a los efectos de fenómeno natural El Niño, en 1992, la empresa se concentró en la engorda terrestre con un sistema de bombeo de 24 horas, lo cual si bien significó un incremento en los costos de operación de la empresa, mejoró el control y el monitoreo de las condiciones de la engorda. Para principios del siglo XXI, se retomó la colaboración con los investigadores de la región la cual continúa de manera sostenida y contribuyendo al desarrollo de la tecnología del cultivo en las áreas de asentamiento larval y cultivo de postlarvas y juveniles. Fue así como durante la década de 1990 se formalizó la integración de un equipo multidisciplinario con investigadores regionales y la primera sociedad anónima para llevar a cabo actividades científicas relacionadas con genética, nutrición y patología, relacionadas con el abulón.

En conclusión, se puede observar que la trayectoria por la cual transitan las especies para lograr su consolidación varía, en parte por: i) la existencia de estudios sobre las condiciones biológicas y tecnológicas de la especie; y ii) su relevancia económica, ésta en términos de su utilización para el consumo humano o industrial. En ambos casos, se advierte que el gobierno federal juega un rol esencial ya que es a partir de su aprobación, con políticas y programas, que la evolución de una especie para su cultivo puede avanzar de manera articulada y rápida con su entorno.

### **3.2 Recomposición de las cadenas de valor: la importancia de la integración territorial en acuicultura**

<sup>28</sup> Tal es el caso de tres jóvenes oceanólogos, cuyo proyecto tenía contemplado la siembra de semilla de abulón, que proporcionarían un investigador de la Universidad Autónoma de Baja California en coordinación con un productor de semilla en California.

<sup>29</sup> El Centro Acuícola se convirtió en un aula improvisada del sector privado, por la cual pasaron, cerca de 10 generaciones de entre 6 a 12 técnicos de todas las cooperativas pesqueras de abulón donde se les daban los cursos para generar el desove, entre otros aspectos (entrevista Benito Altamira, 2014).

El análisis de las cadenas de valor del ostión japonés y del abulón rojo, tiene como propósito identificar a los actores que participan como proveedores en cada uno de los eslabones (insumo biológico, producción, industrialización y comercialización) que integran la cadena, con la finalidad de puntualizar cómo los actores locales agregan valor al proceso productivo incrementando así la relevancia de las competencias territoriales para el desarrollo de la actividad acuícola : Cadena de valor del ostión japonés cultivado en Baja California. (Figura 1).

**Figura 1. Eslabones de la cadena de valor del ostión japonés**

Fuente : Celaya (2014).

Primer eslabón: Insumo biológico. Se hace referencia a la proveeduría y/o producción de larvas y semillas. En cuestiones de proveeduría de larvas y semillas, se identificaron distribuidores en el extranjero específicamente en la costa oeste de Estados Unidos y en Santiago de Chile (Cuadro 5).

Los proveedores a nivel regional y local se caracterizan por ser laboratorios de producción de larva y semilla, o bien, ostricultores que cuentan con el ciclo completo de cultivo, que sí bien, producen su propia semilla también la comercializan. Es necesario precisar que en el caso del insumo de larva fijadora de ostión, los proveedores principales se ubican en Estados Unidos ya que cuentan con certificados sanitarios por parte de los laboratorios y garantizan que las larvas no presenten ningún agente patógeno certificable (CONAPESCA, 2008).

**Cuadro 5. Proveedores de larvas y semillas de ostión japonés**

| Escala     | Total de proveedores | País   | Estado              | Sector privado | Sector público |
|------------|----------------------|--------|---------------------|----------------|----------------|
| Extranjero | 3                    | USA    | Washington          | 2              |                |
|            |                      | Chile  | Santiago            | 1              |                |
| Regional   | 3                    | México | Baja California Sur | 2              |                |
|            |                      | México | Sonora              |                | 1              |
| Local      | 2                    | México | Baja California     | 2              |                |

Fuente: elaboración propia con base en Guevara *et al.* (2010) y Tapia *et al.* (2013)

Con relación a la participación en el mercado estatal de proveedores, en 2008 predominaron los laboratorios estadounidenses con el 90%. Esto señala la alta dependencia que tienen los productores en Ensenada en la proveeduría de larvas y semillas. Los proveedores locales o

regionales no cuentan con la suficiente infraestructura para abastecer a la región CONAPESCA (2008). En la proveeduría de servicios tecnológicos, ésta puede estar orientada hacia el desarrollo y/o a mejoras en técnicas biotecnológicas como lo son: i) la reproducción de microalgas, ii) la maduración de reproductores, iii) el desove de reproductores, y iv) el período larvario. Los servicios son ofertados por las Instituciones de Educación Superior (IES), los centros de investigación e instituciones de carácter privado, todos ellos de carácter local y/o regional.

Segundo eslabón: Producción. Con base en información del CESAIBC (2014) se detectaron un total de 29 unidades de producción. Como se observa en el mapa 1, este molusco se cultiva a lo largo del Pacífico en la zona III (específicamente en la Bahía de San Quintín). Los cuerpos de agua donde se ubican las granjas acuícolas están certificados por la Comisión Federal para la Protección contra Riesgos Sanitarios (COFEPRIS) para su exportación a Estados Unidos. Es un cultivo semi-intensivo, lo que significa que se controla la subsistencia de los equilibrios biológicos a procedimientos artificiales, como lo es la regulación de temperatura, la salinidad, el bombeo, la filtración y niveles de oxígeno, para la fijación de la larva. Las técnicas de cultivo<sup>30</sup> varía y éstas pueden ser: i) en sarta, ii) *FLUPSY*, o sistema flotante de flujo ascendente (siglas en inglés), iii) *long-line* y iv) francés (Tapia *et al.* 2013).

En el eslabón de producción (Figura 1), la proveeduría gira en torno al esquema de cultivo, el equipo de trabajo de los empleados utilizados para la siembra y la cosecha, el transporte y los servicios tecnológicos. Con base en una desagregación básica de los materiales y equipo, se identificó el material que utilizan los productores para la construcción de sus artes de cultivo, ya sea para la fijación de la larva o bien para la pre-engorda y la engorda de la semilla (Cuadro 6). Como se advierte, los proveedores son locales a excepción del proveedor de estacones (vara tomatera) que se ubica en el estado de Sinaloa, al sur de Baja California. El equipo de trabajo refiere al equipo de buceo para el movimiento del producto en el mar; la botas, los delantales y los guantes, accesorios necesarios para los trabajadores y los distintos empaques que se utilizan una vez que el ostión es cosechado, son de proveeduría local. En tercer lugar, se identificó la proveeduría de transporte marítimo para llevar el producto a tierra. La proveeduría de transporte terrestre es utilizada para llevar el ostión a la planta empackadora o bien a intermediarios, distribuidores, comercializadores, restaurantes de la región o carretas. La proveeduría de transporte en ambos casos se da a nivel local.

**Cuadro 6. Proveeduría de material, equipo y servicios especializados para el cultivo de ostión**

| Concepto | Fase                       | Características  | Proveedor |

Fuente: elaboración propia con base en información de CONAPESCA (2008) y Guevara *et al.* (2010) y Tapia, *et al.* (2013).

Los servicios tecnológicos giran en torno al desarrollo o perfeccionamiento en las técnicas de cultivo existentes, estudios y análisis para la certificación de las aguas y del producto, pues la mayor parte del cultivo del ostión japonés se produce en el mar, lo que implica filtración,

ingestión, absorción y asimilación de nutrientes. Por tanto, es indispensable asegurar que el producto esté libre de patógenos para el consumo humano. De ahí que sea central la capacitación a los productores y técnicos en el manejo de buenas prácticas.

Tercer eslabón: la industrialización. Las transformaciones aplicables al ostión giran en torno a su presentación: desconchado, en media concha, ahumado o bien empacado al vacío. En Ensenada, México, la única presentación que se coloca en el mercado es en concha fresco-vivo. Por lo tanto, en este eslabón participan solo empresas que cuentan con una planta procesadora o de empaque y donde el mayor grado de industrialización que se le da en valor agregado al producto es la presentación en cajas de *foam* con hielo en gel para mantenerlo fresco y el empaque en cajas de cartón encerado para su venta en México y en mercados de exportación (CONAPESCA, 2008). Al momento de hacer esta investigación se identificaron 6 empresas empacadoras para exportación en México, de las cuales 5 están en Ensenada (Cuadro 7). Las plantas de empaque cuentan con dos líneas de producción: ostión fresco vivo en su concha y ostión vivo en su concha a partir de los estándares de calidad de exportación. En envíos aéreos el ostión se empaqueta en bolsa y se coloca en una hielera de poliestireno con hielo en gel, para mantener el producto frío y que garantice mayor vida anaquel. Es importante señalar que las plantas deben de estar certificadas y autorizadas por el Programa Mexicano de Moluscos Bivalvos al igual que los cuerpos de agua, (PMSMB) y ceñirse a los lineamientos del *National Shellfish Sanitation Program* del *Food Drug Administration* para la exportación.

Cuarto eslabón: la comercialización. La mayoría de los productores de ostión venden en los mercados locales, regionales y nacionales a grandes intermediarios y/o centros de acopio. Los propios productores son los encargados de mover su producto. Se identificaron 29 unidades de producción. El 48% de los empresarios atiende la demanda nacional (entidades fuera de Baja California). El 24% atiende al mercado regional (municipios de Baja California). Y el 24% restante a una combinación de mercados nacionales e internacionales vía Estados Unidos: mercados de Los Ángeles y Boston.<sup>31</sup> Un aspecto importante entre los ostricultores es que su proximidad geográfica ha generado un asociacionismo, sin importar si son micro, pequeñas o medianas empresas. La red de productores hace frente a las dificultades en cada uno de los eslabones de la cadena productiva. Las dos empresas integradoras que existen actualmente ofrecen a los productores acuícolas diversos servicios que varían desde el abasto de las artes de cultivo, compras e importación de insumos biológicos utilizados para desarrollar su actividad hasta aspectos administrativos, como contables, servicios de acopio, procesamiento, comercialización, asistencia técnica y adopción de nuevas tecnologías.<sup>32</sup>

### ***Cadena de valor del abulón rojo cultivado en tierra en Baja California***

El abulón rojo, se cultiva en tierra lo cual implica un mayor control de los productores en cada uno de los eslabones que integran la cadena. Si bien, los componentes en cada uno de los eslabones no varía mucho en comparación con el cultivo de ostión japonés, si se observa una disminución en los servicios especializados en parte por sus cultivos están en tierra y no en mar (Figura 2).

Figura 2. Eslabones de la cadena de valor del abulón rojo

Fuente: elaboración propia

Primer eslabón: Insumo biológico. Los proveedores de semilla de abulón cultivada se dividen en dos grupos: a) dedicados a la producción y venta de abulón cultivado en cualquiera de sus etapas de desarrollos y b) dedicados a la producción de abulón para repoblamiento. La proveeduría de semilla es desarrollada por tres laboratorios ubicados en el estado de Baja California. Dichos recintos forman parte de la infraestructura de las tres empresas que llevan a cabo cultivo de abulón para comercialización o repoblamiento. En los laboratorios también se cultiva el alimento de las postlarvas, juveniles y los reproductores (microalgas) en sustratos artificiales tales como bales de plástico, estanques circulares de fibra de vidrio, láminas onduladas o planas de cloruro de vinilo, policarbonato y fibra de vidrio. En la proveeduría de servicios tecnológicos, se identificaron gira en torno a la mejora de semilla a partir del desarrollo de técnicas biotecnológicas para cuestiones de genética, nutrición y patología. Estas actividades se fortalecen y complementan con el desarrollo de proyectos a partir de contratos con las IES, centros de investigación e institutos privados a nivel local con CICESE y IIO y a nivel regional, con el CIBNOR.

Segundo eslabón: Producción. Las granjas de abulón rojo se ubican en un predio privado, el cual se encuentra dentro de la zona III de cultivo (Mapa 2). En el Ejido Eréndira se ubican las dos empresas que comercializan el abulón. Las empresas que comercializan el abulón, se caracterizan por tener un sistema de producción intensivo; el cultivo se hace en estanques

de cemento con densidades de producto muy altas, intercambio de agua cada 24 horas al igual que el monitoreo y con parámetros continuos. Los procesos que se siguen, al igual que los métodos de cultivo, los desarrolla el empresario acuícola. Ellos no compran la tecnología de engorda, pues tanto la biotecnología como el desarrollo de tecnologías se han desarrollado internamente con las modificaciones requeridas en determinados momentos. Al igual que en el sector ostrícola privado, las empresas son propiedad de Oceanólogos. Asimismo, los empresarios especializados de este sector llevan a cabo todas las fases del cultivo, lo que implica que ellos mismos desarrollan su propia semilla; en algunos casos incluso se han diversificado y producido semilla de ostión japonés. En este sentido, la proveeduría de servicios tecnológicos ha girado en torno a la mejora de tecnología para el asentamiento de larvas, cultivo y postlarvas, y mejora de líneas genéticas, en tecnología para alimentación, y en el control sanitario.

Tercer eslabón: La industrialización. La presentación tradicional del abulón es en fresco-vivo, enlatado en salmuera y congelado. En el caso de las dos empresas que comercializan el abulón en Ensenada, ninguna de ellas cuenta con planta procesadora, siendo la proveeduría del empaque local. Cuarto eslabón: La comercialización. Son los propios productores los que distribuyen su a partir de la demanda de abulón en vivo en Estados Unidos, y abulón procesado en China y Singapur.<sup>33</sup>

**Mapa 2. Empresas que integran el cultivo de abulón (2015)**

Fuente: elaboración propia con base en información del CESAIBC (2014).

A partir del análisis de la cadena de valor del ostión japonés y abulón rojo cultivados en Baja California, vemos que sí bien la proveeduría de material para la construcción del sistema de cultivo es local, el desarrollo y mejoras de arte de cultivo es llevado a cabo por los empresarios acuícolas. Ello difiere de los servicios tecnológicos en los eslabones del insumo biológico y de producción, donde se requiere absolutamente la red de colaboración con las IES, las instituciones privadas y los centro de I+D para la obtención del organismo acuático, y generación de condiciones necesarias para su siembra, crianza y cosecha.

#### ***Servicios especializados e innovación territorial***

La proximidad geográfica entre los productores acuícolas de Ensenada les ha permitido generar esquemas de organización a partir de empresas integradoras dedicadas a ofrecer servicios especializados de: i) el abastecimiento del insumo biológico de larva y semilla de

<sup>33</sup> Entrevista a Enrique Vázquez, 2013.

osti3n,<sup>34</sup> ii) el 3rea de producci3n, con lo que es el suministro de artes de cultivo, embarcaciones con equipo de buceo, as3 como equipo de transporte; iii) la industrializaci3n, donde se contemplan servicios de empaque en plantas certificadas; iv) servicios de comercializaci3n, aunado a la compra de osti3n. Aqu3 la red de intercambio de informaci3n opera de manera formal y son consideradas como modelos para el desarrollo biotecnol3gico que podr3an potenciar la actividad acu3cola en la regi3n.

Si bien las integradoras han absorbido algunos servicios especializados, los productores est3n conscientes de la necesidad de colaborar mayormente con las IES, instituciones privadas y centros de I+D para la mejora de sus l3neas gen3ticas y as3 disminuir perdidas por compras fuera de la regi3n. Tambi3n pueden ayudar a mejorar la dietas nutricionales de las especies. Los dos aspectos disminuir3an la mortalidad en las fases de pre-engorda y engorda y situaciones patol3gicas (Primer Foro de Acuacultura en Ensenada, 2013). Por lo tanto, la colaboraci3n de los a3os siguientes deber3 enfocarse a los servicios tecnol3gicos, al estudio sobre patog3nesis, al diagn3stico de enfermedades y al an3lisis de agua, as3 como cursos te3rico-pr3ctico sobre tem3ticas relacionadas con las enfermedades y control sanitario de moluscos bivalvos, y repoblamiento del abul3n. Actualmente los productores han accedido a los servicios de capacitaci3n pero la red con las instituciones de apoyo gubernamental opera de manera espor3dica.<sup>35</sup>

En el mapa institucional de apoyo a la acuacultura en Ensenada es importante destacar el papel del Comit3 Estatal de Sanidad Acu3cola e Inocuidad de Baja California (CESAIBC) como intermediario y promotor de: a) cursos de capacitaci3n en materia de sanidad acu3cola, b) divulgaci3n de las acciones sanitarias, es decir como tratar y preservar en condiciones sanitarias 3ptimas a los organismos que cultiva; c) muestreos para la vigilancia epidemiol3gica, y d) promoci3n de eventos internacionales como el Simposium Internacional de Sanidad e Inocuidad Acu3cola, celebrado recientemente.

### **Conclusi3n**

La acuacultura es una actividad de creciente importancia en M3xico. Sin embargo los retos son a3n may3sculos si se quiere acercar al peso que tienen otros pa3ses latinoamericanos en el contexto global de las exportaciones de productos acu3colas en el mundo. A pesar de ello hemos visto que la maduraci3n de redes de conocimiento y la configuraci3n de un sistema productivo regional como el acu3cola no corresponde a procesos que puedan implantarse con facilidad y donde la transferibilidad de tecnolog3as entre regiones no asegura el cambio o el dinamismo productivo. Queda claro, con la metodolog3a inductiva y comparada, que incluso a nivel de producto (especies marinas) en una misma regi3n suele haber diferencias importantes que requieren redes de conocimiento y colaboraci3n espec3ficas para el manejo de insumos biol3gicos, el impulso a las innovaciones, la transferencia de tecnolog3a, el cuidado de las semillas, los procesos de engorda y la comercializaci3n. La centralidad que tienen los servicios de biotecnolog3a en el desarrollo de la acuacultura es otro hallazgo importante. Debido a la gran variabilidad de los ambientes en los que se deben desarrollar los productos marinos para el consumo humano la acumulaci3n de conocimiento es vital, pero no como un aspecto de recuperaci3n constante, sino para el desarrollo de innovaciones tecnol3gicas. Los procesos de aprendizaje son procesos de aprovechamiento y destrucci3n

<sup>34</sup> En ambos casos deben de tener un certificado sanitario de calidad de origen.

<sup>35</sup> La capacitaci3n se ha enfocado en de fortalecer competencias a partir de cursos para validar nuevas t3cnicas de cultivo y el intercambio de experiencias sobre el uso de tecnolog3as, pr3cticas de manejo y medidas de control sanitario aplicadas para reducir la mortalidad.

de conocimiento. Las redes de los productores e investigadores, son vitales para la innovación como base del desarrollo biotecnológico y acuícola. El apoyo del gobierno federal y estatal, tampoco garantiza per se la consolidación de ambos cultivos. La capacidad de las instancias gubernamentales como de las universidades y los centros de I+D radica en avanzar conforme a las necesidades técnicas de los cultivos, que pueden variar incluso de ciclo en ciclo por las condiciones del ambiente. El mejoramiento de técnicas y servicios biotecnológicas para el desarrollo genético puede incrementar la calidad de las especies reproductores, pero ello no se puede anticipar con seguridad, o bien asegurar en el futuro cuando una técnica ha sido exitosa.

Los servicios especializados en Ensenada y su fuerte arraigo territorial son determinantes para avanzar en una mayor colaboración. No obstante, se ha identificado con la exploración de campo que la red no tiene esquemas constantes. El desarrollo de actividades de I+D dependerá de las problemáticas que enfrenta la actividad acuícola. El objetivo común es disminuir la dependencia del extranjero en los insumos biológicos, primer eslabón de ambas cadenas de valor y sector clave para desarrollar servicios de innovación biotecnológica.

## **Abstract**

The aim of this study is to analyze the flow of trade services from Latin American countries except Cuba, with emphasis on exports of services during the years of 2002-2012. To this end services are separated, according to Jimenez (2012) into three categories: contact services, shared services and services for skills development. As results: i) contacts services were more significant than shared services. ii) the trade balance of services in Latin America was deficient, only Panama, Costa Rica, Dominican Republic, Uruguay have a surplus balance in services every year; iii) although travel and transport (contact services) have the largest shares, the rates of growth of shared services indicate changes in the region. These changes may be related to the growth of manufacturing activities related to FDI and also with FDI inflows linked to offshoring of various services. Thus, the participation of Latin America in the value chain in services can be crucial for their development.

## **1 INTRODUCTION**

According to the Brazilian Network for the Integration of Peoples (REBRIP, 2006) since the nineties, have been perceived three global trends in the service sector, although with different manifestations depending on the region.

First, the increasing share of services sector in the structure of employment and production in developed countries and some developing countries such as Latin American. In developed countries, the services sector has increased participation related to the demand, diversification of the pattern of consumption beyond the industrial and agricultural goods, but also a trend of increasing the supply of new services, which incorporate the technology, making it important to the performance of the industrial and agricultural sectors. In Latin America, this trend is associated with high levels of urbanization, the existence of a middle class with high purchasing power, and also a greater supply of workers.

Secondly, the services sector has increasingly responded by capital accumulation of the capitalist economy, favoring privatization, mainly of services. Privatization processes have allowed greater flexibility to economic groups offer services directly from their respective countries (via trade) or through foreign direct investment (FDI).

Thirdly the privatization process tends to lead to the formation of global oligopolies in the service sector. The greater presence of developed countries in trade in services is accompanied by a rise in FDI.

For Lopez (2009) the service sector has a growing share of global FDI flow because: i) delay of the service sector in the internationalization process; ii) increase in the share of gross domestic product (GDP) in most countries; iii) deregulation and privatization processes have extended access to foreign investors; and iv) the outsourcing process, which increased the demand of firms for services contracted out, since the development of telecommunications allows to search for new suppliers in other countries; v) technological changes that facilitate the development of offshoring.

The growth of international trade in services is explained with the development of global value chain (GVC) or the value chain. The CGV is split into large activities of companies, and the main activities are in the matrix, while routine activities, such as administrative management, human resources, accounting, among others, are held in subsidiaries located in third countries or outsourced to independent companies. So subsidiaries or subcontractors are introduced in the value chain as service providers (LOPEZ, NIEMBRO and RAMOS, 2011).

For the authors, the trade in services is an opportunity for developing countries to generate foreign exchange and jobs. They emphasize that Latin American countries have the possibility to enter and occupy a stable role within CGV in the segments of services. Latin Americans countries have advantages to compete in the services market, such as labor costs, skilled human resources, ICT infrastructure relatively developed, knowledge capacity in some sectors, similar time zone with the United States and cultural affinities.

Lopez, Niembro and Ramos (2011), claim that every year the flow of Latin American services trade increases. The larger trend is in the share of non-traditional services such as business services, IT and computing, communication services, financial services, insurance and engineering services and construction, which include greater intellectual content services, compared with traditional services, such as transportation and travel.

In 2012, among the non-traditional services, business services accounted for almost 32,100 million dollars in exports of services, accounting for about 64% of total exports to Latin America. The main exports classified in the category of business were: architecture and engineering (34%); other services (26%); and accounting services, administration and public relations (24%). These services account for 84% of exports of business services. The main exporters of business services were Brazil and Argentina with 74% and 16% of total respectively. The Brazil as the first ranking in Latin America, stands out in exports of architecture and engineering (TRADE MAP, 2014)

Within this context, the aim of this study is to analyze the flow of services from Latin American countries except Cuba, with emphasis on exports of services. To this end services are separated according to Jimenez (2012) into three categories: contact services, shared services and services for skills development.

The contact service is set to lower value-added activities, low level of qualification and limited production integration with local companies. The services in this category are: agribusiness services, transportation, travel, personal cultural services, business service with customer relationship and computing services and networks and applications. The main factor of this segment is associated with the use of natural resources and existence of low operating costs.

Shared services are central to boosting the scaling to a higher added value. The activities have a higher added value and require a medium level of qualification, with limited possibilities for productive integration with local companies. Companies that decide for this service work as unit cost, seeking skilled labor to streamline the operation of the company, with the goal of greater efficiency. These services require all the skills needed by the contact service, and also a workforce that has knowledge in professional technical level of accounting, finance and human resource management. Shared services include construction services, communication, financial, insurance, royalties and licenses, IT and computing and also the business services related to enterprise resource management: architecture, civil engineering, computer science and information technology, accounting and finance.

Services for skills development are related to research and development and information technology, software and consulting services. This segment has the highest added value and the high level of capacity characteristics in international business, mechatronics engineering, nanotechnology and materials research; require highly skilled labor and has an integration with national productivity. The main characteristic of this service is the free

movement of qualified international certifications and a strong bond and a strong local business group with direct links companies in the host country.

The period of analysis are the years 2002 to 2012, and the database is the International Trade Centre, which brings together data from the International Monetary Fund reports, the World Bank, UN, UNCTAD and WTO.

The work is divided as follows: in addition to this introduction, the second topic describes trade in services; the third topic presents the trade flows in Latin America and the fourth the conclusions.

## **2 TRADE IN SERVICES**

The definition of trade in services has been adapted to reality as exchanges of invisible or intangible products and the transfer of knowledge between countries and economic units (BRAZIL, 2010). Given the intangible nature of trade in services, measuring the flow of services and collect statistical data is still a challenge. Overall rates may not be levied on service transactions, except transport and travel. Therefore, the barriers to trade in services are mainly non - tariff, such as quotas, prohibition and government regulations (AMANDOR; CABRAL, 2009).

For the WTO, trade in services comprises different situations involving the borders of transposition: i) Cross-border services - involves the right to provide services between the two countries. There is movement of factors of production nor the recipients of the service. Are similar goods transactions; ii) consumption abroad - refers to services consumed by nationals of a country in another country where the service is provided, and therefore provided to consumers that is not in your country of residence, tourism is an example; iii) commercial presence - when a service provider leaves his country to settle commercially in another country in order to provide a service, which can be through any type of business or professional establishment, as, subsidiaries, affiliates, offices and joint ventures; iv) temporary movement of natural persons - this mode applies only to individuals of a country who settle temporarily in another country in order to provide a service (BRAZIL, 2010).

According to Pereira (2002, p. 545)

"the distinction proposed in trade in services between the modalities commercial presence and cross-border is the same as occurs in trade in

goods. Goods can be traded by international trade flows or through the presence of foreign subsidiaries in the domestic markets. The importance of foreign capital is recorded via direct investment in the balance of payments, and can be produced statistics on the share of sales of foreign affiliates in the domestic market, which would also apply to the service sector".

According to López, Niembro and Ramos (2011) for the service trade are used the balance of payment statistics collected by the International Monetary Fund (IMF) to cover the Cross-border services, and data on FDI to the form of commercial presence. As for consumption abroad and temporary movement of natural person does not have any precise information.

There are some uncertainties about the statistics regarding the actual volumes of trade in services and their effective growth rate. These uncertainties are due to several factors such as: (i) many of these services are new activities for which there is not yet sufficient consensus on the best forms of assessment; (ii) a large part of export segments is intangible nature, which hinders its registration; (iii) international services transactions occur in various ways, not always collected completely and homogeneously by statistics.

Part of the increase in world trade flow services reflected by statistics can be attributed to the record by several countries that previously did not do so or to the progress of the measurement and estimation techniques of those who already accounted for. In addition, there is the homogeneity of the data, which makes international comparisons or inter temporal assessment of the available information.

The WTO annually disclose aggregate statistics on foreign trade services, divided into three broad categories: transport, travel and other services. For Lopez, Ramos and Torres (2009) transport services, involving the movement of cargo, passengers and auxiliary services that are performed by residents of one economy to residents of another economy; Travel services are related to the services acquired from an economy by a foreign tourist; communications services involve postcard services, mail and telecommunications; insurance services cover the supply of various types of insurance to non-residents by resident companies; Construction services cover work projects carried out by construction company and employee installation outside the local market; financial services involving financial intermediation; computing and information services include software-related services, data processing, news agencies and the like; royalties and licensing cover franchise fees, royalties, licenses and other proprietary rights; business services comprise the provision of business

services not included in other accounts, such as legal, accounting, architecture and advertising, engineering, research and development, agriculture and services related to rents and marketing; personal, cultural and recreational services include audiovisual services, sports, education and health, and finally government services involving transactions by embassies, consulates, military units and agencies.

### **3 FLOWS OF TRADE SERVICES IN LATIN AMERICA**

According to Appendix A, in 2002 the value of exports to Latin America was 46,815,592 million, and in 2012 exports almost tripled, with a value of 126,163,795 million dollars. The countries that exported more were Brazil, Mexico and Argentina and the least exported Haiti, Nicaragua and Bolivia. The international crisis of 2008 had little effect on the countries for exports of services, with a small reduction in almost all countries in 2009, but exports rose again in 2010. In Appendix B is shown the value of imports of services. Brazil, Mexico and Argentina were the countries that imported more and the least imported were Haiti, Nicaragua and Bolivia. In Appendix C we observe the trade balance of service for each country in Latin America in the years of 2002-2012. Only Panama, Costa Rica, Dominican Republic and Uruguay showed a surplus balance in every year.

As can be seen in Table 1, exports of contact services are superior compared to the shared services in each year of 2002-2012. Also observed a greater focus on contact services in imports of services. In Latin America the total value of imports exceeds the total value of exports, which makes the balance of trade in services deficit.

#### **3.1 Contacts Services**

Table 2 show the composition of the contact services, divided into transportation services, travel and cultural and personal. The total value in 2012 amounted to 76,993,948 million dollars. The countries that more exported were Mexico, Brazil and Chile, respectively. Of all the contacts service, can highlight the trip, which refers mainly to tourism, with the highest concentration in almost all countries except Chile, Panama and Paraguay. This service represent 64.67% of total contacts services.

By analyzing table 2.1, the average annual growth rate of personal travel is superior to business, 7.9% and 7.5%, respectively. In relation to personal travel, stands out with the highest average annual rate, related to education services with 10.1% and health with 5.2%. All countries exported travel services in 2002-2012. Mexico had greater representation, followed by Brazil, Dominican Republic and Argentina. In business services the countries that more exported were Mexico, Argentina, Venezuela and Chile and related to personal travel services were Mexico, Brazil, Dominican Republic and Argentina.

The transportation service was a representation of 34.40% of total contacts services. The countries with the highest export value were Chile, Brazil and Panama and Argentina. The shuttle showed an annual growth of 11.9% with a higher share of Mexico and Chile; air transport by 8.2% load with greater participation of Uruguay, Argentina, Brazil and Colombia and the passenger a 9.4% stake. Brazil was the most exported marine services by loads followed by Panama, Chile and Argentina.

Exports of personal and cultural services (services related to culture, recreational services, audiovisual, education and health) totaled 715,443 million dollars in 2012, which accounted for 0.93% of total contacts services. (Table 2). The countries with greater representation were Argentina, Ecuador and Mexico, respectively. In Table 2.1 we observe that this service had the lowest average growth rate, with only 2.3% annual.

In business services, with lower added value was not possible to verify its weight due to aggregation of data. Agricultural services and mining, accounted for as a part of business services, have an average annual growth rate of 101.6%. Only Brazil, Argentina and Costa Rica exported such services.

### **3. 2 Shared services**

In 2012, exports of shared services totaled 49,167,847 million (Table 3). The country with the largest representation was Brazil with more than half of total exports, followed by Argentina and Chile. Shared services which were more exported were business, IT and computing, and financial.

The communication service had a share of 6.54% of the total shared services with Brazil, Panama and Guatemala countries that exported more this service and Paraguay, Costa Rica and Haiti the least exported. This service had an average annual growth rate of 5.9% (Table 3.1). In the e-mail and messaging services, Argentina stood out for higher volume exported followed by Venezuela. The telecommunication service the highlights were Mexico, Brazil and Colombia (table 3.2).

With regard to building service, Argentina is the largest exporter, beating Brazil in 2012. This was the service with the lowest representation, with 12.16% of total exports of shared services. The average annual growth rate of the construction service exports in Latin America was 6.0% (Table 3.1).

In insurance, Mexico was the country that exported more, followed by Brazil and Peru. Costa Rica, Haiti and Ecuador had no exports in 2012. This service represented 7:54% of all shared services. In Table 3.1, it appears that the insurance service had an average annual growth rate of 10.3%. El Salvador, Ecuador, Panama exported services of life insurance and pension fund.

**TABELA 2.1- América Latina: taxa de crescimento anual das exportações de serviços de contatos, 2003-2012**

Fonte: TradeMap(2014)

In Freight insurance services, the main exporters were Guatemala, Brazil and Panama. Mexico, Honduras and Peru were the main exporters of reinsurance service. Ancillary services were exported by Brazil, Paraguay and Argentina (Table 3.2). In financial services, Brazil has more than half of the total contribution, followed by Panama and Chile. The average annual growth rate of exports in the 2003-2012 was 18.6% (Table 3.1).

Regarding the IT service and computing Argentina participated with 36.6% of the total and Costa Rica with 38.0%. Mexico, Ecuador, and Haiti did not export this service. Table 3 shows that this service had a share of 9.90% of the total shared services. The average annual growth rate was 27.8% (Table 3.1).

Fonte: Trade Map (2014)

In Royalties & License Services, Brazil stands out for having the largest representation in exports. The average annual growth rate for this service was 10.8% (Table 3.1). Business services were the most exported by Latin America in 2012, with the value of 32,098,223 million, representing 65.28% of shared services. The largest exporters in 2012 were Brazil and Argentina (Table 3). The average annual growth rate (table 3.1), was 16.7% .

Table 1 summarizes the main information on imports and exports of services in each country in Latin America. Can be observed that exports of contact services are concentrated in travel and transport services in all countries (except Cuba) and shared services in business, communication, financial services and insurance. Imports of contact services are basically transport and travel to all countries; and shared services in most countries correspond to business and insurance. Competence development services showed no records of exports and imports in Latin America during these years. Regarding the trade balance, this presents a deficit every year in most countries.

#### **4 CONCLUSION**

By analyzing the flow of services from Latin American countries except Cuba, divided into three categories: contact services, shared services and services for skills development, are found that:

i) In the year 2012, contacts services were marketed more towards shared services. There has been a marked concentration in the category of travel, which refers mainly to tourism, with emphasis on Mexico and Brazil, and services shared the highlights were, Brazil and Argentina with a large stake in the business services, informatics and information and financial .

ii) In the years 2002 to 2012, the trade balance of services in Latin America was deficient, however in an analysis by country, only Panama, Costa Rica, Dominican Republic, Uruguay have a surplus balance in services every year.

Generally countries with large volume of exports of services have further increased volumes of service imports, thus presenting deficit trade balance. The possibility to increase exports and reduce deficits is one of the main reasons which justify specific public policies for this sector.

**QUADRO 1- Summary of imports and exports in Latin America, 2002-2012**

|                    | Exports              |  | Imports              |                                   | Trade balance          |                          |

Services related to international travel are the most significant in deficits in most countries. The increase in the deficit on international travel is problematic because trips are not direct inputs to add value or product differentiation, being much related to leisure and entertainment.

Of the twelve countries with trade balance surplus, all belong to the region of Central America (except Argentina, Chile, Uruguay and Paraguay). Thus the region of Central America has great potential for the production of services and therefore for export. Although the database can not identify the destination of exports, it is assumed that in view of strong economic bond of the countries of central region with the United States most of the exports of services in this region are aimed at Americans.

For South America one policy to increase exports could be to incorporate services into goods in order to create new types of trade specialization. The incorporation of services into commodities (servitization) could be a complementary approach to their industrial processing. This strategy yield benefits also in terms of employment creation, technical progress, product diversification and quality improvement.

iii) Although travel and transport (contact services) have the largest shares, the rates of growth of shared services indicate changes in the region. These changes may be related to the growth (upgrading) of manufacturing activities related to FDI and also with FDI inflows linked to offshoring of various services. Thus, the participation of Latin America in the value chain in services can be crucial for their development.

The challenge is the competitiveness of exports of services to improve the ability of countries to attract or retain in its territory the segments of higher value-added services. To this end, countries should expand institutions to encourage the growth of exports of services. Institutions to develop services should facilitate the creation of specific instruments and public goods category, as an inexpensive common telecommunications infrastructure and transport, access to skilled labor with international certificates and agreements that allow free qualified labor movement

# **La compétitivité des entreprises locales face aux multinationales dans les pays sous-développés d'Afrique : le rôle de la qualité des services**

Birahim GUEYE, Dan Rani Guero Bilyaminou & Chabi Benoit Kpassi Gobi

Laboratoire Saint-Louis Etudes et Recherche en Gestion

Université Gaston Berger de Saint-Louis du Sénégal

## **Résumé**

Depuis environ deux décennies, les marchés des pays sous-développés sont la cible des grandes firmes multinationales. Ces dernières ont des moyens financiers et techniques dont ne disposent pas les entreprises locales, qui sont pour la plupart des micros, petites ou moyennes entreprises. Aussi, les entreprises étrangères ont le bénéfice d'une image de marque et une réputation de qualité plus importantes, cela notamment en raison de la forte diffusion des TIC et l'accès aux chaînes de télévisions étrangères qui font la publicité de ces grandes marques. Il est également possible d'expliquer l'attrait des marques des entreprises multinationales comme étant une des conséquences de la colonisation des pays africains où le mythe du "blanc" est encore très vivace au sein des populations.

Dans un contexte aussi défavorable pour les entreprises locales, comment ces dernières peuvent-elles tirer leur épingle du jeu? Cette question mérite d'être posée car il est difficile aujourd'hui de citer des champions locaux dans la quasi-totalité des secteurs d'activité où ce sont très souvent les entreprises étrangères qui dominent le marché. Dans cet article, nous faisons l'hypothèse que les entreprises locales pourraient jouer sur les services (Vargo & Lusch, 2004), notamment leurs dimensions intangible, immatérielle et "culturelle" ou "locale" (Vargo & Lusch, 2008b), pour renverser la tendance en leur faveur.

Pour tester cette hypothèse, nous avons choisi d'étudier le positionnement stratégique des entreprises locales dans le marché fortement concurrentiel (d'Aveni, 1997) de la distribution des hydrocarbures au Sénégal. Ce marché est dominé par les "majors", des entreprises multinationales telles que Total et Shell. La présente étude sera de nature exploratoire par la méthode des cas (Yin, 2009). Ainsi, notre choix s'est porté sur deux acteurs locaux importants dans le marché des hydrocarbures au Sénégal. Il s'agit de Elton et EDK qui se caractérisent par leur positionnement essentiellement basé sur la création de valeur pour les clients en leur offrant une diversité de services. Nous démontrons dans cette recherche que les entreprises locales peuvent affronter les multinationales à travers la proposition d'une expérience-client différenciée et innovante. Elles peuvent réaliser une croissance durable en misant sur des services de qualité à travers certaines dimensions (Vargo & Lusch, 2008a) spécifiques pour se différencier des concurrents.

## Introduction

La concurrence entre entreprises locales et FMN semble être devenue une thématique intéressante de recherche à partir de la fin des années 1990 et du début des années 2000 (Dawar et Frost, 1999 ; Gorynia et Wolniak, 2000 ; Lavie et Fiegenbaum, 2000 ; Li, 2002 ; Grosse, 2003 ; Zeng et Williamson, 2003).

En Afrique, la libéralisation économique qui a marqué les deux dernières décennies du 20<sup>ème</sup> siècle a contribué à accentuer les défis auxquels devaient faire face les acteurs économiques locaux. Cette libéralisation s'est caractérisée par une arrivée massive des multinationales. L'arrivée des firmes multinationales sur un marché d'un pays émergents s'apparente le plus souvent à une sentence de mort contre les entreprises locales (Dawar et Frost, 1999). Zhang (2008) affirme d'ailleurs que les multinationales visent souvent à défenestrer purement et simplement les entreprises locales de leurs propres marchés domestiques.

Cette tendance pourrait se justifier par la saturation des marchés domestiques des multinationales et/ou de la forte croissance enregistrée dans les pays sous-développés. Elle pourrait également s'expliquer par l'émergence et le développement d'une classe moyenne dans les pays sous-développés, la participation des femmes à la vie active, et dans certains cas la possibilité d'accéder à des ressources stratégiques par l'implantation locale. Ces firmes multinationales ont des moyens financiers et techniques dont ne disposent pas les entreprises locales. Aussi, les entreprises étrangères ont le bénéfice d'une image de marque et une réputation de qualité plus importantes, cela notamment en raison de la forte diffusion des TIC et l'accès aux chaînes de télévisions étrangères qui font la publicité de ces grandes marques. Il est également possible d'expliquer l'attrait des marques des entreprises multinationales comme étant une des conséquences de la colonisation des pays africains où le mythe du "blanc" est encore très vivace au sein des populations.

Dans un contexte aussi défavorable pour les entreprises locales, comment ces dernières peuvent-elles tirer leur épingle du jeu ? Cette question mérite d'être posée car il est difficile aujourd'hui de citer des champions locaux dans la quasi-totalité des secteurs d'activité où ce sont très souvent les entreprises étrangères qui dominent le marché. Dans cet article, nous faisons l'hypothèse que les entreprises locales pourraient jouer sur les services (Vargo & Lusch, 2004), notamment leurs dimensions intangible, immatérielle et "culturelle" ou "locale" (Vargo & Lusch, 2008b), pour renverser la tendance en leur faveur.

Pour mener cette étude de nature exploratoire, au niveau des pays en développement, nous avons choisi une démarche qualitative. Nous nous sommes intéressés à un secteur en pleine mutation et fortement concurrentiel au Sénégal : celui de la distribution des hydrocarbures qui est un secteur soumis à une régulation stricte de la part des autorités publiques. Ce secteur dominé, pendant longtemps, par les FMN que l'on qualifie de majors dans le jargon spécialisé, voit l'arrivée d'acteurs nationaux que depuis récemment. C'est seulement en la faveur de la loi 98-31 du 14 avril 1998 libéralisant les secteurs du transport et de la distribution des hydrocarbures que l'on a vu émerger des acteurs locaux plus ou moins importants dans ce secteur. Malgré l'adversité et les difficultés, ces acteurs ont cependant su se faire une place au soleil. Ainsi, entre 2005 et 2012<sup>1</sup>, les parts de marché cumulées de ces acteurs locaux (indépendants et réseaux de distribution intégré) sont passées de 12,47% à 37,58% pour le réseau terre et de 18,37% à 67,09% pour le réseau pêche. Avec une telle percée spectaculaire, les entreprises locales sénégalaises de distribution des hydrocarbures peuvent être citées en exemples de réussites locales. Ceci justifie l'étude de leur positionnement stratégique et de ses soubassements afin de voir en quoi ces expériences peuvent enrichir la littérature et le débat autour de la concurrence entre FMN et entreprises locales de façon particulière et de façon générale les relations de concurrence asymétriques. De même elle peut avoir une portée éminemment pratique en ce sens que des pistes de positionnement stratégique et de construction d'avantages concurrentiels peuvent être clairement dégagées.

Dans le cadre de cette recherche nous nous attardons d'abord sur le débat autour de la concurrence entre FMN et entreprises locales. Nous présentons par la suite l'approche de la Service Dominant Logic (SDL) qui nous sert de cadre d'analyse. Nous exposons ensuite la démarche méthodologique adoptée avant de présenter les principaux résultats de la recherche et enfin la conclusion.

## **1. La problématique de la concurrence entre FMN et entreprises locales**

Il a été largement admis, et pendant longtemps, que les entreprises locales n'ont aucune chance de faire bonne figure dans un marché auquel s'attaquent des FMN (Dawar et Frost, 1999 ; Mathews, 2006). Au mieux, de l'avis même de certains dirigeants d'entreprises locales, trois options « stratégiques » de survie s'offraient à des entreprises locales dont les marchés domestiques sont attaqués par des FMN (Dawar et Frost, 1999). Il s'agit :

- D'un retrait pur et simple de l'entreprise locale du marché ;

---

<sup>1</sup> Numéro spécial Magazine Réussir Mai-Juin 2014

- D'un interventionnisme étatique pour freiner les FMN ;
- D'une capitulation déguisée pour être absorbée par les FMN et devenir ainsi un « vassal » pour elles.

Selon cette thèse, il serait inutile, voire suicidaire, pour une entreprise locale de vouloir user de stratégies offensives à même de lui permettre de prospérer face à la concurrence des multinationales étrangères.

Cependant, à partir de la fin du siècle dernier, quelques chercheurs (Dawar et Frost, 1999 ; Gorynia et Wolniak, 2000, 2005 ; Lavie et Fiegenbaum, 2000 ; Li, 2002 ; Grosse, 2003 ; Zeng et Williamson, 2003 ; Jaffe et al., 2005 ; Xie et White, 2005, 2010 ; Khanna et Palepu, 2006 ; Mathews, 2006 ; Wu et Pangarkar, 2006 ; Arindam et al., 2008 ; Chang et Xu, 2008 ; Poulis et al., 2011 ; Ramamurti 2012 ; Barki et al., 2012 ; Azmeh et Nadvi, 2014) se sont mis à s'intéresser à la problématique de la concurrence entre FMN et entreprises locales en termes de stratégies pouvant conduire au triomphe des entreprises locales. L'une des particularités de ces recherches est qu'elles se focalisent généralement sur la confrontation entre FMN et entreprises locales dans des pays dits émergents. La question essentielle que posent les chercheurs est alors de savoir s'il existe une ou des stratégie(s) qui pourraient permettre aux entreprises locales de ces pays émergents de construire un ou des avantage(s) concurrentiel(s) qui pourraient les conduire à des performances solides et soutenues.

Dans de nombreux pays dits émergents, on a assisté, à bien des égards, à une opposition farouche entre des firmes multinationales et des entreprises locales. En effet, alors que les multinationales profitaient de l'ouverture progressive des marchés pour exporter ou s'implanter dans ces pays (Dawar et Frost, 1999 ; Lavie et Fiegenbaum, 2000), certaines entités locales ont pu se développer de façon spectaculaire à tel point qu'on est arrivé à parler de multinationales émergentes pour certaines d'entre elles (Mathews 2006 ; Xie et White, 2005, 2010). Pour essayer de contrer la puissance financière, l'expérience, le savoir faire et la notoriété des multinationales ; ces entreprises locales ont mis en œuvres diverses stratégies grâce à divers avantages concurrentiels dont elles ont pu se doter.

Tout d'abord, les entreprises locales sont supposées avoir une plus grande facilitée à construire une meilleure adaptabilité de leurs réseaux de distribution et à en assurer une meilleure couverture (Dawar et Frost, 1999 ; Lavie et Fiegenbaum, 2000 ; Li, 2002 ; Grosse, 2003 ; Jaffe et al., 2005 ; Xi et White 2005 ; Barki et al., 2012). De même, elles sont réputées avoir une meilleure maîtrise des aspects culturels locaux qui peuvent conférer une plus grande

valeur, une plus grande visibilité et une plus grande notoriété dans l'esprit des consommateurs à travers une « *connaissance intime* » de ceux-ci (Arindam et al., 2008). L'avantage dont disposent les entreprises locales peut aussi se traduire par des campagnes de communication mettant en avant des vedettes de la scène culturelle locale à travers ce que Barki et al., (2012) qualifie de « *proximité émotionnelle* » (Dawar et Frost, 1999 ; Xie et White, 2005 ; Xie et White, 2010 ; Barki et al., 2012). Dans ce cas, on peut donc considérer que les entreprises locales peuvent considérer les spécificités socioculturelles comme des facteurs clés de succès en leur faveur. La meilleure maîtrise de ces spécificités constituerait ainsi un avantage concurrentiel notamment par rapport la distribution des produits et de la communication autour de ceux-ci.

En outre, des croyances locales particulières sont susceptibles d'influencer la perception des consommateurs. De telles croyances peuvent notamment être relatives au bien-être physique (considérations sanitaires et hygiéniques) et/ou psychique (considérations spirituelles et religieuses) que procurent les produits et/ou services des entreprises locales (Lavie et Fiegenbaum, 2000 ; Xie et White, 2005, 2010 ; Wu et Pangarkar, 2006 ; Zhang, 2008). Ces perceptions peuvent alors devenir des déterminants sur lesquels les entreprises pourraient jouer pour renforcer l'apriori d'une meilleure qualité de leurs produits et services. De même, les entreprises locales peuvent disposer d'une meilleure maîtrise des réalités sociales et/ou climatiques locales qui sont souvent inédites pour les multinationales. Ceci peut notamment permettre à ces entreprises d'offrir des produits et services présentant une meilleure adéquation par rapport à de telles réalités (Lavie et Fiegenbaum, 2000 ; Ramamurti, 2012). Dans cette perspective, les éléments des croyances locales, des goûts locaux et des conditions socio-écologiques locales deviennent donc pour les entreprises locales des facteurs clés de succès. Elles pourraient ainsi en tirer un avantage concurrentiel en termes de qualité perçue par les consommateurs des offres de ces entreprises.

Les éléments de stratégies identifiées ci-dessus permettent d'avoir la certitude qu'il est possible pour des entreprises locales de lutter et d'être performantes face à des multinationales qui s'attaquent à leurs marchés domestiques. Cela est d'autant plus sûr que des entreprises des pays émergents ont pu le faire au point de se transformer en multinationales pour certaines d'entre elles (Mathews, 2006). Ainsi, la question pertinente que l'on doit se poser n'est plus de savoir s'il est possible pour des entreprises locales des pays en développement de pouvoir faire la même la chose. Il serait plutôt plus judicieux de se demander comment ces entreprises

locales des pays en développement pourraient parvenir à faire la même que certaines de leurs semblables des pays émergents.

S'il y a une constante que l'on peut dégager concernant les leviers stratégiques, ci-dessus, identifiées par différents auteurs comme pouvant être à la base des succès des entreprises locales des pays émergents face aux FMN ; c'est la valorisation de leur offre par la clientèle. En effet, il transparaît que les entreprises locales s'appuient moins sur la qualité intrinsèque de leurs produits que sur la façon dont les consommateurs locaux les valorisent dans leurs esprits. Cette valorisation tient pour beaucoup aux services que les clients se voient offrir et notamment à certaines dimensions intangibles de ces services. Il est, dès lors, permis de penser que la concurrence se fait sur la base d'une logique dominante du service rendu au consommateur ou perçu comme tel par lui. Cela fonde l'intérêt de mobiliser le paradigme de la Service-Dominant Logic comme cadre d'analyse dans cette recherche.

## **2. Le paradigme de la Service-Dominant Logic**

Pendant longtemps et de façon traditionnelle, la littérature en marketing a mis en avant le produit et certaines de ses attributs comme les principales sources d'avantages concurrentiels (Vargo et Lusch, 2004a ; Lusch et al., 2007 ; Vargo et Lusch, 2007 ; Besson et Moreno, 2009 ; Vargo et Lusch 2008a ; Vargo et Lusch, 2008c ; Vargo et Akaka, 2009). À titre d'illustration, l'une des visions les plus célèbres développée en marketing, celle des « 4P », tourne fondamentalement autour du produit à bien des égards et de l'échange dont il peut faire l'objet. En effet, même si les différentes composantes sont assez distinctes, de façon plus ou moins évidente, on peut renvoyer chacune des trois autres à celle du produit :

- Le produit doit être au bon prix ;
- Le produit doit être à la bonne place ;
- Le produit doit avoir la bonne presse.

Ce n'est d'ailleurs pas étonnant si l'une des premières définitions que l'on a donné au marketing, celle de l'American Marketing Association (AMA) dans les années 1930 ; est qu'il est « *un ensemble de mesures prises afin de permettre au producteur d'écouler ses produits et services auprès du consommateur*<sup>2</sup> » (Kotler et al., 2004). Cette vision et cette définition s'inscrivent dans ce que l'on a qualifié de paradigme de la « Goods-Dominant » Logic (GDL) (Vargo et Lusch, 2004a ; Lusch et al., 2007 ; Ballantyne et Varey, 2008 ; Vargo et al., 2008 ;

---

<sup>2</sup> Traduction libre

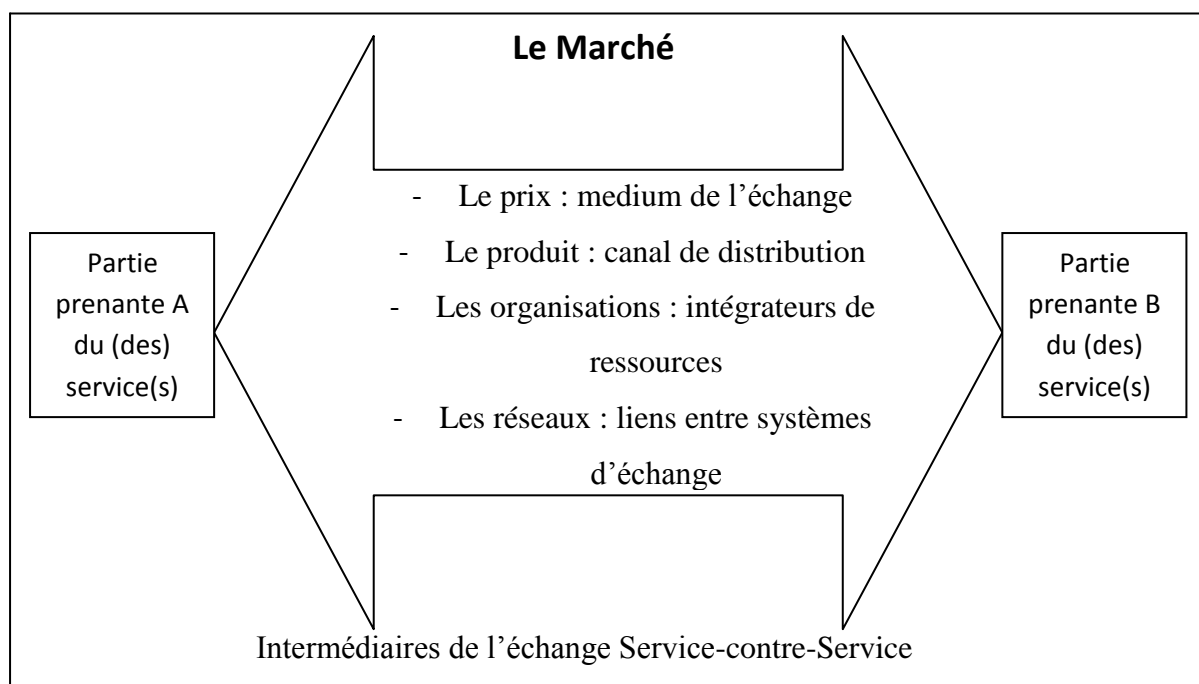

Vargo et Lusch, 2008a ; Vargo et Lusch, 2008b ; Vargo et Lusch, 2008c ; Vargo, 2008 ; Vargo et Akaka, 2009). Cette logique consiste à considérer que l'entreprise crée de la valeur qu'elle met à la disposition du consommateur au travers de son produit. En échange, le consommateur paie l'équivalent de ce produit en argent (Vargo et Lusch, 2004a ; Vargo et al., 2008 ; Vargo et Akaka, 2009). Le client serait donc intéressé, non par la valeur du produit qu'il achète, mais par le produit en tant que tel. Cette conception relève notamment de la théorie économique néoclassique qui sous-tend la vision traditionnelle du marketing (Vargo et Lusch, 2004a ; Vargo et Morgan, 2005 ; Moreno et Besson, 2009 ; Vargo et Akaka, 2009).

À partir des années 1990, plusieurs voix se sont mises à remettre en cause l'évidence de la pertinence des théories marketing s'inscrivant dans la vision classique dont l'origine remonte aux années 1950 (Moreno et Besson, 2009). L'une des remises en causes parmi les plus tranchantes de cette vision traditionnelle du marketing est celle défendue par Gummesson (1993) qui « *mettait déjà en évidence que les clients n'achètent pas des biens ou des services, mais qu'ils achètent des offres qui créent de la valeur* » (Moreno et Besson, 2009). En fait, les évolutions multiples et souvent radicales et spectaculaires apparues dans l'environnement économique ces dernières années rendraient caduques beaucoup de présupposés sur lesquels se fonde cette vision classique du marketing (Vargo et Lusch, 2004b ; Moreno et Besson, 2009 ; Lusch et al., 2007 ; Vargo et al., 2008 ; Béji-Bécheur, 2010). C'est ainsi que Vargo et Lusch (2004a) vont proposer une (r)évolution « *paradigmatique* » majeure afin de prendre en considération l'ensemble des paramètres induits par ce nouveau contexte. Il s'agira de passer de la « Goods-Dominant » Logic (GDL) à la « Service-Dominant » Logic (SDL). Il faut néanmoins garder à l'esprit que si la « Goods-Dominant » Logic peut être considérée comme un paradigme à part entière (Vargo et Lusch, 2008a ; Vargo et Lusch, 2008b ; Vargo et Lusch, 2008c ; Vargo et Akaka, 2009 ; Béji-Bécheur, 2010), la « Service-Dominant » Logic ne le serait pas encore totalement (Vargo et Lusch, 2008c ; Vargo, 2008).

Dans cette nouvelle approche la notion de service, au sens de rendre service (Béji-Bécheur, 2010), devient une (la) notion centrale (Vargo et Lusch, 2004a ; Vargo et Lusch, 2004b ; Béji-Bécheur, 2010). Ici, le service, au singulier, pourrait être considéré comme « *un processus de faire quelque chose pour quelqu'un* » (Vargo et Lusch, 2008a). Mieux encore, on peut le définir d'une façon englobante (Béji-Bécheur, 2010) comme étant « *l'application de compétences spécialisées (connaissances et savoir-faire), au travers des actions, processus, et performances pour le bénéfice d'une autre entité ou pour l'entité elle-même* » (Vargo et Lusch, 2008c). Cette définition du service centrée autour des connaissances et du savoir-faire

permet de considérer que le service est l'élément clé qui permettrait, sinon la construction, assurément l'exploitation d'avantages concurrentiels par une entreprise (Vargo et Lusch, 2004a ; Lusch et al., 2007 ; Vargo et Lusch, 2008b ; Vargo et al., 2008).

La SDL « propose de ré examiner la vision dominante centrée autour des échanges de produits pour lui substituer une logique centrée autour des échanges de service » (Moreno et Besson, 2009). Elle propose d'aller au-delà des simplifications qui justifient l'orientation produit et même celles qui justifient l'orientation marché (consommateur) pour considérer une orientation dite « Service » (Lusch et al., 2007). Il faudra donc parler, dès lors, des réseaux ou coalitions d'acteurs qui interagissent pour délivrer des services les uns aux autres dans des relations complexes (Lusch et al., 2007 ; Vargo et Lusch, 2008a ; Vargo et Lusch, 2008c ; Ballantyne et Varey, 2008 ; Vargo et Akaka, 2009). Ainsi apparait, en marketing, la notion de parties prenantes qui s'échangent des services dans le but de se satisfaire mutuellement. Le produit ne devient, dès lors, qu'une manière, un intermédiaire parmi tant d'autres qui permet de délivrer de la valeur : le service mutuellement rendu aux uns et aux autres (Vargo et Lusch, 2004a ; Vargo et al., 2007 ; Vargo et Lusch, 2008b ; Vargo et Lusch, 2008b ; Vargo et al., 2008 ; Moreno et Besson, 2009). Les autres intermédiaires les plus évoqués sont le prix, les organisations et les réseaux (Vargo et Akaka, 2009 ; Moreno et Besson, 2009).

Ainsi, la conception selon laquelle le service est la base des échanges constitue la première proposition parmi les dix auxquels vont aboutir les travaux sur la SDL (Vargo et Lusch, 2004a ; Lusch et al., 2007 ; Vargo et Lusch, 2008b ; Vargo et Akaka, 2009). L'ensemble de ces propositions ainsi que leurs justifications sont reprises dans le tableau ci-dessus.

|      | Proposition   | Justification  |
|------|---|--|
| FP1  | Le service est la base des échanges   | Le service est échangé contre un autre service   |
| FP2  | Les échanges indirects masquent la base réelle d'échange.   | Les produits, la monnaie et les institutions masquent l'échange de base qu'est le service pour un service.                     |
| FP3  | Les biens sont des vecteurs de distribution du service.   | La valeur des biens (durables ou consommables) est définie par leur usage, par le service qu'ils fournissent.                  |
| FP4  | Les compétences spécialisées et connaissances constituent la principale source d'avantage compétitif. | La capacité comparée à provoquer les évolutions souhaitées guide le jeu concurrentiel.   |
| FP5  | Toutes les économies sont des économies de service.   | Le service devient plus apparent aujourd'hui du fait de la spécialisation accrue et de l'externalisation.                      |
| FP6  | Le client est toujours co-créateur de valeur.   | La création de valeur se fait dans l'interaction.  |
| FP7  | L'entreprise ne peut pas délivrer de valeur ; elle ne peut que faire des propositions de valeur.      | L'entreprise peut proposer ses ressources pour la création (interactive) de valeur mais ne peut pas la créer / délivrer seule. |
| FP8  | Une logique centrée sur le service est naturellement orientée client et relation.                     | Le service est déterminé et co-créé par le client ; de ce fait il est naturellement orienté client et relationnel              |
| FP9  | Tous les acteurs économiques et sociaux sont des intégrateurs de ressources.                          | Le cadre de la création de valeur c'est le réseau des réseaux, l'intégration de ressources complémentaires.                    |
| FP10 | La valeur est toujours déterminée de façon unique et phénoménologique par le bénéficiaire.            | La valeur est idiosyncratique, contextuelle et chargée de sens.  |

Ces évolutions dans les approches théoriques en termes de logiques vont induire une évolution par rapport aux différents concepts et discours grâce auxquels on explique la nature des relations qui existent entre les parties prenantes (Vargo et al., 2008 ; Vargo et Akaka, 2009 ; Béji-Bécheur, 2010).

**Tableau traduit de Lusch et Vargo, (2006 : 286)**

| Concepts GDL           | Concepts de transition | Concepts SDL            |
|------------------------|------------------------|-------------------------|
| Biens                  | Services               | Service                 |

Source : Béji-Bécheur (2010)

L'une des évolutions conceptuelles les plus remarquables de la SDL est celle qui a consisté à marquer le passage de la focalisation sur le concept de la valeur ajoutée à ce lui de la co-crédation de la valeur. Désormais la concurrence, qui se fera au travers du service (Lusch et al., 2007), nécessitera l'implication effective et affective des consommateurs dans la co-crédation de ce service (Lusch et al., 2007 ; Vargo et al., 2008 ; Vargo et Lusch, 2008b).

Ainsi nous avons choisi de nous focaliser sur trois propositions parmi celles proposées dans l'approche SDL.

Au Sénégal, le secteur des hydrocarbures étant étroitement régulé et réglementé, avec notamment des tarifs uniques fixés par l'autorité publique, on peut supposer que le positionnement stratégique des entreprises du secteur se fait essentiellement sur la base du service rendu aux clients.

P1 : Le service, base des échanges, et la qualité du service sont la base essentielle des positionnements stratégiques des entreprises de distribution d'hydrocarbure au Sénégal (FP1).

Par ailleurs, les multinationales disposant des moyens nettement plus importants et d'une image de marque qui est plutôt en leur faveur, les entreprises sénégalaises de distribution d'hydrocarbure peuvent et doivent s'appuyer sur les connaissances et la maîtrise des spécificités socioculturelles locales pour réussir face aux majors du secteur.

P2 : Les compétences spécialisées et connaissances constituent la principale source d'avantage compétitif (FP4).

Les entreprises sénégalaises de distribution d'hydrocarbure peuvent optimiser leurs avantages concurrentiels au détriment des multinationales en impliquant davantage le client dans le processus de création de valeur et en faisant de lui un co-acteur à part entière de leurs activités.

P3 : Le client est toujours co-crédateur de valeur.

### 3. Méthodologie

L'objectif poursuivi dans cette étude est d'explorer les réponses stratégiques des entreprises locales sénégalaises du secteur de la distribution des hydrocarbures confrontées à la concurrence des « majors ». Nous avons opté pour une démarche d'études de cas (Yin, 2003) et avons choisi d'étudier de manière exploratoire les réponses stratégiques mises en œuvre par Elton et EDK.

Comme cela a été déjà précisé, le marché des hydrocarbures au Sénégal a pendant longtemps été dominé par les « majors » Total et Shell. À ces deux grands acteurs est venu s'ajouter le libyen Oilybia qui a racheté le réseau de Mobil. Cette configuration va changer avec le vote de la loi 98-31 du 14 avril 1998 libéralisant le marché. C'est en l'an 2000, dans la foulée de la première alternance politique à la tête de l'état, qu'une entreprise sénégalaise, ELTON, va s'engager dans ce secteur dont les barrières à l'entrée sont très élevées du fait de l'importance des capitaux nécessaires mais surtout les difficultés d'accès au pétrole lorsque le pays n'en produit pas malgré l'existence de la Société africaine de Raffinage chargée d'approvisionner les distributeurs.

C'est à ce double défi qu'une poignée de sénégalais s'est attaquée pour bâtir ce qu'ils vont fièrement nommer "la première entreprise hydrocarbure 100% sénégalaise", le Groupe ELTON. Pour se faire une place, l'entreprise se devait d'offrir une gamme de produits et de services pouvant apporter une valeur supplémentaire aux clients. C'est ainsi que le concept Oasis fut présenté comme une offre différente, un cadre où automobilistes et autres personnes voulant trouver un endroit où se désaltérer et se restaurer peuvent se retrouver. Ainsi, l'entreprise se positionne comme une alternative aux géants du secteur.

L'orientation stratégique revendiquée par l'entreprise est fondée sur "l'expertise et la capacité d'adaptation de nos hommes, la qualité du service au client, la mise en œuvre d'une politique rigoureuse de sécurité et de protection de l'environnement, valorisant (l') image d'entreprise citoyenne, responsable et professionnelle" selon les dires de Manar Sall, le nouveau DG de la holding ELTON International. Pour la réussite de sa stratégie, l'entreprise déploie une multitude d'activités regroupées autour des grands axes suivant:

- Distributeur de produits et services pétroliers à travers un réseau de station-service et pompe pêche
- Offre de services diversifiés dans le réseau de Boutique Eden's et d'Espace Auto et d'Espace d'E-Services

- Fournisseurs de produits et services liés aux carburants et lubrifiants aux industriels des PME et PMI mais aussi aux grandes entreprises du secteur minier

- Représentant exclusif de la marque de Lubrifiants Castrol au Sénégal et dans la sous région
- Exporte des produits pétroliers dans la sous région (Mali , Guinée, Guinée Bissau)

Fondé en 2009 par un ancien émigré sénégalais aux Etats Unis et au Japon, EDK (Etablissements Demba Kâ, du nom fondateur de l'entreprise), se veut être « un ensemble de stations multiservices d'essence, gasoil, mais aussi d'entretien tous véhicules, de supérettes, de restaurants, de fast-food, de boulangeries, de pâtisseries et de banques crédit-agricoles ». L'entreprise exploite aujourd'hui un réseau de onze (11) stations multiservices dans plusieurs parties du pays. La majorité d'entre elles sont situées à l'entrée (la sortie) des grandes agglomérations sur la route nationale. Ce positionnement est assimilable à celui des aires de repos au niveau des grandes autoroutes dans les pays occidentaux. L'investissement moyen pour bâtir une station est estimé autour de 500 millions de francs CFA.

Le fondateur est présenté comme un autodidacte qui a profité de ses voyages pour imaginer le concept EDK. Sa démarche n'a pas été planifiée. Dans la foulée de la loi libéralisant la distribution des produits d'hydrocarbures, M. Kâ a créé sa petite station dans une zone résidentielle en devenir. Il a rencontré au départ des vagues de protestation du voisinage qui n'a pas toujours apprécié cette implantation malgré la participation de l'entreprise à des projets d'utilité publique notamment l'assainissement de la zone. Sa stratégie s'affirme véritablement avec l'ouverture de la première station multi-services à Bargny à la sortie de Dakar (à environ 30 Kms). L'adhésion populaire des usagers de la route mais également des populations locales qui trouvent en l'endroit un lieu de vie vont convaincre le promoteur de poursuivre sur cette voie. Des ouvertures emblématiques vont suivre dans des villes symboliques : grands centres religieux (Touba et Tivaoune), carrefours internationaux (Saint-Louis, Kaolack), etc.

L'entreprise, pour assurer son développement, est aujourd'hui portée vers le recrutement de professionnels dans les domaines techniques, administratives, financières et commerciales. Les stations sont en gérance directe depuis le siège à Dakar. Les gérants sur place sont des managers-salariés. Ce choix engendre d'importants coûts de gestion et de coordination à cause notamment des longues distances pouvant séparer le siège et quelques unes des stations. Saint-Louis est 270 Kms tandis que Kaolack est à 200 Kms.

Nous avons effectué au moins 30 entretiens formels. Les personnes interrogées ont la plupart du temps objecté le fait de ne pas avoir l'autorisation formelle de leur hiérarchie. Nous n'avons donc pas pu enregistrer les entretiens sauf pour le Gérant de la station EDK de Saint-Louis. Nous avons également pu récupérer deux entretiens du Directeur Générale d'ELTON paru dans la presse écrite (Magazine Réussir, mai-juin 2014) et une vidéo (diffusée par la chaîne panafricaine Africa 24). Ces données ont été complétées par d'autres de sources secondaires (presse nationale et internationale), sites institutionnels des entreprises, rapport sur le secteur au Sénégal. L'ensemble des données exploitées avoisine 300 pages.

Toutes nos données ont fait l'objet d'analyse de contenu après retranscription des entretiens audio (Miles & Huberman, 1994 ; Blanchet & Gotman, 2001 ; Mucchielli, 1998). Nous avons poursuivi une logique inductive en eux deux phases : une première phase de catégorisation afin d'identifier les grands axes thématiques pouvant nous permettre d'apprécier les réponses stratégiques des deux cas étudiés. Dans la deuxième phase de notre analyse, nous avons cherché comment les différents thèmes revenaient dans les données collectées.

#### **4. Résultats**

Notre étude a révélé que les facteurs sur lesquels jouent les deux entreprises étudiées (Elton et EDK) pour être compétitifs dans le secteur de la distribution des produits hydrocarbures au Sénégal sont :

- Le professionnalisme
- L'innovation et l'accroissement de la valeur pour les clients : une station devient un « lieu de vie »
- La connaissance client et la proximité socio culturelle
- La personnalisation de la relation client
- Avoir une responsabilité sociétale

#### **L'importance d'avoir une image professionnelle**

Le carburant est un produit sensible. Pour avoir la même reconnaissance, sinon plus, que les entreprises multinationales, les entreprises locales doivent manifester une attitude professionnelle à tout point de vue. D'abord au niveau des produits. Ils doivent ainsi s'approvisionner chez le même fournisseur que les majors. Au Sénégal, le fournisseur

reconnu par les autorités étatiques est la Société Africaine de Raffinage (la SAR). Au-delà du choix du fournisseur, les entreprises étudiées veillent à réduire le risque de comportement opportuniste des transporteurs qui sont des indépendants à l'égard aussi bien des distributeurs que de la SAR. Ainsi, comme le rapporte le gérant de la station EDK de saint-Louis :

*« Quand le camion arrive au niveau de la station, y a une température et une densité qu'on écrit sur leur feuille de route. C'est au niveau de sa sortie au niveau du dépôt. Cette température là et cette densité là doivent être les mêmes à l'arrivée à la station, à quelques degrés variables, en fait avec une marge d'erreur. Arrivée au niveau de la station on a un thermo-densimètre pour vérifier cette température et cette densité, pour vérifier la qualité du produit. »*

Elles veillent ainsi à offrir aux clients qui viennent s'approvisionner dans leurs stations la meilleure qualité de carburant possible sur le marché. Des tests journaliers sont également effectués pour éviter que l'eau soit en quantité anormale dans les cuves.

Pour en arriver à ce résultat, les entreprises étudiées disent recruter des personnes qualifiées, la plupart ayant déjà une expérience dans les entreprises multinationales comme Total et Shell. Les employés sont également sensibilisés à propos de l'importance du client. Un client nous conta :

*« un jour, un agent d'ELTON m'a accueilli d'une manière inhabituelle. J'étais venu nettoyer la carrosserie de ma voiture et il m'a suggéré de rajouter d'autres services que je n'avais pas prévu sous prétexte que le lavage carrosserie (seulement) est fatiguant et mal payé par le client... A mon retour, pour récupérer le véhicule, je me suis rendu compte que le service était mal fait. Lorsque j'ai voulu en parler au gérant, l'employé m'a supplier de ne rien dire car il risquait ainsi son travail. Et que s'il s'était comportait ainsi, c'est par ce qu'il était dans un mauvais jour, à cause de son épouse malade... »*

Ces propos confirment ceux du directeur général d'Elton disant :

*« nos stations sont en gérance directe, cela veut dire que les employés qui sont dans nos stations sont nos employés..... si un client n'est pas satisfait de la façon dont il a été traité..., s'il se plaint, on peut faire partir de suite l'employé qui n'a pas fait correctement son travail ».*

Les mêmes règles sont respectées pour les autres activités notamment la restauration et dans les boutiques pour la distribution de produits divers. Les responsables de ces entreprises considèrent ainsi qu'ils accompagnent la professionnalisation de ces secteurs où pendant longtemps ont régné l'amateurisme, l'informel, le non respect des règles d'hygiène et de

salubrité. Toutes choses qu'ils veillent à corriger avec leurs stations multi-services qui deviennent de véritables lieux de vie dans des contextes où les offres existantes ne sont pas toujours satisfaisantes.

## **L'innovation et l'accroissement de la valeur pour les clients : une station devient un « lieu de vie »**

La propension à innover, à apporter de nouvelles solutions, adaptées aux besoins réels des populations est un élément essentiel dans la concurrence entre les entreprises locales et les firmes multinationales dans les secteurs matures comme la distribution de produits hydrocarbures. Les entreprises sénégalaises étudiées dans ce secteur en font une condition pour être compétitive. C'est dans cet esprit qu'il faut inscrire la création de stations multi-services. Selon les responsables de ces entreprises, l'importance des investissements à consentir ne doit pas constituer un frein à l'innovation.

*« C'est une innovation. Il faut que les gens sachent oser et innover... si vous voyez, les stations dans les régions, on les construit à l'extérieur des habitations... et les gens viennent. » (Gérant EDK SL)*

*« Il y a aussi que nous avons une grande réactivité au moindre mouvement dans notre marché de même qu'une forte capacité d'anticipation. Un brin de créativité qui nous permet d'explorer de nouveaux concepts. » (DG Elton)*

Les stations de distribution de produits hydrocarbures ne sont plus seulement des lieux où se rendent des automobilistes qui veulent se réapprovisionner en carburant. C'est devenu « *des destinations où les clients peuvent bénéficier de plusieurs services.* » Les clients vont dans ces endroits pour se restaurer, faire leurs courses, effectuer une opération bancaire, ou encore se reposer lorsqu'on fait un long trajet avec la possibilité de se doucher, faire ses prières (dans un pays à plus de 95% de musulmans). Le gérant de la station EDK de Saint Louis a insisté sur la propreté des toilettes.

*« tous les jours, de 7h00 du matin jusqu'à 00h, des techniciens de surface s'occupent uniquement de nettoyer les toilettes de la station. ... ici cinq personnes s'occupent du nettoyage des toilettes... »*

Il compare cette pratique avec ce qu'il a connu chez un concurrent multinational où il a travaillé plus d'une dizaine d'années et où ce sont les pompistes qui à leurs heures perdues s'occupent du nettoyage des toilettes.

En offrant au client dans leurs stations, une plateforme de services, les entreprises Elton et EDK cherchent ainsi à se différencier et se donner une image plus proche des préoccupations de la clientèle.

## **La connaissance client et la proximité socio culturelle**

En déclarant « *L'Afrique est notre continent, ..., le client africain, nous le connaissons mieux que quiconque...* », le DG d'Elton souligne ainsi l'importance de la connaissance client pour être compétitif aujourd'hui sur ce marché. Ainsi le profil socio-culturel des clients est considéré par les entreprises afin de leur apporter une attention la plus adaptée possible. Par exemple, les employés d'EDK Saint-Louis sont sensibilisés sur le fait que la ville est une porte d'entrée dans le pays pour les émigrés et pour les étrangers notamment les mauritaniens qui viennent par la route. Ceux qui passent pour la première fois sont guidés par les agents de sécurité qui leur présentent l'ensemble des services dont ils peuvent bénéficier dans cet espace. Leur argumentaire est ainsi présenté :

*« il y a des toilettes derrière, vous pouvez vous lavez. Il y a aussi un restaurant, une mosquée. Vous pouvez bien vous reposer avant de repartir. Si vous avez besoin de services bancaires également, ... ».*

Au-delà de l'offre commerciale, c'est aussi une manière pour ces entreprises d'apprendre à mieux connaître les clients. La création de toilettes chez EDK serait ainsi la conséquence des sentiments exprimés par les clients dénonçant l'insalubrité et le caractère exigüé des toilettes dans les stations services.

Selon le lieu d'implantation et le profil des clients à servir sur place, le profil du personnel peut varier. Du fait de la proximité avec l'Université Gaston Berger de Saint-Louis, EDK veillent à y affecter des salariés manifestant des habilités à bien communiquer aussi bien en français qu'en langues nationales avec les clients. Des marges de manœuvre sont également laissées au gérant sur place pour élaborer des facilités de paiement aux composantes de l'université du fait des procédures complexes et le plus souvent l'absence de liquidités.

*« pour certains gros clients, on leur fait des réductions de différente nature. Ce sont des avantages qu'on fait pour certains gros clients. Pour les autres, les clients crédibles, on leur fait des avances, on leur fait des prêts, des crédits. Par exemple, pour l'université c'est un gros marché pour Saint-Louis. L'université ne paie pas à*

*temps. Pour chaque UFR ou bien le rectorat ou bien le CROUS, on leur fait des avances. Par exemple quelqu'un qui fait un engagement de 2000 litres, on lui fait une avance de 500 à 1'000 litres. Le temps que l'engagement soit traité par l'agence comptable. Alors que les autres compagnies ne le font pas. »*

Il y a ainsi une certaine forme de personnalisation de la relation client pour créer une plus grande proximité avec la clientèle.

## **La personnalisation de la relation client**

Les entreprises Elton et EDK insistent sur la nécessité de fidéliser la clientèle. Pour ces entreprises, la satisfaction du client est essentielle pour le maintenir mais au-delà, il faut jouer sur les relations personnelles. Ainsi les employés sont encouragés à renforcer leur proximité avec la clientèle. Le gérant de la station EDK de Saint-Louis atteste ainsi à propos des clients :

*« ils viennent, ils garent leurs véhicules, des fois ils laissent leurs véhicules avec les graisseurs et ils rentrent chez eux, ils vont travailler, ... Et puis avec la conscience tranquille que leurs véhicules ne seront pas endommagés, rien ne sera volé ... Ils sont tranquilles. Des fois moi, quand je ne suis même pas là, y a des clients qui viennent ... Et puis bon moi, personnellement, j'ai cultivé ça : ma relation personnelle avec le client. En fait, pour moi c'est très important : avoir une relation particulière avec le client. Partout où je les vois, je vais les saluer, passer une à deux minutes, discuter, voir si tout va bien. Bon se soucier de leurs véhicules, se soucier de leur santé, ... Bon, c'est des petits gestes qui pèsent. Parce que un client il veut toujours être bien traité. Savoir prendre en charge le client, ça c'est extraordinaire ! »*

Cette volonté de gestion personnalisée des clients peut même déterminer les choix en matière d'investissement ou d'orientation stratégique. Ayant opté pour une implantation à la sortie /entrée des grands centres urbains afin de se doter de grands espaces pour implanter ses stations, EDK a, entre autres raisons, considéré le fait que certains clients peuvent disposer de bons de carburant. En déplacement, ils peuvent avoir besoin de se réapprovisionner. C'est ainsi que la stratégie du groupe a été légèrement modifiée pour une plus grande satisfaction de la clientèle, en ouvrant une station en zone urbaine dans la région dakaroise.

## **Avoir une responsabilité sociétale**

Les entreprises locales se différencient de leurs concurrentes multinationales en manifestant un engagement plus ferme dans la gestion des préoccupations des populations locales. Elles participent ainsi à la gestion de problèmes dus à des causes naturelles comme les inondations très fréquentes. EDK a ainsi participé à la canalisation de la zone où est implantée la première station du groupe (dans le quartier des Maristes). Cela a permis d'atténuer les frustrations de certaines parties prenantes qui ne souhaitaient pas leur implantation sur le site.

Dans le même ordre d'idées, l'entreprise (EDK) se fait l'obligation de recruter un personnel local pour combattre le chômage de masse et lutter contre la pauvreté endémique dans les zones où elle s'implante.

*« à Saint-Louis, 80% du personnel habite Sanar et Bango et Saint-Louis. D'ailleurs on a 40 personnes qui travaillent ici à Saint-Louis. quand on s'implante à Saint-Louis, il faut que les gens de Saint-Louis bénéficient de cette station là. Même par rapport aux partenariats, à l'UGB : toute manifestation qui se passe à l'université, si les gens nous sollicitent on fait notre participation. il faut participer au développement local. Par exemple dans cette mosquée là, c'est nous qui avons acheté les radios et tout. Donc c'est comme ça qu'il ... La mosquée de Sanar.*

Ainsi les facteurs clés de succès à maîtriser pour faire face à la concurrence des entreprises multinationales dans le secteur de la distribution des produits hydrocarbures sont : avoir une image professionnelle, une offre de services diversifiés, une bonne connaissance client et une proximité culturelle, une relation personnalisée avec le client et enfin être socialement utile dans la communauté où sont implantées les stations. Tout cela passe par une propension à innover au-delà des activités classiques du secteur pour offrir aux clients des solutions dans leur vie de tous les jours. Dans ce contexte, il est impératif de s'implanter dans des espaces larges et accessibles. Les stations doivent avoir des entrées et des sorties dégagées. Tous les compartiments doivent être propres. Les salariés doivent être reconnus à travers leur tenue de travail et leurs identifiants personnels (nom, prénoms, etc.) pour faciliter les interactions avec la clientèle.

Ces différents éléments corroborent notre hypothèse de départ stipulant que c'est la qualité de services valorisés par la clientèle qui in fine permet aux entreprises locales confrontées à la concurrence des firmes multinationales de pouvoir supporter la comparaison. Nous considérons ainsi que les propositions que nous nous étions proposés de tester sont vérifiées à travers les résultats de notre étude exploratoire dans les entreprises Elton et EDK au Sénégal.

## **Conclusion et discussion**

Cette étude sur la concurrence entre FMN et entreprises locales nous permet de pouvoir tirer un certain nombre de conclusions. Tout d'abord, il ressort clairement que les entreprises locales peuvent très bien s'en sortir face à des multinationales même dans des secteurs strictement régulés et difficiles. Dans le secteur des hydrocarbures, les entreprises sénégalaises ont réussi la prouesse de tripler et quadrupler leurs parts de marchés cumulées entre 2005 et 2012, respectivement pour les réseaux terre et pêche. En effet, celles-ci sont passées de 12,47% à 37,58% et de 18,37% à 67,09%.

Il ressort notamment de cette étude que les entreprises ne sont guère contraintes de se contenter des miettes que leurs laissent les majors. Dans le secteur de la distribution des hydrocarbures, les entreprises sénégalaises parviennent à élaborer et à dérouler des stratégies ambitieuses qui conduisent à des innovations et à des résultats considérables. S'il est vrai que certaines entreprises locales, à l'instar de Touba oil, finissent par adopter une posture classique, celle de la collaboration avec les multinationales, d'autres par contre préfèrent s'opposer à elles frontalement.

Les entreprises multinationales disposent généralement de moyens nettement supérieurs à ceux des entreprises locales. Ces dernières s'appuient donc généralement sur des connaissances spécifiques (Vargo et Lusch, 2008c), des spécificités socioculturelles (Dawar et Frost, 1999 ; Lavie et Fiegenbaum, 2000) et de la proximité émotionnelle (Dawar et Frost, 1999 ; Xie et White, 2005 ; Xie et White, 2010 ; Barki et al., 2012) pour pouvoir s'affirmer sur leur marché domestique. Nos résultats montrent cependant qu'il faut manifester une bonne attitude professionnelle et avoir une utilité sociétale auprès des communautés où sont implantées les entreprises. Ces résultats constituent des apports utiles par rapport aux travaux antérieurs qui ont souvent considérés que les entreprises locales doivent focaliser leur attention sur les stratégies suivantes : profiter de la flexibilité de leur réseau de distribution (Dawar et Frost, 1999 ; Lavie et Fiegenbaum, 2000 ; Li, 2002 ; Grosse, 2003 ; Jaffe et al., 2005 ; Xi et White, 2005, Barki et al., 2012) ; bâtir leur argumentation commerciale à travers leur proximité culturelle (Arindam et al. 2008) suivant une communication plus adaptée (Dawar et Frost, 1999 ; Xie et White, 2005 ; Xie et White, 2010 ; Barki et al., 2012), tout en respectant la culture et les croyances locales (Lavie et Fiegenbaum, 2000 ; Xie et White,

2005, 2010 ; Wu et Pangarkar, 2006 ; Zhang, 2008) ; en définitive, adapter l'offre aux réalités locales (Ramamurti, 2012).

La pertinence de la SDL est clairement mise en exergue au niveau des stratégies élaborées et déroulées par les entreprises locales. Le service est considéré comme étant au cœur de la relation. Celle-ci n'est pas qu'une simple relation d'échange d'un produit contre rémunération, elle devient un partenariat qui consiste en un échange de service. Les différents acteurs en jeu sont alors considérés comme des parties prenantes ce qui rend caduque la dichotomie offreur/consommateur. Celui que l'on qualifie jusque là de consommateur, devient donc un co-créditeur du service au travers duquel est proposée une solution à son problème à travers des expériences uniques et riches.

Il faut cependant se rendre à l'évidence que les entreprises locales n'ont pas l'exclusivité des avantages concurrentiels construits et perceptibles au sens d'une approche SDL. Les multinationales ont très souvent une longueur d'avance par rapport à certains aspects. Dans le secteur de la distribution des hydrocarbures au Sénégal, on peut relever les partenariats que les majors ont noué avec des multinationales d'autres secteurs d'activités. Ces partenariats aboutissent généralement à une offre de service alléchante, à travers des ventes croisées, et unique dont les entreprises locales auront du mal à surmonter. C'est notamment le cas des partenariats entre Total et certaines entreprises de droit français ou des filiales d'autres multinationales : le partenariat Total-orange, permettant au client de bénéficier d'avantages auprès de l'opérateur de téléphonie en achetant son carburant dans les stations Total, ou encore celui entre Total et Eiffage permettant au premier d'avoir l'exclusivité pour implanter des stations tout au long de l'autoroute A1 exploitée par l'entreprise de Génie civil. Ces « ententes » entre FMN sont le plus souvent qualifiées d'injustes ou de déloyales par la concurrence locale, à son égard. Elton et EDK sont à la tête de coalition comportant des membres de la société civile locale et demandant à l'État de prendre des mesures visant à protéger les opérateurs nationaux en réglementant les conditions de partenariat entre firmes de secteurs différents.

Les orientations stratégiques des entreprises locales sont de plus en plus copiées par les FMN qui ont tropicalisé leur management, ouvert les capitaux de leurs filiales à des opérateurs économiques nationaux et revendiquent de plus en plus une utilité sociale au niveau local. Cela montre que la bataille est permanente entre entreprises locales et FMN obligeant les

premières à adopter une propension à innover régulièrement afin de maintenir la pression sur les FMN.

En dépit de ses apports théoriques et managériaux, notre étude pourrait être enrichie en allant notamment au-delà du point de vue des entreprises locales en interrogeant les clients ainsi que les entreprises multinationales afin de mieux apprécier les leviers sur lesquels les stratégies des nationaux doivent être bâties dans le contexte spécifique des pays en développement.

# **Innovation in Public Services: A descriptive analysis of award-winning innovative experiences in Brazil**

*Lear Valadares Vieira<sup>1</sup>, Antonio Isidro da Silva Filho<sup>1</sup>, Mauro Célio Araújo dos Reis<sup>1</sup>*

<sup>1</sup>University of Brasília

*This paper provides a descriptive analysis of innovative initiatives performed by Brazilian public organizations and awarded in the Innovation Contest in Public Federal Administration over the last 15 years (1999-2014). The analysis performed provides a set of characteristics of the public sector in Brazil, which includes a focus on back office initiatives and on incremental and improvement innovations. Complementary elements, such as barriers, facilitators and inductors to the innovations are also described. We also provide a discussion of possible pathways for incentivising relevant innovations in the Brazilian public sector, as well as suggestions for future studies in this theme.*

## **1. Introduction**

The Innovation Contest in Public Federal Administration is an action of the National School of Public Administration (ENAP – Escola Nacional de Administração Pública), together with the Ministry of Planning, Budget and Management, targeting entities of the Federal Executive Power, in any location on the national territory (Petrucci; Rua, 1998). The first contest was executed in 1996 and it was named National Contest of Innovative Experiences of the Federal Public Administration, and it was promoted in order to identify, reward and publish successful innovation initiatives performed by Federal Executive Power organizations, as well as value public employees by recognizing their initiative and performance (Petrucci; Rua, 1998). From 1999 forward, the contest went into a new phase, where its main goal was to recognize best practices. On this edition, and every edition after, the initiatives were judged by the success, quantitative and qualitative, measured by performance indicators specified correctly.

The ENAP prize has an evaluation process for the initiatives that consists of five steps. In the first stage, application go through an internal screening, in which the constant basic requirements of the regulation are verified, such as minimum implementation time, not having an award in another edition of the contest, belong to the federal executive branch, among others. The second step is an initial assessment of the reports by the Judging Committee, which grades each criterion in order to select the 20 initiatives that will receive the visit of the Technical Committee. In the third stage, teams of two members from the Technical Committee visit the 20 selected initiatives. During the site visit, the technical evaluators aim to investigate and deepen the information contained in the report, as well as answer any questions from the members of the Judging Committee, who receive and evaluate the technical visits reports in the fourth stage. The fifth step is a meeting of the Judging Committee, with

the participation of the technical evaluators in order to increase the knowledge on the initiatives and to support the choice and classification of the ten award-winning innovations (Pereira, 2013).

The Innovation Contest in Public Federal Administration is not an idea contest, but of practices that are already working (Moraes, 2004). Using the knowledge of this contest, and having as an assumption that an innovation happened in all awarded experiences, this study aims to provide a description of this experiences. With this description, we expect to identify the administrative structure and general characteristics of the public organizations with awarded innovation, as well as highlight the main types, barriers, facilitators, inductors and benefits of the innovations from the selected experiences. This paper attempts to provide an overall understanding of the past and present characteristics of innovation with a high degree of relevance in the Brazilian public sector, which can potentially serve as a basis to the definition of future trends for the innovations in this context.

To this end, this paper is structured as follows. After this introductory section, we present a brief overview of the innovation in public services field, followed by a description of the methods employed in this study. We present, in the methods section, a detailed description, using keywords, of the categories used for coding the experiences. All the descriptive analysis are presented after. Finally, in the last session, we present our conclusions, highlighting potential future trends for innovation in the Brazilian public sector, as well as suggestions for future studies in this area.

## **2. The present state of innovation in public services**

Innovation in the public sector has been defined as the creation and implementation of new processes, products, services and service delivery methods that result in a significant improvement on efficiency, effectivity and efficacy of results (Mulgan; Albury, 2003). Innovation is a tool to achieve the purposes of the public service, and, for innovation to occur effectively, a synergic relationship between leadership, management, human resources and technology must exist (Anggadwita; Dhewanto, 2013). In this sense, the implementation of innovations in the public sector provides considerable opportunities for economic growth and attract investors (Avlonitis *et al.*, 2001). To Koch and Hauknes (2005), innovation is the implementation or performance of a new way of social action, which is implemented by an entity in the context of its objectives and activity functionalities. Different from the private sector, the public sector involves a complex and multifaceted process of decision making and performance assessment about the innovation implementation, besides being characterized as work intensive and decentralized, which implies directly on management difficulties (Nelson; Yates, 1978).

Gallouj and Zanfei (2013), in investigating the gaps in the innovation in public sector literature, suggest that there is a need of more studies about public services in order to answer issues related to theoretical, empirical, methodological and political gaps. Other authors, such as Djellal *et al.* (2013), also raise a few arguments to the growth of the field. Firstly, is paradoxical to believe that public administrations are ambivalent in the sense of wanting to support innovation, but ignore innovation to its own benefits. A hypothesis raised in this point is if an administration that innovates for itself can

better support innovation in other economic agents, in a perspective that approximates to the inversion approach proposed by Gallouj (2010). Second, there are some specific sectors in public services in which innovations are indisputable and well documented, but not necessarily on innovation studies, such as public universities and health services (Rosenberg; Nelson, 1994; Djellal; Gallouj, 2007). The third argument refers to the blurring of limits between public and private services, being observable, in some cases, competition between public and private services. This could limit, for example, the lack of competition in the public sector as an innovation barrier. Lastly, economic and demographic crisis can be seen as important factors to the innovation in public services, seen that they lead to society pressure.

Due to the lack of specific studies in this area, some concepts derived from other streams of the innovation theory can be useful to the understanding of innovation in the public sector (Koch; Hauknes, 2005). The integration or synthesis approach, initially proposed by Gallouj and Weinstein (1997), provides an analytical framework that allows the study of any kind of innovation, goods or services. This perspective can be easily amplified to public services, especially when the borders between public and private services become more blurred. The integration approach has been improved in the last years, in some cases with the explicit goal to better reflect the public services, and it has been applied to many public services (Djellal *et al.*, 2013).

### **3. Method**

To achieve the proposed objective for this study, we collected data about the award-winning experiences on the ENAP prize from 1999-2014, totalizing 206 selected cases. The first three editions of the prize were discarded because they presented only a brief account of the experiences and did not fit the standard of description adopted from the fourth edition forward. On the editions from the last 15 years, each step of the case is described in distinct topics, namely: introduction, characterization of the previous situation, description of the experience, proposed objectives and desired results, actions taken, implementation steps, resources used, characterization of the current situation and lessons learned. According to Flick (2009), this is one of the limitations of the document analysis, as available resources may force researchers to be selective, instead of using all available documents.

The information obtained on these selected cases were categorized by a content analysis, using the three steps described by Bardin (2006). First, we executed a pre-analysis, consisted of the selection of documents described previously, and the organization of the material in order to make it operational. Next, we proceeded to the exploration of the material, in which we defined categories, or coding systems, and identified registry units, which are the units of meaning to be encoded in correspondence to the content segment aimed at categorization. The Innovation Type category was established after a literature review, from which the Gallouj and Weinstein (1997) typology was chosen for the coding procedures. The other categories presented on Table 1 were built from the content analysis, and only after were compared to the literature to validate the variables chosen to the present study. Besides the variables presented on Table 1, data about Levels of Government, Administrative Structures and Thematic Areas were collected directly from the experiences' reports and did not have to be treated through the coding procedure. The final step was data

treatment, inference and interpretation, being these phase destined to the condensation and the highlight of information for analysis, leading to the descriptive interpretations presented on the next section.

In order to obtain the highest level of reliability to the data collection process, a researcher triangulation was executed. According to Denzin (1989), to perform such triangulation, different scholars are employed to detect or minimize biases from the researcher as a person. In our case, twelve members from a research group of the University of Brasilia, which specializes, among other themes, on innovation studies, performed the coding procedures independently from each other. Any difference in categorization was discussed in the group meetings in order to achieve consensus on the categories, avoiding biases by any singular researcher.

After the coding procedure, the data collected was inserted in a database. Each category is presented in a binary format, in which 1 means the presence of that category in the correspondent experience, and 0 means its absence. The choice for the binary format was based on the variables which do not have mutual exclusive categories, such as Barriers, Facilitators, Inductors and Benefits. For these variables, it was possible to find none, one, or more than one categories at the same case. For the Innovation Type variable, a singular category had to be selected per experience. The remaining variables, Level of Government, Administrative Structure and Thematic Area were part of the experiences' report submitted, and didn't have to be coded by the researchers.

### **3.1. Categories' description**

A standard description and defined keywords, borrowed from the academic and legal literature, for each category within each variable was provided to all coders in order to guarantee a levelled knowledge between all participant researches. This description aimed at solving any doubts pertaining the definition of the categories, as well as ensure a better and standard coding procedure for all researchers. The keywords of the categories coded is provided on Table 1.

| INNOVATION TYPE   |  |
|---|--|
| Category  | Keywords   |
| Incremental   | Implementation; addition; exchange or substitution of elements   |
| Improvement   | Improvement; optimization  |
| Radical   | New; novelty; unprecedented; different   |
| Formalization   | Standardization: unification; clarification; ordering of characteristics   |
| Recombinative   | Reutilization; junction; combination of characteristics  |
| Ad Hoc  | Problem solution; consultancy; particular problem; error correction  |
| BARRIERS  |  |
| Category  | Keywords   |
| Resistance  | Resistance; distrust; insecurity; fear; lack of commitment; breaking paradigms; culture change; functional instability; refusal; discredited; fear; unbelief   |
| Human resources limitation                                      | Lack of skilled labor; lack of qualifications; lack of specific technical training; workload; lack of resources for hiring; high turnover; ignorance of the process; unpreparedness; human error; team work challenge; inexperience  |
| Infrastructure, material and technological resources limitation | Lack of material resources; lack of material resources; lack of technological resources; lack of structure; lack of information structure; need of constant improvement of technology; lack of resources; lack of infrastructure; insufficient equipment; limited use of tools                                   |
| Conflic of interests  | Conflict of interest; lack of support; public management model; difference of opinion; assignment conflicts; tampering; negotiation among multiple actors;   |
| Data and systems fragmentation                                  | lack of standardization systems; lack of standardization of information; unregistered information; inconsistency of data and information; computer problems; diverse data sources; scattered information; data collection difficulty; absence of concrete information; bank of unreliable data; database absence |
| Routine and processes fragmentation                             | Bureaucracy; bureaucratic process; non-standardized processes; difficulty in data transfer; difficulty in processing information; different methods; consolidated culture of absence   |
| Financial and budgetary limitation                              | Lack of financial resources; lack of budget provision; commercial difficulties; lack of resources; credit contingency; funding challenge   |
| Deadline limitation   | Delay in response to demands; failure to comply with time; short-term; very short space of time; narrow term   |
| FACILITATORS  |  |
| Category  | Keywords   |
| Resource availability   | Internet; public funding; budget provision; use of free technologies; available technology; use of the tool  |
| Teamwork  | Dialogue; partnerships; interdepartmental work; shared management; decentralization; involvement and participation of all stakeholders; work group; teamwork; participatory development; trading space   |
| Legitimacy and commitment                                       | Motivation; awareness; responsiveness; stimulus; participation; commitment; technical support; government support; political will; membership; cooperation; engagement; dedication; personal commitment; interest  |

Table 1. Variables, categories and keywords for information coding

## 4. Analysis

Our analysis consists of descriptive observations based on the count of frequencies for the categories on each variable. These descriptions provides us an initial understanding of the structure of the award-winning public sector innovations in Brazil, and based on this first level of analysis we can infer some characteristics and future trends for these public services.

The first variable analysed is the level of government. This variable consists of two categories: central government, which is composed of organizations located in the Federal District, and local government, composed of organizations located outside the Federal District. The results of this variable shows that central government organizations represent the majority of those awarded in the ENAP prize. This can be due to some reasons. First, ENAP, the institution responsible for the prize, is located in the Federal District, and the divulgation of the prize can have a bigger diffusion through organizations near it, meaning that more central government organizations would have knowledge of the prize and submit their experiences. Second, central government organizations tend to be bigger in size than the local government organizations, and, due to their size, it is possible that the same institutions are submitting many experiences, and the smaller local government organizations are focused on fewer strategic innovation initiatives. Third, many of the actions taken by the government to give incentives to innovation on the public sector, as is the case of the prize, start at the central level, and these organizations will have easier access to knowledge, systems and practices to help establish their own strategic initiatives. In a general sense, we observe the need to work on the diffusion of innovative structures and practices to local government organizations, especially in a continental country as Brazil, where a high percentage of the population is not directly affected by organizations located in the Federal District. Table 2 shows the distribution of cases on the variable levels of government.

| Level of Government | No. of cases | %     |
|---------------------|--------------|-------|
| Central Government  | 123          | 59.7  |
| Local Government    | 83           | 40.3  |
| Total               | 206          | 100.0 |

Table 2. Levels of Government

Our second analysis consists on observing the administrative structure of the organizations awarded. This variable is composed of two categories. Direct structure refers to services integrated in the administrative structure of the Presidency and the Ministries. Indirect structure is composed of entities with their own juridical person, such as autarchies, public companies, mixed economy societies and public foundations. The percentages of this variable are close to those observed in the level of government. Since most of central government organizations have direct structure, this result was expected. The difference in the number of cases is due to indirect structure organizations located in the Federal District. The results for administrative structure are presented in Table 3.

| Administrative Structure | No. of cases | %     |
|--------------------------|--------------|-------|
| Direct                   | 111          | 53.9  |
| Indirect                 | 95           | 46.1  |
| Total                    | 206          | 100.0 |

Table 3. Administrative Structures

On thematic area, there are five categories. These areas are defined by the prize, and each organization must point the theme closest to its experience at the moment of the case submission. The most incident category was processes optimization and improvement, which refers to the establishment of quality parameters, analysis and implementation of continuous improvement, and simplification and streamlining of procedures. The second most used category was a close one, organizational planning and management, related to initiatives focused on strategic planning, strategic management, budgetary and financial management, cost management, knowledge management, construction and application of management indicators, and performance assessment and institutional results control. The finalistic categories, service delivery and public policy, which refer, respectively, to processes aiming at directly answering the citizens and experiences on creation and implementation of monitoring or evaluations systems to public policies, came in third and fourth place. The least incident category was information management, pointed in experiences about management computerization and use of technologies to redesign processes and to open communication channel with citizens. Although there is a small percentage difference among the categories, they are roughly evenly distributed. Nevertheless, we can observe a preference for initiatives focused on back office improvements, which can, arguably, have an indirect effect on the finalistic areas, such as service delivery and public policy. Table 4 provides the distribution of cases among the thematic areas.

| Thematic Area                          | No. of cases | %     |
|--|--------------|-------|
| Processes optimization and improvement | 49           | 23.8  |
| Organizational planning and management | 46           | 22.3  |
| Service delivery                       | 43           | 20.9  |
| Public policy                          | 37           | 18.0  |
| Information management                 | 31           | 15.0  |
| Total                                  | 206          | 100.0 |

Table 4. Thematic Areas

On innovation type, we evaluated the cases based on the six categories proposed by Gallouj and Weinstein (1997). The majority of cases (76.7%) were concentrated on two types. The first one, incremental innovations, refer to marginal changes in the system by the addition or substitution of elements. The second, improvement innovation, consists of cases which focus on improvement of certain characteristics without alteration of the system. These results show a trend of Brazilian public organizations to employ initiatives focused on improvement or incremental addition of elements to already existing services. This can be due to the limitation, budgetary, legal, and otherwise, to the creation of new services, and the need for development of services already offered, be it from the addition or substitution of elements such as IT systems, or from the overall improvement of the service. Radical innovations, referring to the creation of a totally new service, computed 9.7% of total cases, and formalization innovations, which compiles cases which implementation gives visibility and optimizes

the degree of standardization of the system's characteristics, represented 8.7% of the experiences. The types with least occurrences were recombinative, the systematic reutilization of certain elements of the service, and ad hoc, which is an interactive construction of a particular problem of a determined client. These two categories represented 2.4% of the cases each. Table 5 compiles the results for innovation types.

| Innovation Type | No. of cases | %     |
|-----------------|--------------|-------|
| Incremental     | 81           | 39.3  |
| Improvement     | 77           | 37.4  |
| Radical         | 20           | 9.7   |
| Formalization   | 18           | 8.7   |
| Recombinative   | 5            | 2.4   |
| Ad Hoc          | 5            | 2.4   |
| Total           | 206          | 100.0 |

Table 5. Innovation Types

One of the aspects that allows us to dive deeper on the structure of innovative cases in Brazilian public organizations is the barriers identified by these organizations during their experiences. Since the same case can have none, one, or more than one barriers at the same time, the total number of barriers computed exceed the number of selected cases, totaling 322 barriers. Close to half the initiatives (42.2%) listed resistance as a barrier, referring to lack of trust, of openness to new ideas and even reluctance to adopt new systems. When added to conflict of interests, which appeared in 19.9% of the cases, we can start to observe a hypothetical need for a cultural change on Brazilian public organizations in order to make it more acceptable and desirable to have changes in the systems currently in place on this institutions. Limitation of resources, be them human, infrastructure, material and/or technological resources, is also an issue pointed by 33.7% of the cases. If we accept the hypothesis of cultural resistance, this could mean that, due to resistance and conflict of interests, the ecosystem of public organizations offer few resources to these institutions to allocate in innovative initiatives, which can then generate the lack of resources observed. One point of notice is that deadline limitation appeared in only 4.4% of the cases. A possible explanation for this low frequency is that most of the innovation initiatives still happen, or at least start, in non planned contexts, and deadlines are not clearly, or at all, established. Therefore, there is low pressure to meet these deadlines during execution of the experiences. The results for barriers are shown in Table 6.

| Barrier   | No. of cases | % (of 206) | % (of 322) |
|---|--------------|------------|------------|
| Resistance  | 87           | 42.2       | 27.0       |
| Human resources limitation                                      | 46           | 22.3       | 14.3       |
| Infrastructure, material and technological resources limitation | 44           | 21.4       | 13.7       |
| Conflict of interests   | 41           | 19.9       | 12.7       |
| Data and systems fragmentation                                  | 36           | 17.5       | 11.2       |
| Routine and processes limitation                                | 34           | 16.5       | 10.6       |
| Financial and budgetary limitation                              | 25           | 12.1       | 7.8        |
| Deadline limitation   | 9            | 4.4        | 2.8        |
| Total   | 322          | 156.3      | 100.0      |

Table 6. Barriers

A complementary analysis to identifying barriers is describing the facilitators to innovation initiatives. Seen that the same case can have none, one, or more than one facilitators at the same time, the total number of facilitators computed exceed the number of selected cases, totaling 449 facilitators. On more than half the cases (55.8%), resources availability was listed as a facilitator to the experience. This can be a reflection of the the resources barrier, which wasn't a major category in the barrier variable. Next, teamwork appears in 46.6% of the cases, followed by legitimacy and commitment, in 39.3% of the experiences. The results of legitimacy and commitment helps describe the resources availability, seen that projects that are legitimated by the leadership of the organization may have access to more resources. This also presents more opportunities to the people involved in the project, which can also help with teamwork. The facilitator least listed was data and processes standardization. This, in addition to the most used thematic area, and the types of innovation most incident, suggests that redesign and standardization of processes is an issue of great importance to Brazilian public organizations. Table 7 shows the frequencies for the facilitator variable.

| Facilitator                        | No. of cases | % (of 206) | % (of 449) |
|------------------------------------|--------------|------------|------------|
| Resources availability             | 115          | 55.8       | 25.6       |
| Teamwork                           | 96           | 46.6       | 21.4       |
| Legitimacy and commitment          | 81           | 39.3       | 18.0       |
| People and competences development | 71           | 34.5       | 15.8       |
| Institutional communication        | 49           | 23.8       | 10.9       |
| Data and processes standardization | 37           | 18.0       | 8.2        |
| Total                              | 449          | 218.0      | 100.0      |

Table 7. Facilitators

To this point, many of the analysis performed identify characteristics of the innovation process. The inductors give a sense of what happens before the initiative begins. The most incident inductors, with similar frequencies, are non-problem oriented and problem oriented. These represent opposite inductors. A non-problem oriented refers to an initiative that begins not to solve a specific problem, but works on the opportunity to generate improvements. On the other side, a problem oriented is an initiative aimed at solving a specific problem, usually responding to an external pressure. The similar frequencies on these categories represent that both scenarios generate innovation experiences in the public sector. A few complementary categories that appeared with less frequency were legal imposition and political impulse, which are a kind of external pressure, but specific on the political and legal contexts that force an innovation to happen. The low counts on these categories suggest a still low interest of the political representatives to induce, in a direct way or indirectly through laws, for example, innovation projects in the public sector. The counts for each inductor are presented on Table 8.

| Inductor             | No. of cases | % (of 206) | % (of 221) |
|----------------------|--------------|------------|------------|
| Non-problem oriented | 88           | 42.7       | 39.8       |
| Problem oriented     | 84           | 40.8       | 38.0       |
| Legal imposition     | 24           | 11.7       | 10.9       |
| Political impulse    | 14           | 6.8        | 6.3        |

|                       |     |       |       |
|-----------------------|-----|-------|-------|
| Technological factors | 11  | 5.3   | 5.0   |
| Total                 | 221 | 107.3 | 100.0 |

Table 8. Inductors

Our last analysis focused on the end of the innovation process, describing the benefits generated by the initiatives. Most of the experiences listed service delivery and/or quality and organizational management improvement as benefits from their projects. Although the service delivery thematic area was computed in only 20.9% of the experiences, being the most listed benefit gives strength to the hypothesis that the innovation projects, even though are focused in other areas of the organization, generate effects on the front office of the institutions. The other side of this description falls on the organization management improvement benefit, and demonstrates that these two objectives can be tackled at the same time when executing an innovation project. Institutional relations and image improvement was listed in 40.8% of the cases. Although the majority of initiatives were not focused on the image of relations of the organization, and this is not even a thematic area listed by the prize, this is a side benefit generated in many of the initiatives. Only 16.5% of the cases were listed as creating an organizational climate improvement. This also reflects the nature of the projects analysed, which focus on creating better processes and using them to impact the service delivery, but not necessarily focusing on the workforce of the organization. At the same time, teamwork was the second most frequent facilitator, which suggests that initiatives focusing on this benefit can improve an important facilitator to leverage another innovation experiences. Table 9 shows the results for benefits.

| Benefit                                       | No. of cases | % (of 206) | % (of 403) |
|---|--------------|------------|------------|
| Service delivery and/or quality improvement   | 144          | 69.9       | 35.7       |
| Organizational management improvement         | 141          | 68.4       | 35.0       |
| Institutional relations and image improvement | 84           | 40.8       | 20.8       |
| Organizational climate improvement            | 34           | 16.5       | 8.4        |
| Total   | 403          | 195.6      | 100.0      |

Table 9. Benefits

## 5. Conclusions

This paper's objective was to provide an overall understanding of the characteristics of innovation initiatives in the Brazilian public sector. To this end, we performed a series of descriptive analysis based on the results of the Innovation Contest in Public Federal Administration from the National School of Public Administration over the last 15 years (1999-2014). A few main observations on these data can be made.

First, we see a slightly higher number of innovations performed on the Central Government and, consequently, of organizations with a Direct Structure. This was expected due to the proximity of Central Organizations with the prize, which is promoted by a public organization located on the Federal District, and the proximity with other relevant public organizations that incentivize innovations in the public sector, such as the Ministry of Science, Technology and Innovation and the Ministry of Plan-

ning, Budget and Management. These two, among many others, are Central Government organizations that not only are responsible for many of the innovative initiatives in the Brazilian public sector, but also support many other experiences in different organizations. Even though this result was expected, a more structure diffusion of the prize and initiatives from supporting organizations could make it more feasible for Local Government organizations to perform more relevant innovation initiatives and produce award-winning cases.

We also observed a focus on back office initiatives, characterized mainly by incremental and improvement innovations. These results may suggest a smaller degree of novelty of the innovations performed, as well as less potential for scalability and diffusion of these innovations. We can also hypothesize that Brazilian public organizations have an internal focus on their initiatives, and attempt to achieve better services indirectly through processes and systems improvements. In this sense, a gap of initiatives focused on direct services to the citizens and radical innovations, through the creation of new services or the complete redesign of current services, can be pointed out. On this topic, it is suggested that future studies assess the impact of coproduction and other citizen-focused practices may have on innovative experiences on the public sector, in order to determine if a closer relationship with citizens can provide a better context for radical and front office innovations.

The barriers and facilitators analysis also highlight some interesting characteristics of the experiences selected. Resistance and conflict of interest appear as the main two types of barriers pointed out on the cases. Our hypothesis is that these two barriers can generate the third most cited, lack of resources. A reflection of these barriers are the two most incident facilitators. First, resources availability have the higher count, followed by legitimacy and commitment. If we consider that resistance and conflict of interest are opposites of legitimacy and commitment as lack of resources is to resources availability, a seemingly paradox of similar variables being listed as both barriers and facilitators is presented. In reality, this shows us that the same variables, if available, are important elements to the execution of innovative initiatives, but their lacking cause difficulties to these initiatives. In this sense, a focus on creating a context of political and top management interest and, therefore, legitimacy that can generate a higher availability of resources is necessary to incentivise relevant innovations in the Brazilian public sector.

This paper's limitations include the sample of organizations considered on the analysis, seen that it was limited to experiences awarded in the ENAP prize, and do not represent the totality of Brazilian public organizations. In addition, the analysis performed on this study is descriptive, and the gaps and suggestions made represent only assumptions that need to be tested with other explanatory analyses in order to support or deny the hypotheses listed on this study. To this end, we suggest that future studies complement the descriptions provided in this paper with initiatives from different organizations, using different databases to collect data. We also recommend the analysis of other constructs related to innovation, such as coproduction, as well as more variables related to innovation or different typologies than the ones considered in this study. Lastly, we suggest that future studies perform explanatory analyses to achieve a higher degree of understanding of the characteristics studied.

# Service Innovation Dynamics in Solid Waste Sector: CDM Landfill Projects<sup>1</sup>

*Silvia Cruz<sup>1</sup>, Sônia Paulino<sup>2</sup>, Delhi Paiva<sup>3</sup>*

<sup>1</sup> State University of Campinas – Unicamp <sup>2,3</sup> University of São Paulo – USP, Brazil

## Abstract

The aim of this paper is to analyze the service innovation dynamics in the solid waste sector to examine the generation of co-benefits resulting from carbon market projects. Two Clean Development Mechanism (CDM) landfill projects are considered: one public and one private. Indicators are proposed to evaluate the social and environmental outcomes that can be generated from CDM landfills, organized into five themes: participation, stakeholder interaction, benefits, environmental quality monitoring and gas emissions monitoring. Data, collected by applying indicators, are organized and analyzed based on two complementary theoretical frameworks: the characteristics-based model and the public-private innovation networks in services (ServPPIN) concept. The focus on competences and techniques interlinked with services produced highlight the importance of organizational and relational aspects and contribute to a better understanding of the opportunities and limitations of CDM in the waste sector.

**Keywords:** ServPPIN; public service innovation; clean development mechanism; solid waste sector; landfill.

## 1. Introduction

The aim of this paper is to analyze service innovation dynamics in the solid waste sector in order to assess the co-benefits generated by carbon market projects. Two Clean Development Mechanism (CDM) landfill projects are considered: Bandeirantes, a public project and Caieiras, a private project.

CDM encompasses activities aimed at reducing greenhouse gas (GHG) emissions by establishing projects across a wide range of sectors, including landfill sites. In line with article 12 of the Kyoto Protocol, these projects must also contribute to promote sustainable development in host countries by generating social and environmental co-benefits.

Although CDM projects have this twofold goal, the United Nations Framework Convention on Climate Change (UNFCCC) only recently began to consider the evaluation of co-benefits generation (UNFCCC, 2012a, 2012b, 2012c).

<sup>1</sup> This work was supported by Grant 2011/00081-5, São Paulo Research Foundation (FAPESP); CAPES Foundation/Ministry of Education of Brazil

According to the Marrakech Accords (Decision 17/CP. 7) the responsibility for determining whether a CDM project activity contributes to sustainable development is defined by the host country and resides with its Designated National Authority (DNA) (UNFCCC, 2001). With regard to participation, the CDM Executive Board requires stakeholders' participation through the entire lifecycle of the activity.

In Brazil, in order to promote local sustainable development the specification of projects must be based on information provided in Annex III of Resolution n.1 of the Inter-Ministerial Commission on Global Climate Change<sup>2</sup>. This establishes both the benefits to the local area and how project activities contribute to each of the following aspects: environmental sustainability; improvement in working conditions and net job creation; income distribution; training and technological development; and finally, regional integration and working in conjunction with other sectors (Brazil, 2003).

Resolution n.1 (Brazil, 2003) also points out the importance of the effective participation of civil society throughout the CDM project's approval process. In the case of Brazil, project proponents should send letters of invitation to all project stakeholders, including local authorities and the chamber of deputies of all municipalities involved; municipal and state environmental departments; NGOs and social movement forums; community associations both directly and indirectly involved in project activities; and State and Federal Public Prosecution Offices.

The Letter of Approval (LoA), a document which confirms that the project contributes to the sustainable development of a particular country, is issued by the DNA and is exclusively based on the expected results (local contributions) of the project in terms of sustainable development and not on verified results.

Within this context, several studies focusing on the analysis of CDM results have demonstrated the difficulties - or even the failure - of GHG reduction projects in contributing to the promotion of local benefits and guaranteeing stakeholder participation (Olsen; Fenhann, 2008; Boyd et al, 2009; Peskett et al., 2007; Kolmuss, 2008; Nussbaumer, 2009; Sutter; Parreño, 2007; Siebel et al., 2013).

In order to address changes in landfills as a result of CDM implementation, 23 indicators are proposed to evaluate the social and environmental outcomes that may be generated by CDM landfills, organized into social and environmental dimensions and subdivided into five themes: three involving the Social Dimension – participation, stakeholder interaction and benefits; and two involving the Environmental Dimension - environmental quality monitoring and gas emissions monitoring.

The data collected by applying these indicators are organized and analyzed using two complementary theoretical frameworks: the characteristics-based model developed by Gallouj and Weinstein (1997), updated by Gallouj (2002) and Gallouj and Savona (2010); and the public-private innovation networks in services (ServPPIN) concept.

This paper is structured into five sections: following this introduction, section 2 discusses the theoretical frameworks used to analyze the public service innovation

<sup>2</sup> Inter-Ministerial Commission on Global Climate Change is the Designated National Authority (DNA) in Brazil.

dynamics, the characteristics-based model and ServPPIN concept; section 3 focuses on methodology, presenting the empirical cases – the profile of the landfills selected and the identification of stakeholders involved in these landfills - and development and validation of indicators; section 4 shows the results and, finally, our conclusions are set out in section 5.

## **2. Theoretical frameworks to analyze the public service innovation dynamics: the characteristics-based model and ServPPIN concept**

Djellal and Gallouj (2012) highlight the importance of public services according to their social or civic output. For the authors, “Public services ‘outputs’ contribute to social cohesion, solidarity and collective and civic identity” (p. 11).

Another aspect of public service provision is the difficulty in identifying and demarcating activities that should be attributed to the public sector as opposed to the private sector, as many services and activities in the public sector are integrated with the activities of the private sector and vice-versa (Bugge et al, 2010; Potts; Kastle, 2010). This aspect is also observed in services related to municipal solid waste, generally carried out via concessions granted to the private sector.

According to Bugge et al (2010) and Bloch and Bugge (2013) the multi-faceted and heterogeneous nature of the public sector is the result of multiple interfaces which characterize public organizations: 1) interface with the private sector; 2) interface between the public sector and citizens; and 3) internal interfaces within the public sector (between government levels and between different areas of activity). These various interfaces illustrate public sector heterogeneity and the permeability between organizations (private, public and the third sector) (Gallouj et al, 2013).

This study adopted an integrated approach to service innovation. This involves having a global perspective to explain service innovation, providing a broad framework, addressing technological and non-technological innovation and taking into consideration all actors involved in the service.

The purpose of this section is to present: 1) the characteristics-based model, useful to describe the interlinking of the vectors of the service’s competences, techniques and final characteristics; and 2) the ServPPIN concept, useful to identify and systematize aspects related to agent interaction, emphasizing the participation of associations and cooperatives close to the landfills.

### **2.1 The characteristics-based model**

Gadrey (2000), based on service relations, suggests the following services definition:

[...] a service activity is an operation intended to bring about a change of state in a reality C that is owned or used by consumer B, the change being effected by service provider A at the request of B, and in many cases in collaboration with him or her, but without leading to the production of a good that can circulate in the economy independently of medium C” (Gadrey, 2000, p. 375).

Gadrey's (2000) concept of 'the service triangle' helps us to understand service production as a social process which is constructed by the actors participating in the service production process and by the context in which actors find themselves (cultural, social, institutional, economic, etc).

Thus, these relationships, characterized by the interaction between client / user and the service provider, highlight the service interface component, as well as the competences (technical and / or human) required for service provision. In this study, the solid waste service is considered by using Gadrey's service logic (2000) and applying it to the context studied, from its generation through to its final disposal.

According to Gallouj and Weinstein (1997), the product (good or service) is understood from a set of characteristics and competences vectors represented by the "characteristics-based approach". In addition, this model, updated by Gallouj (2002) and Gallouj and Savona (2010), includes the technical characteristics of both providers and customers. In Figure 1, [Y] represents the service characteristics, [T] the internal technical characteristics, [T'] the external technical characteristics, [C] the internal competences and [C'] the external competences.

**Figure 1: The product as a conjunction of vectors of characteristics and competences (characteristics-based approach)**

Source: Gallouj and Savona (2010)

Thus, a service can be defined as the mobilization of internal and external competences and internal or external techniques (tangible or intangible) to produce the final characteristics of a good or service.

A recent contribution to the model was proposed by Windrum and García-Goñi (2008) suggesting the inclusion of the government in the Gallouj and Weinstein (1997) and Gallouj and Savona (2010) model. Windrum and Garcia-Goni (2008) show that the quality of a good or service depends on the sets of competences belonging to service providers / producers and users. Service provider competences are described as *back office* competences and *user facing* competences are emphasized as the competences required to interact with users.

Different types of actors are involved in the innovation process. In this way, the multi-agent service provision model enables the development of complementarities and synergies between the various agents, each with specific goals and competences (Windrum; García-Goñi, 2008; Weber; Heller-Schuh, 2013; Windrum, 2013).

Having outlined the characteristics of multiple interfaces and the heterogeneity of the public sector, the ServPPIN concept can be useful to identify and systematize the aspects related to agent interaction.

## **2.2 ServPPIN concept**

One of the factors behind the interest in examining Public-Private Innovation Networks is the growing recognition of the important role played by public sector organizations in the innovation process. Public administrations are thus no longer restricted to playing a supporting role in innovation processes.

Similar to public-private partnerships (PPPs), ServPPINs are collaborative networks involving public and private organizations. However, in contrast to traditional PPPs, they are more comprehensive, open and flexible. In PPPs, relations between actors tend to be more rigid, involving predefined functions, rules and formal procedures (particularly contracts), making the process more bureaucratic, thus limiting its potential for innovation.

The high number and diversity of participants in a ServPPIN tend to lead to a multi-faceted and intensive process of interaction. Given the many channels that are opened, large amounts of heterogeneous information and knowledge (tacit and non-tacit) are likely to be exchanged. In other words, ServPPIN can be thought of as a multi-agent service relationship system (Djellal; Gallouj, 2013).

The innovation network<sup>3</sup> concept is biased towards manufacturing and technology. This concept, in the traditional sense, has a number of deficiencies, namely, a technology bias (where tangible technological innovation predominates), a manufacturing bias (linked to the latter), and a market bias (the private sector is central to innovation dynamics). In short, this means that innovation networks are mainly focused on technological innovation produced by the collaboration of private actors in the manufacturing sector.

The ServPPIN concept provides a way of overcoming these various biases (Djellal and Gallouj 2013; Gallouj et al., 2013; Labarthe et al. 2013, Windrum, 2013). It goes beyond the technologist view of innovation<sup>4</sup>, providing a broader perspective which incorporates non-technological types of innovation such as: organizational, ad hoc (defined by Gallouj and Weinstein (1997) as interactive solutions to the specific problems of particular clients), social and bricolage innovation (defined as innovation resulting from non-programmed activities, trial-and-error processes and adaptation to random events) (Fuglsang, 2010).

<sup>3</sup> Innovation networks and systems have been extensively analyzed by literature in the areas of economics, sociology and management (Callon, 1992; Edquist, 1997; Latour, 1999; Lundvall, 1992; Nelson, 1993 among others).

<sup>4</sup> The technology issue is taken into account in the designs of carbon market projects and in the promotion of social and environmental local co-benefits. In the cases studied, all Project Design Documents (PDD) and Validation Reports indicate the development and dissemination of technologies through project implementation, highlighting the following aspects: training, technology development and transfer.

Through the ServPPIN concept, Gallouj et al (2013) emphasize the importance for service innovation of multiple links and feedbacks (interfaces) between the public and private sectors as well as users – in our case, the association representatives from the communities surrounding the landfills – and policy-makers. As pointed out by Djellal and Gallouj (2013):

ServPPINs are multi-agent service relationship systems. The actors involved in interaction have to deal with the ill-defined nature of their respective products, their non-stockability, a diversity of systems of interaction, the multiplicity of possibly competing value systems and the fact that their products are located in different spatial and temporal scales. ServPPINs introduce the traditional research questions of service economics into network-based analyses of innovation. (Djellal; Gallouj, 2013 p. 30. highlighted by the authors).

Thus, the multi-agent framework is particularly well-suited to studying the public-private innovation networks concept. The Windrum and García-Goñi (2008) model<sup>5</sup>, in particular, (inspired by Gallouj and Weinstein, 1997) is an analytical framework representing interactions between the various agents from the political, economic and social spheres.

In short, this model differs in that it includes the government as an important agent in the innovation process in order to highlight the importance of considering the preferences of different actors. Furthermore, this model also emphasizes the importance of organizational and relational competences - in particular with regard to the interaction between service providers and users - in steering the trajectory of service characteristics.

According to Bučar et al. (2013), ServPPINs can be understood as a space for social interaction and the construction of social relations aimed at innovation. Nevertheless, when considering all case studies studied in the ServPPIN research project<sup>6</sup>, a considerable number were not explicitly oriented towards innovation. For example, in some hospital case studies the main objective was to reduce costs in the use of technologies.

Similarly, the explicit aims of the CDM landfill projects we examined were a reduction in GHG emissions rather than the promotion of service innovation. In fact, technology and innovation appear to be additional outcomes of the local co-benefits generation. Interesting changes and innovations are likely to emerge from such networks which may then be retrospectively labelled 'innovation networks'. With regard to non-technological, incremental and unprogrammed innovations (*ad hoc*, *bricolage*, rapid application etc.), it is also possible to consider even those networks not explicitly (or immediately) oriented towards innovation as ServPPINs.

ServPPIN contributes to introduce the traditional innovation network concept to new actors, that is, market and third sector organizations (NGOs, associations etc.). It extends potential forms of participation to specific actors, for example, civil society, involved in decision-making and consultation processes. This is particularly the case

<sup>5</sup> See also Windrum (2013)

<sup>6</sup> ServPPIN is an EU-funded research project which focuses on the role of public and private services on growth and welfare and the particular role of public-private innovation networks. For more information: <http://www.servppin.com/>. The main results of the project are also published in Gallouj, Rubalcaba and Windrum (2013).

with regard to civil society's role in the ServPPIN context – helping to translate social preferences not fully reflected by market prices (Fuglsang, 2013).

In addition to highlighting the importance of integrating users into the service innovation process, the ServPPIN Research Project findings indicate that the participation and involvement of both non-profit organizations and service users (citizens) is still limited. Thus, as argued by Labarthe et al (2013), it is not end-users, or individual users, who are integrated within networks, but rather, the collective organizations representing these groups - and in our case, the representatives of associations of the communities surrounding landfills.

### **3. Methodology**

This section shows, first, the research's geographical boundaries featuring the case studies and stakeholders and, subsequently, the procedures used to validate the indicators for co-benefits evaluation.

#### **3.1. Research Context and Empirical Cases**

The São Paulo Metropolitan Area comprises 39 municipalities with approximately 20 million inhabitants, generating around 16,000 tonnes of solid waste per day (Cetesb, 2013). Landfill projects are concentrated in the south-eastern region of the country, 23 of which are located in the State of São Paulo (UNEPRisoe, June, 2015). Thus, our research focuses on the São Paulo Metropolitan Area and outlines two CDM projects. The landfills in this empirical research were selected on the basis of the following criteria:

- a) Project scope: landfill projects;
- b) Location: São Paulo metropolitan area;
- c) Methodology used to measure GHG emissions reduction: ACM0001 – flaring or use of landfill gas;
- d) Monitoring period established: at least one monitoring period to the beginning of the empirical research (February, 2014);

Given the criteria above, the following landfills were selected: Bandeirantes and Caieiras. CDM landfill projects data were collected from 2003 to 2014 and obtained through documentary research using two databases: The United Nations Environment Program (UNEPRisoe) database and UNFCCC - CDM Registry which enabled access to monitoring reports project design documents (PDDs) and project documentation based on Annex III of Resolution No. 01/ 2003 of the Inter-ministerial Commission on Climate Change (CIMGC) (document describing the promotion of social and environmental co-benefits).

In order to map stakeholders, specific and additional information was analyzed regarding the representatives of the associations in the communities surrounding landfills directly affected by the activities of the enterprises. The following databases were examined:

- The recyclable material cooperatives register, available from the Department of Environment of São Paulo State website – SMA<sup>7</sup>;
- The “register of civil society organizations – 2009-2011 database”, available from the Integrated Water Resources Management System (SIGERH)<sup>8</sup>, taking into account data related to the Alto Tietê Basin Committee for the geographical area selected for the study;
- The websites of the municipalities affecting Caieiras;
- The websites of the sub-district Perus (city of São Paulo);
- Public audiences minutes related to carbon credits;
- FEMA (Environment and Sustainable Development Fund) and Confema (Special Fund for the Environment and Sustainable Development Council) resolutions related to CDM projects (in this case, exclusively for Bandeirantes);
- Direct searches with the Google web search engine, using the following keywords: the names of the landfills, cooperatives and associations/communities surrounding the landfills.

### 3.2. Indicators: Development and Validation

In order to evaluate the social and environmental co-benefits of CDM projects in landfills, 23 indicators were proposed and organized into the social and environmental dimensions and subdivided into five themes:

- Social Dimension: a) Participation, concerns the quality and coverage of the participation of different stakeholders in all phases of the CDM projects development. b) Stakeholder interaction, concerns the interaction between agents involved in the CDM projects, encompassing public and private sectors and users (associations and representatives of civil society, recycling cooperatives; etc.) c) Benefits, concerns the benefits promoted by the CDM with reference to urban solid waste;
- Environmental Dimension: d) Environmental quality monitoring, relates to identifying the potential for reducing negative environmental impacts with regard to the landfill sites; and e) Gas emissions monitoring, concerns the efficiency of the landfills’ biogas capture systems.

The process for developing indicators was participatory: the indicators were presented and discussed with stakeholders and took into account expert validation using the Delphi technique (Linstone; Turoff, 1975; Ristola, 2012; Tuominen et al, 2014). The literature on Delphi clearly indicates that not only (technical) experts may be involved in the validation process, but it may also include decision-makers and other relevant stakeholders able to provide information on the topics covered by Delphi (Linstone; Turoff, 1975; Ristola, 2012, Varho; Tapio, 2013; Tuominen et al, 2014).

In this research, 2 experts participated in the pre-test phase (October, 2014), 10 in the first round (November, 2014), and 9 in the second round (January, 2015). The online questionnaire was divided into two sections with the following main objectives:

<sup>7</sup> <[www.ambiente.sp.gov.br](http://www.ambiente.sp.gov.br)>

<sup>8</sup> <[www.sigrh.sp.gov.br](http://www.sigrh.sp.gov.br)>

a) to evaluate the significance level of the indicator (based on the Likert scale - very low, low, moderate, high, and very high); and b) to qualitatively analyze the indicators' descriptions. The instructions given to evaluate the indicators were, essentially: a) to analyze the indicators' description; and b) to evaluate the indicators' level of significance. Table 1 shows the indicators organized into social and environmental dimensions and into the five topics – participation; stakeholder interaction; benefits; environmental quality monitoring; and gas emissions monitoring.

**Table 1: Proposed indicators subsequent to Delphi rounds.**

| <b>Social Dimension</b>  |   |   |
|--|---|---|
| <b>Topic I: Participation</b>  |   |   |
| <b>Indicators</b>  | <b>Description</b>  | <b>Variables</b>  |
| Number of participants and stakeholders involved   | Identifies the number of participants both in meetings and public audiences related to CDM projects; and participants and stakeholders involved   | Number of participants in the meetings;<br>number of participants in the public audiences related to CDM projects |
| Channels for recording complaints  | Identifies the Number of complaints / year; % of complaints resolved in order to first, evaluate the existence of channels for recording complaints and second, to identify responses   | Number of complaints / year;<br>% of complaints resolved  |
| Projects' acceptance by the population and environmental non-governmental bodies   | Identifies the Number of formal complaints and/or suggestions / year by the population and environmental non-governmental bodies related to CDM projects  | Number of formal complaints / year;<br>Number of formal suggestions / year  |
| Disclosure to stakeholders of the activities proposed in PDD, based on Annex III aspects                                       | Identifies the Number of published documents (including digital media) disclosing to stakeholders the activities proposed in the PDD based on Annex III aspects in order to evaluate whether actions are disclosed to stakeholders, as well as the means of communication used  | Number of published documents   |
| Language and clarity of documents  | Identifies suitability of documents; evaluates the language and clarity of key documents related to the project   | Suitable; unsuitable  |
| Consultation period  | Identifies the suitability of the public comments and consultation period - 30 days - established by the UN / UNFCCC (after validation by the Designated National Authority)  | Suitable; unsuitable  |
| Public consultation before implementation and during project execution   | Identifies the Number of meetings conducted in order to evaluate whether users were consulted before the implementation and during project execution; the level of stakeholder satisfaction with the consultation conducted; and whether the landfill post- closure plan was participatory and included the communities surrounding the landfills | Number of meetings;<br>satisfactory, not satisfactory   |
| <b>Topic II: Stakeholder Interaction</b>   |   |   |
| <b>Indicators</b>  | <b>Description</b>  | <b>Variables</b>  |
| Communication between municipal departments  | Identifies the Number of meetings and / or number of published and/ or disclosed documents in order to evaluate whether there is Communication between municipal departments on the CDM projects  | Number of meetings;<br>Number of joined up initiatives and activities focusing on CDM projects                    |
| Communication between municipal departments and concession-holders managing the landfills                                      | Identifies the Number of meetings and / or number of published and/ or disclosed documents in order to evaluate whether there is Communication between municipal departments and concession-holders managing the landfills  | Number of meetings and / or number of published and/ or disclosed documents                                       |
| Communication between municipal departments and representatives of associations from the communities surrounding the landfills | Identifies the Number of meetings and / or number of published and/ or disclosed documents in order to evaluate whether Communication between municipal departments and representatives of associations from the communities surrounding the landfills exists; and the level of stakeholder satisfaction with                                     | Number of meetings and / or number of published and/ or disclosed documents                                       |

|   |   |  |
|---|---|--|
|   | procedures adopted  |  |
| Communication between municipal departments and concession-holders responsible for LFG <sup>9</sup> recovery and power generation   | Identifies the Number of meetings and / or number of published and/ or disclosed documents in order to evaluate whether Communication between municipal departments and concession-holders responsible for LFG recovery and power generation exists   | Number of meetings and / or number of published and/ or disclosed documents                          |
| Communication between concession-holders managing the landfills and concession-holders responsible for LFG recovery and power generation in relation to the landfill closure plan | Identifies the Number of meetings and / or number of published and/ or disclosed documents in order to evaluate whether Communication between concession-holders managing the landfills and concession-holders responsible for LFG recovery and power generation in relation to the landfill closure plan exist | Number of meetings and / or number of published and/ or disclosed documents                          |
| Communication between concession-holders responsible for LFG recovery and power generation and representatives of associations from the communities surrounding the landfills     | Identifies the Number of meetings and / or number of published and/ or disclosed documents in order to evaluate whether Communication between concession-holders responsible for LFG recovery and power generation and representatives of associations from the communities surrounding the landfills exists    | Number of meetings and / or number of published and/ or disclosed documents                          |
| <b>Topic III: Benefits</b>  |   |  |
| <b>Indicators</b>   | <b>Description</b>  | <b>Variables</b>   |
| Cooperatives benefiting from CDM revenues   | Identifies the number of Cooperatives benefited and the number of people benefited in order to verify whether CDM landfill projects have benefited cooperatives surrounding the landfills   | Number of Cooperatives benefited/ Number of people benefited   |
| CDM projects contributions to environmental education initiatives   | Identifies whether CDM landfill projects contributed to improve/develop environmental education initiatives; Number of people benefited; training; in order to verify projects' contribution to environmental education initiatives aimed at USWM <sup>10</sup> ; and the level of stakeholder satisfaction     | Number of environmental education initiatives provided by CDM; Number of people benefited; Training; |
| CDM projects contribution to technology and methodology development   | Identifies the number of technologies and methodologies developed by landfill CDM projects  | Number of technologies and methodologies   |
| <b>Environmental Dimension</b>  |   |  |
| <b>Topic IV: Environmental quality monitoring</b>   |   |  |
| <b>Indicators</b>   | <b>Description</b>  | <b>Variables</b>   |
| Surface and underground water monitoring  | Identifies the number of Samples taken every months and the Number of nonconformities every 6 months, obtained from surface and underground water monitoring results  | Sampling / 6 months; Number of nonconformities/ 6 months   |
| Leachate monitoring   | Identifies possible changes in leachate (litres / hour) provided by monitoring results throughout the project development period  | Nonconformities samples during the entire project development period                                 |
| Geotechnical monitoring: soil stability   | Identifies the Samples taken every 6 months and the Number of nonconformities every 6 months obtained from the geotechnical monitoring results on soil stability in order to prevent accidents caused by landfill slope movements   | Sampling /every 6 months; Number of nonconformities/ 6 months  |
| Landfill closure plan   | Identifies Suitability of compliance with landfill closure plan   | Suitable; unsuitable   |
| Odors   | Identifies air quality (odors) monitoring; the quality of data obtained; and the number of complaints / year by stakeholders regarding unpleasant odors.  | yes; no; Suitable; unsuitable; number of complaints / year   |

<sup>9</sup> Landfill gas

<sup>10</sup> Urban solid waste management

| Topic V: Gas emissions monitoring |  |   |
|-----------------------------------|--|---|
| Indicators                        | Description  | Variables                                       |
| Fugitive gas emissions            | Identifies volume of fugitive gas every 3 months from monitoring results   | volume of fugitive gas / 3 months               |
| Biogas capture                    | Identifies the amount of biogas captured Nm <sup>3</sup> /year, allowing for adjustments and corrections in the landfill gas drainage system in order to eliminate odors | volume of biogas captured Nm <sup>3</sup> /year |

During the two Delphi rounds, the answers provided by the experts in accordance to the Likert scale were tabulated using the Minitab® statistical software and statistically represented by the median, the first and third quartiles. At the end of two rounds, the interquartile ranges were analyzed - comparing the differences between the first and third interquartile of the first and second rounds. Qualitative data on indicators descriptions were compiled in order to identify trends and / or discrepancies between Delphi participants' responses. Stakeholder data were collected in face-to-face interviews through the application of a semi-structured questionnaire in April 2015.

## 4. Results

This section will first present the results of the characteristics-based approach model adapted to the CDM landfill context, followed by results based on the ServPPIn concept, in order to identify the promotion of social and environmental co-benefits through innovation and stakeholder participation.

### 4.1. The characteristics-based approach model adapted to the CDM landfill context

The Gallouj and Weinstein's (1997) characteristics-based approach model and additional contributions were adapted<sup>11</sup> to the CDM landfill context in order to analyze competences and techniques and examine the potential mitigation of environmental impacts resulting from this activity, taking into account soil, air, surface and groundwater contamination.

Considering the context studied, is it important to highlight the relevance of regulations (especially aimed at controlling odors emissions and gas monitoring) affecting the use and selection of techniques by direct and indirect service providers. Figure 2 shows the representation of products related to solid waste final disposal in the CDM landfills:

<sup>11</sup> Contributions made by Gallouj (2002), Gallouj and Savona (2010), and Windrum and Garcia-Goñi (2008).

**Figure 2: The product as a conjunction of vectors of characteristics adapted to the CDM landfill projects context**

Source: The authors.

The service characteristics vector (Y) highlights the key features which justify applying resources to this service. Services related to final waste disposal in the CDM landfills, service characteristics (Y), are: volume of treated waste, environmental quality of final waste disposal and volume of biogas produced. The focus on providers and users techniques (T, T', T'', T''') and competences (C, C', C'', C''') to produce services related to final waste disposal take into account soil, air, surface and groundwater contamination.

With regard to the analyzed context, the appropriateness of emphasizing the role of regulations (particularly focused on odor control and gas monitoring) was observed, given their potential influence on the use and selection of techniques by direct and indirect service providers.

The representation of services in terms of their characteristics is a theoretical approach which enables the move from the conception of product (good or service) towards innovation, based on the changes in service characteristics and considering the different agents influencing service production.

In general, technological and non-technological innovations are identified and focus on the operational efficiency of the landfills' biogas capture systems: the final cover layer in the landfill post-closure phase and the biogas generation prediction model. It became apparent that air quality monitoring linked to odor emission control - considered as a key-point for the communities surrounding the landfills - is a problem, thus exposing the deficiencies of methods, standards and competences in the researched context, that is, odor emission control is a co-benefit which has not yet been achieved.

As previously discussed, in Brazil, the public service of urban solid waste management is mostly performed by private companies. The Government grants concession-holders the right to perform this service. Therefore, based on the theoretical model adopted, municipalities are considered to be indirect service providers, and concession-holders, direct service providers. The communities surrounding the landfills are considered direct service users, and society at large, indirect service users, given the emphasis on the generation of local co-benefits from the CDM landfill projects.

The quality of a good or service is the result of the set of competences held by providers and users (Gallouj; Weinstein, 1997; Windrum; Garcia-Goñi, 2008) including the providers' competences to produce the service (back office competences) and to interact with users (user facing competences). That is, the competences of the actors involved in the "service triangle" in order to establish, produce and deliver the final service.

The direct (T) and indirect (T') service providers' technical characteristics vectors and the direct (T'') and indirect (T''') users' technical characteristic vectors make up a set of techniques used to produce a product. These techniques may be tangible (computers, machinery, equipment, and other infrastructure items) or intangible (mathematical methods, working methods).

In the researched context:

Direct service provider techniques (T) encompass waterproofing system / drain leachate; leachate treatment system; collection and rain water storage systems; biogas capture system; fugitive gas emissions methods and monitoring equipment.

Tangible techniques predominantly relate to landfill maintenance equipment, machinery and materials. In the CDM landfill projects the incorporation of new equipment, particularly in relation to the thermal power plant operation and the final waste cover, is highlighted. Intangible techniques relate to adjusting (tropicalization) the model to provide for potential biogas production.

The aim of gas monitoring is to detect possible gas migration and the risk of explosions. The results of the monitoring analysis enable adjustments and corrections to be made in the landfills' gas drainage systems, eliminating odors and assisting in the efficient and safe handling of gas.

Indirect service provider techniques (T') relate to the supervision of activities carried out by concession-holders. They comprise rainfall recording monitoring methods, checking the performance of surface drainage equipment used, monitoring and piezometric levels readings, physiochemical and microbiological analyses of surface, groundwater and leachate samples in order to check for possible deviations over the monitored period. Methods for monitoring the biogas produced were also incorporated. In terms of equipment, the main instruments used by the indirect service providers to conduct landfill inspections were superficial signs of landslide, water level meters, piezometers and gas manometers. In terms of intangible techniques, visual inspection methods to identify geotechnical problems are highlighted.

The key difference between the direct service providers (utilities) and indirect providers (public sector) techniques relates to the fact that the former are responsible for sample production, development and analysis and the latter, for the supervision/inspection of the procedures performed by the direct providers.

No direct or indirect user techniques - (T') and (T'') - which influence service characteristics were identified.

Competences are incorporated into individuals, a group of individuals or an organization and are the result of activities such as training, experience and interactions. These competences are tacit and not likely to be transferable.

Within the research context:

Direct service provider competences (C) related to knowledge (theoretical and practical) and routines. The theoretical and practical knowledge for adapting and applying biogas estimation models considering the parameters compatibles with the Brazilian panorama are highlighted.

The first step in biogas capture and utilization for power generation includes initial theoretical studies which must take into account parameters, tests and experiments appropriate to each case analyzed (Kaimoto et al, 2006). Therefore, this gives rise to the need to provide more conservative parameters, adapted to the Brazilian biogas production context, considering that the first CDM landfill projects did not meet generation estimates for certified emission reductions (CER) during the first accreditation period.

In order to address this shortfall, new theoretical knowledge was acquired by adapting the model to predict the biogas production potential. Initially, the projects applied the United States Environmental Protection Agency (US EPA) model in order to reduce uncertainty regarding biogas generation throughout the project development phase. Other methodologies were applied by the CDM projects that took part in the second accreditation period.

In relation to the practical knowledge of direct service providers (C), CDM implementation required extensive initial training to guarantee landfill maintenance in accordance with the PDDs during the entire project cycle. Project expertise is required for the gas capture and treatment operation system. Practical competences for biogas capture drainage regulation and operation stand out, as do biogas capture supervision system records.

In general terms, essential practical knowledge required for biogas capture activities in landfills relate to handling systems, equipment and technological resources suitable for biogas capture; inputting information into the systems according to the standards required by the CDM / designated operational entities (DOE) / Environmental Sanitation Technology Company (CETESB); identifying solutions for problems caused by the inappropriate use of systems and work equipment; care in the use of systems and equipment; rapid decision-making relating to operational problems; sharing relevant information; identifying potential operation system errors, equipment and technological resources.

In relation to routines, the Designated Operational Entities (DOE) are the international or national bodies responsible for validating CDM landfill projects. DOEs are involved in the initial phases of project design, validation, registration and also throughout the accreditation period. Project monitoring takes place periodically and the CDM Executive Board is requested to issue CERs with mandatory validation by the DOEs. The validation process may change or introduce new procedures and processes in landfills, affecting routines, processes and operations.

Indirect service providers competences (C') relate to knowledge (theoretical and practical) about the biogas capture system. Subsequent to the implementation of the biogas capture system, the identification of cracks and/or leakage in landfill sites becomes a relevant topic.

Thus, in relation to routines, trained technicians conduct careful visual inspections in order to identify signs of geotechnical problems. If anomalies are perceived, they are recorded and analyzed, instigating appropriate actions, interventions and / or repairs.

No direct or indirect users' competences - (C'') and (C''') – influencing the service characteristics in the final waste disposal of CDM landfill projects have been identified.

In this context, the need to develop regulations to control odor emission and gas monitoring is highlighted. Regulations can influence direct and indirect service providers in terms of their selection and use of techniques.

It is important to note that when the system of capture, drainage and combustion in isolated wells, and the waste cover system perform correctly, in accordance to environmental standards, sulfur dioxide (SO<sub>2</sub>) and other gases are eliminated, preventing their release into the atmosphere, thus mitigating a side-effect that particularly afflicts the communities surrounding the landfills.

However, air quality monitoring linked to odor emission control was considered a priority by the communities surrounding the landfills. Thus, the lack of development of techniques and competences by service providers to control odor emissions is a service provision deficiency.

#### **4.2. ServPPIN and the relational aspect in the innovation analysis**

Returning to the literature on ServPPIN, in order to analyze innovation within the context studied, five types of interaction are considered: a) between concession-holders and direct users; b) between different concession-holders (private enterprises); c) between public organizations; d) between public organizations and direct users; and e) between public organizations and concession-holders.

##### *a) Interaction between concession-holders and direct users*

The use of extremely technical terms in the documents prevents direct users from attending meetings. This situation can be remedied by developing the competences of direct and indirect providers' [(C) and (C')] to produce illustrative/ easily understandable material containing the main points of the project and future actions to be taken with CDM resources.

It is important to note that the 30-day period provided by UNFCCC for stakeholders to submit comments and suggestions to the projects is too short. Direct and indirect providers have the opportunity to develop techniques [(T) and (T')] and competences [(C) and (C')] in order to close the communication gap, seeking new interfaces with users and providing appropriate access to information about CDM projects. For this to take place, direct and indirect providers, and direct users [(C), (C') and (C'')] are required to have competences comprising knowledge / qualifications in understanding and communication, taking into account user needs.

Direct users are unaware of Annex III aspects. Once again, it is important to highlight the difficulties in understanding the content of documents related to the projects due to the technical language and terms used. Therefore, direct and indirect providers, and direct users [(C), (C') and (C'')] need to develop competences in order to establish an effective common language among different agents.

A possible solution would be the development of community newsletters / brochures describing the actions to be taken in the community with project resources. However, in this study, local cooperatives benefiting from CDM resources have not been identified.

#### b) *Interaction between private concession-holders*

The Bandeirantes landfill is operated by two direct service providers. In this case, the interactions between the private concession-holders can be subdivided into technical report information; changed routines; meetings in the "AS5" landfill area; and the landfill closure plan. Compared to other experiences of landfills managed by a single concession-holder (managing the site and operating the biogas system) which tend to be more successful in terms of tasks and activities performed, in Bandeirantes, a considerable amount of time is spent in disagreements and other bureaucratic issues, because there are two direct service providers operating in the same site.

In both landfill cases studied (Caieiras and Bandeirantes), the development and dissemination of technologies related to project implementation are cited in the PDDs and validation reports. According to the data analyzed, incremental innovation resulting from CDM implementation stands out with regard to the improvement in the biogas system of collection, drainage and combustion in isolated wells, resulting in greater biogas capture efficiency, that is, in a reduction in the amount of fugitive gas from the landfills - a direct service provider technique (T).

In addition, still regarding direct service providers techniques (T), advances have been observed in the model used for establishing parameters to estimate LFG generation adapted to the reality of the landfills. These innovations required the establishment / improvement of direct service providers competences (C) related to the acquisition of theoretical and practical knowledge (to develop and apply methods and technologies) and routines for monitoring landfills.

#### c) *Interaction between public organizations*

In general, public sector participation in CDM projects is very small, especially in projects developed by the private sector. However, the public sector, as the body responsible for service provision, must ensure that the service is being adequately provided. Thus, the public sector must have a leading role as a regulator, in surveillance, providing support and as a planner.

It has been observed that indirect service providers (C') need to develop relational competences, routines, communication channels and information sharing strategies to interact with other stakeholders, particularly with direct service users. Therefore, further interaction between private-public sectors and joint actions should be implemented seeking to improve and produce co-benefits related to CDM projects.

d) *Interaction between public sector organizations and direct users*

No competences - (C') and (C'') – or techniques - (T') and (T'') – influencing co-benefits generation related to service direct providers and direct users interaction have been identified.

It was observed that the programs, projects and activities to be carried out with carbon credits resources are based on fuzzy and superficial guidelines and deadlines. Thus, it is important to highlight that direct service providers need routines and communication channels (C') to interact with other stakeholders, particularly with direct users.

Interaction deficiencies and a lack of access to data/ information on the part of direct users prevent the landfill from adequately fulfilling local demands. In this way, this study observed the need to develop indirect service providers' competences (C') to monitor whether municipal budget projections are being met, in addition to indirect service providers' techniques (T') related to data access and accountability methods and procedures.

e) *Interaction between public sector organizations and private concession-holders*

Innovations also include building on indirect service providers' techniques (T') in relation to methods for monitoring and investigating the activities performed by direct service providers through the visual inspection of geotechnical problems perceived.

Furthermore, it is worth noting the importance for indirect service provider engineers and technical staff supervising the landfills of knowledge (C') related to handling systems, equipment and technological resources, as well as knowledge related to understanding the biogas capture process.

According to the direct service providers, indirect service providers need to develop competences (C') to promote innovation, in particular with regard to establishing effective routines and communication channels. Currently, communication occurs through the submission of environmental quality monitoring reports and on-site periodic inspections of indirect service providers.

Another point to highlight relates to regulations and standardized methods for odors and gas monitoring and sampling. The periodic inspections are performed on a case-by-case basis, according to the criteria set out by the inspector visiting the landfill. Therefore, techniques (T') must be developed in order to define procedures to evaluate the adverse impacts produced by landfills activities.

## 5. Conclusion

The aim of co-benefit indicators is to contribute to the analysis of the innovation dynamics in order to clarify service changes and expose deficiencies in terms of the amendments demanded by stakeholders so as to fulfil the requirements related to the promotion of CDM project co-benefits.

By using the characteristics-based model and the ServPPIN concept, the main goal of this study was to evaluate to what extent the projects have fostered innovation in landfills whilst promoting social and environmental co-benefits and the participation of stakeholders.

The focus on competences and techniques related to services produced is based on the analysis of innovation in order to contribute to a better understanding - and discussion - of the opportunities and limitations of CDMs in the waste sector.

The focus on the interaction between public and private sectors and users is based on the ServPPIN theoretical approach, highlighting the importance of relational aspects.

Finally, in terms of the implementation of CDM projects, it is suggested that the development of techniques, competences, and stakeholder interaction should be fostered so as to contribute towards the improvement of solid waste public services in the context researched, in particular, during the last stage of service provision: the final disposal in landfills.

# A labour process approach to derived typologies for service innovations for Mexican KIBS

Leonel Corona-Treviño<sup>1</sup>

National University of Mexico UNAM

## Abstract

An innovation typology is developed based on the historical technology labor process changes taking into account services and goods at each stage. This dynamic approach goes together with productivity which is a function of the speed of capital flow depending on the economic cycle. The different kinds of services have an impact on innovation according to their function in the capital cycle: production, circulation or both. This top-bottom analysis is complemented with the application of these theories to 35 knowledge intensive business services, KIBS, in Mexico (mainly software & ICT) contrasting their output in innovations and market positioning with their inputs in investment in R & D, workers' qualifications, components used in innovations and external knowledge links.

**Index Terms** *KIBS, software, typology, labour process, capital cycle, Mexico.*

## 1. Introduction

In a context of economic crisis Schumpeter's innovation and entrepreneur concepts are related to the swings of "creative -destruction"<sup>2</sup>. The long term economic waves of prosperity-recession, and depression- improvement result in the development of service economies that is, economies with half or more jobs in services (Schettkat & Yocarini, 2006), (Fuchs, 1968) (Evangelista & Savona, 2003). In this context, that is the evolution towards knowledge societies, we need to follow up the emergence of Technology goods and Knowledge intensive business service, KIBS, and the decline of different industries over time<sup>3</sup>.

Research on innovation has been oriented towards measurement and the positioning of firms, regions and countries which has been very important for comparative studies<sup>4</sup>. But this development has put aside Schumpeter's theoretical approach of innovation (Drejer, 2004). So, the purpose of this paper is to point out the importance of

<sup>1</sup> This paper is a product of the research supported by DGAPA UNAM under the project PAPIIT IN305913, in which Blanca Borja and Dioselina Obispo provided help for data analysis.

<sup>2</sup> The process of creative-destruction can be analysed at firm or industry level, as a process of industrial change and renewal which is fundamental for economic growth and development (Schumpeter, 1976).

<sup>3</sup> „the innovation process, and service activity within that process, suggesting that service-centered perspectives relating to consumption and technological innovation will become more central to the competitive advantage of firms and nations“ (Howells & Teller, 2004).

<sup>4</sup> The OECD has worked for 50 years on the development of science, technology and innovation indicators. Today, innovation raises measurement challenges that are either new or require urgent attention (OECD, 2010).

going back to consider some abandoned theories such as the different kinds of labour processes and the functional spheres of the capital flow for both goods and service innovations.

So, innovations involving new products, processes, markets, resources and organizations are key concepts for theoretical and empirical research.

## 2. Literature Review

The evolution of the economic analysis of services and particularly of service innovation has been characterized in the following approaches: assimilation, demarcation and synthesis (**Coombs & Miles, 2000**). In the assimilation approach, service innovation is regarded as similar to innovation in manufacturing, while in the demarcation approach as services are different, they are considered to need a specific method. Then, anticipating a synthesis, the interrelations between goods and service innovations (**Omachonu & Einspruch, 2014**) involve a combination of new and old theories and concepts (**Djellal & Gallouj, 2013**).

Comparing service innovation with goods innovation, there is a 'reverse innovation cycle' which differs from the classical manufacturing one, as in the consumer services industries innovation begins with the efficiency of delivering the service, followed by process innovation that develops service quality, and finally, service product innovation achieved through new kinds of services (Barras, 1986).

In order to classify service innovation four characteristics are proposed (den Hertog, 2000): service concept, client interface, service delivery, and technology which are related to personal, organizational, marketing and competing capabilities. Another approach involves considering which factor is undergoing most change: physical (goods), information, Knowledge-based or people, or stressing intra-services differences in terms of the patterns of technologies used, relevant market characteristics and the technical skills required (Miles, 2008).

However the labour process and the capital cycle flow have not been considered in the literature to explain service innovation.

## 3. Methodology

We used a deductive, top-down approach which involves: 1) considering historical changes in the labor process separating goods and services at each stage; 2) classifying services considering: a) whether they are part of the production or circulation processes, as in the case of financing and marketing; and, b ) whether the client is a consumer or producer or both: service co-terminality, and co-production or client interaction (Kvålshaugen, et al., 2008) – thus, they could be part of consumption or/and production<sup>5</sup>.

<sup>5</sup> Co-terminality, when "service product, process, and service consumption take place at the same time and place". (Miles, 2008). Co-production is when "the production of services by KIBS is often the result of a joint effort of service provider and client" (den Hertog, 2000).

First, the evolution of the labor process is classified into both services and goods used in production. The point of departure is the artisan process which needs hand instruments and knowledge related to specific skills. Then follows the industrial revolution that has two phases: one, manufacturing based on the division of labor between workers and two, the introduction of machinery using steam energy. So, machine-tools demand different services from maintenance on up to specialized skills, organizational services and energy require prospection and distribution services (Table 1).

As the labor process tends towards automation, there is demand for supervision, control, information and computing services, as well as software and design. Next, science incorporates intellectual and creative knowledge, R&D, information systems, and networks services into production.

Besides labor, machinery, energy, information and commodities, the consumer who also serves as co-producer is added, generating a kind of co-producer and self service<sup>6</sup> (Table 1).

Secondly, services are classified accordingly to their function in the process of the Circulation of Capital. So services could be inputs in production (e.g. design, business consulting), or they are part of the circulation process, mainly services of marketing and finance. If the product is a Service, S, it is delivered to the client -so it does not become a commodity as in the case of Goods; a different kind are the tradable services<sup>7</sup>. Also, some services are finished by the client, adding use value to it (eg. a transaction made in an ATM).

The two approaches are applied together, considering that the labor processes are all present as heterogeneity can be observed, meaning that the hand craft and manufacturing are present along with automated processes.

An inductive, bottom-up approach was then used starting with 35 Mexican KIBS applying this general typology and a specific indicator related to innovation and diffusion (INDICO<sup>8</sup>), as well as the four-dimensional model of service innovation based on 1) service concept, 2) client interface, 3) service delivery, and 4) technology, thus establishing different patterns in the relationship between the supplier, service firm and client (den Hertog, 2000).

A correlation analysis is made with the data of the 35 firm in order to test the hypothesis of differences in the causes of innovativeness and service innovation patterns in function of: labor process, position in the circulation of capital, firm size (number of workers), R&D investment, client participation and knowledge-intensive service.

<sup>6</sup> [., ]by exploiting new digital technologies, firms like Apple, Lending Club, and AirBnB have made customer co-creation of value central to their business models and in doing so now rank among the world's most innovative and valuable firms" (Barry, et al., 2015).

<sup>7</sup> Tradable services are: Education, Health, FIRE( Finance, Insurance, Real Estate), Architectural and Engineering services, ICT and New Media, Producer Services (Business consulting, Marketing, Management, Accounting, Legal, etc.), Transportation and Logistics, Government services, Cultural services (Goldberg, 2009).

<sup>8</sup> The INDICO Index is explained in (Corona, 2015).

## 4. Results

A way to generate a typology is proposed based on the separation of the labor processes into goods and services, and the kind of economic activity in relation to the capital cycle, providing a new explanation to the descriptive variables presented in the literature, considering the heterogeneity of services and innovations.

An exploratory study of 35 innovative firms is made through direct interviews, along 2013 and 2014, based on a questionnaire<sup>9</sup>.

First an index of the firm innovativeness, called INDICO (Innovation, Diffusion and Competitiveness), has been proposed base on its capabilities and results.

Second, after different correlations to explain the firms' innovativeness, the following linear regression accounts 60% of its dispersion:

$$IN = 1.97 + 1.81CI + 0.38KC + 3.35 k; \quad R^2 = 0.60 \quad (\text{eq. 1})$$

t,    (3.36)   (2.27)        (1.10)        (6.28)

Where,

IN, Indico Index (0-10) which expresses the firm's innovativeness (note 6).

CI, client participation in the innovation (0-1).

KC, capital cycle phase: production (2), market (1) and finance (0).

k, proxy variable of the knowledge intensity of firms' innovations: Software design and engineering.

t, t-Student.

The knowledge intensity of firms is used instead of the labor process index which was rejected statistically. This could be because there are different kinds of innovations depending on the level of labor, from artisan up to automated production and the scientific process. So, a more detailed analysis would be necessary.

Therefore, considering that most of the firms selected are related with software either because they sell it or use it, software and design and engineering knowledge content is applied as a proxy variable of knowledge intensity (k). For this variable the regression coefficient is the largest, explaining the marginal growth of innovation, 3.35. In second place comes client-producer participation with a coefficient of 1.81, which is only affirmative in 20% of the firms. So, a policy for promoting client inclusion for innovation could benefit the other 80% of the firms selected.

Unexpectedly, lifecycle (firm's age), labor process, R&D expending and firm's size (number of workers), show a low correlation with the innovation index, as these variables have been statistical rejected (t-student).

<sup>9</sup> Of the 35 firms are 4 producing goods and 31 services. 24 are in Mexico, 10 in Girona, Spain and 1 in Costa Rica. The main business activities are software (18), informatics (5), marketing (3) and others (tourism, health, consulting and food services).

Finally, according to the position of the firm in the phases of capital, innovation increases 0.38 if the firm is in marketing or twice this value if it is in production; and void if it is in the financial phase.

## 4.1 Discussion

The labor process as an explanation variable of service innovation has not been statistically proved at firm level. So, problems for future research include: 1) differentiating between varying types of innovation depending on the kind of labor process, and 2) applying our methodology to in a larger sample of firms. Nevertheless, there is a difference in the evolution of the labor process due to the coexistence inside the firm and between firms of artisan, manufacturing, automation and scientific processes. This notable heterogeneity has real impacts of innovation opportunities based on the ICT and could be a possible explanation for the importance of software and design and engineering in the firms' innovativeness (eq.1).

In contrast, the position in the capital cycle has the lowest impact on service innovation (0.38, eq1). Accepting the analysis of the capital cycle, future research, it will need to look into its phases in more detail, perhaps dividing them or establishing other complementary functions<sup>10</sup>.

Client participation on innovation it is at present widely studied. Co-terminality of services (Miles, 2008), based on the viewpoint of "use value", needs to be complemented with the "potential value" of client participation which is implicitly transferred to diminishing firm's production costs (Fig1). Thus, the consumer-as producer can increase innovation in 1.81 times. Hence, another line of research is to develop a typology of client participation in production, both as a value-user and in value-transfer.

## Conclusions

This paper addresses the following approaches to explain the variety of services:

- 1) Services and goods are both part of the evolution of the labor processes, from artisan, manufacturing, automation up to scientific processes (Table 1). As these labor processes coexist in a given period of time, they generate a production heterogeneity which is wider in services.
- 2) Mainly through services the Consumer- (as) producer is added to the traditional production components, Labor, Machinery, Energy, Information, Science (knowledge). The client's participation as co-producer is impacting the production of services as well as on innovations.

<sup>10</sup> Dividing the capital cycle phase, KCb into direct participation (2 for production, 1 for distribution, 0 for financing) and support activities (1; 0.5; 0, respectively) the resulting correlation is:

$$IN = 1.94 + 1.17CI + 0.56KCb + 3.39 k; \quad R^2 = 0.62. \quad (eq2)$$

$$t, \quad (4.41) \quad (1.50) \quad (1.69) \quad (6.23)$$

- 3) Service innovations are influenced by the position of the firm in the phases of capital cycle.

The regression analysis of 35 firms shows that software and design and engineering knowledge has the largest marginal impact growth on innovation, 3.35. In second place comes the client-producer participation with a coefficient of 1.81; and thirdly, the position of the firm in the phases of capital, 0.38. (equation 1).

# Co-production of the Service Recovery – Embodiment Perspectives for the Innovation from the ICT-centric Service Encounter

Jannick Kirk Sørensen

<sup>1</sup>Center for Communication, Media and Information technologies,  
Aalborg University

*In this paper we apply Dourish' (2001) conceptual framework of embodied interaction on a ICT-centric service encounter, namely the use of the online self-service system for reporting of tax and tax reduction claims offered by the Danish tax authority. An expected short and straight-forward service encounter developed in this case into to a two weeks long service journey involving several human and computer actors as the reason for the service failure (represented by a blank pop-up window instead of the expected online form) could not be found. The case, which is seen as paradigmatic is used to test the potential of using Dourish' frame for a better understanding of the co-production of a service recovery. Bringing together service research, HCI and design research, this paper is an attempt to discuss whether the embodied interaction framework is productive for the analysis of the interaction and the service recovery process, thereby informing the innovation and design of ICT-centric service encounters.*

## 1. Introduction

Typically, when an ICT-based service encounter develops differently and less easy than anticipated by the customer / user, one would talk about “low user-friendliness” or “bad design of the system”. Professional usability experts can conduct tests and examinations to single out the problematic elements in the interactive system. This approach is often normative in the sense that ideally all usability problems should be eliminated. Where this approach appears straightforward when simple systems and simple interactions are in question, the normative usability approach becomes less operational when we look at complex service journeys with both human and ICT-based touch points. This is particularly the case when the service journey develops unexpected and becomes much longer due to a non-functioning interaction between the different elements in system, including human service workers and the user. Finding the reason or reasons for the service failure might be futile in a complex service journey. Widening the scope of understanding from a narrow usability-oriented explanation we can speak of a service failure in an ICT-based service that calls for a service recovery.

The starting point for this paper was an unexpected long service journey I had with the Danish tax authorities. The service encounter evolved into search for the cause of a fatal error: a blank pop-up window instead of an online form for reporting tax reduction claims. The service journey involved a web-based self-service, a family member, two browsers, two plug-in browser extensions (3<sup>rd</sup> party software), a login- / authentication service, three service helpers in a phone-based hotline. The aim of the

paper is however not to conduct a usability test or evaluate the specific service recovery process, but to use this case as a starting point for a discussion of the potentials in applying Dourish' (2001) embodied interaction framework on the analysis of the interaction between the different actors / entities in the service encounter and service recovery process. The question is whether an embodiment-informed approach, can provide a better description of the interaction between the different human and technical elements in a ICT-based service encounter than the traditional face-to-face oriented service encounter and service recovery literature. We question thus whether the different conditions for ICT-based service encounter produce a need for a different analytical approach. The aim is to provide new insights into and an understanding of the complex ICT-based service encounter, e.g. one where service failure and service recovery plays a central role.

With this paper we thus aim to examine and discuss whether the embodiment approach to the analysis and design of ICT products as proposed by Paul Dourish (2001) is productive for the analysis of ICT-based service encounters. Dourish' main claim is that our understanding of the use of IT products and services should acknowledge that the use is embedded in a physical (tangible) world as well as in a social world. Derived from the embodiment-informed analysis of a specific ICT-based service encounter, which revolves around the co-creation of the service recovery, we discuss whether the embodiment approach offers new ways to innovate from the ICT-centric service encounter, particularly those which needs service recovery. The question however how far Dourish' embodiment framework can be extended on very cognitively dominated service encounters, such as tax reporting or the search for solutions of service failures in ICT-systems.

## **1.1. Research questions**

The questions we ask above lead to the following research questions:

- What is the relation between Dourish' concept of embodiment, and service failure, problem search and service recovery in the ICT-based service encounter?
- Can Dourish' embodied interaction framework contribute to the understanding of the possibilities for innovation in ICT-based service encounters?

## **1.2. Expected results**

Through the detailed analysis of a specific ICT-based service encounter through the concept of embodied interaction the interplay between the different human and technical elements in service encounters may be described in a more comprehensive and general way than traditional usability methods or service recovery literature allow. The embodied interaction framework helps identifying the particular conditions for the ICT-centric service encounter, which are different from the face-to-face service encounter. This can contribute to the understanding of complex ICT-based service encounters, and provide perspective for innovation from these encounters.

## **2. Theoretical background**

### **2.1. Embodied interaction**

Paul Dourish' (2001) embodiment approach to user-interaction with computers is rooted in the historical development of computing from large experimental main-frame computers that were programmed manually to compute well-defined mathematical problems, to today's ubiquitous use of computing in almost all aspects of life. His point is that where the starting point for computing was highly cognitive and abstract, today's use of computing is embedded in a social and tangible world. We, as normal users, do not approach computers as abstract calculators, but as representations of real-world phenomena. His book "Where the Action Is – The Foundations of Embodied Interaction" (2001) could thus be described as an examination of the tension between the strict logic of computing inside the machines and the rich and complex diversity of the real world situations in which they are being used as tools. Dourish is thus interested in how meaning is created by users in a specific context, and subsequently in how the principles for the design of social and tangible computing should be phrased.

Dourish' book (ibid.) is written before the commercial break-through of touch-screens and social network services, which could be described as examples of respectively tangible and social computing. The book's more general approach to embodiment makes however its analytical framework relevant also today. As Dourish (2001, 100) observes, the idea of embodiment is not new. His account is based on thorough studies and discussions of "The Phenomenological Backdrop" (2001, 103-116). Space does not allow an equally detailed introduction to the phenomenological thinkers Husserl, Heidegger, Schutz and Merleau-Ponty. Instead we build on Dourish's formulation of embodiment in a computing context.

#### **2.1.1. Embodiment as Tangibility**

Dourish's starting point for the discussion of embodiment is the common sense notion that smooth interaction appears to be based on some kind of "familiarity" (ibid. 99). To develop the "familiarity" concept, he introduces two elements: tangibility and socialibility. Together they form the embodiment. He allocates two full book chapters to discuss each of the aspects of computing. Our presentation of his thoughts must necessarily be shorter. A starting definition sounds:

"Embodiment is the common way in which we encounter physical and social reality in the everyday world. Embodied phenomena are the ones that we encounter directly rather than abstractly" (Dourish, 2001, 100)

The embodiment is however not reserved for physical objects alone. He extends the embodiment concept to encompass also "other phenomena that unfold directly in the world; conversations, mutually engaged actions" leading to a definition of embodied phenomena as "those that by their very nature occur in real time and real space" (ibid. 101). The interesting point here is what he understands as 'real' and where reality stops and becomes abstract.

Dourish is not perfectly clear about this, but he observes an interesting property of computation: Computers have a dual nature since they at the same time are physical

devices powered by electric power, as well as medium for information (ibid. 140-142). The binary signals, which they contain and process are at the same time information that represents real world embodied objects. Computers are at the same time abstractions and implementations that make the abstractions real. However, as Dourish observes, computers are also themselves objects, e.g. with specific properties in memory and processing speed. The embodied computing relies thus on a tight coupling between the abstract data, the representation of it and the real tangible world.

### **2.1.2. Embodiment as Sociability**

The other component in embodiment is the social character of the interaction: He argues that “[e]mbodiment denotes a form of participative status” (ibid. 101). Inspired, among other sources, by the research in computer-supported collaborative work (CSCW), Dourish (ibid. 186) stresses that the use of computers often takes place in a “community of practice” (cf.: Lave and Wenger 1991; Wenger 1998). This concept indicates that learning often takes place as “legitimate peripheral participation” where the learner in a kind of apprenticeship is peripherally associated with a community of practice. This community of practice is held together by the shared histories, identities and practises. For Dourish, the technology plays an active role in these communities of practice: “the technology does not simply afford certain sorts of actions, but (...) [it] also reflects particular sets of assumptions, conventions, and practices within a community” (ibid. 186). There is thus as mutual interaction between the community of practice and the tools being used in this community.

### **2.1.3. Computing as a medium in itself**

In the discussion of the coupling between the real world and its representation in the “parallel world” of computing, Dourish first of all makes us observe that computing has a dual nature of being both symbolic representation but also an actual physical phenomenon taking place as electrical currents in circuits. The computing can thus be seen as a medium in itself, a medium through which meaning is being modulated in the same way as “as signals modulate media” since “technology is embedded in a set of practices” (ibid. 166). It is however the users, not designers of the systems that create and communicate meaning – the mental coupling between real-world phenomena and their representation in the IT-systems: “Coupling is a matter for users, not for developers” (ibid. 173). He extends this argument to claim that embodied technologies participate in the world they represent (ibid. 177). The question, which is not discussed by Dourish, but which is central to our case, is: How well does computing modulate real world practices? Is tangible and social knowledge being lost in the computing if it cannot be modulated?

## **2.2. Embodiment in ICT-based service encounter**

In its physical sense tactility is a central concept in a traditional face-to-face service encounter. Some (e.g. Henten, 2012) would even define a service through the simultaneous production and consumption, as inseparability of the service customer and the service render. Others would conversely mention the intangible nature of the service – a property that by definition contradicts the idea of embodiment, at least if embodiment is understood narrowly as a physical object.

Shostack (1982, 51-52) introduces the term “service evidence” which could be described as an embodiment of the service encounter. There are two types: Peripheral service evidence plays only a minor role in the service encounter, e.g. a confirmation of the service, such as an airline ticket. It has no independent value. The essential service evidence, Shostack argues, cannot be possessed by the customer, but is e.g. used to produce the service: “it may be so dominant in its impact on service purchase and use that it must be considered virtually an element in its own right” (ibid. 52). An example would be the physical aircraft that transports the passenger.

When we look at ICT-based service encounters, this distinction is challenged. The service encounter has no physical manifestation neither as peripheral or essential service evidence. The service rendering on the interface is just made by pixels, LCD dots powered by electricity. Nevertheless, service customer may still perceive the service evidence. Besides the physical properties of the end-user equipment (e.g. PC-screen, smart phone or tablet) which physically renders the service, there are also other types of service evidence, e.g. the confirmation email, the access code, the user name, the ‘confirm’ dialogue box, the error message, etc. Although intangible in nature, these fulfil the role as service evidence in the ICT-based service encounter.

### **2.3. Innovations from ICT-based service encounter**

This paper attempts to apply the analytical framework of embodied interaction on ICT-service encounters to look for new approaches for conceptualising innovation in and from these encounters. The research in service encounters, and particular on innovation from ICT-based service encounters provides thus the other base for this paper.

The field of service research, including service encounters, is broad and well established, as well as research on e-services and service encounters in these. One discussion in this field revolves around the nature of ICT-services: In some aspects they appear to like goods, in other aspects they appear to have service properties (Sørensen & Henten, 2014). Lusch & Vargo (2006) introduce however in their discussion of the properties of goods and services, the idea that one can talk about either about a goods-dominant logic or a service-dominant logic. The latter is however increasingly dominating also in the traditional goods industries: Goods are also being marketed and sold as services.

If we look more specifically on research on innovation from service encounter, a recent research project (ICE – Innovation in the Customer Encounter) has contributed with a new empirically informed understanding of the field. Sundbo, Sundbo & Henten (2015) examines empirically the factors that influence the innovativeness of service encounters. Seven propositions, hereof two which is ICT-related, are tested in qualitative field-experiments in nine service organizations. The ICT-based service encounter is not the particular focus for the researchers. Instead, it is examined whether “[i]t is particular conducive to idea creation if the customers have the opportunity for face-to-face communication besides the ICT-network communication (e.g. via hotlines)” (proposition 5, ibid. 262) or whether the “[a]nalysis of the ICT-encounter basis (e.g. website) can produce knowledge about which factors in the site trigger the customers to enter an interaction process and provide good ideas for innovation. The

more interactive an experimental the site are, the more it can be assumed that the consumers react by presenting new ideas” (proposition 7, *ibid.* 262).

In relation to proposition 5, one field experiment included customer interviews combined with innovation seminars, Facebook communication and GPS tracking. This experiment did not produce particularly much innovation from service encounter. Another field experiment that used Facebook and Youtube showed that innovation was possible without face-to-face encounters. In relation to proposition 7 two field experiments showed that the indirect observation of users without their direct involvement do produce innovations. Two other field experiments showed mixed but positive experiences with direct ICT-mediated interaction with customers e.g. via mail and Facebook.

The question whether the conditions for and the character of innovation from the ICT-based service encounter are different is however less researched. Drawing on the media richness, innovation and service encounter research literature Henten (2012) offers a theoretically informed analytical ‘service approach’ framework of categories of services to analyse the dynamics of innovations from ICT-based service encounters. Sørensen and Henten (2014) look at Co-creation of Innovations in ICT-Based Service Encounters by including research from Human Computer Interaction (HCI), user centred design and interaction design traditions. The implications of the particular characteristics of the communication between customers and service providers in ICT-based service encounter are discussed in relation to innovation: Which roles do the lower media richness and the rigidity of interfaces and interaction (cf.: Harris & Henderson, 1999) play in ICT-based service encounter compared to the face-to-face service encounter? Is innovation impeded or improved? The hypothesis (*ibid.* 70), now open for empirical testing, is that incremental innovations are easier to communicate in the ICT-based service encounter than radical innovations, and thus that the incremental type would dominate in the innovation from the ICT-based service encounter.

## **2.4. ICT-based or ICT-centric**

Another outcome of the Sørensen and Henten (2014) article was the observation that much research of ICT-based service encounters appears to take the vantage point of traditional face-to-face service encounters when looking at ICT service encounters. This idea is developed further by Sørensen & Skouby (2015). The technology is often seen as an element inserted into or added the face-to-face encounter (cf. Bitner, Brown & Meuter, 2000; Froehle & Roth, 2004). This implies that the particular properties of ICT as material for design (cf. Löwgren & Stolterman, 2004) of service encounters may not be acknowledged when ICT-based service encounters are conceived. This has again implications for the potential for innovation from the ICT-service encounter, as we can see the one cannot expect the same type of innovation from this encounter as from the face-to-face encounter. If innovation potential in the ICT-based service encounter should be utilised, it is required that the particular properties of the ‘design material’ ICT is understood.

This shift of vantage point invites to view the entities “customer”, “service provider” and “ICT” as three entities in their own independent right, however with mutual relationships: In the same way as the customer has a relationship with the service provider (as institution, company or organisation), there are also relationships between

the customer (user) and the ICT, as well as between the service provider and the ICT. The claim in (Sørensen & Skouby, 2015) is that in both cases do the ICT contribute to shaping the service encounter. The ICT is not a neutral tool.

To reflect this we use in this paper the term “ICT-centric”, not the term “ICT-based” (see e.g. Sørensen & Henten, 2014; Henten 2012). “ICT-centric” indicates that rule-based logic in ICT shapes the service encounter, where as “ICT-based” mere point at the use of ICT in the service encounter (cf. Froehle & Roth, 2004) or is “infused” into it (cf.: Bitner, Brown & Meuter, 2000). We aim for the discussion of how ICT changes the service encounter, how ICT sets the conditions for the service journey. This perspective enables us to understand the problems that occur during the service journey not just as simple usability problems, as deviations from the planned and expected path for the service encounter, but also as productive information about the nature of ICT.

There is conceptual link between the idea of service blueprints (Shostack, 1982) and ICT services, as computer systems are constructed of rules (computer code) that require a very high degree of regularity, which again reflects the ideal bureaucratic organisation, cf. Harris & Henderson (1999). Zysman, Feldman, Kushida et al. (2013, 99) observe: “When activities are formalised and codified, they become computable. Processes with clearly defined rules for their execution can be unbundled, recombined, and automated. The codification of service activities allows the rapid replication, analysis, reconfiguration, customization and creation of new services”. The authors’ view of this “algorithmic revolution” of services appears to be primarily economical. The quality or customer perception of the encounter is not in their focus.

One central question of “the algorithmic revolution”, which is not discussed by Zysman et al. (2013), is the degree to which actual service encounters follow specific patterns or rules. This question is also raised by Harris & Henderson (1999). They maintain there is a big gap between the ideal bureaucratic workflow and actual workflow (ibid, 90). Bureaucratic praxis do thus accommodate “the particularities” of each case by fitting it to the rules, changing the interpretation of the rules, which subsequently may lead to changes in the rules. This pragmatic flexibility also makes organisations more efficient: “Since enforcing obedience to the norms is costly, those who maintain the integrity of an organization must be sensitive to dissent and must make pragmatic tradeoffs to keep the organization viable” (ibid. 90). The problem Harris and Henderson point at is that IT systems seldom have this flexibility or any contextual or situational awareness. IT-systems typically reflect an idealised image of a bureaucratic organization where no particularities exist. But as we will see in the following empirical material, some service encounters are so complex and particular that they do not offer themselves for automation. Conversely, as we will see, the automation itself produces a longer, more complex and less satisfying service encounter.

## **2.5. Co-production of the service recovery**

The marketing literature on co-production and co-creation of value in services is extensive. Vargo & Lusch (2006) assert in their definition of the characteristics of the “service-dominant logic” that the “customer is always a co-creator of value”. The focus is thus often on the managerial and economical benefits for companies. The classic example of co-production could be customers’ self-service in supermarkets. An exception is Bendapudi & Leone (2003) scenario-based empirical studies of the

“Psychological Implications of Customer Participation in Co-Production”. In the following we will however focus specifically on the much smaller literature on co-creation in relation to the service recovery.

Dong, Evans and Zou (2008) look at what happens when a co-created service fails. Service failure is inevitable in the service industry. The company's reaction on the service failure has however big implications for the customer's perception of the company. Potentially it could either reinforce customer bonds or convert a small and annoying incident to a very negative position. Dong, Evans and Zou (2008) examine through a laboratory experiment where 200+ undergraduate students were confronted with a service failure either in the set of an Internet connection or in the registration of courses. Unfortunately, the authors do not examine the detailed interaction during the service failure or the students' possibilities to co-create the service recovery, e.g. by reporting an error or helping each other, since the test persons only evaluate a short written scenario that describe a specific but hypothetical situation and not a real-world service recovery journey using a e.g. a ICT service. The usefulness for the understanding of the service recovery in ICT-centric service encounters is thus little, particularly regarding the implications for design. It is questionable if a laboratory experiment evaluated with statistics can produce the necessary operational insights into the customer participation in an ICT-based service recovery that are relevant for the design of ICT services.

Roggeveen, Tsiros & Grewal (2012) present like the above study a statistically informed paper with laboratory experiments where students were asked to imagine themselves in scenarios related to a delayed airplane. The details about the service failure (delay) and recovery (economical compensation) were different for the individual students. Students were subsequently asked evaluate different statements on a Likert scale indicating their satisfaction and willingness to co-create the service recovery. The co-creation of the service recovery could e.g. be to search for a new flight. For our research question, the problem remains the same as with the paper by Dong, Evans and Zou (2008): It predicts the statistical likelihood for the customer participation, but methodologically the scenario-based approach does not produce much knowledge of how a real-world service failure and service recovery eventually would be co-created, or how the service design (hereunder interaction design) could anticipate the co-creation of the service recovery.

Methodologically for the study of particularly ICT-centric service encounters it could be interesting to use other methods than scenario-based, since this only operates on the customer's cognitive level and only look at hypothetical situations which is open for the test-person's interpretation. If customer-participation in service recoveries were studied as a sequential process extended in time, capturing both the customer's considerations and reflections, as well as the detailed interaction with the system as well as the human service staff, a more fine-grained and thus more operational understanding of the potentials and risks in the customer participation in the service recovery could be achieved. The research should obviously extend beyond the technical problem finding, and also include customer satisfaction and willingness to future co-creation.

### 3. Method

This paper is based on the detailed recording and description of a specific ICT-centric service encounter with the online self-service interface for reporting of tax and tax reduction. After an initial analysis of causes and effects in the service encounter and its service recovery, Paul Dourish' (2001) framework of embodied interaction is applied to identify knowledge that extends beyond the single case, but which could be relevant for the design of ICT-centric service encounters.

The analysis presented in this paper is based on a single case. Obviously, this is a weakness if one wants to present general claims or proofs. The case concerns a specific service encounter with one relatively long service journey. It can be argued that many other service encounters in the same self-service system (Skat.dk) are possible. At a few nodes in this service journey, the journey could have developed very differently if other options in the interface had been chosen or if the reason for the problem had been discovered earlier. The aim is however not a general usability-centred criticism of Skat's self-service system, but to use the case paradigmatically "[t]o develop a metaphor or establish a school for the domain that the case concerns" (Flyvbjerg, 2006, 203). It is thus very possible that other case studies of Skat.dk could contradict the analysis presented here. Instead of engaging in a discussion of the most representative case or the most typical usability- or service design problems, we here want to examine a more general phenomenon, namely interplay between a user, a system and a use context, as it looks like through the analytical approach of 'embodiment' as suggested by Dourish (2001). Our point of reference is thus the phenomenon of the specific case presented below.

We document and present the case in detail in an attempt to capture all phenomena and events, which could inform the analysis of the case from the embodiment perspective. To document the case we have during the service journey numbered and described every step (defined as any interaction with the system, with other persons or as own my problem-searching reflections) in a log text (diary). Along the description of each step, a screen dump was made when possible of the actual appearance of the interface in the web browser.

The 'steps' are defined as 1) an action performed in an interactive system (e.g. a selecting and clicking a button) 2) as the user's reflection, e.g. on change of strategy, 3) events during a conversation between humans (e.g. between me and my mother, or between me and a hotline service worker). Steps thus can be different in length and importance. I include the 'micro' interaction of e.g. clicking "OK" buttons in the interface in our log. The micro interaction is also embodied interaction, although not cognitively present to the user. This type of micro interaction may not take of user's attention, but it slows down the service journey: e.g. the logon procedure via NemID it requires 6 to 7 steps of typing in user name, password and secret key number. I have translated the Danish terms, which appears in the interfaces, tax regulation descriptions and other documents.

The method we used could thus be described as a modification of classic "think-aloud" test / "cooperative evaluation" (Ericsson & Simon, 1984; Wright & Monk, 1991). In this case the task to be performed is a real case (with economical consequences) that is defined by reality outside the typical lab-based test-situation for "think-aloud" tests. As a researcher I also must add an extra element of self-observation since I need to describe every step of my actions and thoughts in detail.

What is different from the traditional think-aloud test is thus that the “thinker” (the user) also is documenting and analysing. We could call the method a “step-by-step self-observing think-n-write documentation of service journeys”. As each small step of the service encounter was described in the text file by the research directly after completion of the step, the dangers often affiliated with self-reporting, such as memory lapse or tendencies to construct explanations and causalities, could be avoided: The research had no idea of where the service recovery journey would go or if the problem would be resolved.

The methodological challenge of when and how to encourage the user’s spoken expression of thoughts to the observer, as discussed by Boren & Ramey (2000), is thus replaced with the methodological challenge of capturing one own thoughts. As the service journey however is sequential, and since the interaction with the self-service system only progresses if the user – in this case me – interacts, there have been very good opportunities to document both actions, screen appearances and thoughts before proceeding to the interaction. An exception here is the telephone conversations, which have been summarized and documented as text immediately after the end of the conversation.

My professional and academic training in interface design and system design may also influence my observations as well as my interaction with the system, and thus influence the analytical starting point for the exercise. However, within the fields of system design, information architecture and usability testing there is a wide-spread use of experts, including the software designers themselves, in the testing of the consistency of the information architecture (navigation) as well in the discovery of usability problems: In cognitive walk-through the system developers or interaction designers examine the logic coherency of the menu options (cf.: Lewis, Polson, Wharton & Rieman, 1990; Polson, Lewis, Rieman & Wharton, 1992). In heuristic evaluation of user interfaces (Nielsen & Molich, 1990; Molich & Nielsen, 1990), a few professional persons evaluate the user interface.

## **4. The Case**

### **4.1. Tax Reporting Service Encounters in Denmark**

The service encounter with the tax authorities in Denmark is for the typical salary earner or receiver of welfare benefits based on self-reporting. This has been combined with increasing automation through Skat’s retrieval of tax-relevant information from employers, pension funds, social welfare institutions and banks. Citizens normally need only in special cases to report to tax authorities. One of these cases is the service-related tax reduction. The service encounter has thus become very automated, and mostly invisible.

Since 1903 the Danish tax system has been based on citizen’s own yearly reporting of tax. This has traditionally taken place through a paper form. During the 20<sup>th</sup> century number of fields grows from initially very few to about 30 fields in the 1950’s (Rigsarkivet, 2014). Since 1970 Denmark has a system of income tax, implying that employers and other payment institutions (e.g. pension companies) pay the employee’s or retired person’s tax directly and report this directly to the tax authorities. Citizens were presented a pre-printed form filled with the financial information already

obtained by the tax authorities, e.g. paid salary and deposits in banks. The citizen is thus only to add supplementary information such as tax reduction or correct wrong information. Since 1996 a web- and phone based self-service allows citizens to report the tax online. The uptake was slow in the beginning, but at year 2000 about 60 per cent of all tax reporting was made through the self-service technology (Rigsarkivet, 2014).

Citizen's self-service in relation to public authorities has been made mandatory via three laws (no. 558 (June 18, 2012), no. 622 (June 12, 2013) and no. 552 (June 2, 2014) (Digitaliseringsstyrelsen, 2014b). Since December 2013 it has been mandatory by law for citizens to use the self-service technology (skat.dk) to report tax (Digitaliseringsstyrelsen, 2014a). This also includes that all communication to and from public authorities takes place digitally (Digital post), as well as a ubiquitous authorisation system (NemID) that is used both by public authorities (e.g. tax) as well as by private organisations e.g. banks. It is however possible to obtain either a permanent or temporary exemption from digital post if a citizen can prove that she or he is incapable of using the digital system or has no access to a computer at home. Other persons, e.g. family members can be authorized to manage the interaction with the authorities.

According to the "Scorecard" on the progress in the digitisation of the public administration, issued by the Danish Agency for Digitisation, currently (July 2015) 353.925 persons are permanently exempted, where as 155.830 persons are temporarily exempted (Digitaliseringsstyrelsen, 2015) out of total population in Denmark of 5.668.743 persons (1<sup>st</sup> quarter 2015, Statistics Denmark, 2015).

## **4.2. The Specific Use Situation**

My mother is born 1937, is retired and has no computer and has no intention getting one. She is exempted from digital post, but she has a NemID login. Since she does not use the self-service system for tax reporting at Skat.dk, so she has authorized me (via the authorization option offered by the tax authorities) let me see and correct her tax. The use of assistance from a family member is typical for elderly citizens, according to a governmental report on the use ICT in the Danish population (Wijars-Jensen, 2014: 13).

My mother lives in her own home and has for 2014 expenses from construction work in her garden, for which she wants tax reduction, according to law that was introduced June 2011 (LL § 8 V in law no. 1017, Oct. 28, 2011; Retsinformation, 2013). The tax reduction has in Danish different names e.g. "BoligJobordningen", "håndværkerfradraget", "servicefradraget". In the lack of an official English name, I translate it to the „Service-related tax reduction“. The maximum tax reduction is DKK 15.000,- (approximately EUR 2.000,-) per year.

## **4.3. Case Description**

The service journey presented below started around April 12, 2015 as my mother leaves a voice mail message to remind me her request for my help to report a tax reduction before May 1, 2015. The service journey ended April 26, 2015 as the tax reporting was finally completed by me through the self-service system. In the follow-

ing the service journey is described in detail in 242 'steps'. For the sake of overview, they have for the presentation here been divided into five phases.

#### **4.3.1. Phase 1: Expecting a straight-forward service journey**

**Step 1 - 3:** My mother asks me, as she has done earlier years, for my help to report tax-reduction to Skat.dk's online system. She does not have a computer and does not know how to use the system. Neither she shows any particular interest in knowing how the tax reporting is made in the Self-service system. We discuss whether the deadline for reporting has been transgressed, but at Skat.dk's landing page for this tax reduction no deadline is mentioned.

**Step 4 - 10:** She asks me to help her login, but she has forgotten her password. I remember that she once has authorized me in the system to take care of her tax, so I press the 'login with authorization' button and is transferred to the national authorisation system "NemID". Here I type in my user name, password and a number code that is printed on a cardboard paper (so-called 'key card') issued by NemID. By mistake do I type in the wrong number and get an error message, but type in the right number subsequently.

**Step 11 - 12:** I am shown a page at Skat.dk where I either can type in a person's civil registration number (CPR number), or press a button called "Show List". I assume that the list will show the person(s) for whom I have authorization, and press the button. That appears easier than typing in my mother's CPR number, with the risk of typing it wrong or in a wrong format.

#### **4.3.2. Phase 2: Problems Begins – looking for alternatives**

**Step 13 - 15:** I get an error message from Skat.dk: "You do not have access to the selected page". I don't understand the reason, I press back in the browser. I get a "Document Expired" message from the Firefox browser, but I press the Try Again. I assume that the document (page) is set to expire due to security reasons. I press 'Try Again', and get a warning message that Firefox needs to resend.

**Step 16 - 18:** I press 'Resend' and now I suddenly can see the CPR number of my mother listed on the page. I press the "Continue" button and the main menu page at Skat.dk for private persons is displayed. I can click on links to see my mother annual tax return for 2014, I can click to correct it (e.g. report a new tax reduction), I can pay back taxes. And finally there is a specific link "Report service-related tax reduction" ("Indberet servicefradrag (håndværkerfradrag)). The latter is precisely what I look for, so I try to click the link. Although the text becomes underline when I move the mouse pointer over, the link does not respond. This appears to be a simple technical problem: In status bar of the browser I can see that the link points to "Javascript void()", which means that there is no action for the software to perform when the link is clicked.

**Step 19 - 20:** I change strategy and click on "Correct tax return for 2014" because I know this way from the previous years. On the next page I see that the link "Report service-related tax reduction" again is inactive, this time marked as so. I start to think that the deadline for reporting anyway has been exceeded, although we did not find any deadline mentioned. On the other hand, this is end April 2015, and the tax reporting concerns 2014, so it may be too late.

**Step 21 - 23:** Even if the link is inactive, I examine a last possibility: to scroll down in the Tax return report to field number 460, which is about service-related tax reduction. Normally, this is the place where I report the figure. Next to the input field, there is an icon that represents a pocket calculator. At least, this is what I find out when I read the help text “You must click on the pocket calculator to change the information in this field”. I don’t understand what is meant with the term “pocket calculator”, until I see the icon. However I will do not know what it will do. I press it, as instructed. A white / empty pop-up window appears on my screen.

**Step 24 - 36:** I assume that the empty pop-up window is a technical error. I switch to see the HTML source, to see if something cannot be rendered, but this is also empty. I assume that my Firefox browser is causing the problem – as it did earlier, so I close the browser and repeat the entire in-log process in Safari for Mac OS. Same result: empty pop-up screen. I ask my mother to ask her to call the tax authorities. I want her to find out if the deadline has been exceeded.

#### **4.3.3. Phase 3: Tax Hotline Encounter – Suspects: 3<sup>rd</sup> Party Tools**

**Step 37 - 72:** My mother calls the tax hotline, call me back on a voice message that deadline is not exceeded. It is however soon approaching: May 1<sup>st</sup>. I call my mother back, and we agree that I try to logon again. The same blank pop-up window appears. I call the tax authorities and find my way through their call sorting system (“Press 1 for..”). While waiting 7-8 minutes in the virtual queue I try the other browser again, but with same result. Now I know I can tell the hotline-helper that the problem is not related to the browser, excluding some of the possible errors.

**Step 73 – 90:** The lady in the hotline believes that the problem is caused by my Java is not up to date. She consults a colleague, and a new voice comes to the phone. She thinks that the blocking of pop-up windows causes the problem. I try to explain that the pop-up window is actually shown. I get the idea that maybe the ad-blocker I have installed as a plug-in in Firefox could produce the problem. I can feel she is getting impatient, so we end the phone conversation. I close the browser and logon again. That doesn’t solve the problem.

**Step 91 – 116:** I download and install Java. I start the browser again. No change.

#### **4.3.4. Phase 4: Bug reporting**

**Step 117 – 145:** In my lack of new ideas I start reading the instructions at Skat.dk for the tax reduction. A pop-up screen opens – correctly – on my screen. It informs about the rules for service-related tax reduction. I click on “More information”. At the new page more can be read about conditions and rules, but one can also provide feedback and rating. What is being rated is unclear, but I can choose between five different smileys ranging from very happy to very unhappy. Out of frustration I choose the most unhappy smiley. I discover the link “Kommentar”, click on it, and am presented with a quite large text input field. Here describe the problem (which I assume) is cause by some combination of browser, operating system, plug-ins and the java scripts on the server. I state the name and version number of the browser, plug-ins and OS. I press ‘send’ and receive a receipt. I close the browser. I open the other browser to examine if the problem still exists. It does. I fill out the comment box again with information regarding the other browser, and I press ‘send’. I receive a receipt.

**Step 146 - 162:** I wonder if I can communicate the problem via mail to increase the likelihood that my message will be read. I search for a possibility to send a mail, but realize that I don't have this option in the interface, probably because I am logged in as advisor for my mother. She does not have an email address. I log out, and log on again as 'my self'. I click on menu item 'Contact'. Here I am encouraged to use the telephone hotline, but I prefer the mail, since I want my message about the bug to reach the right place in the organisation, and since it is a bit complicated to describe. I click "Write email", and a pop-up window appears. When selecting "Send secure mail to Skat", I am prompted to select from a long two-level drop down menu the topic that fits my query. I don't find any "report a bug" option so I select "Håndværkerfradrag (servicefradrag)" (the type of tax reduction in question). When arriving at this page, I am presented with FAQ's and different guides. Again I am encouraged to use the phone hotline. Finally, at the bottom of the page, I can click on "write mail".

**Step 163 - 170:** I start writing, describing the problem, as previously, as a technical problem. Out of a sudden I get the idea to see if this "pocket calculator" which should be used to report the tax reduction information, works in my case. It is easy to find out, now when I am logged in as myself. I open a new browser window, and follow the path to report a fictitious tax reduction for me. I don't plan to send it, just to see if the "pocket calculator" opens correctly. The pop-screen is shown correctly! I understand that the problem is related to my login identity. I reformulate the email to reflect this, but still mentioning the technical details. I press 'send'.

**Step 171 - 177:** Shortly after I see in my email client that I have got mail from Skat.dk. I click on the link in the mail to see the response. I am taken through the logon procedure again at NemID. I open the email, which states that Skat gets many questions regarding this tax reduction, so this is a standard mail with FAQs. In other cases, one is encouraged to use the phone hotline... So I'm back where I started, not being able to report the bug or problem. I am not closer to being able to report my mother's tax reduction, even if I can do. She cannot logon as herself because she has forgotten the password, and I cannot report on her behalf.

**Step 178 - 205:** A couple of days later I try to logon again with authorization to report her tax. My small hope is that someone at the tax authorities has seen my message and corrected to problem. But the problem remains and I still get a blank screen.

#### **4.3.5. Phase 5: Hotline contact number 2 – final problem solving**

**Step 206 - 211:** I call the tax hotline. After going through the call sorting system and waiting 4 minutes, I get in contact with a lady. I explain the problem. She asks me my mother's civil registration number, which I tell her. She says that my mother hasn't authorised me to report tax reduction, only to see her tax. There is a check mark to be marked at the authorisation webpage. I thank the lady and hang up. I speculate that it would have been nice if I had got this error message or explanation in the first place.

**Step 212 - 222:** I want to call my mother to get her a new password, so she can logon and grant me the authorisation. She is not home. I go to skat.dk, type in her username and click on forgotten password. I am redirected to "NemID". At the NemID page I see that I have to submit the serial number of her key-number cardboard card, which I don't have. I call her again, but she does not pick up her phone. Some time later she calls me back. I explain what she has to do, and she gives me the serial

number. I type it in while she is on the phone, and I tell her what the system responds: she will receive a letter in a couple of days.

**Step 223:** Two days later, in the evening she phones me to tell me that she has received “a letter with a lot of numbers”. That evening I am busy with other things, so we agree that I call her back the following day. We then agree to meet three days later. I ask her to bring all the documents with her.

**Step 224 - 238:** We meet Saturday April 25. My mother created her new NemID password. She logs on (with my help) on Skat.dk. I guide her to the “report a service-related tax reduction” page, and I type in the information needed: Amount, registration number of the service company and the date of payment. I check to see whether the tax return message on the screen already has been changed, but that is not the case.

**Step 239 – 242:** I look for the place at skat.dk to change the authorisation rights, so I in the future can report my mother’s tax reduction. I find it easily, and mark with my mother’s consent the check mark that means that I get full rights. I log out. Case ends.

## 5. Case analysis

The service journey involves human actors, interactive systems (interfaces) as well as the different software that affords the interactivity. With concept of affordances borrowed from the HCI research (cf.: Gaver, 1996; Turner, 2005; O’Neill, 2008) we can thus see them as interconnected, comprising an ecological entity. During the service journey interaction between a user (me); a customer (my mother); two different browsers; several GUI’s / interactive services: Skat.dk, NemID (embedded in Skat.dk, as well as independent page), two different browser plug-in software (Ad-blocker and Java); the Java download webpage; the Java installing procedure on the PC, the Google search engine; a voice response system at Skat’s hotline; and three unnamed service workers at Skat. All these entities are embodiments of the service encounter.

Until the appearance of the blank pop-up screen (step 23), three small episodes deserve attention: 1) My mother’s inability to remember the password, 2) my own wrong typing of my own password, and what appears being a pure technical problem 3) my mothers CPR number is not shown as default at the list of person for whom I administrate the tax reporting. In the first two ones, the simple and very fast real-world experience of being recognized as “you” by another human being, or in this case making the service provider aware of my person and the information related to becomes a relatively long service journey when it is embodied in computer code. We can explain this through the need for data protection and privacy. The analytical focus on the many steps involved in the login procedure is however very good example of how the embodied interaction approach helps describing how the ICT-centric service encounter is different from other types of service encounters.

In the latter episode my mothers’ name is not default displayed. When trying first time a ‘no-access’ message is shown, the second time my mother CPR-number is however shown. Retrospectively seen, this episode could be seen as an early sign of the problem which persists for the next 180 steps as the search for the cause for the

blank pop-up screen goes on. Phenomenologically seen problem can thus be described as the conflict between my a priori mental model of the service encounter (my cognitive construction of it), my cognitive model of the self-service system and the actual embodiment of the service through the computer code rendering the interface. Since the interface is the actual embodiment of the service encounter, I can do little with my cognitive models, except trying to make them fit to the actual embodiment of the service encounter. We here see how the embodiment of the computer code has a power, which cannot be found in non-computer based service encounters. The embodiment of the ICT-centric service encounter is not up for discussion or negotiation between the customer and the service provider. The interface is silent about the reason for not providing me the desired service. The self-service system is trapped in its own embodiment (seen from the customer perspective): the computer code can only produce what it has been programmed to do.

**Figure 1: “Access with authorization” – empty list (no access) Skat.dk accessed April 14, 2015**

Later in the service journey I experience human representatives (embodiments) of the service provider, with whom I can conduct a more open dialogue. This experience requires me to re-conceptualize my mental model of the service provider into two distinct and different entities, one that consist of ecology of browsers, third-party plug-ins, screen interfaces, keyboard, mouse, internet protocols, server-side scripts and all the other digital elements in the self-service encounter and one which is the dialogue with the human service helpers. When I have passed the embodiment of access control to the human service staff, namely the phone menu where I have to press 1 for... and 2 for.. I do actually experience a very different kind of service provider, namely human service representatives. With varying degrees of success they suggest causes for the problem, and finally lead me to its resolution. I thus need to connect and integrate this experience with the embodiments of the interface that do not respond in the way I anticipate.

The co-creation of the service recovery could be described as the user's (mine) active application of different strategies for the sequential testing of different hypotheses about the cause of problem. The most prominent strategies are to change browser, as well as retrying after some days. Where the first strategy assumes a local, browser-related cause, the latter assume technical problems at the server-side. Both strategies are however challenged by alternative or supplementing possible reasons: The inactive links as well as the problems of showing my mother's CPR number in the list of 'administered persons' could point both in a technical direction,

as well in an 'administrative' direction (deadline overdue or other formal reason why the service is not available). The multiple hypotheses leads to a blurred choice of strategies – sometimes one strategy is followed, sometimes another, this often without a logical consistency. One of the strategies is also to seek advice through the phone hotline provided by "Skat".

When we look at the conditions for applying the strategies, there are big differences between the self-service encounter and the phone-based encounter: Where the self-service encounter offers endless possibilities for retry and experimenting through the change of technical context for the service encounter (e.g. change to a different browser or logon as another person), the human service encounter is characterized by being condensed in time, leaving little time for consultation or cooperative problem search. Experimenting is not possible, but instead a deeper and wider contextual understanding is possible, to the extent that the service person successfully can see and understand the problem, e.g. through an enhanced display of settings and user-rights. The service encounter could thus also be described as an explorative examination of a (partly) unknown space of possibilities calling for a break-through insight (cf. Perkins, 2000), as a situated learning experience (cf. Lave and Wenger 1991; Wenger, 1998), however without the reward that normally is affiliated with situated learning, namely to get closer to centre of a community of practice, or the general reward of achieving generic skills.

My attempts to contribute to the service recovery, and to prevent future service failures, namely by reporting what I assume is technical problem, fail. I do not know if the relevant persons read my message, but from the standard response on my email, I realize that Skat wants handle dialogical customer encounters such as questions and complaints via phone. As I want to report a software problem, this embodiment of the interaction / service recovery interfaces appears not suitable for the purpose. The co-creation of the service recovery could thus in this case be described as (failed) attempts to communicate discoveries and potential causes of errors to the service provider. The attempts fail because the service provider has not one, but two entry points: An ICT-based which is not designed for this type of feedback, and a human (phone-based) which is not capable of seeing or understanding the technical embodiment of the service encounter.

## **5.1. Signs of ICT-centricity of the service encounter**

In the theoretical introduction I suggested to make a distinction between "ICT-based" and "ICT-centric" service encounters. Where ICT in the first type do not shape the service encounter in any noticeable way, ICT in latter type defines what Harris and Henderson (1999) would call the "mythology" of the system design. What I here suggest as "ICT-centric service encounters" is my application of Harris and Henderson's (1999) "Standard Mythology of System Design" on the service encounter. This standard mythology represents a wide-spread but problematic set of assumptions often applied by system developers: 1) that system requirements are clear and well defined, 2) that the system architecture can meet all system requirements, 3) that it is possible to define clear choices for users when they interact with the system, 4) that it is possible to maintain consistency throughout the design (ibid. 89). As Harris and Henderson (1999) point at there are some fundamental assumptions behind this: 5) that "[t]he parts of the system must interact according to a pre-established harmony defined during its design" 6) that "[t]he job of the designer is to discover, clarify, and

when necessary invent the rules that define that harmony, and embed them into the computer system". 7) that "[t]he users must interact with the system in terms of the language or ontology that these rules create." (ibid. 89). The problem of these assumptions, according to Harris and Henderson is shortly described that real world seldom follow a fix set of rules that can be modulated in a system, but instead do 'the particularities' of the real world require a constant re-interpretation of rules.

In the ICT-centric service encounters, my hypothesis would be, this mythology flows from the ICT system itself to all other parts of the service encounter, including the human service providers. It is thus not the use of ICT in the service encounter that is interesting, but rather how the 'mythology' influences the whole service design. The hypothesis would thus be that when particularities occur in the service encounters (the deviation from the ideal service blueprint, e.g. a "service failure") the process of service recovery must also acknowledge the ICT-centricity of the service encounter. It means that the service recovery must include and embrace the technological embodiments of the service encounter on the same level as the users expectations, e.g. through the ways a service failure can be discussed between the customer and the service provider. The service recovery must also be mediated between the embodiment of the technology and the embodiment of the user's mental model of the service and the system. But the self-service encounter is framed rigidly through the user paths in the system, designed by system developers and interaction designers. The human service encounter includes the possible deviation from the plans and trajectories already set, the deviation that can foster the 'break-through thinking' necessary to escape the trap of the service failure problem.

## 6. Discussion

The starting point for Dourish is that "[e]mbodied phenomena are those which by their very nature occur in real time and real space" (2001, 126) but he develop this definition to: "Embodiment is the property of our engagement with the world that allows to making it meaningful" (2001, 126). Embodiment is thus the general phenomenon of making sense of the world (starting with being in and acting with the world, not as an initial cognitive model of the world, which then successively is projected on the observation of the world (cf.: Schear, 2013).

As introduced in the beginning of this paper, Dourish' vision for tangible and social computing is based on this embodiment of the world:

"we encounter, interpret, and sustain meaning through our embodied interactions with the world and with each other (...) [t]angible computing encourages users to explore, adopt, and adapt interactive technology, incorporating it into their world and into everyday practice. It allows users to create and communicate the meaning of the actions they perform, rather than struggle with rigid meanings encoded in the technology itself. Social computing similarly recognizes that meaning is something that users create through the ways in which they interact with technology and with each other" (Dourish, 2001, 127-128).

Now the question is to which extent these ideas makes sense in the relation to the above-presented service encounter. A first observation could be that the service encounter does not seem to have been designed with tangible or social aspects of the interaction in mind. Some social interaction is produced by my mother asking me to

help her, as well by the contact with the hotline service workers at Skat. The tactility seems apparently absent: No touch-sensitive technologies (e.g. a tablet or smart phones) are used and the service encounter has hardly any physical representation. Finally, the “content” of the service encounter is highly cognitive: Tax reporting. In this way, the case appears hopeless as an example of embodied interaction.

If we start with the common-sense concept of ‘familiarity’ we can observe that the graphical designers have transferred and transformed the visual identity and the structure of the traditional printed paper forms to the webpage. If we compare the tangibility with the earlier tax-reporting method, where citizens received a partly pre-filled form, some tangibility has disappeared. The printed paper version afforded private notes in the draft copy that was kept by the citizen. The paper version would not prevent entries in the form or show a blank page. However, nor the citizen would, as in the digital version, receive immediate feedback if a figure was wrong or entry in a field was not permitted. The paper version would not, except the citizen’s signature that confirms the correctness of the information, keep track of the identity of the person entering the information. The paper version of the self-assessment tax form is essentially a static one-way communication multi-user platform.

The central visual concepts in the tax declaration remain the same. The familiarity, we would argue in the following, however disappears when the printed – static - pages now have become electronic - dynamic – forms. The much cited Heidegger concept (which also Dourish builds upon) of the tool which is “ready at hand”, becoming one with its user, versus the tool that becomes “present at hand” e.g. because the tool does not fulfil the desired function or where the user reflects over the possibilities of the tool, could be useful here (cf. Dourish, 2000, 109; Winograd & Flores, 1986). As a tool for user action, the electronic form resists in a fundamental way the user’s activity and becomes “present at hand” when no text can be entered in the input fields or when the form is not displayed at all. The printed paper form, which is still used as visual reference, only becomes “present at hand” if the user does not know what to write in the specific field, or if the pencil is broken. The visual familiarity is thus misleading since it indicates affordances that are not there: If an input field is write-protected or a page shown as blank, the promised familiarity breaks down as the tangibility is absent.

Using a wider less physically oriented definition, one could argue that the case contains much tangibility. On the most basic level a single binary electronic signal (that can be set to “false” or “true”) prevents the display of the screen where the tax information can be submitted: The check-mark of the relevant rights is not checked. This state produces all the following consequences. The tangibility is very well hidden: one should know that “it is there” somewhere in the system, or rather that this checkbox interface could be rendered on my screen if I know the right commands. It is a brilliant example of Dourish’ observation (2001, 140) that computers have a dual nature of both carrying representations of the real world as well as being “abstract” embodiments (in terms of code and processing in the medium of electric currents).

The discussion above about the tangibility – or the lack of tangibility – in this ICT service encounter reveals some uncertainty about the concept. What does the “real world” actually mean and where does it stop and becomes virtual? This discussion obviously expands beyond this case, and points at a much larger philosophical discussion in which Dourish engages. The purpose of this paper is not to attempt to contribute to this discussion, but to test the applicability of Dourish’ concepts. Where we observe lack of clarity in the distinction between ‘cognitive’ and ‘tangible’ in this

case, we can instead simply note that the tangibility in this case can be translated to agency: When the action which the user wants to perform cannot be executed due to phenomena external to the user, the user agency is lost. We would thus simply argue that the tangibility in effect is about user freedom to act. What we mean by “external to the user” is that the hindrance does not lie within what the user recognizes as him- or her self. The hindrance would be internal if I have a broken arm and could not write, or if I know that I don’t know where to click in the user interface and blame myself for my lack of knowledge. The absence of tangibility equals the lack of agency, even in the case where I am overwhelmed with clickable options in the interface. I would argue that in the situation, the user’s perception may change forth and back from Heidegger’s “ready at hand” and “present at hand”, as the “ready at hand” here means that I engage in yet another attempt to solve the problem and go “in dialogue” with the interface, and “present at hand” means that I reflect on the lack of success and maybe consider a new strategy. The tangibility – or lack of tangibility – moves across these two situations. The “ready at hand” situation is not more tangible than the “present at hand”, although it may look so.

If I instead blame the providers of the ICT based service and conclude that nothing in my control could mend the problem, it becomes clearly external to me, and obviously also “present at hand”. The service encounter presented above oscillates between being an internal cognitive process in me where I speculate about possible causes on different levels, an interactive ICT based encounter between me and the different interfaces that are shown on my screen which in itself oscillates between being “ready at hand” and “present at hand”, and finally social interaction – conversation – between me and my mother, my mother and the tax hotline, and between me and tax hotline service staff which also have elements of being both “ready at hand” (e.g. when we experience that we understand each other) and “present at hand” when I am presented with limitations of the conversation, e.g. the queuing system / voice response system that interrupts my direct desire for a conversation, or when I am not understood in the phone, or when I am redirected to another service person which needs the explanation one more time.

The service encounter here is embodied in all its smaller parts such as the abstract concept of a tax reduction (which essentially means money), the less abstract objects of interfaces that are visible representations of rules (on different levels), and the complex structure of different software code that physically, but invisibly, produces the screen interface and the (lack of) interactive options. But all these elements or entities do not form a coherent body. If we should look at the entire service journey, it consists from the user’s / customer’s (my) perspective of a number of disintegrated ‘body parts’ that are embodiments but do not work as one body. Independently they work and function well and perform their designated task, but they do not operate together.

We suggest that concept of embodiment is based on inter-subjectivity (cf. Dorish, 2001, 132): Inter-subjectivity appears in the different ways the interface is rendered when I am logged in as administrator for my mother, as ‘my self’, or when my mother is logged in. In the first case I see a blank page, in the two others I see the interface correctly. Here the inter-subjectivity however takes a radical form through the three different user-logins / user accounts, that each shows a different interface options, or as in the central example, just a white page. The different user accounts produce thus different embodiments of the service encounter. The strong coupling between a specific user account and a specific embodiment of the interface prevents me from

understanding the problem. One could provocatively say that the strong concept of embodiment hinders my cognitive understanding of the problem, and thus also my learning process of understanding the problem on a higher level. It appears thus as if the embodied interaction approach could contribute in future research to the conceptualisation of customisation and personalisation (cf.: Fan & Poole, 2006; Sørensen, 2013; Sørensen, 2015)

### **6.1. Skat.dk as a ‘community of practice’?**

Besides the concept of tangibility, the social aspect plays a central role in Dourish embodiment concept: Computer systems are used in communities of practice (cf. Lave and Wenger 1991; Wenger, 1998) as well as they serve as communication tools. While they shape the practice they are also at the same time expressions of this practice, reflecting its assumptions and conventions, Dourish observes (ibid. 186).

If we now apply the concept of “communities of practice”, a concept which traditionally is used in the work-oriented studies of computer use, on the service encounter with Skat.dk, the first observation is that I as a user stuck in this particular problem do not belong to the centre of this particular community. The reason for that is produced by the subjectivity of the situation as discussed above and my peripheral status in the “community”: I do not have the full overview of how the different logins / user-identities (my own, my administrator role, my mothers) produce different affordances in the interface. Step by step I construct this overview, which however only is completed when I talk the second time to the hotline service staff, who looks up the rights assigned to me and tell me that my mother should grant me rights also to report a tax reduction. We could thus depict the service encounter as an apprenticeship where I learn from practice (clicking around in the interface) and from the advices from the masters (the hotline staff). One could argue that it is problematic to apply the concept of “communities of practice” on the service encounter, but as the service encounter also becomes a praxis-oriented learning process and as it includes more knowledgeable persons, I will argue that the concept also is productive outside a work context.

The problem with learning interpretation of the situation is that I initially was neither prepared for this process of exploration and learning nor interested in it. Conversely, I assumed myself to be a customer, a sovereign user, who acts in a service encounter by controlling my interaction with the system. As the blank screen is presented to me, the expected ICT service encounter breaks down and my role is converted to being an apprentice or pupil in the search for an answer. The experience of the service is thus radically changed in a very short moment: The service failure appears suddenly and without any previous indicators. This sudden service failure produces a breach in the embodiment of the service that possibly are less often and less sudden in service encounters with human beings.

## **7. Conclusion**

If we should try drawing more general conclusions from the single case that have been presented above, it would be that Dourish’ embodied interaction framework do offer some new perspectives for the understanding of the ICT-centric service encoun-

ter. It does so, because the focus on the embodiment of the interaction relocates the analytical vantage point from a top-down structural view, which could be represented in service blue print, to sensitivity in the observation and description of an actual service encounter. Thereby we are able to acknowledge how the ICT as material for design of service encounters (cf. Löwgren & Stolterman, 2004) shape the service encounter, maybe in a way, which is not desirable. Examples could here be the many steps involved in the authentication process or the enigmatic blank pop-up window. The embodiment approach is thus particularly helpful in the analysis of the service failure, since it allows a dual focus both on the technology and the human actors.

The embodied interaction approach is also helpful in conceptualising the apparent disconnectedness between the many human and technical actors in the service failure. Instead attempting to point out one single source failure, which in many cases – also in this – in reality is impossible or problematic, it turns our attention to intersubjectivity in the interaction: Each human or technical actor in the service encounter is perfectly embodied, but the different ‘body parts’ do not work as one body.

Finally, the embodied interaction approach points at some – in this un-utilized - possibilities in the co-production of the service recovery process: if the embodiments of the service encounter, such as the customer experiences them, can be communicated to the service provider in their complete embodiment (e.g. here that the hotline worker could see my screen, or that provides full and comparative overview of its settings (e.g. that I initially have not been assigned with full rights to my mother’s tax reporting), the service recovery could be eased. This is not the place to suggest practical solutions, but the idea that I try to convey is that if the service recovery was facilitated as an embodied co-production process, not as a cognitive trail-and-error search process, the quality, speed and ease of the service recovery process could be improved. What we also can observe here is a user who actively attempts to contribute to the service recovery, almost taking over the responsibility for its successful end. Now, it is open for empirical research how this also would be the case in other service encounters, as well as identifying the conditions for the user’s active participation in the service recovery, but potentially this is also managerial interesting to understand, in the light of the general value created through co-creation and co-production. In this way the embodied interaction approach to the ICT-centric service encounter could produce innovative solutions, as well as the improvement of the dialogue with customers involved in ICT-centric service encounters could contribute to the innovation from the ICT-centric service encounter.

In other aspects it is less clear if the embodied interaction approach can be helpful for the analysis of ICT-centric service encounters, and their eventual failure and recovery. The service encounter chosen for analysis in this paper could be described as a cognitively dominated one: The subject for the service encounter is a highly abstract matter – reporting of a tax reduction claim – and the service encounter takes place in ICT environment which is not very embodied in a common sense understanding: there are no tangible interfaces and very little social interaction via the ICT-system itself. The social interaction takes place via telephone. It is thus a strange and difficult case to analyse as embodied interaction. With Dourish (2001) we however extend the concept of embodiment also to encompass the embodiment of the computer code in the for humans visible form: interfaces, and for machines understandable way: as electrical current. Now the danger becomes that we have a definition of embodiment that is so broad that it does not produce any new knowledge. This appears to be a weakness of Dourish’ concept: It is unclear whether he understands embod-

ied interaction only from a human perspective, thus requiring computer code to be a perfect representation of the world, or whether he also acknowledges the computers' embodiment in terms of their code and electric currents, but thereby do not really do much than describing the eternal problem of all programming of computers: the gap between the real world in all its diversity and the reduced representation of it in the descriptions of the world, here descriptions that are made in computer code.

Our choice of case is a service encounter which in two ways are defined by rules, namely both the rules that make up the computer code, but also the rules make up the tax legislation and legislation on mandatory self-service. In a double way it thus points at the conflicts emerging between the assumed regularities of the service encounter (the service blueprint of the straight forward typing in data in the online tax-reduction form), and the particularities emerging when this service encounter breaks down for unknown reasons. The discussion of the tension between regularities (which can be foreseen in computer code) and the particularities that constantly emerge due to the complexity of the world (cf. Johnson, 2001) is however difficult to find answers for in Dourish' (2001) work. It appears as if he assumes a very regular world, one which can be modelled, but this would contradict is starting point in the embodied world. The question is whether Dourish' embodied interaction approach promise a service encounter experience that in many cases can not be fulfilled due to the emerging particularities? It is also unclear if we with Dourish (2001) should strive for creating a service encounter, which is very tangible and social (embodied), and try to avoid the cognitive parts in the service encounter? Where this approach in some very simple service encounters could make sense, it would indeed be a problematic approach in the case tax reporting. Also in the more general situation of the co-production of the service recovery in the ICT-based service encounter, a very naïve understanding of embodiment as the opposite of cognition would be problematic: It would assume a user which is not cognitive contributing to the service recovery, thus not offering any substantial co-production to it. If we instead understand the embodiment as the acknowledgement of all the detailed elements, interactions and circumstances that comprise the service encounter, and in the case of the ICT-centric service encounter also shapes it radically, the embodied interaction approach could contribute to the innovation of the ICT-centric service encounter, and service recovery in it.

A central element, and the actual reason for the service failure in the above case, is the different user accounts and their respective embodiments of the information in the system. While this situation may occur relatively seldom in ICT based service encounters, it provides us with the sensitivity of the subjective nature of also the ICT-centric service encounter. This inter-subjective nature of the service encounter may rather be expected in a face-to-face service encounter, which is produced by humans, equal to what Shostack (1982, 55) describes as the difference between the potential and the rendered service. Surprisingly we must also categorise the ICT-centric service encounter as subjective, although it is produced of the same code. That means that ICT-centric service encounter is as little standardized as the face-to-face encounter, and that it possibly cannot really be standardized.

We also observe a tension between the different entities of embodiments: The different software systems (operating system, browser, plug-ins, server-side code, html), the tax regulation, the access rights are each complete and coherent embodiments, and not just abstract ideas, but their embodiments do not interact in this specific case. We develop the idea that the abstract understanding and overview is neces-

sary if the user – customer – citizen should have any chance of co-producing the service recovery. The pure vision of embodiment as suggested by Dourish requires foreseeing all possible problems (tensions) between the different embodiments (here software systems). We instead argue for increased user agency also when this requires the user's abstract thinking. If the vision for the service encounter is changed from a naïve vision of a simple input – output process to the co-production of the tax report, users may in the first place be required to be more cognitively active, but they will also become a more equal partner in the service encounter. We suggest different ways in which the service encounter better can be presented as the learning process it was in this case, and is in other cases where the service fails in the sense that the user cannot achieve the desired goal for administrative or technical reasons. If the process of interacting with the self-service system is seen as co-production of knowledge, then the use of the support both from the side of the service provider, as well as from other users could be conceived differently.

The embodied interaction approach to the study of the ICT-centric service encounters helps elucidating and describing how the character of this type of service encounter is different from all other service encounters. The embodied interaction approach also offers a platform where the face-to-face encounter is seen as the ideal prototypical service encounter, but where the ICT specific elements can be conceptualised into the design of the service encounter. This produce a productive platform for the analysis and design of ICT-based service encounters, as the embodiment of ICT – the ICT-centricity – can be treated not as a side effect the use of ICT, but as an active design condition. This could open for new types of conceiving the dialogical co-creation of the service encounter and service recovery.

# Online Review Site Data in Service Innovation

*Tuomo Eloranta*

Aalto University, Department of Industrial Engineering & Management

*The recognized importance of customer understanding and involvement to successful service innovation has resulted to the development of various cocreation approaches striving for tight integration between customers and the company. While sometimes methods of tight coupling are essential, there is also a need for lighter means for gaining customer understanding amidst the organizational reality of limited budgets and time available. Given this, the objective of the study is to examine ways of virtual customer integration, namely utilizing feedback customers give on public online review sites as an idea source and inspiration for service innovation. This study brings new understanding on how firms can best leverage this tool as a part of their customer integration tool portfolio to support their development activity.*

## 1. Introduction

The idea of companies integrating their customers to boost their development efforts is nothing new. Benefits of such approach have been discussed in the innovation literature for a long time, both in product (e.g. Von Hippel, 1986; Gruner and Homburg, 2000) and service (e.g. Alam, 2002; Magnusson et al., 2003) contexts. This discussion is all but waning thanks to the diffusion of service dominant logic (Vargo and Lusch, 2011) thinking, emphasizing the increased focus on supporting customers' value creation processes. Succeeding in this requires thorough knowledge on the needs and desires of the customer and value-in-context. One effective way to achieve this is to increasingly integrate customers to development processes to cocreate new offerings and operational improvements.

Various means for realizing customer integration in new service development have been proposed such as customer observations (Edvardsson et al., 2012), CUDIT methods (see Magnusson et al., 2003) or having users as a part of the development team (Alam, 2002). Gustafsson et al. (2012) found increased benefits in more active and in depth collaboration with customers compared to passive and unidirectional ways of involvement. Similarly, Witell et al. (2011) have argued that companies should strive for methods that allow tight integration with customers. However, the issue is not strictly black and white. Magnusson et al. (2003) noted that too closely integrated customers might cause them to develop similar mental constraints that professionals working in companies have, which can harm their capability to suggest novel ideas. Second and perhaps more importantly, what are particularly emphasized in real life situations inside companies when selecting means for customer involvement are the costs of the endeavor, both in financial and human resource terms (Alam, 2002). Thus, while more integrative and in depth methods have lots of argu-

ments for them, it is important to also examine the more lightweight methods as they certainly have their place in the hectic daily life inside companies.

In this sense, IT mediated customer interaction is very interesting for various reasons. First, the cocreation activity can be asynchronous and not necessarily tied to a specific time or place. Second, due to the proliferation of user generated content containing consumer opinions on products and services in various virtual environments such as discussion forums, social networking sites and public online review sites, companies can access vast amounts of data containing information about what their customers like and dislike about their offering quickly, simply and nonintrusively (Lu and Stepchenkova, 2015). Interesting in these customer involvement arenas is the fact that customer's themselves are the active party in providing feedback, which has been noted to be very rare when it comes more traditional interaction channels (Alam, 2002).

Online review sites - public web-based services that allow consumers to rate and give open feedback to service producers - are in this sense especially interesting as their main purpose is sharing of product and service evaluations between consumers and companies. They are used voluntarily without monetary incentives, making them an inexpensive approach for collection of customer insight. Unlike facebook, twitter etc. modern social networking sites, which' content is in practice difficult to search and access (see Lu and Stepchenkova, 2015), online review site data is technically rather easy to utilize. Finally, as those generating the content have direct experience from a real life service use situation and context (insitu & incontext), they should have the possibility reflect on the key value drivers and problems and solutions of actual service use (see Edvardsson et al., 2012).

Still, the suitability of online review sites for gaining insight for service innovation is not trivial. They might contain insincere (Mayzlin, 2006) or only overwhelmingly positive content (Brejla and Gilbert, 2014), based on which gaining ideas and inspiration for development might be difficult. Moreover, open innovation research has shown that when customers air their ideas and feedback in virtual environments, they don't necessarily spend much time doing it (Majchrzak and Malhotra, 2013). This raises questions whether the input is profound enough to act as input for development activities. Existing research on utilizing online review data for service development has been conducted mainly in tourism context and has largely focused on quantitative analysis (e.g. Brejla and Gilbert, 2014; Stringham and Gerdes, 2010) which might lead to misinterpretation of data (Banyai and Glover, 2011). Thus there is a pressing need for qualitative in depth analysis on what kind of input collection and analysis consumer reviews in public online review sites can provide for the purposes of companies' service innovation activity. The present study aims to address this gap, the main research question being:

### ***How can online review data support service innovation activity?***

The focus is especially on understanding the content users post in their reviews, in order to understand purposes online review site data can best serve.

## 2. Literature review

In essence, online review sites are virtual platforms, which allow consumers to share their opinions with other about various goods or services they have purchased. Usually in practice this concretizes in a numerical rating and a brief text based description of whether the person was satisfied with the purchase and why. Such services are being increasingly popular and there is variety of platforms available for different topics such as Metacritic for entertainment, Rotten Tomatoes for movies, Tripadvisor for travel and Trustpilot for various consumer goods and services to name a few. Tripadvisor solely contains over 200 million traveler reviews on hotels, restaurants etc.

In addition to their immense popularity, scientific interest in online review sites and consumer review content in the Internet in general has been driven by the fact that such services can have notable influence on people's purchasing behaviour (Senecal and Nantel, 2004). As such, it has garnered attention especially from marketing and sales scholars, aiming to understand this process in more detail by mapping for example the various antecedents and consequences of the phenomena (see King et al., 2014 for broader review).

Majority of this research seems to refer to online review content using the term electronic word of mouth (Hennig-Thurau et al, 2004; Sen and Lerman, 2007; Litvin et al., 2007), though other terms such as online product recommendations (Senecal and Nantel, 2004), online feedback mechanisms (Dellarocas, 2003) or Word of mouse (Stringham and Gerdes, 2010) have been used as well. Electronic word of mouth (eWom) is usually defined as informal communication between independent consumers about a company or its offering (Litvin et al, 2008). Accordingly, the utility of ewom has from company perspective has been mostly focused on how to manage and leverage these processes indirectly to one's benefit, by for example encouraging posting of positive reviews through increased understanding of how consumers determine helpfulness and quality of others' reviews (Sen and Lerman, 2007; Mudambi and Schuff, 2010), drivers of posting reviews (Cheung and Lee, 2012; Hennig-Thurau et al., 2004), or their effect on purchase decisions (Senecal and Nantel, 2004).

Because the present study is mainly focused on companies utilizing directly, instead of indirectly leveraging the informal virtual consumer to consumer information transfer process as most eWom research, I will refer to the content posted to public online review sites as online review data instead of eWom. Also, in terms of online communication arenas, much of eWom research has been conducted in contexts other than online review sites, such as discussion forums etc. As the present study is only focused on only online review sites, there is little reason to use the broader term of eWom.

Some research on how online review data could be directly used in company decision making has been conducted, especially in the travel industry. Litvin et al. (2008) argued that online review analysis can help tourism companies in developing their offering, increasing customer understanding, reputation management and evaluation of their competitive strategy. Brejla and Gilbert (2014) utilized content mining in order to understand which travel service components have the biggest impact on cus-

customer satisfaction and cocreation processes during service provision. Similarly, Stringham and Gerdes (2010) content mined reviews to examine where hotel owners should focus their development resources.

While the tourism literature seems particularly interested in the potential of online review data, studies in other contexts have been conducted as well. Dellarocas et al. (2007) studied how movie popularity could be forecasted based on public review activity. They found that complementing traditional sales forecasting models with review activity measures resulted in a very well-functioning model which could help in marketing design and operative decision making of movie theater owners. In another study, Clemons et al. (2006) examined how companies opting for a particular differentiation strategy can leverage online review data to develop their product positioning. Finally, though it utilized discussion forum instead of online review data, particularly interesting is the study by Andreassen and Streukens (2009), which studied how such content could be leveraged for service innovation purposes. They developed a typology of online discussion content (see Table 1) and found that such data can provide rich information about the desires and needs of consumers with regards to current and future products and services.

| <b>Meta Themes</b> | <b><i>Business practice issues</i></b>  | <b><i>Usage experience issues</i></b>   | <b><i>Information requests</i></b>   | <b><i>Commenting product launches / developments</i></b>  |
|--------------------|---|---|--|---|
| <b>Themes</b>      | Quality of customer service<br>Quality of dealers<br>Availability of dealers<br>General business conduct of company | Quality of service<br>Price - Quality ratio<br>Experience with specific features / functions of service<br>Emotional experience | How to use product / service<br>Technical questions<br>Requests for additional information<br>Experience with category | New introductions<br>Expectations regarding new introductions<br>Comments/desires regarding new introductions |

*Table 1: Andreassen & Streukens' (2009) conceptual framework of online discussion forum content with regards to service innovation*

Notable similarity between the studies listed above is their quantitative orientation, based on algorithm based content analysis (Brejla and Gilbert (2014), examination of numerical ratings given in reviews by themselves (Clemons et al., 2006) or in conjunction with word occurrence counts (Stringham and Gerdes, 2010) and combinatorial measures of review activity including volume, valence (positive vs. negative) and dispersion (Dellarocas et al., 2007). Andreassen and Streukens (2009) are a notable exception with their qualitative content analysis. However, while the resulting typology provides an important starting point for scientific discussion around using online review data for service innovation, their work provides only one anecdotal example from product context about the concrete insight that can be utilized for development

purposes. In accordance to Gustafsson et al. (2012), who criticized customer integration research for being too overly conceptual and focused on listing generalized types, I feel that we need more qualitative, in depth examinations of what kind of benefits various consumer involvement methods have and where do they fall short. Quantitative approaches to online content analysis as used in the research mentioned above, while enjoying notable popularity, run the risk of failing to capture or misinterpret key aspects of service experience (Banyai and Glover, 2011). Thus we need also qualitative examinations of online review content in order to better understand potential of online review data.

Though it seems that online review data has much potential in terms of innovation activity, naturally there are potential issues as well. Various challenges related to the quality of information in online reviews have been noted. First question is the objectiveness of the information. It is for example possible that individuals hostile towards the company post highly critical reviews with little connection to real life consumer experiences. Various technical approaches has been suggested to tackle this problem, though their use is not necessarily unproblematic (see Liu et al., 2007). It has also been noted that companies themselves spread information disguised as consumer reviews in order to gain new customers (Mayzlin, 2006). This might create challenges for example if focal company's goal is to understand better how to improve their distribution network and their vendors are manipulating their online review data.

Other fundamental issues related to the online review sites as communication medium should also be considered. Online review data is usually limited to text based content and numerical scorings. Thus the content is less rich than face-to-face discussions especially when it comes to contextual cues critical for message interpretation (Dellarocas, 2003). However, Gustafsson et al. (2012) found that the communication medium in customer involvement does not have significant effect on the successfulness of new innovations. Second, it is possible that those consumers who are active in posting online reviews do not sufficiently represent the customer base as a whole. In online movie reviews, majority of posts have been noted to originate from less than 30 years old males (Dellarocas et al., 2007), whereas in tourism, single women under 35 seem to be the most active reviewers (Brejla and Gilbert, 2014). The issue of skewed population does not automatically make online review content meaningless, but if the company lacks understanding of the nature of the data, issues can arise (Edvardsson et al., 2012). Final, but perhaps the most crucial question related to content is naturally the extent of which it contains relevant information related to development efforts in the first place. Brejla and Gilbert (2014) noted in their study in tourism context that posted feedback was on the whole skewed towards positive end of the spectrum. This raises questions is there enough critical reviews to gain improvement ideas, calling for further research.

### **3. Material & Methods**

To answer the research question, a qualitative multiple case study of two cases was conducted. Online review data for two software-as-a-service companies was collect-

ed from online consumer review site Trustpilot.com<sup>1</sup>. Trustpilot allows consumers to post reviews on products and services they have purchased from different companies. It contains both official company review spaces created by firms themselves and unofficial company review spaces started by active consumers. Each review consists of a short title, review text itself and overall score (1-5). All analyzed reviews were publicly available and visible for anyone visiting the site. Raw data was collected using a self-made ruby script. For each review, it stored the review title, review text, score, time and date of review and reviewer id. The resulting dataset was imported to Atlas.ti for further analysis.

In selecting the cases, several important aspects were considered. First, the amount of unique reviews needed to be large enough to ensure adequate variation in reviews. Second, the company needed to have an official, registered review space. Unofficial space might encourage lower quality and less constructive reviews. Third, industry and offering of the company should be of such that is likely that large share of customers use Internet regularly to minimize the possibility that the online reviews represent the views of very limited portion of the customer base.

Based on these criteria two companies were selected, hereafter referred to as Streaming and Storage. Both had gathered over public 100 reviews to their official Trustpilot review space for their main consumer offering. Streaming offered an online video streaming service, allowing users to watch TV-series, movies etc. from the Internet with various devices for a monthly fee. Storage offered a cloud based file hosting service, which users can use to store whatever they like to the company servers and if so desired, share it with their friends. Storage offered both free and monthly fee based service, which differed mainly based on storage space size and access speeds. As both cases were essentially Internet based software-as-a-service (SaaS) service products, it could be presumed large part of their customer base were active users of the web. In terms of content, Streaming was selected as a baseline case. Its average rating from reviews was approximately 3.8 and provision of feedback was not incentivised. Storage's average rating was higher, approximately 4.5 and the company provided users who posted a review to Trustpilot with extra storage space. Storage as a second case was included partly in order to gain more understanding about the context specificity of usefulness of online review data for innovation and the effects of more positive reviews and incentivizing.

The analysis process started with reading through all reviews and making notes. Based on the first analysis round, the typology of Andreassen and Streukens (2009) seemed to fit the data quite well, even if it was originally developed in slightly different context (online discussion forums). Therefore, both datasets were next coded at the paragraph level following the Andreassen and Streukens (2009) frame using Atlas.ti. Next, content coded for each code was examined first for each case separately and finally cross-compared to understand in depth what the reviews were discussing.

<sup>1</sup> <https://www.trustpilot.com>

## 4. Results

On average a single review consisted of one short paragraph of 3-4 sentences and seldom covered a large variety of topics, focusing instead on 1-2 key issues. Thus while there were some more holistic overviews among the reviews, majority of them focused on a handful of more specific aspects of the service and service experience. Most often discussed topics were usage experience issues, various features of the service offering and perceived ease of use of the service.

The content the reviews in the two datasets had some surprisingly distinct features. Reviews on Streaming were more critical and thorough, discussed use experiences of larger variety of service features and contained more information on explicit and tacit desires related to the service development. Storage reviews on the other hand contained more explicit recommendations to test and use the service and descriptions of what the service does and what kind of features it has without going into detail of use experience. Hence, stereotypical review of Streaming focused more on what one liked and disliked about the service, whereas that of Storage mainly underlined what one can do with Storage and that it won't let one down. This suggest that the nature of online review content can be quite case specific, which can have important implications in terms of using it for innovation purposes.

In terms of trustworthiness of the data, amount of reviews which appeared insincere or not grounded on real life use experiences seemed rather low. For both cases there were a few individual reviews, which seemed more like advertisements than actual reviews but as a rule the reviews seemed like they were communicating opinions based on actually using the service.

### 4.1. Service experiences and contexts

In the online review content there was ample discussion about the service use experience containing especially descriptions of personal use cases, reasons for positive or negative use experience and information about the context of service use. Many reviews contained remarks about how the service is connected to the consumers' own value creation processes and other key resources providing a window to the daily reality of the consumer:

*I've been using Storage as a means to transfer files from one computer to another and never thought how much time and effort it saved me. I store all my important images knowing that a catastrophe with my system doesn't mean losing years of priceless photographs and other important documents. Couldn't rate the service from Storage highly enough Brilliant. [Storage, online review #1]*

*Originally payed for the service so that my son could watch TV in his room from his xbox. App installed relatively simply and after initial problems getting it to work on the way the setup works in the parental control settings on the xbox, we were away. --- We frequently due to 'conflicts of interest' are watching three different things on various devices or TV's. [Streaming, online review #2]*

Esp. in Streaming case, some reviews reflected on the service concept and how it was changing the everyday practices of consumers. The following example providing interesting insight on what the reviewer sees as the key sources of value from his personal perspective:

*We love Streaming, it's so convenient, not having to drive to the video store, and the catalog is so much larger - every time we went to blockbuster, it takes 45 minutes of slowwwwly walkingggg arounnnndddd the place - but with Streaming we can easily choose all the favorites and create like a calendar of movies. And another pain with blockbuster was the merchandizing at the counter - geez they even sell those silly band things, 80 types of candy, t-shirts, breath mints...whatever they can make a buck on. This is not a rant against blockbuster, but I am really happy with Streaming. thank you.*  
[Streaming, online review #3]

Reviews also discussed various parts of the service use life cycle, including where one learned about the existence of the service, how did one end up trying it, what the purchase decision process was like and in the more critical cases why did one stop using the service or change to a competing supplier. There were also reviews which discussed use experiences and perceptions of the alternative solutions. This content included information about the perceived advantages and disadvantages in terms of price, technical features and service quality, as well as explicit discussion on the perceived positioning of the service. Reviewers' reflection on the competition was not limited to direct alternatives, but discussed also other types of services providing similar end results but with different means as well illustrated by the following review:

*If you have it for 2 months its super easy to watch everything esp. when you have dish/cable. --- It almost seems like a Fox Movie Network on demand. Great if you don't have 500-600 channels on a dish/cable company. I will add, its killing our video/rental stores off. –*  
[Streaming, online review #4]

Content addressing quality of customer service included both unspecific praise and criticism, and more elaborate narratives on experiences dealing with the customer service. For example, several content customers were specifically thanking certain customer service workers for being nice and helpful. More critical reviews usually dealt with billing related problems and perceived mismatch between marketing material and the reality and company responses to such complaints. The narratives tended to be written in a rather personal manner, including information about the positive or negative emotions experienced during the process and reasons behind them.

## **4.2. Service quality and features**

Usually explicit discussion of quality of service were limited to rather general level comments of liking or disliking the service, but some reviews did tie quality to certain features or other aspects of the service. When specific dimensions of service quality were discussed, most often mentioned issues by reviewers in both cases were technical reliability of service and ease of use. Consumers also commented extensively their views on the price/quality of the service. However, price/quality content as a whole was quite self-contradictory containing similar amounts of comments praising

and critiquing value for money. As a whole, reviews discussed a wide variety of matters from more broader topics like user interface, to more specific technical issues as in the examples below.

*"Great service, but poor range of titles. The service Streaming provide is great - the site is easy to navigate, the movies stream really fast and the price is great. The only downside is that the range of title available is pretty small." [Streaming, online review #5]*

*Been searching for a new file host that can autoplay a hotlink SWF file on my folio site. Many say they can but then can't. Storage actually does it. [Storage, online review #2]*

As said, certain features were also mentioned a lot more often than others. This phenomena was particularly strong in the Streaming case where the range of TV series and movies available for viewing in the streaming service was a theme of significant interest. This interest was also translated to more thorough reflection on the topic as illustrated by the following quote:

*Series: If you enjoy tv-series it is definitely worth to try if you are a series freak: it is best for tv-series you can watch all the seasons in high quality. Never had a problem with streaming. Always smooth and if you pause it next day it will start again from where you were.  
Documentaries: it is quite ok with documentaries and "docutainment".  
Movies: not the latest, best or blockbusters movies. IF you are cinema lover, might be worth to try other services, I hope they'll improve the database [Streaming, online review #6]*

These more elaborate pieces of analysis tended to contain implicit remarks about users' desires on how the service could be improved and developed as well as who the service currently suits best. Explicit development suggestions were made as well.

*-- I would like to see instant service include dvd and blu ray extra features like making of and deleted scenes then we can do away with discs altogether. After all you main selling point is the alternative film viewing option from renting discs or buying them. Lets face it we get them for the extra features otherwise we would make the effort to see the film in the cinema. --- [Streaming, online review #7]*

Such explicit suggestions as above were usually rather incremental and thus probably already recognized by the company. Many users were also suggesting very similar improvements. Therefore it seemed that main utility of analyzing ideas proposed by users would be to gain understanding about the amount of users yearning for a specific improvement, instead of actually gathering new ideas. Important thing to note is that such analysis should not be limited to examination of explicit suggestions solely because of the fact that majority of the reviews were communicating consumer needs and desires for improvement implicitly.

## 5. Discussion

Overall, the present study finds somewhat mixed evidence in terms of utilizing content from consumer reviews posted in online review sites in service innovation activity. The amount of distinct new ideas proposed in the reviews is rather low and those ideas which are presented are mainly incremental and likely to be already known to the company. Thus we contribute to the literature on open innovation (e.g. Bayus, 2013; Sigala, 2012; Ebner et al., 2009) by showing that public online review sites do not seem as a particularly suitable for virtual idea collection purposes in light of the present data, especially if the goal is to seek new radical ideas.

However, this does not imply that online review data is not meaningful in terms of service innovation activity in general. There were surprisingly elaborate analysis esp. in the Streaming data on who the services suit best and why as well as ample information related to the service experience, including various use cases, how the service brings value to customer, context of service use, causes for positive and negative service experience, perceptions of competing solutions etc. Gustaffsson et al. (2012) have argued that customer cocreation is not solely about understanding customers, but also their context of service use. The results suggests that analyzing online review data is one interesting lightweight method for providing an intriguing albeit small window to how, why and where consumers use the service in question. The findings bring new understanding to the discussion on methods for customer integration (Edvardsson et al., 2012; Magnusson et al., 2003; Alam, 2002) by showing the potential of online review site data in gaining insight on consumers' service use experiences and contexts. sa

The results also contribute to the literature on collecting and managing electronic word-of-mouth activity by highlighting issues in incentivizing consumers to voice their opinions online. According to Dellarocas (2003) it is important to motivate users to eWom activity to ensure high amounts of feedback. However, my results suggest that such approach might mean compromising review quality over quantity. While Storage received a much larger amount of feedback, the reviews were significantly less elaborate and informative, but contained more explicit recommendations and praise. Thus, based on our limited dataset, companies striving to increase positive eWom about their services should offer incentives for consumers voicing their opinions, but firms more interested in constructive feedback might be better off by refraining from doing so.

The results suggest that usefulness of online review data for development purposes can be highly context specific. It seems that even between similar types of offering and feedback gathered using the same technology, informativeness of reviews can vary significantly from case to case. Thus the main limitation of the study is the limited sample of two services from the same category of software-as-a-service solutions. More research using larger samples and cross offering and industry datasets are needed in order to make better generalizations about using public online review data in service innovation.

Several other interesting avenues for future research could be considered. As the scope of a single review was usually rather small, gaining holistic broader understanding of customer needs, value creation processes and use contexts required processing a notable mass of reviews. Also, there was large amounts of redundancy

especially in terms of some more popular themes in the reviews. Thus it seems that there is potential in increasing the efficiency of the processing of online review content. One interesting topic for further research could be methods for using automated content analysis to identify those reviews which are less generic in terms of discussed themes and should be examined more in detail. Such approach could decrease processing of redundant content without notably losing richness in end results. Another intriguing topic for further research could be utilizing non-text based consumer generated content for service innovation purposes. The present study is an example of analysis of text-based content, which has received majority of attention in studies of user generated content (see Lu and Stepchenkova, 2015). With the raise of digital services like Instagram<sup>2</sup>, which enable sharing of photographs, videos and other visual content, consumers are increasingly voluntarily providing a visual window to their daily activity. Such data could be highly interesting in terms of service innovation especially for increasing understanding about service use contexts. Research on whether such data could be utilized in service innovation and practical as well as ethical challenges related to doing so would be highly valuable.

# XXV. International RESER Conference: ICT-based service encounters as an innovation arena

*Hannamaija Määttä<sup>1</sup>, Inka Lappalainen<sup>2</sup>*

<sup>1,2</sup> VTT Technical Research Centre of Finland

*The digitalization of services has been increasing during the recent years and thus there is a call for service innovations, particularly in the finance and insurance industry. The research on service encounters is shifting towards examining ICT-based service encounters, which is a greatly under-researched area. This paper examines ICT-based service encounters as an arena for continuous innovation. It elaborates the existing categorisation of ICT-based service encounters and examines the ICT-based face-to-face encounters from the perspective of value expectations of different actors and alternative innovation logics. By providing preliminary empirical illustrations this paper contributes to bridging the research gap between theory and empirical evidence.*

## 1. INTRODUCTION

It has long been acknowledged that ICT plays an increasingly important role in service innovation, and that, with other resources enabling the rebundling and transfer of information in different contexts, it creates new opportunities for service exchange and innovation (Vargo & Lusch, 2004, 2008a, 2008b; Lusch and Vargo, 2014). More often nowadays, the service itself is ICT-based, for example in e-services. This is particularly evident in the banking and insurance industry, where the focus is increasingly shifting towards service- and customer-orientation enabled by digitalisation (cf. Vargo & Lusch 2008; Lusch & Nambisan 2015). According to this view, customers are considered to be active key resources, and thus service encounters are put to the core not only of daily value co-creation but also of innovations when seeking new means for differentiation (e.g. Edvardsson et al 2012). A great deal of research has focused on studies on service encounters, particularly in service management and marketing research as well as recently service innovation studies (e.g. Bitner et al., 1990; Payne et al. 2008; 2009; Sørensen et al 2013; Sundbo et al. 2015).

In the service encounter, and particularly in innovations stemming from this encounter, frontline employees have a key role. Recently, service encounter-based innovation has been defined as *innovation which is developed from the ideas, knowledge, or practices stemming from frontline service employees' interaction with users during the service delivery process* (Sørensen and Jensen, 2012; Sundbo et al., 2015).

Some contributions have been made in the recent years to the service encounter-based innovation, and particularly the role of front line employees in service development, (Fuglsang & Sørensen, 2011; Sørensen et al, 2013; Sundbo et al., 2015; Engen & Magnusson, 2015). Also, the organizational conditions have been researched for service encounter-based innovation and the competences service employees require in discovering and communicating customer input (Sørensen et al., 2013; Sundbo et al., 2015).

However, the service encounters in which ICT is utilised not only in value co-creation and related interaction but also to acquire ideas for service innovation have not yet been much studied (cf.; Henten 2012; Sørensen & Henten, 2014; Sundbo et al., 2015). Consequently, ICT-based service encounters are increasingly gaining research interest. In their recent studies, Henten (2012) and Sørensen and Henten (2014) investigate *theoretically* the ICT-based service encounters from an innovation condition perspective by exploring service innovation, media and communication as well as human computer interaction (HCI) studies. Their exploration reveals the variety of ICT-based encounters depending on the ICT tools as the mediator. This interesting review provides an ideal basis for further examination. Sørensen and Henten (2014, 76) suggest, for example, that ICT services have both elements of goods dominant logic and service-dominant logic, potentially making them less sensitive to innovation in a service encounter. However, due to the lack of empirical evidence on how innovation is induced in ICT-based service encounters (Henten 2012; Sørensen & Henten, 2014), we claim that there is still a need to further investigate the forms of ICT-based service encounters and their potential for innovation. In this paper, we attempt to fill this research gap. Nevertheless, due to ongoing empirical case studies and thus tentative empirical illustrations, our paper is more conceptual in nature. Our empirical context is in the insurance industry where, as in many other industries, digitalization is increasing rapidly. In our case study, we examine a large Finnish networked insurance company, where both the service mindset and digitalization is highly topical.

In our paper, we will focus on examining the ICT-based service encounters *as an arena* for (service) innovations. We have thus set the following research questions considering ICT-based service encounters as an innovation arena to enhance value co-creation and co-innovation:

- What type of value expectations do different actors have of ICT-based F2F service encounters?
- What kind of innovation logics occur for utilising ICT-based F2F service encounters?

The paper is structured as follows. In the second section, we discuss the theoretical frameworks that form the starting point in our study. Firstly, we consider it necessary to elaborate the categorisation suggested by Henten (2012) on the basis of our empirical study. In our examination, we realized that one type of ICT-based encounter is missing: the ICT-based face-to-face encounter, where interaction is enabled via ICT, more precisely meetings between service employees and customers that occur via video conference tools. The elaboration is required, as this missing type of ICT-based service encounter is at the centre of our empirical focus, and from a managerial perspective highly topical, particularly in the finance and insurance branch. *Secondly*, we utilize the principals of service-dominant logic (later S-D logic) in value co-creation and innovation (Vargo & Lusch, 2008; Lusch & Nambisan 2015). When

studying these specific ICT-based service encounters *as an arena* for (service) innovations, we highlight an understanding of value expectations and value in use for beneficiaries, such as customers and other actors, like front-line employees and managers. (e.g. Rintamäki et al. 2007; Payne & Frow, 2014; Edvardsson et al. 2012; Yuan et al. 2014). Thirdly, we also examine the top-down directed and bottom-up experimental innovation logics in *ICT-based* service encounter based innovation (Sørensen et al. 2013; Toivonen 2010; Saari et al. 2015; Kallio et al. 2013). The third section presents the design of our research and the empirical case context. The fourth section summarizes the tentative results, and in the final section we present our concluding remarks and suggestions for further research.

## **2. THEORETICAL BACKGROUND**

### **2.1. From service encounters towards ICT-based service encounters**

There is a great deal of research into service encounters, particularly in service management, marketing and relationship marketing traditions. The focus has been on customer satisfaction and loyalty (Czepiel, 1990; Bitner et al., 2000; Massad et al., 2006), but there is also some research into service encounters from the perspective of value co-creation and the design of service encounters (e.g. Payne et al. 2008; 2009). Payne et al. (2008) suggest that three broad forms of encounters facilitate value co-creation; 1) communication encounters, which are primarily carried out in order to connect with customers, and promote and enact dialogue (e.g. through advertisements, brochures, internet home-pages and manuals); 2) usage encounters which relate to customer practices in using a product or service and include the services which support such usage (e.g., using an internet banking service) and 3) service encounters that are customer interactions with customer service personnel or service applications (e.g., via a contact centre). In this paper, we focus on the third form, which Sundbo et al. (2015) further define as a meeting between the producers of a service and its users at the different touchpoints of the marketing, negotiation, delivery and after service processes. In their view, this encounter is crucial in terms of the service experienced by the customer as well as the service company's user-based innovation. The role of frontline employees is highlighted, as they are the people who interact with the customer in the service process.

Sundbo et al. (2015) consider the service encounter from the innovation perspective, and examine how innovation stems from the encounters between employees and customers. The role of employees and customers is crucial in this type of innovation, which bridges it to user-driven innovation (UDI) and employee-driven innovation (EDI) traditions. Nevertheless, Sundbo et al., (2015) differentiated encounter-based innovation from EDI and UDI, as the focus is on the interaction between the employee and user. In order to understand innovations stemming from encounters between employees and customers, Sundbo et al. (2015) suggest the term co-innovation should be used, which can be defined as "innovation in encounters between employ-

ees and customers in services” (Sundbo et al., 2015; Yenyurt, Henke & Yalcinkaya, 2014). Further they see the employees in playing the main role (Sundbo et al., 2015).

Though the research into service encounters and encounter-based innovation is quite significant, little research has been carried out into technology-based service encounters. More often nowadays, services include some ICT-based elements due to digitalization. Henten (2012) and Sørensen and Henten (2014) have studied the ICT-based service encounters from a theoretical point of view. Sørensen and Henten (2014) suggest that, when a service encounter is mediated via ICT, the conditions for co-innovations also change, hence, the innovation potential in the ICT-based service encounter differs from that of traditional face-to-face encounters. Henten (2012) has suggested a framework of three main modes so as to categorize the variety of ICT-based service encounters. Due to the lack of research on ICT-based service encounters, this categorization remains quite vague, which is why we elaborate the modes with the help of examples from the insurance industry, which is our case context in this paper.

The first of Henten’s (2012) categories is *face-to-face service encounter with ICT-enabled interaction between employees and customers*. By this, he refers to the marketing, contacting, ordering, payment and feedback phases of service processes. In this mode, the ICT is considered “circumstantial” to the core service. We further characterise these as meetings that occur face-to-face in a physical location, and where ICT is used as a tool in service exchange, but the company and the customer are both physically present, i.e. the interaction occurs simultaneously. In the insurance context, this could, for example, be unscheduled or pre-scheduled meetings between customers and employees in branch offices regarding the purchasing of insurance services.

The second of Henten’s (2012) categories is *ICT-based service encounter with ICT-enabled interaction between employees and customers*. In this category, the ICT forms the core of the service as, for example, in e-banking. These kinds of services include data, information and knowledge of the customer, which is entered in digital media and transported on communication networks. We specify this mode as interaction that occurs *only* via ICT-enabled tools, and where the presence of service provider is electronic/virtual. Interaction may occur simultaneously or with a time delay, depending on the means of communication. In the insurance services, this could be the customer service phone line, chat, e-mail or online contact sheets.

The third category is *ICT-based service encounters in which customers are a key part of creating the service*. The content of the service is created by the users of the service, though the platform for the service is under the control of the service provider, for example, Facebook or YouTube. In that sense in the insurance industry, this category has its limitations regarding the dominant customer role due to the legislative and regulatory nature of the service. Though following the S-D logic (e.g. Vargo and Lusch 2008), it could be argued that the value of the service is always co-created by the service organization and customer, something which we discuss in greater detail in Chapter 2.2.

Reflecting the Henten categories in our case context, we notice that an important mode of ICT-based service encounters is missing. Thus, we would like to bring forth a fourth form: *ICT-based face-to-face service encounters with ICT-based custom-*

*er/employee interaction*. In this mode, interaction between customer and service employee occurs face-to-face via ICT-tools, such as video conferencing. The company representative and customer are virtually present and are able to see each other, thus enabling simultaneous and reciprocal interaction in the service exchange. What differentiates this mode from the first one is that it enables location independence, as the customer can interact face-to-face with the front line employee, for example, from home. We also differentiate this mode from the third one on the basis that, although provided entirely using ICT, this suggested fourth mode enables face-to-face interaction via video, which changes the nature of the service exchange and innovation potential discussed in the chapters following. There are also no time delays in the interaction, as there can be in e-mails or calls to the customer service phone lines. An example of this mode in the insurance industry can be unscheduled or pre-scheduled video conference meetings between customers and employees via ICT tools (computers, tablets or smartphones). All of these modes are presented in Table 1, in which we have placed the new mode between the first and second modes suggested by Henten (2012).

| Modes of ICT-based service encounters (Henten, 2012)   | Description  | Examples from the insurance industry   |
|--|--|--|
| 1) Face-to-face service encounter with ICT-enabled interaction between employees and customers           | Meetings that occur face-to-face in a physical location. ICT is used as a tool in service exchange, but the company and the customer are both physically present. Interaction occurs simultaneously.   | Unscheduled or scheduled meetings between customers and employees in branch offices  |
| 2) ICT-based face-to-face service encounter with ICT-enabled interaction between employees and customers | Meetings at which face-to-face interaction is enabled by ICT, and ICT is used as a tool for the service exchange, the company representative and customer are virtually present, but can see each other via video. Interaction occurs simultaneously and reciprocally. | Unscheduled or scheduled video conference meetings between customers and employees via ICT (computers, tablets or smartphones) |
| 3) ICT-based service encounter with ICT-enabled interaction between employees and customers              | Interaction that occurs only via ICT-enabled tools, presence of service provider is electronic/virtual<br><br>Interaction may occur simultaneously or with a time delay, depending on the means of communication (chat, e-mail)  | Customer service phone line, chat, e-mail, online contact sheets   |
| 4) ICT-based service encounter where customers are a part of creating the service                        | Customers play the main role in service exchange while the company only provides ICT-based service platforms.  | Rather limited in the insurance industry; however, relevant from innovation perspective.                                       |

Table 1. Elaborated categorization of ICT-based service encounters (modified from Henten, 2012)

In this paper, we will not examine all of the modes in detail, but focus on the ICT-based F2F service encounters with ICT-based customer/employee interaction that we brought forth.

## 2.2. Identifying value in use, value expectations and innovation potential enhanced via ICT-based F2F service encounters

As presented in the introduction, we consider it relevant to explore more the conclusion of Sørensen & Henten (2015, 76) that: *ICT services have both elements of goods-dominant logic and service-dominant logic, **potentially making them less sensitive to innovation in the service encounter***. They ended their exploration of ICT-based services (consisting of various ICT-based service encounters), by stating that the most important criterion is that, while services are defined as having inseparable consumption (simultaneousness of production and consumption), goods as well as e-services are regarded as having separable consumption. From that point of view, ICT-based services (e-services) possess some of the same characteristics as goods, while maintaining some of the characteristics of services (cf. Calborg et al. 2014). Thus ICT-based services are something 'in between', which contributes to the innovations deriving from the service encounters in ICT-based services. (Sørensen & Henten 2015, 67.) Furthermore, by referring to the argumentation of Vargo and Lusch (2006) that goods-dominant and service-dominant logic are combined in various ways and with different emphases in daily economic and social exchange, Sørensen and Henten (2014) concluded that ICT-based services/service encounters have a strong element of goods-dominant logic.

However, due to the great variety of ICT-based service encounters with assumed differences in their innovation potential, we explore more the specific form of ICT-based F2F service encounters (defined in Chapter 2.1) from a service-dominant logic (later S-D logic) perspective by stressing the innovation potential. Firstly, according to S-D logic, *the Service* is defined as the mediating factor in the *reciprocal process of value creation*, while single "services" and "products", (such as insurance products, finance and ICT tools), are seen as *vehicles or distribution mechanisms* for service provision (Vargo & Lusch 2008). Thus, service can be provided directly or through a good, but it is the common denominator of social and economic exchange (Vargo and Akaka 2009). Moreover, service is seen as the *application of operant resources (knowledge and skills) for benefit of another*, being the basis for all exchange (Ibid.), which characterized also strongly knowledge-centric insurance industry.

Secondly, the fundamental premises of S-D logic state that value is always co-created with beneficiaries, and therefore the *customer is always a co-creator of value* (Vargo & Lusch 2008). Consequently, the firm cannot provide value, but only offer value propositions (Ibid.). Thus, customers are seen to play an active role not only in service exchange, but also in the innovation activity. Service innovation is defined as complex network- and information-centric value co-creation by rebundling of diverse resources that create novel resources that are beneficial (i.e. value experiencing) to some actors in a given context (Lusch & Nambisan 2015, 162). Thus, collaborative innovation is embedded in the everyday service exchange among different actors, including beneficiaries such as customers. This definition is aligned with recent studies of collaborative service innovation and service encounter research from both an innovation and value creation perspective (e.g. Payne et al. 2008; 2009; Sørensen et al 2013; Sundbo et al 2015).

Therefore, it is crucial to create *supportive environments* for resource integration and value co-creation in novel ways, such as in our case by means of ICT-based F2F service encounters. Accordingly, we see that ICT-based F2F service encounters via video connection provide flexible mechanisms that facilitate reciprocal interactions

between actors and enhance the transparency of activities in an increasingly complex and networked knowledge-intensive branch such as insurance. According to Sørensen and Henten (2014), the critical for innovation potential is the degree of formalisation of the communication, and they thus conclude that ICT-based encounters provide narrower opportunities for innovation. However, we suggest that ICT-based F2F service encounters via video connection enable reciprocal and rather informal interaction for knowledge sharing in the verbal, textual or visual forms between front line employees and customers, as well as related evaluation and negotiating. From the S-D logic perspective that is resource integration and re-bundling so as to enhance service exchange and also the potential for novel ideas for innovations.

Fourthly, S-D logic argues that the use context and contextual experience are essential in value co-creation: *value is always uniquely and phenomenological determined by the beneficiary* (Vargo & Lusch 2008). The role of the provider is to offer input and support the customers' activities, but the customer determines what is of value in their own context. Recently, Chandler and Vargo (2011) have used the term "value-in-context" to describe this phenomenon. Therefore, *understanding value in use* for the beneficiaries, such as customers and other actors involved, is crucial for competitiveness and the differentiation of companies. Concerning our case, we may assume that ICT-based F2F service encounters via a video connection support value co-creation in a more flexible manner in terms of time and place independence. That enables a *need-basis service in the use context of insurance service*, such as at home, when customers have suitable time to resolve these issues, a health care centre or even accident sites. Furthermore, we suggest that these kinds of encounters may also enhance novel idea generation when they occur closer to the use context, that is, when value is realized and experienced by customers and other beneficiaries. Edvardsson et al. (2012) have pointed out the understanding of customer value in use by two dimensions: in situ or ex-situ related to customer involvement, and context or ex-context, which concerns a resource constellation available for customers to enable value co-creation. We discuss more about the topic in the next chapter.

S-D logic also makes the difference between value co-creation and co-production, which has been a common observation among service researchers (Kallio & Lapalainen 2014; cf. Sørensen & Henten 2014). Co-production refers to the customer's participation in the creation of the value proposition (the firm's offering), which is optional and depends on the conditions of the provider and the customer (Vargo and Akaka 2009). As stated, in order to create competitive value propositions, it is crucial to understand the *value expectations and needs* of the customers and other beneficiaries. Vargo and Lusch (2004) have highlighted the interactive, relativistic, and experiential nature of customer value. Rintamäki et al. (2006, 624) concluded their literature review on *customer value* by stating that: *customer value (or rather value in use) is always defined by customers' subjective perceptions and evaluations of the total customer experience. Customer value proposition hence is an encapsulation of a strategic management decision on what the company believes its customers value the most and what it is able to deliver in a way that gives it competitive advantage*. Furthermore, they conclude that a customer value proposition should: 1) increase the benefits and/or reduce the sacrifices that the customer perceives as relevant; 2) build on competencies and resources that the company is able to utilize and develop, 3) be recognizably different (unique) from competition; and 4) result in competitive advantage (Rintamäki et al. 2006, 624).

In order to examine the value expectation of customers (and other beneficiaries) towards ICT-based F2F service encounters via a video connection to enhance value co-creation and co-innovation, we found their four hierarchical dimensions of customer value to be relevant. It starts from *economic and functional*, and moving towards *emotional and symbolic value*. Moreover, they present the framework, where the value dimensions are hierarchically structured in the form of a customer value matrix. The value dimensions range hierarchically from more objective to more subjective, from more concrete to more abstract, from more utilitarian to more hedonic/psychic, and from more transaction-based to more interaction-based. As it becomes obvious, the customer's role as value-creator increases from economic towards symbolic values, also reflecting better means for differentiation from the company perspective. Furthermore, as they pointed out, customers may not experience value in a hierarchical manner, even though the value proposition is typically constructed of several values. However, from the point of view of the company's competitive advantage it is essential to identify a point of difference. That is, whether focusing on price and economies of scale, solutions, customer experience or meaning. (Rintamäki et al. 2007.) The latter ones call for deep customer understanding as well as interest and competences for co-innovation from both beneficiaries, companies and customers.

While this value hierarchy helps in identifying critical customer value to construct tempting and competitive value propositions, some other frameworks may be called for in order to identify value expectations of other beneficiaries or stakeholders, as suggested by Frow and Payne (2011). They provide a broader view of value through the creation of value propositions for key stakeholders, although not exploring value dimensions in more detail. Instead, Yuan et al (2014) in their article, considering a resource mapping framework for value co-creation in social media, differentiate three main value dimensions relevant for all beneficiaries, such as *Beneficial value*, *Knowledge value*, *Social capital value*. By the concept of beneficial value, they refer to Vargo et al (2008, 148) who defined "*the adaptability and survivability of the beneficiary system*" as the core and main measurement of value in S-D logic. It remains rather vague, implying the contextuality, and may also include the knowledge and social capital values. Furthermore, they highlight that value-in-exchange is the negotiated measurement provided and obtained (e.g. money and value proposition) among exchange partners. Therefore, it serves a means of measuring relative value within a context of surrounding systems, such as competitors. As they specify, *the process of co-creating value is driven by value in use, but mediated and monitored by value-in-exchange*. (Vargo et al. 2008, 150.) ***In this paper, we focus on examining the value expectations of different actors, while our empirical cases are at the experimental stage on service innovation.***

When moving towards a service approach, new kinds of coordination mechanisms are called for, such as co-constructing a *common (service) mindset* and *architecture of participation*, suggested by Lusch and Nambisan (2015) among others. In their article, Lusch and Nambisan (2015) suggest that ICT fosters service innovation through the establishment of a value network, and allows the sharing and integrating of resources and knowledge within that network. We propose that *ICT-based F2F service encounters can be applied in this manner as arenas for collaborative innovation*. In addition, strategic coordination and systemic support are necessities due to network- and knowledge-centricity within and between (organizational) actors. In the

next chapter we focus on alternative innovation logics relevant when utilizing ICT-based F2F service encounters via video as an innovation arena.

### **2.3. Innovation logics in service encounter-based innovation processes**

In the concept of encounter-based innovation, Sørensen et al. (2013) highlight the daily service encounters as an innovation arena, and both employees and customers as active innovators. As a basis of encounter-based innovation, Sørensen et al. (2013) suggest two different innovation logics; directed (top- down) and practice-based (bottom-up). Alternative innovation logics have been studied respectively by Toivonen, (2010) and Kallio et al. (2013) in knowledge intensive services among others. However, these innovation logics have not yet been researched much in the context of ICT-based service encounters (Henten, 2012; Sundbo et al., 2015). The directed (top-down) innovation logic has the same characteristics to that of a stage-gate approach in terms of formal structure. In stage-gate approach the innovation process is organized in certain phases: 1) the emergence of an idea at the fuzzy front end; 2) the development of the idea; and 3) the application of the idea to the markets and customers (de Jong and Vermeulen, 2003). In directed innovation, the ideas emerge in the service encounter, but only managers have the resources to bring the input into the development processes (Sørensen et al., 2013). The stage-gate approach to innovation with reliance on its pre-planning, linear process structure, top-down and provider-centric nature has been considered particularly problematical with service innovation due to its interactive and knowledge intensive nature. The provider-centric nature of this innovation logic has been criticised, particularly in service exchange where close contacts with customers are essential. Also, the order of innovation process phases can vary, as innovation can start from a change in practice, instead of from a specific, recognized idea (Toivonen, 2010).

It is also argued that innovation can occur as practise-based change processes, where employees make small, unintentional changes in their daily service process. However, the innovation potential of the practise-based changes has been ignored in many service organizations (Sørensen et al., 2013). The practise-based changes are of a similar nature to so-called rapid experimenting processes that have emerged as alternatives to linear stage gate models; they aim at testing the emerged idea immediately with customers. If the idea receives approval, it is developed further, and in this way the innovation activities are integrated into service practice and co-development with users (Toivonen, 2010; Heinonen et al., 2010). Co-innovation is characterized by dynamic interaction among different interest groups or individuals occurring in practice through concrete and collaborative experimenting, experience and renewal (Kallio et al., 2013). Employee-driven innovation (EDI) is in the core of practise-based bottom-up innovation logic, as it emphasises the initiatives of employees in bringing forward their ideas arising from the interaction within service encounters. Also, the term bricolage is important in EDI literature as it is the process of co-shaping an emerging path through a continuous learning cycle, where competences are developed by learning by doing and through interaction (Saari et al., 2015). The roles of employees in innovation activities has been studied from the innovative behaviour perspective (Tuominen & Toivonen, 2011). Innovative work behaviour is considered to be one type of extra-role behaviour, meaning that it is not expected of employees, but generating new ideas and sharing them within the organisation is

encouraged. In-role work behaviours, on the other hand there are activities that are expected from an employee in a certain organisational role (Merton, 1957; Katz and Kahn, 1978). Although innovative behaviours might not be formally required, these actions are important for the survival of organisations (Tuominen & Toivonen, 2011).

The needs of customers are highlighted in employee-driven innovation, as the problem-solving takes place in the interaction with customers. Regarding customer integration to the service development within these innovation logics, Edvardsson et al. (2012) have suggested that it is essential to capture information on value in use in the terms of context and situ in order to understand customers and the aspects of value co-creation that are critical to them. In their novel framework, customer data (and data collection methods) are firstly classified either as in situ (data captured in a customer's use situation) or ex-situ (data captured outside the use situation). Secondly, data is categorized as either in context or ex-context, which concerns a resource constellation available for customers to enable value co-creation (ibid.). Within this framework, Edvardsson et al. (2012) further present four roles for customers to be involved in service development: 1) *the correspondent-role*, where the customer is in a value-creating situation, has experience of the service context and where information can be gathered from a real life service situation; 2) *the tester-role*, where the customer has knowledge of the service context outside and can test the service in simulation of the real life service; 3) *the reflective practitioner-role*, where the customers has experience from the service context, but is not in a real life service situation; 4) *the dreamer-role*, where the customer has learned about the service context from outside, but is not connected to a real-life value-creating situation.

To implement the practise-based improvements and ideas of employees emerging from interaction with customers, management has to support, recognize and organise the bottom-up processes (Hoyrup, 2010). We argue that this is even more crucial in ICT-based services, as when the encounter is mediated via ICT, important properties of the service change (Sørensen & Henten, 2014). Sundbo (1996) has suggested that innovative service organisations consist of a dual structure; an informal social system that produces ideas and a management system that supports the personnel and selects the ideas to be developed.

To summarize, the service encounters thus provide a dynamic interactive arena for innovations in terms of challenging the current way of carrying out and modifying service activities iteratively by experimenting, reflecting, and developing further the ideas stemming from the encounter between customers and frontline employees. It is important to consider relevancy of these alternative innovation logics also in ICT-based service encounters, where ICT does not only change the nature of the service exchange, but the nature of interaction and of work of frontline employees.

### 3. THE RESEARCH DESIGN OF THE CASE STUDY

We specify our research questions considering ICT-based F2F service encounters as an innovation arena to enhance value co-creation and co-innovation as follows:

- What type of value expectations do different actors have of ICT-based F2F service encounters?
- What kind of innovation logic occurs for utilising ICT-based F2F service encounters?

In order to answer these questions empirically, we found a qualitative case study approach relevant to our study due to its explorative nature (see e.g. Yin 2008; Eisenhardt 1989). We study the innovation activities of a large Finnish insurance company, which consists of a network of 19 regional insurance companies, located all around Finland. Our case company is dealing with the comprehensive changes going on in the insurance industry regarding value creation and innovation logic with a growing emphasis on digitalization. The increasingly tight competition has boosted not only the digitalization trend, but also a search for novel business and growth opportunities. In recent years the company has invested a great deal in a transformation towards stronger service and customer orientation. The company operates both in B2B and B2C markets, the latter being our research target in this paper, but still keeping in mind synergies between them (for further research). In the case of consumers, the service offering of the company already consists of a variety of ICT-enabled service encounters, from telephone consultation to online services. However, a paradigmatic change in the company's innovation logic has boosted different kinds of *novel experiments* in the service development enabled by digitalization.

For our paper, we have chosen a mini case of this kind, which focuses on ICT-based F2F service encounters, via video connection. The mini case is thus aimed at developing the new type of service channel to enable the customers an alternative way for service exchange with the service personnel as regards insurance matters. The video connection enables visual, immediate and reciprocal interaction with a service person. Consequently the needs of the customers to visit the branch office will be reduced. The purpose is to provide "remote locality"; giving the customer the sense of a person-to-person service, but with more flexibility as regards their own location. The ICT-application is designed for two interfaces; a remote "digi-corner" (resembling an old phone booth) with a video screen, which can be located, for example, in shopping centres or grocery shops; and a mobile application enabling a video connection, which can be downloaded into a smart phone or a tablet. The application is developed in collaboration with an external IT-company.

The development work of the mini case is located in one of the 19 regional companies within the entire company group. It was originated by the proactive and visionary management of the regional company, which operates in 14 localities in the western part of Finland and has a bit over one hundred employees. Within the company group the regional company currently ranks somewhere in the middle in terms of revenue, and is in the top three with their growth rate. The development work started at the end of year 2014, and is currently moving towards experimentation with customers.

As a method, we utilize semi-structured thematic interviews. They were targeted to the managing director of the regional company in charge of the mini case and the representatives of management of centralised service development in the company group. Altogether, four interviews were conducted and analysed in May – June 2015. Each interview took approximately one and half hours and was conducted by two researchers so as to ensure coherency of the interpretations. In addition to memos from the discussions, all interviews were recorded and later transcribed. The qualitative analysis was conducted based on our two research question and the main conceptual frameworks presented in Chapter two. Value expectations of actors of ICT-based F2F service en-counters (via video connection) were analysed by following S-D logic approach (e.g. Vargo & Lusch 2008; Vargo & Akaka 2009) and based on value dimensions defined by Yuan et al (2014), Vargo et al. (2008) and Rintamäki et al (2006). Characteristics of alternative innovation logics which occur for utilising ICT-based F2F service encounters were examined according to concepts of Sørensen et al (2013), Tuominen and Toivonen (2011) and Edvardsson et al. (2012).

## 4. MAIN FINDINGS

### 4.1. Value expectations of actors of ICT-based F2F service encounters (via video connection)

Based on our first research question, we summarize our main tentative findings regarding the value expectations of different actors of ICT-based F2F service encounters via video connection. These encounters are supposed to enhance value co-creation and co-innovation. As different actors we identified the managing director of the regional company in question (later regional manager), front line employees, the representatives of centralized service development, external partners and customers (in B2C market).

In the interview with the regional manager, he raised the rethinking and renewing of their means of differentiation such as locality and customer proximity in the digitalized world as the key value expectation, which also seems to be the driving force in their development work in question. Primarily it is justified by changing customer needs and value expectations. Consequently they call for novel ways for organizing and developing resources in the long run, while having a geographically wide market area to serve with diminishing resources (competent employees and small offices). Therefore, the primary value expectation strongly reflects the so-called **beneficial value** defined as “adaptability and survivability of the beneficiary system” by Vargo et al (2008).

According to the regional manager, regarding simple insurance issues *customer value* focuses strongly on promptness. The more specific customer value expectations were only in the basis of rough ideas, such as that in IT-based F2F service encounters via a video connection customers *seem* to value the flexibility related to time and location dependence as well as material sharing in multiple forms to facilitate negotiation and decision-making activities. Furthermore, personal, F2F interaction and resource integration is particularly valued regarding the more complex personal risk insurances. These deeply concern taking care of personal well-being, and/or the well-being of family and other communities (such as companies). Thus, they are de-

rived from fundamental human needs such as a feeling of security, and even continuous renewal (in terms of new programmes towards a healthier life style with various impacts). Here, even virtual F2F service encounters are still seen to have certain limits from the regional manager and customer viewpoints.

By applying the customer value hierarchy developed by Rintamäki et al. (2007) the former can be interpreted as **functional** value and the latter as **emotional** or even **symbolic** value. This seems rather obvious, and also reflects a general shift from tangible towards increasingly intangible, or operand resources, as the core in value co-creation, aligned by S-D logic too (e.g. Vargo et al. 2009). As the regional manager crystallized, that customers wanted to be “in the swim”, which may be linked to functional value, or even *symbolic value in terms of identifying with so-called pioneers*. Moreover, the *possibility of collaborative innovation can be interpreted as symbolic value*, which reflects strongly the chosen experimental innovation approach in their development work. In addition to these customer value expectations highlighted by the customers themselves, the regional manager himself refers to emotional value when describing special features of ICT-based F2F service encounter, such as privacy needs and “look and feel” issues.

When turning back to the value expectations of the regional manager himself, understanding value in use for customers by taking them as an active part of collaborative innovation can be interpreted as **Knowledge value** which he stressed. This is discussed in greater detail in the next chapter. However, the regional manager emphasized two strategic partnerships, from which another one related to deepening the customer understanding; the students from the local university as an external facilitator and co-learners. The other he mentioned was the IT-provider of resources related to video connection. He described their mutual interests in being pioneers in developing novel ways and alternatives for service encounters to enhance value co-creation and co-innovation in the insurance branch. This could be interpreted as **beneficial value in a systemic sense**, but also stresses the expectation of **social capacity value**.

The value expectations of the front line employees (based on the interview with the regional manager) focused on **beneficial value**. That is manifested by their willingness to be involved in innovation activities by experimenting and co-constructing the value creation activities with customers. This can be interpreted as understanding the necessity of renewability and adaptability in order to enhance the competitiveness of all beneficiaries (personal and company). In that sense, the **Knowledge value** is highlighted such as learning and competence building.

The value expectations of the representatives of centralized service development of the company group of ICT-based F2F service encounters via a video connection were rather limited, because they had conducted the local development work rather independently. According to the regional manager, novelties with scalability potential were expected and supported by providing company-specific guidelines and knowledge. The systemic approach and strengthening service mindset combined with the digitalization approach were also strongly highlighted in the interviews with representatives of centralized service development. Thus, they altogether refer to strong and shared acknowledgement of the fundamental **beneficial value**, as well as **Knowledge value (built-in) in terms of capability building and mutual learning competitively in the systemic sense**. In addition, when regarding so called value in exchange (Vargo et al 2008), both the regional manager and the representatives of

centralized service development shared the same expectations focused on growth targets, such as great increase in sales concerning current and new customers and thus revenue in an increased profitable manner.

## 4.2. Innovation logics in developing ICT-based service encounters

The changing needs of customers, the pressure to differentiate in the markets and staying on top of the increasing digitalization of service exchange were highlighted in our case study as drivers of innovation. Our interviewees discussed that there is still a need to serve customers locally, however, the digitalization trend calls for new ways of interacting. This is the challenge that is pursued to be tackled in our mini-case: how to be locally present in the digital world. The development of new solutions was started after the management of the regional company decided to follow the digitalization trend in the industry, and develop something new by themselves, rather than waiting for well-planned guidelines from the strategic management of the company group (Toivonen, 2010; Heinonen et al., 2010). In our interviews, the development processes of the strategic management were described as slow and heavy, which is why the regional management decided to pursue with a “do it yourself”– approach, which can also be described as bricolage (see Fuglsang, 2010). Though the development was started without the formal agreement with the top management, they have been notified about the development goals and related investments. From the perspective of the entire company group, the impulse for the development can be said to originate from bottom-up. Still, the development cannot be described strictly as practise-based, where small, unintentional changes are made by front-line employees to improve the service processes (Sørensen et al., 2013). Instead, the vision (based on value expectations presented in Chapter 4.1.) and the main concrete development steps are based on strategic alignments within the regional company.

The development approach in the mini-case is to go bravely and quickly to the customers so as to gain feedback and ideas to develop the service further (see e.g. Toivonen, 2010). The nature of the development is thus *experimental*, and the focus is on continuous learning from experiences in the service encounter. The role of both employees and customers is thus highlighted in the innovation activities. In the mini-case, the employees have been activated to present their ideas in developing the digi-corner and mobile video conference application. So-called “lead-user employees” are named to test the new solutions in practise together with customers. In their encounter with the customer, they receive valuable knowledge and feedback on how the customer experiences the ICT-based F2F service encounter. From an innovative behaviour perspective (Tuominen & Toivonen, 2011), the employees can be said to have an *expected in-role* in the development, as resources are allocated for them to develop the service, unlike in directed innovation, where only managers usually have the resources to do this (Sørensen et al., 2013). This role is in line with employee-driven innovation (EDI) as the emphasis is on the initiatives of employees in bringing ideas arising from the service encounters forward through a continuous learning cycle (Saari et al., 2015). To experiment with the digi-corner, a pilot version of it will be placed in a local grocery shop, close to a branch office. The role of employees is important in the experimentation of the digi-corner, as they have to encourage existing customers to try it out.

It is also critical to gather customer information on the *value in use* to understand the aspects of value co-creation that are critical to customers (Edvardsson et al., 2012).

Just in the beginning of the development work, an understanding of the customer needs regarding digitalization and novel ICT based F2F service encounters in insurance branch were gathered with the help of the students during a management course in the local university. Customers have thus been engaged in a *dreamer-role*, where they have learned about the service context from outside, but are not connected to a real-life value-creating situation. When needed ICT applications have been developed with IT-partner, the customers are given a possibility to out the digi-corner in dealing with insurance related issues, as an alternative to a traditional face-to-face encounter. In this experimentation, the customers have a *correspondent-role* as they have experience of the service context, enter a real-life value-creating service situation from which information can be gathered. Further, to test the mobile video conference application developed, students from the local university have been employed to market the new service to people in various events with iPads, to ask people their opinions about the service in use. With the iPad, it is possible to make a test connection with an employee of the company to see how it would work in practice. The students gather data from the customers so that it can be utilized in further development. In this situation, the customer's act in a *tester-role*, as they learn about the service from outside its actual context, but test the service in a simulated use situation (Edvardsson et al., 2012). Essential is to note that multiform customer and employee involvement, defined here as the collaborative innovation, not only have contributed to ICT based F2F service encounters as such, but also to entire service system (cf. e.g. Lusch & Nambisan 2015).

Our tentative interpretations of our empirical results regarding the innovation logic in the development of the ICT-based F2F service encounters are summarized in Table 2.

| Dimensions   | CASE STUDY: Development of a "Digi-corner" and a video conferencing mobile application for insurance services   |
|--|---|
| Characteristics of the ICT-based service (encounter) | ICT-based face-to-face service encounter with ICT-enabled interaction between employees and customers<br>Video conferencing tools to enable reciprocal value-creation |
| Impulse for the development                          | Bottom up<br>Bricolage  |
| Approach in innovation process                       | Fast prototyping<br>Experimenting<br>Learning by doing  |
| Roles of customer                                    | Correspondent<br>Tester<br>Dreamer  |
| Roles of Employees                                   | In-role (expected)  |

Table 2. Tentative empirical interpretations of results

## 5. DISCUSSION AND CONCLUDING REMARKS

In this paper we have examined ICT-based service encounters as an innovation arena from the perspective of value expectations of different actors and the manifestation of different innovation logics within the ICT-based service development. In order to examine the potential for innovation lying within ICT-based service encounters, we argue that it is first necessary to specify the forms of ICT-based service encounters. With our empirical case study we were able to discover a new form of ICT-based service encounter within the frame suggested by Henten (2012): *the ICT-based face-to-face service encounter with ICT-enabled interaction between employees and customers*. In our empirical case study, the ICT-based F2F encounter is enabled by a video-conferencing tool, more precisely in the form of a digi-corner located in a grocery shop and a mobile video conference application which can be downloaded into a smartphone or a tablet. Our preliminary illustration from the case study serves as a starting point for narrowing the gap of empirical evidence on how ICT-based service encounters function as an arena for innovation. Due to the discovery of a new form of ICT-based service encounters, we argue that there is potential for innovation still to be researched and consequently to even better utilize in practice.

After on our specification to the categories of ICT-based service encounters, we are able to firstly conclude our research question regarding value expectations of different actors of ICT-based service encounters in service exchange and co-innovation. Based on our tentative empirical results, expectations related to Beneficial value was highlighted and shared among regional management, centralized service development and even frontline employees, in addition to strategic partners such as IT-provider and Local University. This notion is aligned with the definition of Vargo et al. (2008) of the beneficial value as the “adaptability and survivability of the beneficiary system” – referring to competitiveness and innovation capability in systemic level. Thus we suggest that our tentative empirical findings also reflect the ongoing transformation towards service orientation with underlying innovation logics and digitalization trend (e.g. Lusch & Nambisan 2015). Identification of the expectations considering Knowledge value (such as understanding value in use, new capabilities and novel ways for value co-creation and co-innovation) and Social capital (such as strategic partnerships) value are built in and are at the core of that profound renewal in the service eco system level, as stressed also by Lusch & Nambisan (2015) among others.

Based on tentative empirical results value expectations of customers focused not only on functional value, but also emotional and even symbolic value (cf. Rintamäki et al. 2007). These on one hand characterized general shift typical also insurance branch from tangible towards increasingly intangible, or operand resources, as the core in value co-creation, aligned by S-D logic too (e.g. Vargo et al. 2009). Thus regarding the more complex personal risk insurances, which deeply concern taking care of personal well-being and derived from fundamental human needs such as a feeling of security, and even continuous renewal. On the other hand the symbolic value can be interpreted as identifying with so-called pioneers and the possibility of collaborative innovation. Finally to conclude, our tentative empirical findings indicate that novel ICT based F2F service encounters have not been developed as such, but their innovation potential has been also acknowledged in the systemic sense.

Secondly, concerning the research question of the alternative innovation logics we discovered that the development of the ICT-based F2F service encounter originates from bottom-up, meaning that it is not guided by strategic innovation processes directed from the group management. This result supports the argument that service innovation does not always occur in a planned and structured manner, but can occur through practise-based changes. Similarly, Sorensen et al. (2013) have shown that innovation activity is typically a more or less informal and continuous practice embedded in dynamic and interactive value co-creation processes within service encounters between employees and customers. The interactivity and continuous learning were manifested in our case study, as the approach of the development is to experiment new ICT-based F2F service solutions together with customers and employees, and if the experiments are successful, they will be developed further, thus integrating innovation activities into service practice (Toivonen, 2010).

The roles of employees in the experimentations are highlighted in our empirical case, and based on our tentative interpretations; we argue that if the innovation activities are integrated in the tasks of front-line employees (expected in-role) and resources are allocated for development work, the ICT-based service encounter will be more successful. ICT does not only change the nature of the service from the perspective of customers, but to a great extent also from the perspective of employees as the way of interacting is transformed. The role of customers was also highlighted in our study, and the variety of different ways of integrating customers into the service development, which are highlighted in the study of service encounter based innovation by Sorensen et al. (2013).

We thus suggest that the ICT-based F2F service encounters can provide a dynamic interactive arena for innovation, if the current way of doing and modifying service activities iteratively is challenged by experimenting, reflecting and developing further in a relevant manner. The experimental, emergent, uncertain and iterative nature of innovation activity is highlighted as innovations are increasingly understood to be created in social working activities in business practice. (e.g. Ellström, 2010; Sorensen et al., 2013; Lusch & Nambisan 2014).

By examining the ICT-based F2F service encounter from an innovation perspective, this paper contributes to the understanding of the resources and management (built in innovation logics) needed to utilize the collaborative innovation potential of ICT-based service encounters. Our results are very tentative but promising; our empirical case study has provided better understanding of the studied phenomenon (Yin, 2008). In terms of validity, we triangulated the results between the researchers and case representatives (Kvale, 1996), however, more empirical validation is needed. As this is the main *limitation*, it also opens up possibilities for researchers to challenge and develop our frames further.

Next, in our on-going project, we focus on digging deeper into our case study and expanding our research also to other similar cases in the company group, also to the B2B sector.

# Comparing methods for involving users in ideation. The use of Future Workshops and Blogs in Library Innovation

Hanne Westh Nicolajsen<sup>1</sup>, Ada Scupola & Flemming Sørensen<sup>2</sup>

<sup>1</sup>IT University of Copenhagen, <sup>2</sup> Roskilde University

*In this paper we discuss how users may be involved in the ideation phase of innovation. The study compares the use of a blog and three future workshops (students, employees and a mix of the two) in a library. Our study shows that the blog is efficient in giving the users voice whereas the mixed workshop method (involving users and employees) is especially good at qualifying and further developing ideas. The findings suggest that methods for involving users in ideation should be carefully selected and combined to achieve optimum benefits and avoid potential disadvantages.*

## 1. Introductions

Innovation and especially involvement of the users / customers has been on organizations' agenda for quite a while. The developments within technology and especially social media has paved the way for a wide range of new technologies such as blogs and wiki which can be used for innovation (Bjelland & Wood, 2008) More dedicated software has also been developed such as e.g. idea competitions and innovation contests (e.g. Ebner et al., 2009; Bullinger et al., 2010).

In this paper we focus especially on the involvement of users in service innovation (Alam, 2006), primarily through the use of technology (Kristensson et al. 2008) and in particularly social media (Scupola & Nicolajsen, 2014) such as blogs, which are widely available at a low price and fairly easy to set up, making them a tool for all organizations, even those with a low budget.

In this paper we discuss and compare two different methods for involving users in the ideation phase. Our understanding of user involvement in the ideation phase entails contributions of various kinds. For example, according to Alam (2006) customer activities in the ideation phase concerns describing needs, problems and solutions. Customers may suggest wanted features and preferences or they may evaluate existing services, pinpoint lackings in the market or come up with wishes for new services. Input that according to Magnusson (2003) often needs to be further developed to be implementable.

The paper is based on two innovation experiments (Sørensen et al 2010) at Roskilde University Library. The experiments were part of a longer lasting longitudinal case study (Yin, 1994) in which we investigated innovation at the Library. The case study found that the major sources of innovation were technological development and inspiration from other university libraries. Sometimes more local innovations were suggested by employees if they saw opportunities, for example inspired by the

service encounters. Thus users were indirectly represented. However, direct user input for innovation was rather scarce (Scupola & Nicolajsen, 2010).

To challenge the lacking user involvement in the library and the top management's skepticism towards user involvement we decided to run two field experiments involving the users in different ways using different methods and with and without close interaction with employees. A blog was developed and library users were invited to come up with ideas (Nicolajsen, Scupola & Sørensen, 2010). Subsequently workshops using the Future Workshop method were held (Nicolajsen, Scupola & Sørensen, 2011). The two methods are rather different and are of course not straightforward to compare. We will discuss the strengths and weaknesses of the two methods with regard to resources spent, outcomes in terms of number of ideas and how elaborated these ideas are, the roles of the involved, the process etc.

Table 1 User roles, innovation phases and methods for involvement (further development of Scupola & Nicolajsen, 2010)

Our research question is; what are the strength and weaknesses of using different methods, more specifically Future Workshops and Blogs, to involve users in innovation? Thus, the paper contributes to existing knowledge about user driven innovation by comparing and assessing the innovation value of fundamentally different, but (perhaps) complementary methods for involving users in innovation. Furthermore, by carrying out field experiments the findings can be of direct practical value for other organizations and for libraries in particular.

The paper is structured as follows: First, we outline the theoretical basis of the paper discussing the potential of user involvement in ideation processes. Second, we describe the method and in particular the set-up of the two experiments. Third, we present the findings from the experiments. Fourth, we compare and discuss the methods and finally, we draw the most significant conclusions that can be made from our study.

## **2. Involving users in innovation**

The intensified focus on innovation in the last couple of decades and not least the involvement of external stakeholders - in particular users and customers - has led to quite an amount of research within the field.

Users may get involved at different stages of the innovation process of an organization taking on different roles through different means. This is illustrated below by integrating the work of eg. Nambisan (2002) working on new product development and different user roles, Alam and Perrys (2002) work on customer involvement in service innovation and different methods and means to involve users (Sundbo et al. 2012).

Users may be involved: 1) as a resource in the ideation phase including idea generation and idea screening; 2) as co-creators in the design and development phase including e.g. in business analysis or service and process design; 3) as users testing products and services and marketing strategies or supporting a service or a product in the market. Earlier research has shown that organizations are best at involving the users in the early or later phases (Alam, 2002) as either a resource or in the role as users, rather than in the development phases.

Involving the users in the ideation phase may be done in a number of different ways and using a number of different media (Sundbo et al., 2012). The development within the area of IT and especially social media has resulted in a whole new wave of solutions as alternatives to workshops, focus groups, complaint boxes, satisfaction surveys etc.

As we are particularly interested in the ideation phase, we will zoom in on this aspect. Our understanding of user involvement in the ideation phase entails contributions of various kinds. For example, according to Alam (2006), customer activities in the ideation phase concerns describing needs, problems and solutions. Customers may suggest wanted features and preferences or they may evaluate existing services, lackings in the market or wishes for new services. Future workshops are expected to adress both critiques and more creative input through the different phases of the workshops: critics, utopians, solutions and implementation.

Several researchers (e.g. Narver et al., 2004; Alam, 2006; Magnusson, 2003) argue that the direct interaction between customer and employee provides an occasion to get both ideas and an understanding of customers needs. For example Magnusson (2003) argues for the benefits of physical meetings between professionals and customers, because meetings may provide the professionals with insight into the customers' needs and understandings and, conversely, the users may get a better understanding of the development conditions allowing them to suggest more realistic ideas. Magnusson's (2003) research further suggests that user suggestions are more creative and useful than the suggestions of the professionals. However, his study also shows that there is a need for professional elaboration of the users' ideas to make them implementable (Magnusson, 2003).

When looking at different types of input from users, Narver et al (2004) distinguish between responsive and proactive market approaches. In the responsive approach focus is on the conscious and expressible needs of the customer. In the proactive approach focus is on the latent needs, these may be unknown to the customer himself initially, some would argue not yet developed.

| Approach                    | Responsive                                      | Proactive                            |
|-----------------------------|---|--------------------------------------|
| <b>Basis of ideas</b>       | Conscious problems and needs                    | Latent and created wishes and needs  |
| <b>Innovation potential</b> | Incremental                                     | Incremental and radical              |
| <b>Methods</b>              | User behaviour and evaluation                   | Creative and constructive approaches |
| <b>Examples of Tools</b>    | Log files, surveys, interviews and observations | Interaction and fantasy              |

Table 2 Responsive and proactive approaches to user involvement in the ideation phase of service innovation inspired by Narver et al. (2004)

The two different approaches are described as separate, though in reality they are probably not. However they provide us with an understanding of different potentials of - and ways to - involve users. The responsive approach leads primarily to incremental innovations. The proactive approach has per se the greatest potential for more radical innovations but the resulting ideas will be harder to implement. In the ideation phase of the innovation process an understanding of the differences between involving users in idea provision and idea creation is important. Idea provision involves asking users about 'good ideas' which are often based on their immediate experiences using existing services. Idea creation are seen as involving a process of developing and identifying latent and upcoming needs, new ways of seeing and doing things. These considerations are summarized in table 2.

Theory thus suggests that different benefits may arise from involving users in ideation processes. Additionally, different empirical studies carried out in different environments have indicated how such benefits may be obtained. In the following we compare the use of different methods in the same innovation context and thereby seek to compare the use of these methods in order to expand and qualify the existing knowledge about benefits and disadvantages of different modes of user involvement in ideation processes.

### **3. Method: experiments at Roskilde University Library**

Our longitudinal case study (Yin, 1994) at Roskilde University Library was part of the ICE project ([www.ice-project.dk](http://www.ice-project.dk)). ICE is an acronym for Innovation, Customers and Employees. The focus of ICE is the many different types of service encounters between employees and customers and how these are or may be used to generate innovations for service organizations.

Since 2008 we have followed the innovation strategies and innovation practices at Roskilde University Library (RUB). RUB is connected to Roskilde University, which is a public university in Denmark located 35 km from Copenhagen. The library provides services to the university students and faculty members, companies and is open to the general public.

In this round of research at RUB we started out drawing a picture of the innovation activities and initiatives at RUB as well as the underlying understanding of innovation, with a particular focus on how employees and customers are involved. A number of interviews were made with employees and management. It became clear that customers are involved in limited and rather local ways. Furthermore, skeptics about the value of user involvement were found within the management group (Scupola & Nicolajsen, 2010). As a consequence we decided in collaboration with the management group at RUB to set up experiments to test the skeptics and qualify the test by generating new insight.

Setting up and or following experiments is an explicit purpose of the ICE project with the aim of generating new insight for organizations and the field of research. Semi-structured qualitative interviews as well as a number of meetings and workshops lasting between 1 and 2 hours with top managers, middle managers, and 'front-line' librarians were the main data collection methods used. Based on the results from these interviews, showing that there was almost no direct involvement of the library users in the innovation process of the library services, an agreement was made between the researchers and the library management to conduct an experiment with social media to collect ideas from the users. Given the library's previous experience with a blog used for internal communication it was decided to implement a blog on the library website, entitled "RUBminds". The establishment of the blog and later on the Future workshops to collect innovative ideas from the customers is here defined as field experiments. A field experiment is an experiment carried out in a natural context rather than in a laboratory. In this type of experiment, some control over the experiment itself is lost (compared with the traditional laboratory experiment), but the advantage is that the "natural settings ensure that the results will tell us something useful about the real world, not just some contrived laboratory setting" (Green & Gerber, 2003, 94). In spite of being a rarely applied method in innovation research such field-experiments have been argued to possess the capability of providing practically applicable knowledge about innovation processes while solving real life innovation problems (Sørensen et al. 2010). Field experiments are similar to other practice oriented methods such as action research, action learning and reflexive practice (Baskerville and Wood-Harper, 1996). Semi-structured interviews and workshops with the library employees that had been involved in the blog experiment were conducted to evaluate the experiment and the results obtained. Other data col-

lection methods used in this study includes library reports, minutes of top management meetings as well as click stream analysis. Below we describe in more detail the set-up of, first, the blog and, second, the future workshop experiments.

### **3.1. RUBminds - a blog experiment**

The first experiment concerned the use of an online media to invite users to communicate ideas for the development of the library following other experiments (eg. Magnusson et al. 2003). The Blog, RUBminds, was set up, with four themes for user contributions. The topics in RUBminds were formulated to get feedback on the services provided by the library and the physical settings. The topics were formulated as questions on the blog: 1) "Do we comply with your wishes?"; 2) "If you should furnish the library....?"; 3) "Is Rub your favorite library?"; and 4) "The future of the library – give us your suggestions". It can be argued that the questions overlap, however the different formulations sought to motivate for different answers. In addition to the questions a small piece of text giving examples of the kind of input looked for was put on the first page of the blog.

The blog experiment was advertised online at the home page of RUB with a direct link to the blog and through posters at the university campus describing the blog. Additionally, bookmarkers with the blog address were handed out to the library users in the library.

To motivate library users to participate in the experiment gift cards were promised at the end of the experiment to two randomly drawn blog contributors. This was written on the main page of the blog. The blog experiment was conducted for a period of three months. To increase credibility of the initiative, the blog introduction stated that the library would follow up on the ideas provided on the blog.

During the experiment, the library employees had the possibility to comment and respond to the users' postings, since the idea was that the blog should function as an interactive platform between the users and the employees. At the end of the experiment period, the ideas collected through the blog were analyzed and discussed by library management in relation to their relevance and implementation potential at a management meeting.

### **3.2. Future Workshops**

The second experiment consisted of workshops based on the Future Workshop method (JungK & Müllert, 1987). Three future workshops ran simultaneously at the premises of Roskilde University Library. We (the authors) facilitated a workshop each. Having the workshops running simultaneously made them less vulnerable to no show participants as all participants would fit into two of three workshops. Due to earlier experiences 6 participants in each of the three workshops was seen as optimal (thus requiring a total of 9 students and 9 employees). 12 students (among 20 who signed up) was invited (as we foresaw a certain amount of no show), the library agreed to match the number of students at the day with an equal amount of employees.

The workshop was placed on a day with few teaching obligations for the library personnel. In addition it was placed late in the year to ensure that students at all

levels of study had been introduced and had had tasks where they were expected to use library services. In addition the workshops were placed in the middle of the project period, as we know that students are too busy in the end of this period as well as during periods of exams. Regarding recruitment of employees we asked for personnel in different positions and no leaders. The request for no leaders was made based on speculations, that leaders presence would make some employees act less freely and thereby limit the creativeness.

The recruitment of students, as the largest user group, was made in the weeks before the workshops. Recruitment sheets were placed in the library loan counter and students were invited to sign up by writing their names, telephone number, email and their semester of study. We used the names and the semester of study to ensure as broad user representation as possible, meaning we invited students of different sex and at different study levels. Students participating were given a symbolic gift card for their participation, the employees were assumed to participate as part of their job, with no further reward given.

To meet and ensure the best possible foundation of comparability across the workshops we developed common guidelines for the workshops. The guide was made with inspiration from Jungk & Müllert's (1987) concept of future workshops. The method provides for creative thinking leading to solutions by separating creativity and rationality, which is often seen as imposing limitations on each other. The first phase is the critique phase here the participants are asked to write down criticism, bad experiences, limitations etc. getting rid of frustrations regarding the theme in focus. In the following phase – the fantasy phase, the participants are asked to dream away - setting up utopian or wishful scenarios. This phase is meant to open up people's minds. In these first two phases the participants are asked to take turns providing input. It is not allowed to place any criticism however expansion on the input is invited for. In the reality phase the participants formulate more realistic scenarios based on the developed utopias. This is followed by the implementation phase where the requirements for implementation is discussed regarding the type and amount of resources needed. Jungk & Müllert (1987) argue for an extended period of time to be used when running through the four phases and preferable more than one day. Here the workshop lasted only 2 hours with 1½ hour getting through the four phases. In our set-up each phase was given 20 minutes. In addition each phase was rounded up by a selection of the most important - critics / fantasies / suggestions / implementations, which was seen as a way to narrow the scope of the following phase.

| <i>User workshop</i>                          | <i>Employees workshop</i>   | <i>Mixed workshop</i>   |
|---|---|---|
| 6 students:                                   | 5 employees:  | 6 participants:   |
| 2 males and 4 females                         | 1 man and 4 women   | 3 female students<br>1 male employee<br>2 female employees  |
| Freshman- master level<br><br>Average age: 24 | 2 younger and three elderly employees (close to pension)<br><br>average age: 52 | Students from 1,3 and 5 semester (one is student assistant at the library)<br><br>middle age employees<br><br>average age: 33 (students 23; employees 43) |

|   |  |   |
|---|--|---|
| Very eager, high participation from all – interested in the method itself and in generating solutions | Reluctant participation. 2 very active, one middle active and 2 very limited | Variation in participation employees in general more active than students however also difference in engagement within the two groups |
|---|--|---|

Table 3 Information on workshop participants and process observations

The process was documented in a number of different ways. The physical outputs (posters with post it notes) of the different phases were photographed and the posters were turned into excel databases, one for each workshop. In addition the workshop sessions were tape-recorded. When the workshops had ended all participants were asked to fill in a questionnaire asking about what they personally saw as the most valuable ideas in relation to the needs of library users.

### 3.3. The blog

During the two month in which the blog experiment was conducted, 1.011 visits were made to the blog and 2572 pages were looked at. On average, the visitors stayed for 1 minute and 35 seconds. The number of contributions indicates that it is difficult to make users contribute even if they get to the page. As can be seen in the table below, there is an overall falling activity from the first to the last theme on the blog. The first theme, which appears on the entrance page have most activity. However, the other themes also score quite a number of hits and the fact that the last theme has more hits than the second last, indicate that some visitors orient themselves on the theme that look more interesting to them and not just the first one.

| Blog-Questions   | Number of hits | "Ideas" | User comments | Library responses |
|--|----------------|---------|---------------|-------------------|
| Do we comply with your wishes?                         | 807            | 11      | 7             | 2                 |
| If you should furnish the University library....       | 632            | 8       | 5             | 1                 |
| Is Roskilde University library your favourite library? | 498            | 3       | 2             | 0                 |
| Libraries' future - give us your suggestions!          | 587            | 5       | 3             | 1                 |
| Across the topics                                      | 2572           | 27      | 17            | 4                 |

Table 4 The number of ideas, and contributions within the four blog themes

The inputs provided address a wide range of "library user activities" indicating that different user roles and use situations are considered. Regarding interactivity among the blog contributors, our results show that the various inputs are primarily independent ideas, as users do not expand upon each other's messages, despite the fact that the technology provides for this functionality. However two users express their agreement in general with the other contributors and one even provide an explanation to the comment of another user.

The Library did not respond to the comments until later in the process. However it was decided to do so to show that the input was received and taken seriously.

A total of 27 “useful” ideas were provided during the period the experiment run. The ideas generated by the users on the blog were very different in nature and covered a wide range of topics as illustrated by the examples provided in the next table. Some ideas are visions of a whole new way of seeing the function of the library - as for example the library as cultural event place. Some are suggestions for new services such as an EndNote course, others suggest big or small changes in the services already offered such as access to computers in the library reading areas. A few comments just criticize the present service offerings, without providing suggestions for improvements.

|  |
|--|
| <ul style="list-style-type: none"> <li>• Suggestion for RUB to provide students and employees with short courses on End Notes software</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Suggestion to change copy machines so that the same copy card can be used both at the University and the Library, thus improving the copy services</li> </ul> |
| <ul style="list-style-type: none"> <li>• Suggestion to extend the time period users can keep the books loaned from other libraries through the Interlibrary Loan.</li> </ul>                           |
| <ul style="list-style-type: none"> <li>• Increase the number of full text resources provided in electronic form</li> </ul>   |
| <ul style="list-style-type: none"> <li>• Establish a Silent room with computers</li> </ul>   |
| <ul style="list-style-type: none"> <li>• Establish small rooms where student groups conducting project work could meet and work instead of only having open space areas</li> </ul>                     |
| <ul style="list-style-type: none"> <li>• Establishment of a cozy lounge area with newspapers, a coffee machine, sandwiches and candy</li> </ul>  |
| <ul style="list-style-type: none"> <li>• Establish open air library services, outside the library building, including Internet access, shadow and shelter in the summer</li> </ul>                     |
| <ul style="list-style-type: none"> <li>• Decrease the noise level generated by the air condition system in the silent area</li> </ul>  |

Table 5 Examples of ideas contributed to the blog

In interviews conducted after the experiment RUB management stated that the blog did bring about some interesting ideas. The ideas were quite different: some ideas were seen as suggestions for radical innovations, while others required incremental changes of what was presently done. Furthermore, a few ideas posted on the blog addressed problems that were well known to the library but had been forgotten or otherwise not taken care of. The library personnel expressed a feeling of pressure to do something about the implementation of the ideas due to the public expressions of the ideas. Some ideas however needed further investigation before the library could evaluate to implement them or not; a few were completely dropped due to implementation requirements such as the establishment of open-air library services during summer time.

RUB expressed the low activities as an advantage because the resources needed to manage the blog were constrained along with the resources to follow up and still the blog did provide some useful insights and branded RUB as being open to constructive criticism.

### 3.4. Future workshops

Taking a broad look at the prioritized ideas there are some similar categories and suggestions across the three workshops, others differ tremendously and the level of details differs.

| <i>User (student) workshop</i>                    | <i>Employees workshop</i>                          | <i>Mixed workshop</i>                   |
|---|--|---|
| Search facilities (5)                             | Communication responsible (5)                      | Group facilities (4)                    |
| Branding of services (3)                          | Visual representation of the physical library (3)  | Visual navigation in the Library (2)    |
| Café (3)  | Better equipment for usage of library material (1) | One access point to online services (2) |
| Close collaboration between faculties and RUB (3) |  | More online resources (2)               |
| RUB as a study place (3)                          |  | Silent rooms with computers (1)         |
| Alternative workshops (1)                         |  | More info to new students (1)           |
|   |  | Hide UDK (1)                            |
|   |  | More advanced course (1)                |
|   |  | Library representatives at RUC (1)      |
|   |  | SMS info on loan returns (1)            |
|   |  | Communication strategy at RUB (1)       |

Table 6 Most valuable ideas reported by the workshop participants (number of participants)

In the student group the students did not know each other in advance. They valued a rather low number of ideas (6) – indicating that some kind of common understanding existed in the group. Five ideas were found valuable by 3 or more students. The numbers indicate that this is a somewhat homogenous group with similar needs and wants.

In the employee group the picture is different. Three of five employees report just one or two ideas as being valuable. This may be seen as a statement, not least because there is agreement on the need to hire a communication employee. Four ideas are reported in total with some agreement, which again indicate that this is a group with rather similar understandings of what is needed and with a focus on back office issues. One reason for the limited number of ideas is that there is a great overlap and more consent on what is important in this group. This may be explained by groupthink and the fact that they do face some fundamental challenges as a group - they are all co-workers, they know each other and have a shared daily workplace. The documentation of the process shows some frustration and difficulties in moving away from the internal challenges faced at the library, which seemed to limit the creativity throughout the workshop.

In the mixed group 10 different ideas were valued and much less agreement was found, most ideas were reported valuable by only one or two participants. This may be explained by the fact that this group is also the most diverse as it consists of both employees and students. The enthusiasm in this group was found to be higher than in the other groups especially with regard to the employees in the two groups. This

may be due to the attitudes of the employees who participated here, however another explanation is that these employees are inspired and feel more obligated to participate as ambassadors for the library because of the interaction with the users in this group.

If we look at the ideas prioritized they also differ in terms of content across the student and employee group whereas they are a mix within the last group. This points to what would also logically be expected that employees and users have different perspectives. The ideas suggested by the employees are just titles with little explanations and they are means to develop and reach for new solutions. In the two groups with student participants we find that both employees and students are more oriented towards arguing why, what they see as valuable is valuable. The explanations are somewhat different and in some instances very specific and in addition they can be argued to point to solutions more than means. We know from the mixed group that the employees to a large extent did take a more active role than students however the outcome reported is rather different from what their peers in the employee group report. Interestingly we find evidence that some of the ideas that came up within the pure student group are almost non-existing in the mixed group - namely the one of a better integration by RUC and RUB which is in fact one of the highest valued ideas in the student group. In addition the students in the mixed group are not mentioning the need to improve the search facilities, which is a priority among 5 out of six in the pure student group.

The workshops indicate that employees do in fact get a better insight into the user preference when meeting the users as suggested by Magnusson (2003). We also found that users get a better understanding of why some possibilities are not within reach – such as the possibilities of a café at the library which at least would require new deals being executed regarding catering at the campus. It was also argued that users' ideas are more creative. We would argue that users do provide for better solutions because they do in fact represent themselves better than what a librarian may, at least regarding some services. This is supported by the fact that an employee suggested a solution to a mentioned problem, however the solution did not fit according to the students; neither did a second suggestion. This discussion about how best to reach students when marketing new services thus developed through a dialogue. However the same solutions were pointed at without the employees. This indicates that students alone may in fact provide very good input for service innovation when just looking at the valued input. However the mixed group did come up with even more ideas and it did educate the librarians in seeing the need for doing things differently and creating a better understanding of what should be done and how. This may in fact turn out as being valuable in the following up on the outcome of all three workshops.

## **4. Comparing the two methods**

What we see from the field experiments is that users may be involved in the ideation phase but that some of this interaction may in fact also involve elements of users as

co-developers, when employees and users get into ongoing communication about particular services.

When comparing the outcome of the blog and the three workshops we see that the blog and the student groups are the best solution if the goal is to get as many ideas from the students. Here ideas are understood in accordance with Alam (2006) who argues, that "ideas" can be many different things such as critics, suggestions for smaller changes or more challenging suggestions. The blog produces more contributions compared to any of the workshops. This measure is sensitive to the time span and also how many ideas the participants in the workshops were asked to report as valuable. The numbers may however point to the fact that while the workshops only involve six participants the blog potentially reach a larger number of users as all students are invited (other groups could contribute as well). The question here is whether the possibility of the blog is visible and if the students are willing and have something they want to contribute. What we see from the workshops is that the student group comes up with ideas that are not presented in the employee group, which indicates that the employees are not necessarily good at representing the users (which does, however, not mean that the employees input is not valuable). What we see is that many of the same ideas appear using the two different methods, however more ideas and more different types of ideas appear in the blog compared to the workshop. An explanation could be that groupthink develops fast in a small intensive group. The differences in outcome between the student group and the mixed group can be explained by the students having a lower voice in the mixed group because they feel intimidated working together with professionals. Another explanation is that students withdraw ideas that employees argue are impossible to meet. We know that some of the ideas on the blog were disregarded, as they are impossible to meet due to e.g. agreements with the world famous architect building the library – which was also a theme in the mixed group.

It is not just a matter of getting many ideas, but getting good ideas, judging what is a good idea is of course difficult. In both methods most of the contributed ideas points to incremental innovations, some provided more radical suggestions (primarily on the blog), while a few comments just criticize the present service offerings, without providing suggestions for improvements. We found it rather surprising that the blog inspired to the wildest ideas, as the workshop would have phantasy and creativity as an integrated element, but maybe the need to report the most valuable ideas swept them out. Nevertheless we thought it would be hard to achieve on the blog, though the introduction did invite users to present utopic ideas.

The other issue in relation to users as a resource in the phase of ideation is idea screening. Idea screening in terms of placing value on the ideas was integrated in the workshop format, the outcome is thus a matter of what the participants as a group found valuable, which gave some rough indications, as it was just small groups. On the blog only few indications were found. There is no common practice in blogs for providing such information, and only few likes were given on the library blog. Likes could be an indicator, but it needs to be taken with caution (likes can be used to indicate acknowledgement of contributions rather than agreement). Comments articulating agreement (or disagreement) (which the blog had a few of) are more straightforward. The workshop format seems to provide more input both in terms of the integrated screening (value setting mechanism) but also through the

discussions, through which arguments for the need would be discussed, it is however easily forgotten if the process is not documented in a form where it is easy to get back to or if the employees do not bring it further – which is only a possibility from the mixed group.

Users are needed not only to suggest input and qualify the input into ideas but are also needed to help evaluate and develop the ideas. Both critics and concrete ideas were found valuable. This means that all the different kinds of input that might come according to Alam (2006) are found valuable (maybe the 'wild' ideas less). However, some ideas and suggestions and in particular critics may be in need for further elaboration to get turned into something valuable to the user. Magnusson (2003) discusses the need of the users to be creative in the first place and then the professionals to turn it into a professional service. Here we see that users are also needed in the further development otherwise small issues like how to market a service may result in too few knowing about a new service.

With regard to ongoing communication a difference was experienced between the blog and the mixed group. In the mixed group the interaction between employees and students did in a few instances lead to ideas getting more developed, if an employee presented a solution to an idea, which was then corrected or further elaborated by the students. This kind of interaction did not appear on the blog. It could be argued that it may happen if a timely response is given to the different ideas. However, this requires that the user returns to the blog to respond or that another user responds which is not always likely. Due to the opportunities of these interactions in the mixed group, it could be argued to combine the benefits of blogs and dialogue with a group of users.

A final insight from the study regards the transparency of user involvement. The use of the blog created a new communication platform for the library with a transparency of the user input not earlier experienced. The library felt obliged to take into serious consideration the ideas posted on the blog, due to the transparency of the documented contributions, a responsibility related to the transparency of online media as argued by Kuhn (2007).

## **5. Conclusion**

Our study shows that both blogs and future workshops with user involvement can provide an organization, here RUB, with valuable information. Whereas the blog and the workshop with users, here students, primarily support ideation, the workshop with both users and employees sustain more interaction, thus supporting that users take on the role as co-creators.

Whereas the workshop primarily resulted in incremental innovation ideas, the blog activated more diverse, wilder and more radical ideas, which was surprising. In addition the blog induced more pressure for action than the workshops, due to its transparency to the public.

It may thus be argued that to obtain the most ideas and to represent the users best an online media, such as a blog, could be used, but to involve users in screening workshops with (the highest) user representation better than the blog media,

further development of the ideas are however best achieved in workshops with both users and employees.

At a more general level the findings suggest that the different methods experimented with in the library provide a number of varied benefits and challenges. Thus, companies and organizations should not blindly apply methods, e.g. blogs or workshops, as a mean to induce user-driven innovation. Instead the chosen method (including also other potential methods) should be chosen with care and be aligned with the organizations' innovation needs and considering the potential negative effects of the methods. Thus, for example, the readiness of an organization to adopt and develop user ideas could make a blog a more or less favorable tool.

Focusing on students representing the users of the library is a somewhat limited approach in the experiments reported in this paper. Teachers, other university personnel and a few external actors could be relevant users too. However, students are the primary user group in the library.

For purposes of generalization the library of course represents a special case. Though the experiments have created new insights about the benefits of different methods for involving users in innovation the results cannot easily be generalized (in a positivist sense) but other types of organizations may still be inspired and learn from the findings. Nevertheless, there is a need for more research on different methods in different environments to develop a fuller understanding of the benefits and potential disadvantages of such methods in various settings.

## **H2: ICT, learning and innovation in health care services**

*Chair: Christian Bourret*

# Gamification as an enabler of mutual learning in complex health care systems

Johanna Leväsluoto<sup>1</sup>, Jouko Heikkilä<sup>2</sup>, Kaupo Viitanen<sup>3</sup> and Joona Tuovinen<sup>4</sup>

<sup>1,2,3,4</sup> VTT Technical Research Centre of Finland Ltd

*In our paper, we present a gamified role switching method which has been developed to promote dialogue and mutual learning in complex health care organisations. Our research is based on two case studies with 25 interviews and four workshops. Our study indicates that the gamified role switching method inspired and gave means for the participants to enhance systemic understanding of their organization and to improve dialogue. The role switching method also made the participants see the situation from the other perspectives and thus promoted collaboration and the change process.*

## 1. Introduction

Major challenges are emerging in the health care service system as chronic diseases are increasing and the population is ageing. At the same time new ICT solutions and citizens' increased expectations have led to the situation where the health care system needs radical changes. New innovations and methods are needed to ensure the quality of health care services. However, at the same time, the service as a whole becomes increasingly complex and the needed change is difficult to specify and describe. Furthermore, this complexity makes it more difficult for the customers to understand and participate to their care processes.

The evaluation of the success (or failure) of an organisational change is difficult because of multiple reasons (Hughes 2011). This makes it challenging to identify the true factors that promote the successful organisational change even though numerous guidelines and models for change management have been published. Jorgensen et al. (2014) note that one key issue for successful change is the consistent engagement of the employees during the change process. The successful "change architects" seek collaboration across the entire organisation. It is also important to notice that in order to promote change, participation of different stakeholder, not only employees of the organisation, are needed. There are also methods developed to promote the participation of different stakeholders. A dialogue between organizations, professionals and customers is essential in ensuring the high quality health care services. (Kivisaari et al. 2004, 2013) One of the most commonly noted challenge was the underestimation of the complexity of the organisation (Jorgensen et al. 2014). This is likely to be based on the lack of the systemic view and understanding of the intrinsic complexity of any social system (eg. organisation).

Gamification is the use of game-like elements and game-design principles in non-game applications (Deterding et al. 2011). For instance, storytelling is a form of gamification that allows systemic aspects of health care processes to be discussed among a group of players: different roles produce different perspectives and coherent storylines involving different

stakeholders concretize the often fuzzy interactions between different actors and actions. We see gamification as a promising tool for collaborative learning and promoting dialogue and innovation. In our previous research (Leväsluoto et al. 2014) we argued that in order to promote change processes in health care, we need shared visions, collaboration, support and education of professionals to adapt to changes which are taking place in health care. These changes also include multi professional work and new electronic ICT-based tools.

In this paper we examine the change process in organizations and whether change can be promoted through gamified solutions. Gamification in this context aims to make the organisational processes more engaging and inspiring. The focus of gamification in our cases has been on improving mutual learning by means of role switching game. Mutual learning can be achieved by creating dialogue and opening perspectives of different actors (Kivisaari et al. 2004). Collaborating across the organisation has been noted as important for successful organisational change (as mentioned above). In our case studies we focused especially on mutual learning as a form of collaboration. The importance of a systemic view and acknowledging other actors in the management of changing systems has been noted both in the literature (see e.g. Reiman et al. 2015) and in our case studies.

The following research questions are guiding our work:

- Can gamified solution inspire to learn and understand the viewpoints of other professions and a system view?
- Can gamified solutions activate dialogue and mutual learning?

The focus of this paper is on the results of the work we have done to develop a gamified role switching method. The further development work towards a “medication game” will still continue and will be finalised by the end of year 2015.

In our paper, at first we describe our theoretical framework which is based on gamification, societal embedding of innovation and role switching. Then we present our case studies and continue to the research results. In the conclusion, we discuss the issues faced in the two cases when promoting dialogue and mutual learning. We end our paper with the conclusions of our research.

## **2. Theoretical background**

Our theoretical framework is based on theories of gamification, societal embedding of innovation and role switching. These theoretical frameworks form our starting point in understanding how to promote dialogue and mutual learning in complex organisations. In the framework of gamification, the factors of engagement and inspiration has been examined as well as the transfer of the engaging and inspiring elements from games to organisation management. How to create dialogue and promote mutual learning is the key issue in our second framework which is societal embedding of innovation. Role switching on the other hand can help to discover or even overcome biases in our reasoning and decision-making. The cognitive shortcuts can cause problems when we are unaware of them or when we apply them inappropriately. Seeing and feeling things from another person’s perspective can elicit some these biases and change the way we understand and reason behaviour.

## 2.1. Gamification

Gamification is the use of game thinking and game design elements (including game mechanics) in non-game contexts. The idea of gamification is to motivate people by means which have been proven to be effective in game environment. Gamification is widely used in marketing and more and more in different forms of media and education (e.g. different competitions). In practice, gamification may be applied everywhere when human behaviour is wished to be influenced.

There are several game-related concepts which may be some times overlapping but which should not be confused. These include: play, game, serious game, and gamification. Caillois (1961) has defined a play (and a game) as an activity which is voluntary, separate, uncertain, unproductive, governed by rules and make-believe. Games, serious games and gamification have many similar features like rules, goals and structure (Herger 2014).

The key difference between game and its “serious counterparts” is that serious game and gamification are aimed to promote the production of something which is useful also outside the game (learning, sales, etc.) whereas a game is played voluntarily “just for fun” because the player finds it attractive. However, by playing games you may also produce something useful and serious games (e.g. flight simulators) may be also used just for fun. Thus, the purpose makes the difference – you may have as fun in both cases. Caillois (1961) suggests the voluntarily is an essential condition joyous attraction of game. This is a notable remark when the game mechanisms are applied for instance in organisation management. Gamification is an activity to make existing or forthcoming process more engaging and inspiring (Chou 2015), while a serious game is a specific engaging and inspiring application which is especially played for serious purpose, e.g. learning something – i.e. a game which is aimed to produce something useful (Djaouti et al 2011).

Games, game thinking and game design elements have been systematically analysed for gamification. Chou (2015) has developed an Octalysis framework for the purpose of evaluation and development of gamified applications. Octalysis presents eight core drivers according to which different game elements may be classified. The key drivers are different aspects which may attract a player. The drivers include:

- Meaning: the goal or the mission the player has in the game
- Empowerment: player is able to express themselves, e.g. create something
- Social Influence: e.g. sense of belonging in a group, social pressure and opportunity to communicate
- Unpredictability: advantageous surprises and exciting turns in the course of events, or experienced tension for waiting surprises.
- Avoidance: player had to avoid something unwanted to happen – typically losing something
- Scarcity: player has an opportunity to get something which is somehow scarce: limited quantity, available at certain time only or for certain group only
- Ownership: player gets, collects or builds something as their own property

- Accomplishment: player achieves something as a result of their effort: points, higher ranking or status, recognition etc.

All these key drivers should be taken into account from the viewpoint of the target group in order to achieve a successful gamification. There are several different known game elements for each key driver.

The flow theory (Csikszentmihalyi 1990) is often mentioned as a psychological basis for game playing and gamification. Flow refers to an optimal experience, a state of mind during which people typically experience deep enjoyment, creativity, and involvement with the activity they are performing. The identified supporting conditions for flow state include: goal-orientation with clear goals, binding rules, feedback, skill is required, challenges and opportunities are provided. These are well in line with both the classifications by Herger and certain key drivers in the Octalysis framework. In addition, the optimal flow experience requires appropriate balance between skills and challenges: too demanding challenges cause a frustrating experience and too easy challenges cause boredom.

As the gamification process and Octalysis framework suggests, an extensive investigation of the key development needs were identified by interviews and discussions with the case organisation representatives. The gamification elements for these needs were then chosen and they appeared to be role switching, storytelling and some visual elements: playing board and cards.

## **2.2. Societal embedding of innovation**

Societal embedding of innovation is a research and development approach which has been developed by VTT in different research projects since 1990's. It has been used in Finland to enhance novel health care services and environmentally friendly innovations (Kivisaari et al. 2004, 2013, Leväsluoto & Kivisaari 2012). It aims at facilitating and initiating new innovations in a multi-actor network. An important objective is to create a dialogue between different actors and give them a possibility to create a shared understanding of the elements of the solution. By opening up the perspectives of the different actors it aims to produce mutual learning.

The approach gives information about the needs of identified actor's, worries and conceptions of the discussed change. An important aim is to identify promoting and preventing aspects of different actors and bring them to shared discussions. The approach is based on thematic interviews, observation and workshops. For the interviews, it's essential to identify all the key actors to ensure that all the aspects are being heard. The information is then processed and used for promoting the change (for example the processed information can be used in organisation management) and planning the workshops. The aim of the workshops is to discuss all these different opinions, create more in-depth understanding of the change and create collaboration and trust. (Kivisaari et al. 2008)

Social embedding of innovation is one of the key theoretical frameworks in our paper as it emphasizes the role of creating dialogue between actors. In our research, role switching method is also based on the experiences of social embedding of innovation. The aim of it is to further develop the approach as an innovative and inspiring method.

### 2.3. Role switching

March and Olsen (2006) state that in most situations humans take reasoned action by trying to answer three elementary questions:

- what kind of a situation is this?
- what kind of person am I?
- what does a person such as I do in a situation such as this?

When role switching puts us in the shoes of another kind of person, we look reference from a new role. It does not change the perception of the situation but it can give us novel ideas on how and why to act in them. For example, when looking at a patient's medications what would a nurse focus on? And what would a pharmacist focus on? These might differ significantly. A pharmacist might look more at the patient's overall medication history and any cross reactions. A nurse looking at patient care from a pharmacist's role might see new practices that could be integrated to the care processes. Changing the perception of the situation can potentially also be achieved by role switching. An actor's view of the causes of his behaviour often differ from those held by outside observers. The actor has a tendency to emphasize environmental conditions. The observer on the other hand has a tendency to emphasize personality characteristics of the actor as causes of behaviour. (Jones and Nisbett, 1972) By assigning an observer to the role of actor and vice versa the situation and what lead to it can be seen in a different light.

## 3. Case context, methodology and results

In the empirical part of our paper we focus on two cases. In our first case, a university hospital was introducing an electronic medication storage unit. Changes in the medication process and operational culture were needed because of this coming change. In the second case, a clinical pathway for geriatric patients was implemented in a central hospital. In order for the clinical pathway to work as planned, changes in operation models are needed in the related private and public social and health care organisations.

The study is based on 25 interviews and four workshops with gamified and role switching aspects. The schedule and the number of participants in the interviews and workshops are summarized in table 1.

Table 1. Schedule and number of participants in the interviews and workshops

| Gaming workshop           | Interviews   | Workshop, case 1                               | Workshop, case 2                             | Brainstorming of game concepts      |

| May 2014, 15 participants | <b>Case 1: May 2014, 9 interviews</b><br><b>Case 2: Spring</b> | <b>Case 1: September 2014, 10 participants</b> | <b>Case 2: December 2014, 9 participants</b> | Case 1: March 2015: 16 participants |

|  |                              |  |  |  |
|--|------------------------------|--|--|--|
|  | <b>2014, 16 inter-views.</b> |  |  |  |
|--|------------------------------|--|--|--|

In the first workshop, the selected board games were played together with health care personnel and researchers in order to get familiar with different game ideas and mechanisms and to get feedback on what kind of gamification may be appropriate for health care personnel. In the fourth workshop the new game concepts to support the medication process were brainstormed together with health care professionals and researchers. The objective of this session was to get ideas how to further develop the role switching workshop approach which is in focus of this paper.

The interviews and the second and the third workshop are introduced below and are the focus of our paper. In between these mentioned five activities the group of researchers together with the representatives of the two case organisations carried out the analysis and development work in several sessions.

In both of our cases, creating dialogue and cooperation as well as seeing familiar situations from another perspective were important aspects of promoting change processes. The interviews gave an overview of the situation on which it was possible to start creating these workshops. The interviews also worked as a channel where employees and other actors could get their voice heard concerning the upcoming changes. The gamified role switching workshops were very similar to each other and were just modified to answer the needs of different cases. We summed up the interviews and the workshops by identifying visions and challenges (table 2 and 3) that prevent the change. Vision and challenges were identified and summarised so that they could provide information for the organisation on how to proceed with the implementation work and communicate the results to all employees.

### **3.1. Case 1: Changes in processes and in culture are needed to implement an electronic medication storage unit**

Our first case organisation is a university hospital in one of the biggest cities in Finland. It provides basic and special services in the field of specialised care, trains health care professionals and promotes scientific research into health. The university hospital is a part of hospital district which provides care for 22 municipalities with population of 520 000.

The university hospital is implementing new electronic medication storage unit and because of this reform changes in medication processes are needed. A unit for renal patient is a pilot unit for implementation of the electronic medication storage unit. The renal unit was chosen to be the pilot unit, because the care of renal patient is highly dependent on medication and the unit uses a large amount of pharmaceuticals.

The change to using electronic medication storage unit is not straightforward as it needs changes in practices and in operational culture. Responsibilities of doctors and nurses need to have some changes as well as the sharing of responsibilities between units. One example of the change that needs to take place before implementing the electronic medication storage unit is the way patient medication data is being processed. If a patient is being relocated from the first aid unit to the renal unit, the medication information needs to be fed to data system before the patient enters the renal unit. Earlier the medication information was re-counted in many different ways and nurses had a chance to carry out the medication more

flexibly. The use of the new medication storage unit requires changes in the medication processes which are not easy to implement in a hospital with almost 6000 employees.

The work for purchasing and implementing the electronic medication storage unit had begun some years ago and was in the phase of planning the implementation when we carried out our research.

### **3.1.1. Methodology**

In this case organisation, we interviewed nine health care experts that work with renal patients. The semi-structured interviews took place in May 2014. The interview questions were divided into five themes. The aim of the first theme was to gather information on the current situation, what are the things that are working and what are the things that need improvement. After that we discussed issues related to quality, safety and efficiency issues. We were interested in learning how the interviewees saw these factors in their organisation. In the third theme, we asked what the interviewee's experiences of previous development project were and what the organisations attitude towards them is. The forth theme concentrated on what were the interviewees visions of their organisation. The last theme was about the coming change and what the interviewees saw as the important aspects of the implementation process. The interviews were recorded and transcribed and we used QSR NVivo qualitative data analysis software for analysing the results. We carried out the analysis by performing a thematic analysis of the relevant research topics and identified the common responses of the interviewees

The workshop was organised in September 2014. Ten health care experts from the pilot unit, other units, pharmacists and project development experts participated in the workshop. The participants represented all the key positions and professions involved in implementation of the electronic medication storage unit. We disseminated a feedback questionnaire to the participants in order to evaluate our workshops and also to evaluate our gamified role switching method. The participants filled out the questionnaire after each part of the workshop. The focus in the workshop was in the renewal of the medication process and also in introducing the concept of the electronic medication storage unit. The aim was to support change process as well as to get feedback about our gamified role switching method. Because the implementation of the electronic medication storage unit requires many changes, which were not all positive to all employees, it was important to share opinions and reasoning behind them. We aimed at encouraging participants to discuss their opinions more freely and also to help the change process by making participants to look at the everyday situation from another perspective. Creating dialogue between participants of the elements of the needed solutions was also aimed.

In the workshop participants developed a story of the care of renal patient. The story was based on maximum ten events which were chosen by the participants. After that participants then picked randomly one card which represented one of the four professions (pharmacist, patient, doctor and nurse). Thinking each event from the perspective of the given profession was then required of the participants. Questions in the profession cards guided the work. The guiding questions were about how the represented professional would perform in this situation, what are the obstacles of acting in a new way and what are the benefits of this action.

### **3.1.2. Results from the interviews**

#### *Working practices*

The interviewees were aware that the official procedures are not followed in all cases and places. There were concerns about the idealistic requirement to always strictly follow the rules even when it is known impossible. Instead, they suggested focusing on finding the correct solutions whenever it is possible. The interviewees showed a generally positive attitude towards pursuing improvements, but also noted that actual change takes place slowly.

The consistency of practices within a hospital was regarded as important factor for fluent and safe operation of the system as a whole. The largest differences can be found between the units. There is not necessarily any mandatory reason preventing harmonization, but people are inclined to stick on the familiar customs and present explanations for why they should not be changed. However, it was noted that there are different practices and in some cases the local differences are necessary. Flexibility is needed because of the differences in situations, experience and skill of actors and the intrinsic uncertainty in health care activities.

#### *Values*

Certain values clearly emerged in interviews.

- Expertise: health care professional should continuously update their knowledge and skills and they should be aware of the limits of them
- Patient-orientation: professionals want to be responsible and work for the best of patients. Initiative and activity is expected also from patients.
- Attitude to changes varies. There have been negative experiences of too frequent changes and failed projects. On the other hand, personnel participate actively to development. Control of errors is regarded as critical.

#### *Information systems*

The up-to-date information on the medication and its documentation in the patient information system was regarded as critical for the functioning of the future system. Currently there are some practices which may make some medication information unavailable to the information system. In the future system, this means that the medicine is not available, either. With current system and practices it is possible to get the required medicine somehow anyway. The doctors criticise the difficulty of using the information system – especially concerning medication. Different doctors may also have varying knowledge on medication: all doctors are not equally capable of extensively assessing the medication of all kinds of patients. This limited capability may make some doctors more cautious to make certain decisions on the medication. However, it was agreed that there should also be change in attitude towards an accurate use of the system. It was assumed that professionals focus on the fluency on their own duties and mostly prioritise lower the tasks which do not are directly useful to them. The role as a part of the care system and a fluent overall care of the patient is not either understood or accepted.

#### *Expectations and concerns*

The particular forthcoming change raised both (positive) expectations and concerns. The electronic medication storages were anticipated to improve patient safety and medicine control, enhance the conditions for work and clarify procedures for medication activities, and save costs. However, there were concerns about the bad usability of the information systems, excessive rigidity of new system, potentially vanishing knowledge on medicines, increasing work load, unpredicted problems in the initialization phase and concern about whether a critical medicine will be available if technical problems appear. Lacking information on the future changes raised concerns in general.

### 3.1.3. Results from the workshop

The results of the feedback questionnaires are presented in this section. All participants returned either fully or partly filled form. The participants expressed that the workshop promoted collaboration between professions. The role switching method was seen useful as it forced the participants to look at common situations from different perspective. It unveiled how little other professions' duties are known contrary to the expectations of some participants. The participants thought that this way you get insight of the reasons of action in different professions and organisations. The reasons of acting in certain way were not always familiar to participants coming from another profession.

Due to the gamified aspect, the workshop was experienced as inspiring and refreshingly different. In addition, the participants felt that they had a chance to influence the change process by participating in the workshop. For the participants, the workshop was in some sense demanding, because it required a full concentration. The task that was given was not immediately understood by the participants and the workshop was quite long.

The workshop produced new ideas and some concrete tools for the participants. Identifying risks and obstacles from different perspectives was an important outcome from the workshop. The workshop also increased understanding of the upcoming change, opened up new perspectives and included positive feelings towards the change. Multiprofessional collaboration was one of the things that the participants considered valuable.

We summed up the interviews and the workshops by identifying visions for the change as well as challenges that may prevent the change happen (table 2). Vision and challenges were identified and summarised to help the organisation for their implementation work.

Table 2. Identified vision and challenges in case 1.

| Achieving the goal together |   |   |   |  |
|-----------------------------|---|---|---|--|
|                             | Patient   | Pharmacist  | Nurse   | Doctor   |
| Vision                      | Is familiar with his/hers medication and can communicate it to his/hers health provider in all situations | To become a one of the key professionals in the patients multi-professional care team | Implementing the patients medication prescribed by a doctor | Prescribing and monitoring up-to-date medication |
| Challenge                   | To become an  | Readiness to  | Clear and practical   | Practical and                                    |

|  |                |  |   |  |
|--|----------------|--|---|--|
|  | active patient | adopt a new role, resources, attitudes of other professionals. | instructions which every professional follows | doable instructions which every professional follows, hurry and extra burden |
|--|----------------|--|---|--|

The top vision represents the attitude that only by working together the change, which is the success in using the electronic medication storage unit, is possible to achieve. Pharmacists were identified as a new important actor in patients care when using medication in hospital renal unit. Pharmacists could have new tasks which would support nurses and doctors work and this has the potential of clarifying the care of patients. For the pharmacists the role is new and it requires learning and resources. Patients on the other hand should adapt to a new role, where the medication information should be clear at all times. This requires being active and participation. The nurses would like to have clearer instructions which are followed by everyone. To doctors the change causes potentially more work and increases hurry. However, if the medication information is up-to-date, the doctors' work will ease eventually and the patient care would be better.

### **3.2. Case 2: Using a clinical pathway for elderly patients requires cooperation and new operation models**

Our second case organisation is a central hospital which offers specialized health care for 13 municipalities. The population is approximately 165 000 and about half of them speaks Finnish, and another half Swedish as a first language. The central hospital is active in participating in research and development projects and is especially known for its work in patient safety issues.

In the beginning of our study a new clinical pathway for geriatric patients (a document) had been produced in cooperation between the hospital, primary health care, social sector actors and the representatives of patient, and the pathway was about to be launched. Putting together a clinical pathway was a great challenge, because the information was scattered and different units and organisations had different ways of working. A number of employees and customers participated in the work of gathering and formulating information to form the new clinical pathway.

The idea behind this development work was to make the customership of the geriatric patient more flexible, effective and safer. Geriatric patients are a special group because of their special needs and vulnerability. For example, it is important to acknowledge in hospital emergency room that geriatric patients need to be helped out of the bed so that they maintain their ability to move around and stay active. Also the medication information is essential to have with them when coming to the hospital. Many small improvements, especially when a patient visits between different organisations, can help make the care more effective which is the aim of the clinical pathway.

#### **3.2.1. Methodology**

We interviewed 16 social and health care experts from the organisation working with geriatric patients. The semi-structured interviews took place in the spring 2014. Like in the first

case, the interview questions were divided into five themes. The aim of the first theme was to gather information on the current situation, what are the things that are working and what are the things that need improvement. After that we discussed the issues related to quality, safety and efficiency issues. We were interested in learning how the interviewees saw these factors in their organisation. In the third theme, we asked what the interviewee's experiences of previous development project were and what the organisations attitude towards them is. The forth theme concentrated on what were the interviewees visions of their organisation. The last theme was about the coming change and what the interviewees saw were the important aspects of the implementation process. As in the first case, the interviews were recorded and transcribed and we used QSR NVivo qualitative analysis software for analysing the results.

After the interviews, we organised a workshop for nine key actors to promote dialogue. For the clinical pathway to function, it requires that every organisation takes a role in introducing it to all employees and starts to make changes in their operation models. It is also important to explain the significance and benefits of a clinical pathway to all employees.

The main goal of the workshop was to support the implementation of the new clinical pathway and to test and develop our gamified method. Workshop also aimed at visualising the situation from different perspectives (patient, emergency care team, nurse and doctor) and how the change would affect to it.

In the workshop, participants developed one story of a geriatric patient. The story was based on 5 events, chosen by the participants, from geriatric patient care pathway. Participants then examined new working method in this particular situation from the new clinical pathway document. In the next phase, the participants were advised to think working practices from the viewpoint of different actor. Participants randomly selected a card which represented one of the different actors. Like in the workshop held in the first case organisation, we used guiding questions to steer the process. The guiding questions in the profession cards were about how the professional would perform in this situation, what are the obstacles of acting in a new way and what are the benefits of this action. At the end of the workshop, a feedback from the participants was collected with questionnaire in order to evaluate our workshop and also to evaluate our gamified role switching method.

Through this gamified storytelling, we aimed at creating a clearer picture of what are the changes required in the organisations, how the change affects different actors, what are the elements in the clinical pathway document and what are the things that prevent the use of the clinical pathway. Altogether, through this role switching and implementing working practices, we aimed at promoting mutual learning and encouraging participants to take the clinical pathway to their organisation and eventually to everyday use.

### **3.2.2. Results from the interviews**

The interviewed experts thought that the situation in their region is quite good compared to other hospital districts. However, they noted that a change in operation models is needed, because the population is ageing and more people are in the need of geriatric care. The interviewees had a common view that the clinical pathway was collected and created in a participatory way and that all the different viewpoints were acknowledged. However, because of the profound nature of the work, the interviewees thought that the clinical pathway document was too long and complicated and it was difficult to utilise in their work. They also

thought that this was the primary issue preventing the implementation of the clinical pathway.

The interviewees agreed that the work which was done to create the clinical pathway was valuable but the implementation work is going to be very difficult.

#### *Expected impact*

The clinical pathway for geriatric patient is going to bring benefits mostly to the patients, according to the interviewees. It was perhaps disconcerting that they didn't see so many advantages to the social and health care professionals if the new clinical pathway document is going to stay as it was at the moment of the interviews. The interviewees thought that the clinical pathway could be more beneficial to the professionals if it's divided into smaller more focused pieces.

#### *Implementation*

Some of the interviewed experts expressed their worry of the attitudes of the employees towards the new clinical pathway. They thought that the employees can easily think that the clinical pathway doesn't give anything new to them and the old ways of working are enough. The implementation was also challenging because there wasn't any single unit that was responsible for the clinical pathway or the implementation of it. It was the responsibility of every single unit and the organisation to introduce its employees to the clinical pathway.

The problem was that in order the clinical pathway to work as planned, it requires that it is used in every organisation. Because the benefits of using the new clinical pathway were so difficult to picture, it was likely that the implementation wasn't going to be easy.

### **3.2.3. Results from the workshop**

To second workshops was evaluated the same way as in the first workshop. The participants filled out the questionnaire after each part of the workshop. Below we present the results of the questionnaires.

The participants of the workshop thought that the workshop was inspiring and promoted collaboration. Because the participants were from different units and organisations, they felt that truly different opinions and aspects were discussed.

Although collaboration and discussions were good, some participants felt that solutions to the identified problems were not found.

The workshop produced new ideas, collaboration, thoughts on what are the issues that need improvements and altogether broader understanding of the change. The workshop also revealed some critical points for the change process which were not recognized before. Our role switching method was enlightening for the participants and it was appreciated as a tool of see things from different perspective.

Visions and challenges are summarised in table 3 which was created the same way as in the first workshop.

Table 3. Identified vision and challenges in case 2.

| Better results of patient care and ease of workload by enhancing the information flow between actors |   |  |   |   |
|--|---|--|---|---|
|  | Patient   | Emergency care team  | Nurse   | Doctor  |
| Vision   | Will get the care she/he needs and hers/his needs are being heard | In addition to emergency care, the team informs all the relevant information to the hospital | Knows how to implement the clinical pathway for geriatric patients in flexible and comprehensive care | Knows how to implement the clinical pathway for geriatric patients and can make use of tools used by other professionals. |
| Challenge  | Patients as a passive participant in care processes               | Information is unavailable   | Clinical pathway is not familiar and information blocks appear  | All the needed information is not available   |

The top vision in the second case represents the idea of what are the benefits of the new clinical pathway for geriatric patients and what it requires. In the vision, patients will get the care they need and they are also seen as an equal partner in care. The role is new especially for elderly people who are not used to be demanding. Emergency team will pay attention much more on the information that is needed in the hospital. This information could be for example medication information. The problem is that all the information is not always available. For the nurses it is important to know the clinical pathway so that the geriatric patient will get special care that she/he needs. Geriatric patients' special needs are not known very well which could cause problems in later phase of the treatment. It is important for the doctors to use the information which has been gathered before to make right decisions of the care.

## 4. Discussion and conclusion

In our first case, new electronic medication storage was planned to be implemented in a hospital pilot unit. In the second case, a new clinical pathway for geriatric patients was about to be launched and implemented. In our research, we aimed at promoting change in the two case organisations and also to develop a new gamified role switching tool for promoting dialogue and mutual learning.

For this purpose we interviewed 25 social and health care professional from different organisations. The interviews had two aims. The first one was to give the employees and other actors a chance to tell their opinions of the change. Second, the interviews gave information to the researchers about the current situation and opinions of different actors. The interviews revealed that the attitudes towards the change varied. The varying attitudes were depending on the previous experiences of the changes in organisation work processes, expectations for the new change, the seen benefits which would result from the change and the

usefulness of the information that was given. In many of the cases, the interviewed experts didn't see or couldn't figure their role as a part of complex health care system where action of one professional effect to the other. The links between professions and organisations were difficult to understand and thus the importance and the action which was needed for the change wasn't clear.

The two gamified role switching workshops, together with the interviews, were in the focus of our paper. The aim of our workshops was to create dialogue and cooperation and give a possibility for the participants to see familiar everyday situations from another professions perspective. This way we aimed at toward mutual learning and thus promoting the change processes in the organisations. We summarised the visions and challenges identified from the interviews and the workshops to provide information to the organisations and help them to steer the implementation work.

Our results indicate that our gamified role switching method inspired and gave means for the participants to enhance systemic understanding of their organization and to improve dialogue. The health care professionals that participated in gamified workshops felt that they are involved in the change processes and that their opinions have an effect. Gamified elements in the workshops made the atmosphere inspiring and opened the mind for new viewpoints. The role switching method made the participants see the situation from the other perspectives and thus promoted collaboration and the change processes. The workshop and the discussion between participants didn't offer solutions to all the problems which were identified. However, solving all the identified problems wasn't the aim of the workshops, but rather to identify the problems, to offer different perspectives and to bring them to the discussion. From the experience of our workshop, we learned that some of the participants from the health care organisations want to see benefits of the event or means immediately. The problem in that is that our gamified solution aims to promote dialogue and mutual learning. The benefits of enhanced collaboration are difficult to demonstrate at that point. The experienced joy from the event may even emphasize the experience of missing immediate usefulness. Quite common belief in serious working life is that "what is fun can't be useful". We need to develop the approach so, that the participants more clearly learn what the benefits of playing are.

Our study indicates that it is useful to simulate being in the roles of others to enhance the understanding of a complex system where the actions of one professional affect the work of another one. We argue that these effects can help to reveal the issues related to organizational changes and also to provide solutions for dealing with them. As many organizations struggle with various obstacles when attempting to improve their activities, gamified solutions can be a valuable tool for assisting the implementation of changes.

# ***Transforming health care through niche service innovations - the perspective of institutional entrepreneurship***

Arto Wallin

VTT Technical Research Centre of Finland

*Although digitalization has profoundly changed the business logic in many industries, health care sector still operates in many areas as in the pre-digital era. During the recent years we have witnessed the rise of new digital health ventures, many of which have revolutionary ideas how to transform the business logic in the health care. However, in many cases the institutional logics in the field of health care are so strong that new ventures have major challenges in breaking these institutional barriers that prevent introduction of digital service innovations. This paper explores how five case companies aim to transform their specific niche area in health care. We analyse actions and the role of digital health ventures in this transformation through the theory of institutional entrepreneurship.*

## **1. Introduction**

During past 20 years ICT has profoundly changed our everyday lives and transformed business logic in several industries. On the one hand, digitalization has initiated massive transformation in several, previously product-oriented, industries e.g. digital distribution of software, music and movies. Hence, information intensive goods are starting to behave like services or “as-a-service” (Ng, Vargo, & Smith, 2012). On the other hand, digitalization is transforming other industries such as banking from physical service activities to standardized digital services that behave more like goods (Ng et al., 2012). Despite digitalization in health care has progressed at much slower pace than in the banking sector, policy makers across globe are now looking to digitalize health care system in order to make it safer, more affordable and more accessible (Agarwal, Gao, DesRoches, & Jha, 2010).

The renewal in health care was for long understood as the adoption of new medical tools and drugs (Djellal & Gallouj, 2008). At the same time service innovations, which aimed to change heavily institutionalized structures and practices, seemed to be very rare and face considerable institutional barriers. However, now it finally seems that digitalization has also started to profoundly reshape health care sector, where the major pressure for change in sociotechnical regimes (see Geels & Schot, 2007) comes from two direction. Firstly, major changes at the landscape level, for example, to age-dependency ratio and spiraling health care costs, have created urgent need to rethink how health and social care service delivery is organized more effectively. Secondly, the sharp rise in new ventures that are aiming to introduce digital health service innovations to specific niche areas (digital health ventures) act as institutional

entrepreneurs (Battilana, Leca, & Boxenbaum, 2009) building up internal momentum for major changes.

While the role of institutional entrepreneurs in the process adopting radical technological innovations is widely acknowledged (Pacheco, York, Dean, & Sarasvathy, 2010), there is surprisingly little research on the institutional entrepreneurship in health care domain. With this paper we aim to increase the understanding of the institutional barriers and entrepreneurship in the context of health care, and provide new insights into the ongoing digitalization in health care from the perspective of digital health ventures. Objective of our study is to explore and explain how these ventures pursue to introduce service innovation to the health care systems by acting as institutional entrepreneurs, and how multiple institutional logics (DiMaggio & Powell, 1983) in health care domain promote and/or resists the change.

## **2. Related research**

### **2.1. Barriers and opportunities for change in health care**

Literature related to the barriers for adoption of information and communication technologies (ICT) in different industries is voluminous, and there has been particular interest on challenges on adoption new ICT-enabled innovations in the field of health care (see reviews Gagnon et al. 2012; Li et al. 2013). Study of Dehzad et al. (2014) is one of the most recent papers that analyses barriers for transforming the logic of health care from treatment of diseases to the prevention of diseases. Their study identifies key barriers for the adoption of mobile health, where three main barriers are integration and interoperability with existing health IT systems, business case and conservative culture.

Although the challenge of initiating and implementing institutional change is often only indirectly covered in the technology adoption and innovation literature, there is extensive literature on this subject that builds on research of institutional theory. From this theoretical viewpoint barriers and opportunities for institutional change can be viewed as the likelihood that organizational field will permit actors to identify and introduce new institutional arrangements and to mobilize resources required to make the transformation enduring (Dorado, 2005). Hence, implementing the *divergent change* that requires breaking existing institutional arrangements and entails “loosening” other actors’ institutional embeddedness can be very challenging due to the institutional inertia (Battilana et al., 2009; Levy & Scully, 2007). Moreover, those actors who benefit from the status quo (“institutional defenders”) almost invariably arise to defend existing set of beliefs, practices and processes at the field and can use counter-strategies trying to protect their established position within the field (Battilana et al., 2009; Levy & Scully, 2007).

### **2.2. Institutional entrepreneur as a change agent**

Eisenstadt (1980) was the first to use the notion of institutional entrepreneur to characterize actors who serve as a catalyst for structural change. Building on Eisenstadt’s work DiMaggio (1988) introduced the concept of institutional entrepreneur-

ship in institutional analysis, with an aim to provide explanation how actors can shape institutions despite pressures towards stasis (Leca, Battilana, & Boxenbaum, 2008). Since the early work of Di Maggio, research on institutional entrepreneurship has grown into compelling and diverse literature that focuses on the self-interested agent who commands and mobilizes resources to alter or create new institutional structures (Pacheco et al., 2010). Two main research streams that are focused on the concept on institutional entrepreneurship are sociology-based institutional theory and economics-based institutional economics. Whereas institutional economists considered institutional entrepreneurs as self-interested agents that influence on the transformation of institutions to capture economic benefits (North, 1990), institutional theorists have very limited discussion related to economic motivation per se (Pacheco et al., 2010). Although these concurrent streams have many common characteristics those are mostly unlinked with each other. Furthermore, neither stream has extensively embraced rich literature on entrepreneurship (Pacheco et al., 2010).

Study of Battilana et al. (2009) is one of the rare papers that aims to bridge gap between institutional theory and academic stream of entrepreneurship. They define institutional entrepreneur as a change agent (individual, group of individuals, organization or group of organizations) that must fulfil two following conditions: (1) it initiates divergent changes i.e. changes that break the institutional logics within the given institutional context; and, (2) actively participate in the implementation of the change. In order that the divergent change can be implemented, institutional entrepreneur has to be able to craft a vision for the change in terms that appeal to the actors needed to implement it (Battilana et al., 2009). Additional, as the diffusion and legitimation of institutional change requires mobilization of support and acceptance of multiple actors, it is crucial that institutional entrepreneur has access to various types of resources needed in this (e.g. cognitive, social and material resources) (Dorado, 2005).

### 3. Methodology

#### 3.1. Research design

This research adopts a qualitative research approach, using a case study approach. Case study is especially suitable as a research method in this context due to the high complexity of the phenomenon and early stage of this field of inquiry (Yin, 2009). Also, our study can be categorized to micro-approach of innovation, focusing on study of individual actors, especially on entrepreneurial founders and teams (Garud, Gehman, & Giuliani, 2014).

Data for the study was collected in form of 28 narrative interviews from which nine interviews were included in final cross-case analysis that is presented in this paper. Interviewees represented managers of five companies, which were developing digitally-enabled service that was supposed to transform specific niche area of health care system. Following table describes the case companies and the contexts of which they operate and aim to transform.

|  | Institutional context | Number of inter- | Main level of institutional | Institutional entrepreneurs | Maturity of the company / growth |
|--|-----------------------|------------------|-----------------------------|-----------------------------|----------------------------------|
|--|-----------------------|------------------|-----------------------------|-----------------------------|----------------------------------|

|        |  | <b>views</b> | <b>barriers</b>                      |                            | <b>phase</b>                            |
|--------|--|--------------|--------------------------------------|----------------------------|---|
| Firm A | Ophthalmology                                | 4            | Policy and practice level            | Company                    | + 5 years / International growth        |
| Firm B | Diabetes treatment                           | 1            | Policy, standard, and practice level | Company                    | +5 years / International growth         |
| Firm C | Mental care                                  | 2            | Policy, standard and practice levels | Entrepreneur/company       | 2-5 years / trial phase                 |
| Firm D | Neuroradiology                               | 1            | Policy, practice level               | Company                    | 0-2 / early sales phase                 |
| Firm E | Treatment and prevention of chronic diseases | 1            | Policy, standard and practice level  | Founder of the new venture | 0-2 years / building the solution phase |

**Table 1. Data related to case companies**

### **3.2. Research questions and data analysis**

We began the analysis with an analysis of 20 cases through the lens of our research questions:

1. What are the main institutional barriers experienced by new digital health ventures aiming to introduce innovation at the health care market?
2. What is the role of institutional entrepreneur in initiating and implementing the institutional change (digital transformation) in the field of health care?

From the 20 cases we selected five cases in which there were 1) clear institutional barriers, 2) there was clearly needed role for institutional entrepreneurs, and 3) digital health venture played an important role in the initiating and promoting the institutional change in some specific field of health care. These case companies were from Ireland, Belgium, Netherlands, and two of them were from Finland. Data from each individual case were then analyzed in-depth with help of content-based coding of narrative interviews.

After each case was analyzed individually, we turned to cross-case analysis with an aim to identify consistent patterns and themes between cases. Our analysis followed iterative process of cycling between theories from existing literature on institutional entrepreneurship and the interview data in order to refine our findings and finally developed those into implications for practitioners and academics.

## **4. Five cases on new ventures aiming for digitalization of health care**

In the following five individual case studies are introduced, each of which are from the specific fields of health care. With help of these cases we aim to explore and explain various types of institutional barriers for the introduction and adoption of new digitally-enabled health service innovations. Moreover, we focus on the role and strategies of digital health ventures as institutional entrepreneurs who pursue to initiate and promote the change.

### **4.1. Case A – Changing institutional logic of ophthalmological professionalism**

First case is focused around the technological innovation that enables cheaper and easier treatment and prevention of eye diseases. One particular challenge in this case was that treatment and prevention of eye diseases and therefore the institutional logic of ophthalmological professionalism vary notably between different countries even within the European Union. Therefore, in some countries changing existing logic of ophthalmological professionalism, which requires more radical transferring of clinical task from one group of medical professionals to other, can be considered to be greater barrier for change. Other major barrier is the logic how many countries still reimburse medical professionals based on the treatments given at the clinic, not including telemedicine consultations.

In this case there was clearly seen how existing institutional logic may be protected by the medical professionals who feel threatened by the change. As an example, one of the interviewed persons told that the union of medical professionals acted very actively in order to prevent the transfer of clinical tasks from ophthalmologists to other health care professionals, which would have enabled new type of business to be created.

On the other hand, a company had managed to create contacts with some key opinion leaders who were highly renowned medical professionals in this field. These key opinion leaders saw new technology as an opportunity for divergent change and they acted as institutional entrepreneurs by actively pursuing to change the institutional logic and actively promoting this change.

### **4.2. Case B – Initiating the change in the reimbursement of outpatient diabetes treatment**

In the second case new digital health venture had created innovative solution for diabetes management that solved the problem of measurement more conveniently than previous existing solutions. In addition the new solution aimed to improve communication between patient and health care professionals, which required the changes in institutionalized practices of the patients and medical professionals related to diabetes treatment.

Besides the need for changing the behavior of the patient and medical professionals, one main institutional barrier that the company faced was the current way how diabetes management devices were procured within the existing health care system. The problem was caused by the fact that new solution was much more expensive than the existing solution, since it was much more technologically advanced. However, as the price was one of the main decision criteria when health care providers procured diabetes management solutions, company couldn't sell new solution without first changing rules and standard procurement practices.

From the perspective of institutional entrepreneurship, one of the most crucial moves of the company was the recruitment of famous medical professional from field of health care that specializes in diabetes treatment. With help of this key opinion leader company was able to promote the introduction of new innovation and institutional changes required to be implemented within the health care system. With help of the key opinion leader company was also able to form group of diabetes treatment specialists that promoted new type of diabetes management around the world. Hence, the major part of company's success was hiring the person who had expertise and legitimacy in the eyes medical decision makers, and who could therefore provide insights how diabetes management of the future should be done.

#### **4.3. Case C – Introducing eHealth to mental care**

The third case company aimed to change institutionalized practices of providing mental care. Their innovation aimed to improve the communication between patient and health care professions during the outpatient care, and one of the key features of the solution was also self-treatment for the patients to prevent relapse in-between the periods of intensive treatment. As a result one of the potential barriers for the adoption was identified to be health care professionals who are afraid that the e-health application would eventually reduce their work and income.

The manager of the company stressed in the interview that it is not possible to change the way how mental care system works if you don't have good relationships with the right people. The company had been lucky to utilize expertise and connections of the person who had retired from high position at the big mental care institution and therefore possessed very good connections to the management boards and decision makers. Hence, the company was able to act as an institutional entrepreneur with help of the person retired from mental care management position. In order to promote the institutional change, company acted also very actively in different types of the media and aimed to create connections with different types of the key opinion leaders in the field.

#### **4.4. Case D – Automation of the analysis of neurological images**

The fourth company aims to radically improve the way how certain neurological diseases are diagnosed. It seems to be inevitable that the institutional logic related to the diagnostics, which has been strongly based on medical professionalism, will be changing radically as the speed, accuracy, and reliability of computer-based analysis will continue to improve. Since this means that the manually conducted clinical tasks are transferred from the medical professionals to the computer, institutional barriers

for implementing this kind of a change can be relatively strong. However, the case company had so far worked mostly with medical professionals who would be classified as innovators or early adopters (Moore, 2014), and therefore the company didn't have clear understanding how strong the resistance for the change would be when service would need to be adopted by the majority of medical professionals.

The company was acting as an institutional entrepreneur with help of key opinion leaders in the field of neurology. Company had been able to create relationships with key opinion leaders, for example, through joint research projects. Important resource in the successful preparation research project had obviously been that the founders of the company had very high academic degrees and had already established good personal networks in the academic world before the company was established. Hence, the previous institutional context of the founders enabled them to act as institutional entrepreneurs in this field.

#### **4.5. Case E – Digital physical activity prescriptions and monitor the results**

The fifth company develops application that enables medical professionals to provide physical activity prescriptions and reliable information for the patients. Application provides also activity monitoring and channel between medical professional and patient, which aims to improve the benefits of prescribing physical activity. As a result, the company aims to advance the transformation from the treatment of chronic diseases to the prevention of those. However, as the whole health care system in many countries has been built on the treatment of diseases, the biggest obstacle for implementing the change are institutionalized practices of the health care providers.

Also this company can be seen as an institutional entrepreneur, which aims to initiate divergent change in institutional logic of the field, and actively participates in the implementation of this change. The most crucial point why the company can act as an institutional entrepreneur is based on the founder's previous work and education through which she is very familiar with institutional context of physiotherapy and exercise science and has good contacts in this field. Although company is very young, they have been already able to initiate notable trials with key players in their home market.

### **5. Discussion and conclusions**

Findings of the study explore how digital health ventures, which aim to introduce new kind of a business logic into health care, respond to challenges that they face when they also need to transform institutional logic of health care system as it conflicts with the new business logic. Through the cross-case analysis of five case studies we identified institutional barriers ranging from professional practices (practice-level), to voluntary set of rules that direct the behavior within the specific health care sub-field (standard-level), and government policies that regulate the specific institutional field or even the whole field of health care (policy level) (Pacheco et al., 2010). In the following we discuss about the institutional barriers at these three levels, and elaborate different roles of institutional entrepreneurs in the implementing the change.

## **5.1. Policy-level institutional barriers – Changing the formal rules of the game**

The case companies selected in the study were aiming to transform health care system from the treatment of diseases towards more prevention-based system. Although this type of transformation is widely present in the speeches of policy makers, in many countries transformation towards prevention-based health care requires so systematic change of the system that it is extremely difficult for individual actors to implement the change. Moreover, many actors who have good position in current health care system defend their position, which creates resistance for the change. Hence digital health ventures have very limited capability to mobilize resources needed for the change. Therefore, those companies whose business logic is built on new prevention-based institutional arrangements are playing with high stakes; they must be able to seize the right moment of the policy change, change their business logic, or they are likely to lose big.

In addition to challenge of making transformation towards preventive care, also the inertia of implementing regulative changes related to the reimbursement of care provided through Internet (eHealth) or mobile phone application (mHealth) was experienced to be a main barrier for new business. Institutional entrepreneurs felt that they were able to better influence on this needed change, but the transformation was very slow and some countries were clearly lacking behind, which made international business more challenging.

Other formal rules that were hindering the introduction of certain service innovations were related, for example, to the laws and regulations governing what certain kind of treatment different type of professionals are allowed to conduct. This issue may also be particularly challenging for companies aiming international markets as the role of different professionals and regulations governing their role differ between different countries and therefore same business logic may not be possible even within the different countries in European Union.

## **5.2. Standard-level change: Transforming informal rules of the game**

The field of health care is full of informal 'standards' which provide relatively strict normative guidelines on, for example, what is the available set of potential care procedures and what is the role of different professionals in this process. This is the area in health care where highly legitimate institutional entrepreneurs may more easily manage to change institutional arrangements. However, as the field of health care is very professionally oriented, many of the case companies had found out that they need to mobilize top-rated medical professionals as key opinion leaders (KOL) to promote the new innovation. In addition, they need to be able to provide clear evidence that the innovation requiring new institutional arrangements results in improved end result compared to the old way of accomplishing the same task.

In case of changing the 'standardized roles' of different health care professionals some companies had experienced or were expecting strong resistance from the field. Traditionally, the field of health care is very hierarchic and it is not allowed to transfer tasks of the higher-level professionals to professionals with lower level of education. Moreover, the health care is largely still based on institutional logic of medical profes-

sionalism, and hence the transformation that aims, for example, to digitalize analysis health data and thereby let computers do the work of the professionals can be experienced in very negative way and lead to strong resistance. Therefore, if business logic is based on transforming tasks from one level to another, or from professionals to computers, institutional entrepreneur should be very careful when communicating the vision, and should preferably use motivational framing (Misangyi, Weaver, & Elms, 2008) to provide strong compelling reasons so that all central actors can support the new vision.

### **5.3. Practice-level change: Changing the institutionalized practices in the field of healthcare**

Third and most easily approachable level of institutional change is related to the change of practices in the field. Unlike standards it may not be that crucial for the actors to follow the certain practices. Nevertheless, since practices help to reduce the cognitive load of actors, reduce uncertainty, and cope with the task at hand more easily, institutional entrepreneurs may have to provide clear and compelling reasons on why new practices are needed.

Institutional entrepreneur should also expected different kind of response from different actors regarding the change of practices. Whereas tech-savvy patients and professionals may be more willing to adopt new practices related to digitalization of health care, medical professionals and patients belonging to late majority or laggards (Moore, 2014) may be much more reluctant to learn new practice and change their behavior. This is particularly important when aiming to diffuse ICT-enabled innovation to whole range of users, as trials involving new ICT-enabled services are often biased by having more innovators and early adopters as users, which may give false positive picture. True test whether the institutional logic can be changed is when the behaviour of early and late majority is pursued to be changed.

## **6. Conclusions**

The first aim of this paper was to explore the institutional barriers that new ventures face when introducing ICT-enabled service innovations to health care markets. Our findings from five case studies suggest that it is important to identify that institutional change is required at different institutional levels: policy, standard and practice-levels. In addition, companies face various challenges when aiming to transform multiple levels of institutional logic at the same time. Some of the challenges may be easier to deal with, such as, digital transformation requiring institutional change in the level of practices – especially if users are tech-savvy professionals and/or patients. However, our findings suggest that policy level change requires substantial work and may not be implemented without strong support.

As a result, role of institutional entrepreneur is crucial in the introduction of new innovations. Institutional entrepreneurs are individuals or organizations who have motivation to initiate change in institutional logics, and who are able to mobilize resources for implementing the change. Hence, in order that an entrepreneur or startup compa-

ny can be considered as an institutional entrepreneur the actor needs to have proper legitimacy to mobilize resources needed to implement the change.

We hope that this paper provides new insights for managers of entrepreneurial ventures that are targeting to the digital health markets. Our aim is also to advance service research by integrating theory of institutional entrepreneurship more tightly in the discussion of service innovations. As this paper is just a beginning of our research in this area, we hope that more detailed analysis of broader data set will bring further insights and better theoretical understanding on the institutional entrepreneurship in the field of health care. Finally, the aim of the further research will be to improve our understanding and capability to introduce systemic health care innovations in organizational fields where multiple institutional logics co-exist (van den Broek, Boselie, & Paauwe, 2014).

*This paper combines entrepreneurial behaviour and innovation with design thinking in order to investigate the use of the IdeaWindow, the ict-based tool planned for employee-driven service development, in a health care organisation. The tool enables participation of heterogeneous group of people to fuzzy front-end of service development. The paper asks how virtual tool can be used for tackling the unknown - tacit knowledge, hidden possibilities and initiatives in this context. What kind of perspectives and topics the employees bring up when using a virtual tool in the front-end of service development. The results are based on IdeaWindow entries and electronic survey data collected in Finnish hospital ward.*

## 1. Introduction

The public health care sector in Finland and other Nordic countries is facing many challenges. These include aging population and changes in the composition of population health. There are more patients with multiple traumas but also new health care challenges caused by changing life styles. The expectations of patients for better and more individualized care have also grown during last years. Rapid technological and medical development is increasing costs but also expanding the treatment for patients that previously could not been treated (Magnussen et al., 2009; Länsisalmi et al.; 2006; Varkey et al., 2008). At the same time reduction of expenditure in the public health services put pressure to increase efficiency and productivity.

The need for innovation in the public sector is widely recognised. Innovation is considered an important mean for promoting welfare and resolving efficiency demands (Saari et al., 2015; Sørensen; Torfing, 2009). In health care sector the need for innovation has become critical to enhance quality of care and there continues to be a quest to balance cost containment and health care quality (Omachonu; Einspruch 2010; Varkey et al., 2008).

Despite the importance, the generation of innovations and their adoption in health care organisation is often complicated (Länsisalmi et al, 2006). Hospital, which is the environment of our study, is considered to be a very complex and hierarchical social organisation. There have been claims that hierarchies and authoritative management styles have caused rigidity in work practices especially in hospitals. The boundaries between different professions are precisely defined and based on the education and certificates. These strong boundaries between work roles affect the renewal and innovation practices in hospital wards (Iedema, 2007). Restricted domains of responsi-

bilities and authority can cause limitations in the abilities to imagine renewals that touch several professional groups and several cross-functional operations.

In the heart of innovations in healthcare there are the needs of the patients and the skills of the healthcare practitioners. According to Omachonu and Einspruch (2010) *“healthcare innovation can be defined as the introduction of a new concept, idea, service, process, or product aimed at improving treatment, diagnosis, education, outreach, prevention and research, and with the long term goals of improving quality, safety, outcomes, efficiency and costs.”* Successful healthcare innovation focuses mostly on three areas 1) how the patient is seen 2) how the patient is heard and 3) how the patients' needs are met. This rises up the importance of healthcare workers in innovation processes. They see and meet the needs of patients in their daily work practices. Innovation requires the activation of corporate entrepreneurs who will articulate problems, opportunities and possible solutions and will exploit the windows of opportunities (Sørensen; Torfing, 2009).

Since, as described it is not always easy to act entrepreneurially and strive for renewal in hospital environment, we experimented if ict-based tool could promote initiative and innovativeness. In this research paper we combine entrepreneurial behaviour and innovation with design thinking in order to investigate the use of the Idea Window, the ict-based tool planned for employee-driven service development (Lahtinen et al., 2014). Idea Window was originally developed and tested together with the health care workers in research project during years 2012-2014. We will investigate how employee-driven service development can be initiated by the virtual co-creation tool. Employee-driven innovations are exploration and exploitation of new processes and work practices that originate from ordinary employees. We are interested to know how virtual tool can be used for tackling the unknown - customer needs, tacit knowledge, hidden possibilities and initiatives in the working life context. We explore what kind of perspectives and topics the employees bring up when using a virtual tool in the front-end of service development.

Our main questions are: 1) How and by whom the virtual tool is used in fuzzy front-end of open and unstructured innovation process? 2) What kind of initiatives are raised up and which proceed into brainstorming phase?

The paper is organized as follows. In the literature review we will shortly describe the core concepts of the paper: employee-driven innovation, fuzzy front end, effectuation, corporate entrepreneurship, collective creativity and virtual co-creation. In the following section, the case selection and the characteristics of the case, action research as a method for data gathering and the principles of data analysis are presented. From there we will continue to the findings, followed by the discussion of the value and implications of the virtual fuzzy front end innovation practices among employees identified as well as some future research opportunities.

This research is part of the project called Entrepreneurial renewal and design thinking in the organisational development funded by the Finnish Funding Agency for Innovation. The aim of the project is to help the organizations to identify and utilize the workers' tacit knowledge and vocational know-how, and to incorporate their ideas to the developing of new services or work practices. The project examines the employee-driven renewal of organizations from entrepreneurship and design thinking perspectives.

## 2. Literature

Our case study focuses on those parts of fuzzy front end (FFE) of innovation process that take place and are mediated by IdeaWindow. Some key tools to fully understand what happens in these situations are concepts like effectual logic, corporate entrepreneurship, collective creativity and co-creation. The concepts are linked to different elements of FFE in different ways. Collective creativity is perhaps most prominently (but not only) linked to idea generation, effectual logic to the idea selection, whereas corporate entrepreneurship to opportunity identification and selection and development elements. The element of co-creation is present in each element. These concepts are also interconnected and overlapping - the concepts of creativity, innovation and corporate entrepreneurship are all linked to each other (Fillis; Rentschler 2010). In the following we will have a closer look at the role of these elements in early phases of employee-driven innovation.

### 2.1. Employee-driven entrepreneurial renewal and fuzzy front end

In order to develop the work practices and service processes, tacit knowledge and skills of the workers should be incorporated to the innovation process. Incorporating the employees - the experts of their own work - into innovation activities, can be seen as co-creation aiming to **employee-driven innovation (EDI)**. By definition, EDI is a new idea created by employees which results in a new, shared, and sustainable practice (Kristiansen; Bloch-Poulsen, 2010; Hoeve; Niewenhuis, 2006; Feldman; Pentland, 2003). Most commonly innovation refers to commercialized invention like a new technology, product or process. Here, the concept is wider. By innovation we understand both radical and incremental renewal of the products and services, processes and work practices alike (Wolff; Pett, 2006).

The innovation process can be divided into three stages: front end innovation, new product and process development and commercialization (Koen et al., 2001). The early phase of development process has been called the **fuzzy front end (FFE)** (Smith; Reinertsen, 1991) or front end of innovation (FEI) (Koen et al., 2001). Characteristic to that phase is that there is no clear objective, no schedule, or no budget, and hence no plan to follow. The nature of work is experimental and unstructured. Despite the fuzziness of this phase, some common elements of the FFE have been identified. According to Koen et al. (2001) FEI – as they call it – consists of five elements, which are idea genesis, opportunity identification, opportunity analysis, idea selection and concept & technology development. Idea genesis can precede opportunity recognition or vice versa. What comes out from the FFE is not certain, since not every idea – and not even every novel and useful idea – gets implemented and utilised in a profitable way (Amabile et al., 1996; Fillis; Rentschler, 2010). Hence, only some creative ideas turn into innovations. Therefore, uncertainty is characteristic for the fuzzy front-end of employee driven entrepreneurial renewal (Smith; Reinertsen, 1991). The end product of the renewal process is still unknown at that stage and the uncertainty of the process is quite similar to business start-up process (Phan et al., 2009) even though the amount of risks and employees role as a risk bearer is different (da Costa; Brettel, 2011).

**Effectuation theory** (Sarasvathy, 2001; 2008), which was originally created to describe start-up process, offers a useful tool for our study to understand the entrepre-

neurial behaviour of employees under uncertainty. Effectuation is a “*general theory of decision making in uncertain situations*” (Sarasvathy 2008, 227). It is a way to proceed in a situation with a given set of means and focus on selecting between possible effects that can be accomplished with that set of means (Sarasvathy 2001). Effectuation logic and causation logic have been contrasted. Some of the recent studies show that they are more complementary than contradictory (da Costa; Brettel, 2011). In the literature four dimensions of effectuation have been identified. Those are means, affordable loss, partnerships, and acknowledging the unexpected (Sarasvathy, 2008). What that means, is that means available determine potential outcomes more than conscious and explicit planning, potential losses are kept in affordable level, other actors are regarded more as potential partners than competitors and contingencies are seen as valuable opportunities. The characteristics of effectuation - such as process driven by given means and contingencies are seen as source of opportunities - are better suited to the FFE of the innovation process, whereas the characteristics of causation logic - like process steered by given targets and expected returns, and the avoidance of contingences - are more in line with the new product process development. (Brettel et al., 2012.) In our case it is interesting to see, if the staff of the ward build their ideas and proposals based on existing resources or do they use causation logic by setting an aim and then thinking what is needed to achieve that aim.

Effectuation logic, fuzzy front end and corporate entrepreneurship are closely linked with each other, as well. **Corporate entrepreneurship (CE)** has been seen as a method of stimulating innovation and utilizing the creative energy of employees in benefit of the organization (Åmo; Kolvereid, 2005). There are several definitions for CE (Hornsby et al. 2002). Simply put, CE can be seen as entrepreneurial activities within an existing organization, or as Sharma and Chrisman (1999, 18) define: “*the process whereby an individual or a group of individuals, in association with an existing organization, create a new organization or instigate renewal or innovation within that organization*”. What does entrepreneurial behaviour look like? How can we recognize entrepreneurial behaviour of teams or individual employees? Entrepreneurial orientation (Lumpkin; Dess, 1996, Dess; Lumpkin, 2005) is one conceptual tool for that. There are some patterns of action that can be identified as entrepreneurial. Those are autonomy, innovativeness, proactiveness, competitive aggressiveness, and risk-taking. There are some organizational factors fostering CE. Those are work discretion, time availability, management support, rewards or reinforcements, and organizational boundaries (Hornsby et al. 2002), some of which are quite scarce in hospital environment. Even if corporate entrepreneurship is often grass root level action, it has mostly been studied from the managerial perspective (Heinonen; Toivonen, 2007). This study aims to partly fill that gap.

As well as there are organizational factors fostering CE, there are **work environment factors** that affect the level of creativity. Commonly mentioned are encouragement of creativity, autonomy or freedom, resources, pressures, and organizational impediments to creativity (Amabile et al. 1996). Motivation for work and creativity was also noticed as an essential factor behind collective creativity already in the seminal work of Teresa Amabile (1988, 1996). In recent years, the interconnectedness of innovation and creativity has been studied on several levels: individual, team, and organizational level. Team level creativity has been shown to be dependent on team climate and processes and leadership style used. However, recent studies have shown no clear dependence between team structure and composition and innovation. (Anderson et al., 2014.) In their review, Lämsä et al (2006) point sever-

al internal factors that facilitate innovations in healthcare organisations. These include: strong leadership, shared and clear objectives, task orientation, participative safety, reflective team practices, active internal marketing, correct timing, motivation and participation of personnel, lack of stress, and sufficient resources.

## 2.2. Co-creation and co-realisation as a part of FFE

**Collective creativity** and co-creation as a manifestation of collective creativity are needed in the FFE. Sanders and Simons (2009) define co-creation “as any act of collective creativity that is experienced jointly by two or more people”. But first, in order to be able to co-create, some creativity is needed. There are several definitions for creativity. Fillis and Rentschler (2010, 51) define it as “*showing imagination and originality of thought in moving beyond everyday thinking*”. Hence, creativity entails an ability to ‘think outside the box’ and combine diverse information from different domains. As one element of EDI, the concept of bricolage is relevant when looking at innovations which arise from the daily practises of employees. According to Fuglsang (2010) bricolage can be seen as a ‘do it yourself’ problem solving that creates structures out of events and opens spaces for new ways of doing things. Saari et al (2015) states that ‘bricolage is the process of co-shaping an emerging path: various actors offer inputs to generate virtuous learning circle’. Learning by doing and through interaction, recombining previously unrelated knowledge, building skills and expanding routines are all at the core of bricolage. In this respect the IdeaWindow works well, since it enables multi-professional co-creation and supports cross-domain learning, which is regarded important for collective creativity (Hirst et al., 2009).

According to Elizabeth B.-N. Sanders (Simonsen; Robertson, 2013) “**Co-creation** puts tools for creativity and communication in the hands of the people who will be served through design. It is only through collective thinking and acting that we will be able to use design to help address the challenges we face today. All people are creative and can participate in co-designing if they are provided with relevant tools and the settings for use.” This view refers to participatory design that has recently paid more attention to long-term collective thinking and acting, and collaborative development processes where jointly designed tools enable dialogue between designers and users and give power of the tool and process development to the users.

In **participatory design** technology is seen as a potential mediator interweaving meaningful connections within wider socio-material system between people, objects and processes (Suchman 2002; Björgvinsson et al. 2010). Recently, the particular attention has been paid to application of participatory tools and techniques in the front end of the design process. Co-creation has been found to be even more relevant at the early front end of the design development process, where probes and generative toolkits operate well (Sanders and Simons 2009).

**Co-realisation** (Hartswood et al. 2002; 2007) is a concept stemming from information systems development, where it means continuous co-creation between designers and users. It aims to create a shared practice between users and designers that is grounded in the experiences of users, and where users drive the process. The key issue in co-realisation is to support ‘design-in-use’ (Henderson; Kyng, 1991), and in recognising that the information technologies and work practices co-evolve over time and that new technical artefacts require effective configuration and integration with work practices (Blomberg; Karasti, 2013). Traditional approaches to technical

systems design assume that systems are designed by technology professionals, and that at the end of the design process the implementation is finished and the properties fixed, and finally they are ‘handed over’ to users (Blomberg; Karasti, 2013). Thus the requirements somehow pre-exist, as something that can be ‘captured’ through appropriate ‘requirements-gathering’ methods (Jirotko and Goguen, 1994; Woolgar, 1994). *Rather, requirements are seen as being constantly evolving and in need of being ‘worked-up’ and regularly revised in the light of the situation at hand* (Blomberg; Karasti, 2013). Co-realisation is well in line with our approach both for IdeaWindow development as well as EDI processes supported by the IdeaWindow – with an exception that in EDI processes the ‘designers’ and ‘users’ are the employees themselves.

**Case-based prototypes** convey design ideas while maintaining their relation to work practices. In addition to providing for the possibility to iteratively gain user input throughout implementation, assessment and redesign; the prototypes also offer the context for discussion and mutual learning. The case-based prototypes allow potential future directions to be assessed in relation to other technologies-in-use, as individual technologies are seen to ‘add value’ to the extent they work together in effective configurations (Blomberg et al., 1996; Trigg et al., 1999). IdeaWindow is developed through case-based prototypes, which are co-created in various work places in different industries.

### 3. Method

#### 3.1. Case: IdeaWindow at the hospital ward

The empirical study is based on a multidisciplinary action research project realized in a large public sector health care organisation in Finland. The case study was realized at the gynaecological ward of Tampere University Hospital in the Pirkanmaa Hospital District in co-operation with the group of personnel of three units chosen to the research project in the hospital, and with the Development Director of FinnMedi who was responsible for the co-operation during the action research.

The ICT-based co-creation tool called Idea Window was developed in a previous project in 2012-2014 at this very same hospital ward. It was designed to be a grass-root level open communication and development tool for employees’ concrete ‘doing’ from real needs of the workers and patients, aiming to empower the grass-root level professionals as developers and innovators of their work and domain. In the previous study, where the Idea Window was co-designed with the group of nurses and doctors, the prototype was preliminary targeted for employees to detect the invisible side of their work and to observe their experiences and ideas relating to services, and to pay attention to the customer's service experience and behaviour. It was to be a tool for tackling the unknown – customer needs, user understanding, tacit knowledge in work, hidden possibilities and initiatives in work context – and to collaborate in a more systematic way. (Lahtinen et al., 2014.)

In busy environments such as hospitals, it is difficult to get personnel to break away from the everyday work for example for bringing up new ideas and views on a variety of development challenges they face in their work. In the project, the IdeaWindow

was tested as a prototype to find out if a simple and easy-to-use kind virtual co-creation tool could 1) help employees to see their work more from the developer or designer point of view by providing them with a channel for sharing their ideas when possible along with their other work, and 2) to be initiative in the work even though there wouldn't be any clear objective or plan to follow for bringing up and sharing their ideas, experiences and thoughts for improving work life. (Lahtinen et al., 2014.)

The previous action research indicated that health care professionals are motivated to participate in designing and using service development tools and methods 1) if the process is based on meaningful and practical frames which matter to health care professionals, 2) if the process fits with contextual restrictions of health care organisation, 3) and if employees have possibilities to modify the process and monitor the impacts and to apply the results in multiple ways. (Lahtinen et al., 2014.) In the current study the situation where the data and results are obtained is a bit different, now the employees can use ready-made instrument for recording their own ideas and proposals for improvement and so starting their own co-creation process.

The project team made a decision with the contact persons in the hospital to widen the use of the virtual co-design tool IdeaWindow in the units chosen for the first experiment. The employees of the units hadn't used the IdeaWindow before although the tool was originally created in collaboration with personnel working in the same department in the previous research project. Therefore, they might have heard something about the device.

This time the IdeaWindow was taken into use in the units without any precise guidance or control. The personnel had relatively free access to try the device and come up with different ways to use it. No certain purposes or objectives were given to them. The only limiting thing that was told concerned the hope that the prototype would be used for developing both individual and co-operative work in the units. The project team allowed personnel to decide topics for their shared ideation and creation.

From the perspective of the 'design-in use', the main objective in the experiment was to explore how the virtual tool could work if the employees are let to use it experimentally and in unstructured ways for their own idea genesis, opportunity identification and opportunity analysis, the three elements typically existing in the front-end of innovation. The experiment would also indicate how well the tool fits with the contextual restrictions of health care professionals. Thus, the research focus would be on how the employees are using the tool alongside their everyday work routines and hectic working hours without exactly defined development case or topic, and without ready-made processes and methods triggering ideas and thoughts into actions.

The Idea Window has been designed to be easy-to-use touch screen computer with simple user functions on the graphical user interface which would be easy to find and available all the time (see Figure 1). It was designed as a platform for workers' findings, initiatives, ideas and solution proposals to develop services. In the Idea Window, employees can enter their observations and ideas on the screen. In addition, an employee can propose solutions and experiments related to the findings and observations of the service experience. All the items can be combined together to form a variety of topic clusters on the screen. Employees can modify and store the clusters in the user interface according to what is meaningful to them. Any employee can anonymously leave a proposal in the Idea Window and read and move the items on

the screen. The Idea Window was originally designed to put the patient at the service path clearly visible and to open the view into the customer's service experience. (Lahtinen et al., 2014)

Fig. 1: The IdeaWindow screen and user interface with the idea and proposal items when the tool had been used about one week.

The IdeaWindow was placed in the coffee room of the personnel at the gynaecological ward, on top of the cupboard by the window. The site of the IdeaWindow can be seen in Figure 2. The screen was positioned so that it was facing the diners at the table. The coffee room was chosen as a location for the IdeaWindow because all the other places for work duties were full of other equipment and supplies and the personnel suggested this one for a place. The staff's coffee room seemed to be the place where they had gathered a lot of work-related notes and information papers, which was detected on the numerous documents on the info board (Figure 2). Therefore it was interpreted as a place where the personnel might have some time for thinking and reflecting their work from the development angle.

Fig. 2: The staff's coffee room where the IdeaWindow was located during the experiment. And the info board in the coffee room with some notes and documents on it.

### 3.2. Data collection and analysis

The research data consists of two kinds of material: first, of 43 idea or proposal items in the IdeaWindow written by the employees during seven week period in the gynecological responsibility area at Tampere University Hospital between April and June

2015, second, of 16 responses to the inquiry which was mailed to the personnel in July 2015 immediately after the IdeaWindow experiment.

The Idea Window data has been read through carefully and categorized under four different themes according to the subject they contain. Themes are placed in ascending order by number of items they contain. Thus, it was possible to survey, for what kind of perspectives and topics the employees used the IdeaWindow and what kind of issues were more common or rare in front-end of service development experiment where the jointly tackling issues were not limited to certain topics.

The IdeaWindow items were also categorised in three different types according to the choice user made on the screen when leaving an item in the IdeaWindow. In the current version of the IdeaWindow there are two types of items/inputs: ideas and proposals. Ideas are categorised as orange, green or red. A proposal can be marked either as a solution or an experiment related to the idea in the IdeaWindow. The idea is orange if the user thinks it is based on a negative finding, or green if it is based on some positive experience, and finally red if the idea is presented as open, as if it was a question. Ideas can exist independently in the IdeaWindow but the proposals are always attached and connected to minimum one idea or maximum five other proposals. In other words, the idea items are like the initial cells in which these proposals are associated with. In our study we also looked at in what kind of groups the ideas and proposals appeared and how the ideas and proposals formed the chains.

Our research data consists also of the inquiry data that was collected and analysed to get more information about profiles of the personnel participated to the study, and also the descriptions of the situations that were the reason behind of their ideas or proposals. In the inquiry, the respondents were also asked to tell how they would like to see their ideas or proposals been developed in their working environment, and how they themselves could contribute to the development.

At the end of the survey, respondents were evaluating how necessary and easy to use the IdeaWindow has been in their work context. These responses are also part of our data and analysed mainly for further development of the tool but also from the point of how the employees have generally responded to this type of artefact as part of the development of their own work.

In the analysis of the IdeaWindow data, we explored what kind of perspectives and topics the employees brought up when they used a prototype of the virtual co-creation tool in the front-end of service development. We were interested, what kind of situations and things the employees pay attention to so that they want to share them with others and what kind of ideas evoke employees to make their own suggestions for a solution or experiment. More generally, what awakens employees' initiative and entrepreneurial spirit? How do they represent their views and insights for improvements or change? How could the virtual co-development/co-creation tool assist and enable the spontaneous action of workers from starting their own initiatives? What are the features in the tool and what would be needed in addition to it for entrepreneurial behaviour and actions arising in healthcare workplaces?

We have also analysed how the personnel described the reasons to use the IdeaWindow. In analysis we have examined how they describe their motivation, anxiety or frustration behind the idea or proposal they have left in the tool, how the topic of their idea or proposal is in relation with their reasoning, and how they evaluate the Idea Window and its feasibility and ease of use.

## 4. Findings

The staff took the initiative already at the very beginning of the experiment. Although the IdeaWindow guidance session at the ward took only about half an hour few participants were listening really carefully and they themselves made an A4-sheet of instruction manual that was available on the coffee room table. Noteworthy in the instruction was how clearly and in inspiring way the writers were describing the intended purpose and use of the IdeaWindow. According to them, the IdeaWindow was primarily meant to be a tool for ideation and brainstorming together and to look at the everyday work from the client/patient point of view: *IdeaWindow has been developed for a tool through which employees can brainstorm and comment on the everyday activities from the customer and patient orientation. Situations may include encounters with clients/patients, remarks on the facilities and practices, or equipment and good related ideas or comments. The idea is to look at our environment and our practices from the perspective of the customer service experience. All written ideas are anonymous.* In their A4 guide, the nurses compared IdeaWindow as an interface to smartphones or tablet computers. In addition, they managed to tell step by step the main principles how to use the IdeaWindow in very compact way. The instruction note made by the nurses in in the Figure 3.

Hi kaikki,

In the coffee room, there appears the Idea Window display screen. The IdeaWindow is part of the service design project that has been implemented in gynecological responsibility area at Toys. IdeaWindow has been developed for a tool through which employees can brainstorm and comment on the everyday activities from the customer and patient orientation. Situations may include encounters with clients/patients, remarks on the facilities and practices, or equipment and good related ideas or comments. The idea is to look at our environment and our practices from the perspective of the customer service experience. All written ideas are anonymous.

The display screen is here six weeks. During the first three weeks we will focus on the hospital department side of things, and during the latter three weeks the issues coming up from the VTO side. Ideation can start immediately. Therefore everyone will feel free to experiment.

The display works by touching and reminds a lot of smartphone or tablet computer. In upper left corner there are three circles. Smiling circles can be used for positive ideas and considerations, sad one for negative ones, and question mark is for open ideas and comments. On the left side of the screen, there is place for active ideas and for describing the idea. The large circle on the right side of the screen is storage for the ideas. From the storage the idea can be dragged back to empty space on the left side of the screen and there the idea opens in bigger size.

Writing on idea requires a title. It is hoped that the titles would be short and concise preferably one word or two short words. Other people's ideas can be read, and it is possible to propose a solution or a trial related to them. Solutions are attached as cells around of the original idea, and they form together the idea clusters. If you try some practical solution, please create a separate idea from it and describe how it worked. The experiment cannot be linked directly to the idea cluster, at least not yet.

If you have any questions related to the IdeaWindow the undersigned and Riitta Ojala are happy to answer to them.

Now feel free to create ideas!

Regards,  
Jaana S., Christina and Jaana K.

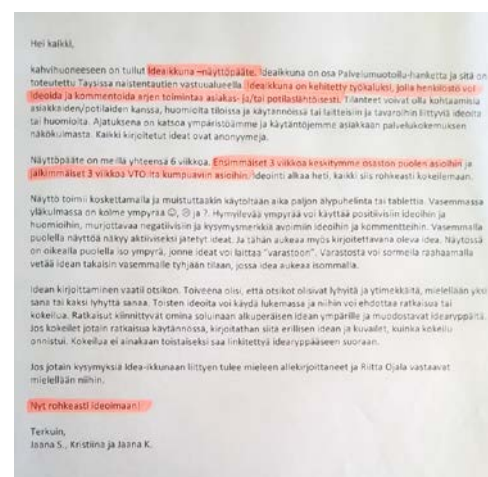

Fig. 3: Instruction for using the IdeaWindow made by three nurses on their own initiative after brief half-hour guidance the research team gave to the personnel in the beginning of the experiment.

During the seven week period 43 items (ideas or proposals) were recorded in IdeaWindow. We categorized all the 43 items in the IdeaWindow into four themes on the basis of the content of the items. The four theme categories are as following and presented in the Figure 4.

## 1. Technology and tools for work

Within the items in the category of Technology and tools for work, employees made remarks related to renewal and acquisition of the equipment and tools they would need in their work. This category was the largest item group in the IdeaWindow data with 17 items:

- **11 of the 17** items were ideas for renewing or acquiring new tools and material, like acquiring more devices often needed at work. More than half of them appeared in the IdeaWindow as single items that were not attached to any proposals for a solution or experiment.

“There are not so many proper machines that would be used for reliable KTG [CTG, cardiotocography] which would show fetal heart beat and movements, and also contractions, mother’s heart rate and RR-measurement. We have to search for the machines from different rooms and wait in a queue to get the proper machine.” (CTG machines)

- **4 of the 17** items were proposals for a solution related to the ideas. These proposals were like points on the checklists.

“To get Avalon-machines, so that every room would have one KTG [CTG]. In this way the machines would be easier to manage for washing, for adding accessories, and there could be always machines available. They would stay in better condition with less moving from place to place.” (In every room)

- **2 of the 17** items included proposals for an experiment. In these items, the employees were listing down their needs for new tools as proposals for an experiment.

“Our own TV too!” (TV)

## 2. Reorganising places and equipment

The items in the category of Re-organising places and equipment contained the ideas and suggestions of employees for re-organizing and re-setting the equipment and space of work. This category was the second largest with 14 items:

- **8 of the 14** items were about the ideas for reorganising places and equipment used at work. Typically, these ideas regarded changing the placement of furniture and technology in working area. 7 of the 8 items in this category appeared in the IdeaWindow as single items which were not attached to any proposals.

“There is no air condition in the rooms. The rooms are hot and stuffy.” (Hot, bad air)

- **2 of the 14** items were proposals for a solution, for example the proposals regarding issues like how the goods and materials could be more easily available in new locations.

“Because there aren’t Avalon machines available for every room, bring the machine into a hallway after KTG [CTG] ends so there is no need to seek and disturb the patients.” (Avalons)

- **4 of the 14** items included proposals for an experiment. These proposals included typically some reasons and explanations why it would be good to do the experi-

ment. Or the employees suggested several different concrete solutions for the problem.

“We could place another table at the window? Why it is not possible to have meal in the day hall?” (Tables)

“Would it be possible to put some more shelves in the wardrobe and in there would be some chronics, cleansers, etc. for cleaning the CTG-machines, etc? Or maybe a separate cart?” (Storage room)

### 3. Organising work

The items in the category Organising work contained the ideas and suggestions of employees for reorganising work routines and practices. This category included 6 items all together.

- **4 of the 6** items were single ideas for reorganising work routines and practices.

“The doctor round in tutkari [research room] works pretty well.” (Doctor round)

“On the department side also, it would be nice if the morning shift would not disappear to coffee room, but would help the shift through.” (Morning shift)

- **1 of the 6** items brought up proposal for a solution related to the work organising issues.

“In the report reading time there is no one else than readers in the office. The earlier shift could have their coffee pause at the same time.” (Proposal)

- **1 of the 6** items brought up proposal for an experiment related to the work organising issues.

“The nurse of the room could give a short report for the nurse in charge, who would plan the working pairs when the overall situation in the department is clear.” (Nurse in charge)

### 4. Customer service situations

Customer service situations items were as large item group as the items in the category of Organising work. Thus it contained 6 items all together.

- **4 of the 6** items were single ideas related to customer experiences and customer service situations. According to the data login of the IdeaWindow all the items within this category were recorded during the last days in the experiment period.

“A patient came up with the idea that people from canteen could go around the departments and sell magazines, etc. for those who cannot go there by themselves.” (Canteen)

“On the department side also, it would be nice if the morning shift would not disappear to coffee room, but would help the shift through.” (Morning shift)

- **2 of the 6** items in the Customer service situations category included proposal for a solution for improving customer service.

“In the report reading time there is no one else than readers in the office. The earlier shift could have their coffee pause at the same time.” (Proposal)

Fig. 4: The items in the IdeaWindow grouped into four themes according to content. The items have been coloured based on the type they appeared on the IdeaWindow user interface.

The themes of the IdeaWindow items were quite similar to the topics that emerged when the IdeaWindow was co-created with the personnel in the previous research project in 2014. Topics such as technology and tools or reorganising work practices were common also then. At that time, the findings showed that the IdeaWindow as enabling open communication, meaningful development, and grass-root level development (Lahtinen et. al, 2014). In both research projects, the IdeaWindow turned out to be helpful in acquiring and sharing knowledge and experiences on new opportunities and ideas more comprehensively than in ad-hoc face-to-face situations in the work community. It can serve as a good starting point for employee-driven development.

Several practical and concrete ideas and proposals in the IdeaWindow showed that employees are interested in each other's thoughts and ideas for improving and developing work life, although the purpose of the ideation wasn't precisely defined and clear in our experiment. However, the staff in the hospital had a need and will to tackle the challenges they face in everyday work. The IdeaWindow was taken into use without bigger resistance or questioning. It seemed to provide the employees a checklist kind of communication tool for their problems and challenges at work, for example for their problems in cooperation or troubles in customer service. It collected and stored the data that mattered to them. The virtual co-creation tool can assist in assembling experiences and thoughts of employees and even other stakeholders, like customers, for a starting point and background for co-creation. But progress from everyday observations and experiences into co-created solutions, reforms, renewed practices and innovations will need some guidance and structure and also trust and transparency from the process and the organisation on a larger scale. The following citations regarding the necessity of the IdeaWindow pave the way for how the tool should be developed in future, but they also underline what should be taken into account when engaging employees in innovation and development.

"To bring up the issues anonymously. For ideas of the personnel for problem solving...Usually the best and easiest way to make developmental change."

"[For subscribing] Deficiencies, in order to remember and wouldn't disappear them among the general complaints."

"If the ideas were implemented the [Idea]window would be more useful. Or if we were at least discussing about the ideas, and the old functions could be called into question, and we weren't only saying that is matter of missing money or that we've always done these issues like that..."

"Maybe the placement [of the IdeaWindow] made it complicated to use. There aren't so many who want to talk about the work issues in the coffee room but instead want to have a very deserved break. Many of the best ideas come up in patient rooms, by the work, and those ideas will not be written down in the coffee room. Ideas will either not been forwarded or they will be presented directly to the supervisors. In a different unit the IdeaWindow could work, but in the intensive care unit the use of it should be reflected more."

Some of the suggestions did not fall in these four categories explained above or suggestions included some words or phrases that led us to conclude that the respondent sees the IdeaWindow to offer an opportunity to express feelings and attitudes of the relationships or overall working climate of the ward. In some cases these kinds of suggestions were easier to interpret but in some cases it stays quite unclear what is the respondent's actual idea or proposed solution. In the first example the respondent's idea and solution is constructed rationally:

"The new and fast thermometers would help the work and save the nerves of the patients and nurses."

The respondent suggested that the department would get the new thermometers to speed up the examination. The respondent seems quite confident that this would also make the job easier not only to the nurses but patients too. In the second example the respondents idea and solution is more challenging to interpret:

"On the department side also, it would be nice if the morning shift would not disappear in to a coffee room, but help the shift through."

The respondent feels important that everybody contributes to the work to get it done. The respondent wishes that the morning shift would help the shift to the end and not leave their duties and go to their coffee break. However it stays unclear why this happens or does it happen all the time and does this concern everybody who works at the morning shift. It is clear that it is reasonable to ask everybody contribute to the work but in this example it stays challenging to recognize the actual solution that would help the whole work community.

Third example draws closer to the second example but it shows some directions where the situation could start to unravel:

"Especially in the afternoon, at the time of silent report, there is lot of noise and disorder in the office. You can't read the report at your peace and you lose your concentration. For the time of silent report the office should be quiet and if the earlier shift has something to report, they could do it just before the shift ends."

The respondent describes the problematic situation where it is hard to concentrate on reading the report. The respondent suggests some new arrangements on the offices

schedule and some new reporting practices for shifts. Although, it would take some time to bring up these suggestions, there is still something one can work with.

In the further use of IdeaWindow, it would be important to find ways to recognize more carefully and categorise these kinds of inputs explained here. These small fragments could easily be ignored as an angry feedback given by employees but we see this as an opportunity for workplace developers to learn more about how employees see the situations and tasks in their own work.

According to the user ratings in the inquiry, the IdeaWindow was considered Quite necessary in the hospital and Easy to use. The Figure 5 presents the user reviews in the table. 9 of the 16 respondents evaluated the IdeaWindow quite necessary, 4 of the 16 respondents found it very necessary, and 3 of the 16 respondents either didn't experience it necessary at all, or couldn't say. 8 of the respondents experienced the IdeaWindow easy to use, 4 of 16 felt it very easy to use, one respondent felt it very difficult to use, and one couldn't say. These results encourage developing IdeaWindow as a low threshold co-creation tool and perhaps particularly as a platform for capturing and sharing knowledge in multidisciplinary collaboration and networks. In the research we tested it as a co-creation tool in front-end of service development but in future the development and testing could be extended also to other phases of innovation. It would be interesting to see how IdeaWindow would work in impact monitoring or in longer-term co-creation.

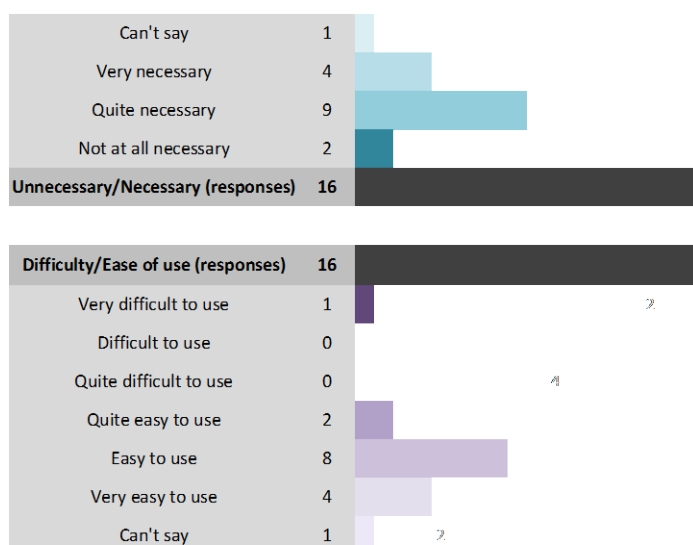

Fig. 5: User evaluations (Unnecessary/Necessary and Difficulty/Ease of use) on the IdeaWindow. Evaluations from the inquiry responses

The IdeaWindow items were also grouped according to how they appeared on the IdeaWindow user interface. In the Figure 5 all items have been placed into groups according to their appearance either as single ideas or as part of the idea/proposal groupings.

Fig. 6: Ideas and proposals of the employees calculated and grouped according to their appearance on the IdeaWindow screen.

26 of the 43 items in the IdeaWindow appeared in groups. And 17 of the 43 were single ideas. The amount of the groups shows that the virtual co-creation tool enabled employees to bring out their quiet, hidden ideas, and to create thinking paths starting from initiative ideas and continuing as far as proposals for solving problems or proposals for some kind practical test or trial to figure out what could finally work as a solution.

Assumption of the research group was that the single idea would be the most common type of the items in the IdeaWindow. Therefore the result was a little surprise. Surely, the IdeaWindow as an interface directs the users to add new items to the existing ideas on the screen. The dialog in the items provides the user with three options to continue when reading the descriptions of the ideas: 1) user can add a new proposal for a solution to the idea, or 2) user can add a proposal for an experiment related to the idea, or 3) shut the dialogue box and enter a new idea item. However, our result may also indicate that reading the ideas of the colleagues in this visualized form may lure user to take the thinking process forward. The experiment produced surprisingly large number of item groups, even if the process itself was blurred and experimental. This inspires to examine more the thinking paths and chains in the front-end innovation and testing and developing methods which might foster collaboration and co-creation at work.

## 5. Discussion

The aim of this paper was to increase the understanding of the ways the virtual tool is used in fuzzy front-end of open and unstructured innovation process and what kind of initiatives are raised up and which proceed into brainstorming phase. The ideas raised up in IdeaWindow could be categorized into four groups. Most ideas were about technology and tools for work. Almost as many ideas and proposals concerned reorganizing of places and equipment. Organising work and developing customer service situations were suggested more rarely. The two first mentioned categories got also most of the proposals. There were altogether 27 ideas and 16 proposals. Hence, many ideas in IdeaWindow gathered proposals from co-workers developing a path of discussion. This is a good example of knowledge sharing and learning in organisation, which both are important elements of innovative environments (Martins and Terblanche, 2003).

Behind the ideas or proposals left in IdeaWindow can be found concerns about the patient safety and well-being, frustration about the time spend in searching for proper equipment and other things needed in nursing, as well as wishes to serve the patients better. Also items that are linked to technology and tools for work or reorganising places and equipment are mainly linked to needs of the patient or improving care. This raises the question should staff members and patients use the IdeaWindow together, and thus complement each other's views and knowledge. The combination of expert knowledge and patient experiences could offer an opportunity for developing new work practises, but also for maintaining good customer service and renewing working culture incrementally more customer-centered.

Those who commented the items in the IdeaWindow were all nurses, except one, although the tool was available for every worker including also physicians and supportive staff in the ward. Because of the relatively low amount of inquiry responses we can not trace how widely the other professions than nurses were using the IdeaWindow. This calls for future discussions and reflection in our research group. Is it important to know how many staff members are using the IdeaWindow? Are the ideas and proposals results of an active but small group of people or is the IdeaWindow regarded as a common arena for all to participate? And what kinds of processes are needed for widening the use of IdeaWindow in front-end of innovation and maybe also in other phases of innovation?

This paper is based on the preliminary findings of the study in progress. Already these findings open up exciting new research opportunities. The preliminary findings indicate that IdeaWindow serves as a good starting point for employee-driven development, but it is not sufficient. As such it does not support corporate entrepreneurship or effectuation. However, many of the ideas that were entered in the IdeaWindow started quite modestly from the resources available, which is in line with effectuation. The flip side of this modesty of the ideas was that there were no totally new, groundbreaking ideas, which would expand the creativity beyond everyday thinking. The self-made instruction sheet by the IdeaWindow can be interpreted as a signal of entrepreneurial attitude. This should be cherished and promoted in case more employee-driven activities are expected from the staff.

Most of the entries in the IdeaWindow were made by the nurses, therefore there were just a few cross-domain learning between professions. In order to better under-

stand how - and if - the work environment in health care or in other domains could generate and foster collective creativity and co-creation, we need more information and studies related to leadership styles, roles of different professions and hierarchical systems and their connections to the employee-driven innovation and corporate entrepreneurship. For that purpose some of the members of the hospital ward will be interviewed later this year and the resulting data will be connected to data and findings of this study.

Results presented here encourage developing IdeaWindow as a low threshold co-creation tool and perhaps particularly as a platform for capturing and sharing knowledge in multidisciplinary collaboration and networks. In the current action research we tested it as a co-creation tool in front-end of service development but in future the development and testing could be extended also to other phases of innovation. It would be interesting to see how the IdeaWindow would work for example in impact monitoring or in longer-term co-creation process. Action-research based studies also in other domains than in health care have been considered in this sense.

When comparing the preliminary findings to the results of the previous research project, some similarities can be found. Based on the results of both projects, health care professionals are willing to create meaningful and practical frames for co-creation at work, and they will participate to the process actively, if it fits to their context. But the employees also show quite clearly that they need to be encouraged and provided with easy-to-use methods and tools, and they wish to be involved in collective processes and decision making that support co-creation at work. Within this palette of means, the virtual insights collecting and sharing co-creation tool could be a kick-start, fuel and side eye on the way.

# **New approaches to patients' services and new uses of ICT (Information and Communication Technology) in Co-operative Interface Organizations as a lever to improve the French Healthcare System**

*Christian Bourret, Corinne Nkondjock*

University of Paris East Marne-la-Vallée (UPEM) – France – DICEN IDF (Information and Communication Devices in the Digital Era) / IFIS (Ile-de-France Institute of Services Engineering).

*As in most developed countries, the French Healthcare System tackles an important crisis with the central question of costs, linked with the key issues of efficiency and performance. Solutions are sought in new uses of information tools and communication actions to promote the involvement of patients and their responsibility. New Interface Organizations developed in the last years between primary care and hospital's sector may have an interesting role, especially to better integrate patients in a co-production of services perspective focusing on considering their emotions and feelings to improve their involvement. We will analyze the case of GPS Diapason in Ile-de-France Region. We also discuss new ways for coordination's innovation in a healthcare local perspective in a sustainable and solidary view.*

*Comme dans la plupart des pays développés, le système de santé français est confronté à une crise importante avec la question centrale des coûts, avec celles de l'efficience et de la performance. Des solutions ont été recherchées dans de nouveaux outils d'information et dans des actions de communication pour favoriser l'implication des patients et leur responsabilisation. De nouvelles organisations d'interface développées ces dernières années entre le secteur de la médecine de ville et celui de l'hospitalisation peuvent jouer un rôle intéressant, spécialement pour mieux intégrer les patients dans une perspective de coproduction de services en prenant mieux en compte leurs émotions et sentiments pour améliorer leur implication. Nous analyserons le cas du GPS Diapason en région Ile-de-France. Nous discuterons aussi de nouvelles approches innovantes de la coordination dans une perspective locale de solidarité et de développement durable.*

# 1. Introduction

The French Healthcare System tackles important contradictions. Considered some years ago as the best in the world by World Health Organization – WHO (2000) especially in term of access to its services for all the citizens, it is also in crisis and may be considered as “out of breath” (Isaac) and must evolve. One can consider that it is effective (good results in terms of care) but expensive (issue of the huge deficits of the Welfare budget) and therefore not efficient: its costs are the highest of all European countries (12% of GDP), only surpassed in the developed countries by the United States (17 %).

The Isaac’s report (2014) proposes a “paradigm shift”: changing from an almost only curative to a much preventive approach, relying on ICT (Information and Communication Technologies). The French Healthcare System is also characterized by numerous divisions or walls, synonymous with poor quality, particularly between the primary care and the hospital sector with the full weight of the hospital sector (“hospital-centrism”).

This is the challenge of improving cooperation and coordination especially through new Interface Organizations (Bloch-Hénaut, Bourret).

Without mentioning particularly the specific texts for the hospital’s sector, many reforms have followed over the past fifteen years with three main Laws. Let's start with the law of March 2002 on “The rights of patients and the quality of the Health System”<sup>1</sup> which particularly promoted the concept of “health democracy” (*démocratie sanitaire*) and valued the Healthcare Networks. The law of July 2009 about “Hospital, Patients, Health, Territories”<sup>2</sup> increased regionalization of health management by transforming the Regional Hospitalization Agencies (ARH) in Regional Health Agencies (ARS) <sup>3</sup>with a view to “*déconcentration*” (managed by the State level and not by Regions), causing quite paradoxical debates: is it a real regionalization of health management or a new way to strengthen the role of the State at this new level? A new law of "Modernization of the Health System" was passed in April 2015. The press document of the Ministry of Social Affairs and Health speaks of nothing less than to "change the daily lives of French" with “strong concrete measures to develop prevention, improving access to care, and create new rights for patients” <sup>4</sup>.

All these changes are largely based on the use of ICT devices meeting the “augmented human” and the “quantified self” issues and the widespread use of data (Open and Big Data with the issue of patients' rights). We will study the approach by co-production services at two levels: between professionals and also by involving patients and their families.

<sup>3</sup> In French, ARH : *Agences Régionales de l'Hospitalisation* – ARS : *Agences Régionales de Santé*.

<sup>4</sup> <http://www.loi-sante.gouv.fr>

After this introduction, we present our methodology and positioning of researchers. We will address the major challenges of the French Healthcare System, which, for us, are mainly challenges of efficiency and coordination - cooperation arising primarily in terms of information and communication challenges and integrating patients' involvement. Then we will study the specific role of interface organizations as shift lever of improvement of the French Healthcare System notably through the case of GCS <sup>5</sup> Diapason. We finish by a prospective conclusion.

## 2. Methodology and Researchers' Positioning

In a constructivist approach of managing complexity (Morin, Le Moigne), we position in the Information and Communication Sciences field, considered by F. Bernard at the convergence of four different issues: that of link (relationships, interactions), that of meaning and that of knowledge for action.

We also position in the approaches of complexity (global and systemic) in the Morin's and Le Moigne's views and in Action Research perspectives: to produce usable knowledge for actions, validated by all the stakeholders, with co-production of knowledge (Meyer) and so in some part of co-production of services between all the actors (including patients and their families) especially through communication actions and shared information.

We begin using the "situational and interactionist semiotic approach" (Mucchielli, 2010) and the notion of "intelligence of situation" (Autissier, 2009). We propose to integrate the experiences of actors including the emotions and feelings of patients, to promote their better involvement, relying in particular with the works of F. Martin Juchat, Bègue-Desrichard, C. Maman or A. Soares integrating these perspectives in a dynamic approach, considering the patient's pathway as a process (in a quality management perspective).

Our work is based on co-operations established in France (particularly around students' works in Masters: observation, participation in meetings, interviews with key actors in different organizations) so with the GCS Diapason in Ile-de-France Region or other French Interface Organizations but also with comparisons with another health interface's organizations in foreign countries as in Spain (Basque Country).

We position in two different and complementary ways: in a rather observatory approach (C. Bourret) and in an involved researcher approach, working in responsibility functions in these interfaces' organizations (thesis of C. Nkondjock).

---

<sup>5</sup> In French, *Groupeement de Coopération Sanitaire*.

### 3. Mostly efficiency, coordination and cooperation challenges

As we have developed before (Bourret, 2010), one of the main challenges facing the French Healthcare System is that of the divisions (in French : *cloisonnements*) formulated primarily by M.-A. Bloch and L. Hénaut (2014) as a challenge of coordination, clarity and coherence of actions and in other countries as “walls” (Glouberman – Mintzberg, 2001).

Referring to H. Mintzberg (1982), they point out that all human activity corresponds to two basic needs: the division of labor between the tasks and the coordination of these tasks, these two aspects can become contradictory. The need for consistency is essential for the number of different jobs existing (more than 180 in just the Healthcare sector).

For them, "Coordination is therefore both a problem and a solution" (2014, 13). It has two aspects: horizontal (between sectors) and vertically (between institutional intervention levels).

Coordination became one of the main axes of the action of the State with the NPM (New Public Management), became in 2012 MAP (Modernization of Public Action). According to E. Minvielle, in the Healthcare sector, it is the creation of ARH (Regional Hospitalisation Agencies) that embodied the "new public management in the French fashion." They became ARS (Regional Health Agencies) in 2010 as part of HPST Law and are at the heart of the new Public Health Law of spring 2015.

Therefore, coordination in recent years has become an obsession of public powers. Faced with this "order to coordinate", medical and medico-social professions evolved, including the emergence of new professions around coordination (case managers, Health Network coordinators or coordinators of MAIA - Houses for Autonomy and Integration of Alzheimer Patients<sup>6</sup>...).

For us the challenge of coordination / cooperation can be tackled at two levels of complementary approaches:

- Information and communication challenges,
- to promote new approaches to innovation for developing co-production of services between all the professions and with patients and their families. Since 2004, France bet on DMP<sup>7</sup> or patient's personal medical record to ensure both traceability of actions and spending efficiency by avoiding duplication of medical acts.

The management of the DMP project was a resounding failure, almost turning to State's scandal. The DMP revived in 2010 from "personal" medical record belonging to the patient to "shared" medical record. This repositioning of the DMP is one of the

---

<sup>6</sup> In French, MAIA : *Maisons pour l'Autonomie et l'Intégration des Malades d'Alzheimer*.

<sup>7</sup> In French, DMP : *Dossier Médical Personnel*.

key measures of Public Health law passed in spring 2015, "so that at every stage of care, professionals and patients have access to all medical information." This "new" DMP should be the main support for the control of care pathways, new formulation of the concept of coordination that gradually asserted in public speeches in last years. The last formulation of coordination is the notion of PPS<sup>8</sup>: personalized plan of care. This evolution of DMP as tool of PPS with development of other ICT tools take place in the whole context of the "augmented human" and of "quantified self", with the specific role of the CNIL <sup>9</sup>.

These evolutions meet the notion of digital care territories or in French TSN : Territoires de Soins Numériques. Proposed as part of the Future Investments <sup>10</sup>, the program "Digital Patient Territory" wants to modernize the Healthcare System by experimenting in some pilot areas, services and the most innovative technologies for e-Health.

Of the 18 projects supported by the Regional Health Agencies (ARS), 5 were selected for their innovative and sustainable character, their adaptation to local realities, their ability to mobilize a majority of stakeholders and their expected impact on value chain development with industrial e-Health: in Aquitaine: XL ENS (Health Digital Space in Landes Department) ; in Burgundy Region: E\_TICSS (Innovative Territory coordinated social health); in Ile-de-France: TerriS@nté ("Digital as Health service in the Great Paris area"); in Rhône-Alpes region: Pascaline (Health Pathway and coordinated access to digital innovation); for the Indian Ocean French territories: PLEXUS OI (exchange platform for new uses of health ICT).

These projects directly affect 1.4 million people, both urban and rural, and respond directly to the challenges identified in the Health National Strategy and the new law on the modernization of the Health System (2015): innovative organization tracks centered on the user and to reinforce the pathway's approach ; better coordination between health professionals, patients and caregivers, with significant mobilization of support services ; support of technological innovations developed through the cooperation of many actors, industrialists, actors in the provision of care, local powers and institutional partners.

Of course these projects within the field of e-health are supported by other projects such as telemedicine projects.

At the end of the program, the solutions that have proven efficiency will be generalized. This view marks an evolution of the experimental approach developed from over 20 years to limit often questionable and difficult to generalize experimentations (Cordier et al., p. 14, quoted by A.-M. Bloch and L. Hénaut).

## 4. Healthcare Interface organizations as a change lever?

Healthcare Interface Organizations may be considered as spaces for innovation, experimentation and development of trust (Bourret, 2010), both for the human actors (individuals or belonging to organizations) and also in digital tools (digital trust), also with the recognition of different roles: that of doctors, nurses, social workers, patients and their families, etc.

Healthcare Networks appeared in the 1980s, especially with the AIDS epidemic and the need for coordination between general practitioners (primary care) and hospital sector and between the medical and the social sector. Their role has been enshrined in the Law of March 2002 already quoted. They also developed for different diseases (diabetes, cardiology, etc.) or for specific situations (perinatal care, addictions, obesity, geriatrics, oncology, etc.)<sup>11</sup>. In different situations their role would be better defined with HAD (Hospitalization at Home)<sup>12</sup> organizations which have developed to maintain patients at home and constitute specific and recognized organizations<sup>13</sup>.

First Healthcare Networks constitute coordination structures of professional activities engaged in different places, often with just a phone center to receive patients' calls and to guide them. We have particularly work with the Healthcare Network Bronchiolitis in Paris, Gérontopastel Network for elderly people in Toulouse, or Arcade Network for Palliative care in Tarbes – Hautes Pyrénées Department.

The rivals of the Healthcare Network, Pluriprofessions Medical Homes<sup>14</sup> include different practitioners on the same site, as it is, for example in Spain for *ambulatorios*.

We must also speak about CLIC<sup>15</sup>, specific coordination structures but without cure or care aspects, favoring coordination and orientation aspects, particularly for elderly people.

In the recent years, the public authorities seem to prefer them and encourage their development, focusing also on grouping and coordinating activities. Thus the Healthcare Network on Diabetes in Eastern Ile-de-France (Revesdiab) became the main actor in the new structure of GCS (Health Cooperation Group) Diapason (in southern Seine-et-Marne department, which represents half of the area of the Ile-de-France Region).

---

<sup>11</sup> <http://www.sante.gouv.fr/les-reseaux-de-sante.html>

<sup>12</sup> In French, *Hospitalisation à Domicile* (HAD).

<sup>13</sup> <http://www.sante.gouv.fr/l-hospitalisation-a-domicile-had,12379.html>

<sup>14</sup> In French, *maisons de santé pluriprofessions*.

<http://www.sante.gouv.fr/les-maisons-de-sante.html>

<sup>15</sup> In French, CLIC : *Centres Locaux d'Information et de Coordination*. <http://clic-info.personnes-agees.gouv.fr/clic/construirePageLogin.do>

Other modalities of cooperation have also emerged in recent years as the PAERPA experiments (Elderly at risk of loss of autonomy <sup>16</sup>) that particularly highlight PPS (Personalized Care Plans) which focus on monitoring of individually sustain or patients' or care pathway, set up by the Healthcare networks, applying in this case to in elderly patients. So GPS Diapason applies a PPS to diabetic patients. MAIA (Houses for Autonomy and Integration of Alzheimer Patients) were mainly intended to be a main entrance in the Healthcare system for patients with this disease and their families. They were put in place by the new CNSA (National Solidarity Fund for Autonomy <sup>17</sup>). They have often considered the arrival of PAERPA as unfair and unnecessary competition.

These interface organizations are an attempt to answer the central problem of the divisions or walls of the French Healthcare System. But their proliferation, often without no real consistency or overall vision, according only to local initiatives of different Health Insurance or Social Security funds or territory collectivities (departments, municipalities, etc.), can ask questions because it can lead to new divisions and perhaps a loss of efficiency ... as outlined by a recent report (Cordier and al., 2013).

Many researchers also emphasized the unreadable aspect of the offer of care services on the territories. This is particularly the case for helping the elderly people with loss of autonomy which the roles and missions of the respective activities overlapping territories are often far from clear between Healthcare Networks, CLIC, HAD, and, more recently, the MAIA and PAERPA.

## **5. To a new patient's approach integrating their emotions and encouraging their involvement**

The role and the responsibility of patients progressively developed, particularly in anglo-saxons countries with the notion of "empowerment".

In France, the role of patients developed particularly with the AIDS epidemic and received a first and important consideration in the March 2002 Law with the notion of "health democracy" <sup>18</sup> with the key role of associations such as the CISS (Interassociative Collective on Health <sup>19</sup>) and with the "judicialization" of healthcare from the perspective of "perfect health" described by L. Sfez: obligation of results and not just of means. In the hospital sector, we must outline as application of the 2002's Law the hospitalized patient's charter of 2006.

---

<sup>16</sup> In French, PAERPA : *Personnes Agées en Risque de Perte d'Autonomie*.

<http://www.sante.gouv.fr/le-parcours-sante-des-aines-paerpa.html>

<sup>17</sup> In French, CNSA : *Caisse Nationale de Solidarité pour l'Autonomie*.

<sup>18</sup> In French, *démocratie sanitaire*.

<sup>19</sup> In French , CISS : *Collectif Interassociatif Sur la Santé*.

As an extension of the Companion - Ghali report (2014), we also insist on the need to promote the role of patients, leading to a true co-production of services through a new local citizenship (new stage of development of "health democracy" (*démocratie sanitaire*) valued in the law of March 2002. This special point is one of the three strong action to "create new rights for patients" in the 2015 Law.

Another aspect deserves special attention: that of the family and relatives who help the patient, who often act as lead coordinator and often threaten their own health, besides the cost of care (lower costs for the Healthcare system but stronger for the patients and their families).

A. Mucchielli (2010) proposed a method to access to meanings and to understand what things mean for an actor: the "situational and interactionist semiotics." Its key concept is the contextualization with linking the conduct or phenomenon with a background for highlighting, to qualify and assess the conduct and the phenomenon. This background is built by actor interpretation. The background for the interpretation defines a situation, split into different frameworks: the intentions and issues of the actors, their cultural background, their positioning in relation to other actors, the quality of relations, historical and temporal framework, a sensory setting. All the meanings build a "global sense" of the phenomenon that is the synthesis of meanings taken in different settings and for the different actors.

D. Autissier (2009) proposed a definition of "situation's intelligence": "the ability of individuals to understand the context and the way people act knowingly, so that any exchange is profitable and produce success". He proposes working from five key concepts: introspection, understanding, interaction, execution and capitalization.

From these two approaches, we propose broader perspectives extended to emotions and feelings of actors (Damasio, Goleman, Martin-Juchat), especially for patients and their families and a dynamic approach to change (process approach / quality management), the patient's pathway can be regarded as a process.

With the whole perspective announced in a recruiting poster for paramedical professions of the Department of Health (2006): "There are people who know that being at your disposal, it is also to hear what you do not say".

We propose to insist on the concept of emotional skills of patients, central element of emotional intelligence. The body is both the mediator from which the individual can sensitize its affects and communication to support them (Martin-Juchat).

Our hypothesis-goal is that to manage the emotions can become a collective objective of improving the quality of care. Social sharing of emotions is essential to promote the group membership (Bègue-Desrichard, 2013). This integration of emotions and feelings in the patient's personalized care can improve the quality of care, for example through better patient adherence to prescription compliance and taking drugs. The notion of recognition is also essential in the discussion groups. We will analyze the role of "mediator patients" already developed in some Healthcare Networks. Thus we place in the perspective outlined by the High Authority of Health<sup>20</sup> (2007) in its recommendations for patient's education, asking to recognize how to

<sup>20</sup> In French, HAS : *Haute Autorité de Santé*.

act in the patient's positioning to analyze his psychological evolution by developing techniques of patient-centered communication (active listening, empathy, encouragement, etc.).

The digital dimension is also essential. The areas of activities of different Interface Organizations can be considered as Digital Care Territories (TSN) in the same way as around individual patient.

The prospects outlined represent a new approach of services co-production integrating emotions and feelings of actors (Maman, 2014) applied in this case to the Healthcare sector. She particularly refers to the work of A. Soares (2003). Soares outlines the interest for the analysis of emotions at work and in organizations in two different perspectives. The first focuses on the emotions generated by the work. The second perspective, focused on the analysis of "emotional labor" and so to the expression of emotions at work service. It is still rather embryonic especially in France. It is this aspect that he wants to especially analyze. The challenge is for him to incorporate into researches, emotions and social relations that shape each other and tackle synergistically analyzes on work aspects and organizations. It will also provide a closer analysis of the complexity of everyday life in organizations.

More generally, this crossing from the individual dimension to the collective dimension is a major challenge to found a new citizenship, particularly in the case of Digital Care Territories (TSN) or also in Health projects as part of Smart Cities project, as outlined by M. Zacklad (2009, 2015).

So with the central concern of the authorities to organize better coordination of activities and cooperation in Healthcare on a territory. In this perspective, we propose to analyze the case of GPS Diapason.

## **6. The case of GCS Diapason**

The GPS Diapason allows us to analyze a concrete way a health innovation on a specific territory, focusing in particular on the notion of PPS for complex patients with chronic diseases. Its main mission is the animation of a part of territory in Ile-de-France region around innovative practices involving the patient, especially diabetic, around the telemedicine project "Diabetes 2.0" (including the Healthcare Network Revesdiab). Diabetes 2.0 is a multi-year large-scale innovative project regarding both the city and the hospital. It provides various tools of tele-consultation, remote monitoring, tele-expertise, as well as virtual tools of therapeutic education. 2.0 Diabetes wants to use telemedicine as a training tool for health professionals and to promote patients' compliance. The ultimate goal is to improve the management of chronic diseases (diabetes here) and complications associated, optimizing care pathways and controlling health expenditures.

Initiated by GCS Diapason, this is an ambitious project that puts numerous economic interests in play. Diabetes 2.0 is the result of a collaboration that began with a call to the ARS project, "Telemedicine and Chronic Diseases". The response to this call for projects brought together complementary skills and visions around the common goal of improving the health status of diabetic patients. Each element of the project was designed to bring together all the necessary factors for patient involvement in their

care, to make available to them a comprehensive evaluation framework and to shed light on future structural arbitrations.

The medico-economic objectives are aimed at compliance with management protocols, in order to specifically prevent diabetes-related complications, improve the independence and quality of life of patients, develop patient skills, reduce avoidable hospitalizations and finally to reduce the costs of care.

The project manages three representative cohorts. A first cohort of newly diagnosed diabetic patients without known diabetes complications. A second cohort of already known and treated patients; diabetics aged 65 and older with glycated hemoglobin greater than 7% and/or having at least one known diabetes complication. And finally, a third cohort of patients ages 65 years and older with loss of autonomy at home or in nursing homes, in diabetes care with risk of hypoglycemia (insulin, sulfonylureas or glinides).

The ARS Ile-de-France, did not finally accept Diabetes 2.0, but remarked the quality of the file. The project was considered as too expensive and it has been criticized for lacking a viable business model in the long term (cf. Cordier's report new position about experiments, 2013). This is the difficulty of promoting a telemedicine project in the long run. However, ARS agrees to work with the GCS Diapason because the project will be more successful financially speaking.

One of the non-medical partners of the project is interested in the establishment of telemedicine with a strong presence for accessibility in Seine-et-Marne Department (77). It has a collaborative vision, in a time of crisis, with resources someone could call, "human". Pressing the territorial coordination seems paramount. How can the health system be changed with the ICT in times of crisis? Most likely with the help and responsibility of the citizen patient.

Collaborative work, with prospective and even visionary solutions, shakes preconceived ideas. The idea behind the project is to leverage the connection points to reach the territories still isolated today. For example, to make an appointment with a specialist remains complicated with often very long delays. The telemedicine solution should not be confined to a single approach. By choice of the cohorts, priority is given to new patients, but also patients who experience complications and elderly patients with reduced autonomy.

To evaluate Diabetes 2.0, one must "test" with defined criteria that produce reliable, readable and replicable results. It begins with a collective space that integrates the needs of the patients in order to bring them a bouquet of services. The second cohort was the one who received the greatest range of telemedicine services.

When evaluating the project, it is important to look to the territory in question, the reasons why or why patients come in order to analyse the support of the project. The patient is at the heart of the project. That is to say, how will he be brought into the project? It is also important to reflect on the method of how to walk alongside the helpers, those who drive the project along. Finally, the challenge of this project is economic with the background idea of setting up prevention methods for future patients who will benefit from feedback from such a telemedicine project.

Given the scale and ambition of the project, in view of current developments in telemedicine and digital aspects, and no longer having the constraints of proposals demands, the rewritten project was envisaged with a wider scope and with the goal of having a generic framework which would allow the development of complementary and articulated subprojects, called "bricks." These are likely to be financed and implemented within a reasonable time according to the financial participation of partners. A communication plan of the project to potential funders is currently underway.

The monitoring of this project, and similar projects are included in the thesis of Corinne Nkondjock. Namely, how ICT can improve the care of patients with chronic diseases while controlling health spending. What are the necessary conditions to change health care organizations in this view, and especially what the real needs of aging patients with chronic illness living at home?

Since the beginning of the thesis, Corinne Nkondjock was able to participate in the early reflections of the project 2.0 Diabetes and has continued to follow the evolution of this project which has been slowed for financial reasons. This is an innovative project that requires real, substantive work and the comparison of similar projects in Europe. The search for understanding the needs of the population of elderly patients with chronic diseases drove Corinne Nkondjock toward a new professional project, coordinating nursing home service project in Hauts-de-Seine Department (92). This new position will enhance her research and enable her to build a concrete picture of the contribution of ICT in the management of patients at home and their limitations.

## **7. New projects for Healthcare innovations on territories**

GPS Diapason corresponds to new approaches to innovation in coordination, consistency and readability of Healthcare management on the territories which meet the new perspectives of "territorial coordination of supports" enhancing in particular the role of PAERPA, CLIC or GPS.

In 2003, the Carayon's report on Economic Intelligence had stressed the vital link between business competitiveness and social cohesion.

From the perspective of promoting innovation on territories (which we consider as Territorial Intelligence), the Godet - Durance - Mouli report (2010) emphasized the role of the Health field as an important innovation's field, pointing in particular the experience of Healthcare Networks (in French, *réseaux de santé*).

At territorial level, institutional coordination is now conducted by the ARS, in relation to Departement Councils (*conseils généraux* became *départementaux* in 2015). To this end, the ARS have specific funds as regional intervention fund (FIR <sup>21</sup>) . Just like what happened in Canada (Quebec), meta-networks develop in a

---

<sup>21</sup> In French, *Fonds d'Intervention Régional*.

perspective of "integrative innovation" valued by M.-A. Bloch and L. Henault (2014). For them, a good approach of integrative innovation is the creation of a CLIC in a territory and then a CLIC Network, then a CLIC – Healthcare Network - MAIA, and finally a CLIC - Healthcare Network- MAIA-PAERPA. They quote the case of CLIC – Healthcare Network – MAIA in Seine-et-Marne Department and that of Paris Centre (2014, 277).

Other achievements correspond to this goal, as the case in the Hautes-Pyrénées Department (Midi-Pyrenees region). It began with the Palliative Care Network Arcade (developed by the Local Disease Office or CPAM <sup>22</sup> as a coordinated care network) at the beginning of the 2000s) and recently develop a partnership with the new MAIA.

In the department of Ariège, in Saint-Girons, the Echo Health (*Echo Santé*) Healthcare Network located within the CHAC <sup>23</sup> is closely articulated to the local home hospitalization structure (HAD) and the new MAIA but on ... different actions territories ... which cannot optimize the co-operations in a first time.

M.- A. Bloch and L. Henault outline in the conclusion of their work several possible improvements for the future. Their first goal is to contribute to "give an overview and inform various stakeholders (2014, 272) to promote ownership by the actors of the new concepts with the essential dimension of the need for information of patients about their disease and the institutions around them.

They also highlight the notion of "shared care" that emerged in Quebec a few years ago, focused on primary care and home care. With the objective to convince health professionals to call on expert resources when they are not able to respond to the patient's need. It was already the idea of the "Guide for Healthcare Networks" published by the DGOS (2012) with the concept of "territorial coordination support" <sup>24</sup>.

They also stress the need to "renew modes of innovation" in two complementary ways. First "integrative" innovation that fully takes into account the context, capitalizes on the existing organizations and develop new devices, with the aim of added value in conducting actions. It must also tackle the issue of disadvantaged areas. They insist on "medical deserts" where there is little potential innovation. They propose the concept of "solidary" innovation: develop innovative devices on disadvantaged areas from neighboring territories better provided (2014, 278 - 279).

We must also mention the European dimension. If Health issues are always managed at the national States level, European projects have enabled significant progress as epSOS (2008 - 2014) <sup>25</sup> for the mobility of patients in the European

---

<sup>22</sup> In French, CPAM : *Caisse Primaire d'Assurance Maladie*.

<sup>23</sup> CHAC : *Centre Hospitalier Ariège Couserans*, corresponding to the Heath area (*bassin de santé*) around the town of Saint-Girons.

<sup>24</sup> In French, *coordination territoriale d'appui*.

<sup>25</sup> EpSOS : <http://www.epsos.eu/france.html>

The main goal is to encourage the mobility of citizens in the European Union by promoting the interoperability of health information systems, especially the Electronic Health Record with the aim of

Union.

We may also mention the Carewell Project <sup>26</sup> for the Development of a New Organizational Model Based on Integrated Care for Chronic and Elderly Patients through ICTs developed simultaneously in 9 European countries and coordinated by Spanish Basque Country organizations.

## 8. Conclusion

This paper corresponds to a work in progress. We propose different tracks from reflections around experiments which we are associated.

Beyond revisited DMP (*Dossier Médical Personnel*), we have mentioned in particular the concept of Personalized Care Plan (PPS), the experiments in Interface Organizations, as GPS Diapason, whose mission is animation of the territory of Seine-et-Marne and testing of innovative practices involving the patient, especially diabetic, around the telemedicine project "Diabetes 2.0" (including the Healthcare Network Revesdiab). In the future, with co-operations with GCS Diapason or Bronchiolitis Network we will discuss the concept of care pathway in its different approaches, especially for "complex patients".

We will propose an extension of the perspectives of the situational and interactional semiotics to feelings and emotions of the actors, especially for patients and their families in a dynamic process of change and continuous improvement. We thus situate in new approaches to innovation everyday (Alter, Godet) with a more integrated experience, emotions, feelings and needs of patients for a co-production of services on the model of Anglo-Saxon empowerment. We will insist particularly on the role of emotions in the services' relationship, in our case, in the healthcare sector, with the specificity of "complex" patient. We also will work on the development of the new professions around coordination challenges.

In a perspective of organizational innovation in the territories, and in the approach proposed by M.-A. Bloch and L. Hénaut of "integrative" and "solidary" innovation, in a perspective of Territorial Intelligence (resilience and reliance of territory), we will work to new ways around "frontier" and "interface" organizations corresponding to a new approach of the territory from the perspective of "sustainable development" according to the Brundtland Report (1987) which cannot be reduced only to environmental issues but is also based on two other pillars: economic (growth) and social (education, health and respect for freedoms) in a perspective of rethinking Welfare State (Rosanvallon).

---

improving the quality and continuity of care. The "summary patient", the "emergency case", the "drug issue" or "e-prescribing" are services designed to enhance patient safety by providing healthcare professionals the necessary medical information for better decision.

# ***App communication on Instagram: a netnographic study of a young human brand Isac Elliot***

*Anu Helkkula, Apramey Dube, Maria Holmlund, Tii Pylvänäinen,  
Arja Hallberg, Maria Hellberg*

Hanken School of Economics, Finland,

*Today social media, with its increasing popularity and rising user base, is the most fast-moving domain. Within social media, Instagram app is currently one of the fastest growing social media. Social media has been analyzed, but little attention has been paid to visual communication apps, such as Instagram. The purpose of this research is to analyze app communication addressing how human brands engage followers on Instagram. Today many celebrities are brands themselves and offer brand extensions of their personal images. We used netnography (Kozinets, 2002) and observed how a young human brand, a Finnish teenager schoolboy Isac Elliot engages his followers on Instagram. Two main themes emerged from the data: 1. Promotion with an explicit, intended outcome and 2. Pictures creating social contact without an explicit, intended outcome. The latter is less frequently focused on in media research, which has mostly addressed communication with intended outcomes focusing on offers, specific actions and the official identity of a celebrity brand. The findings indicate that Instagram is a suitable media to create social contacts in an intimate way for human brands to become an everyday partner in followers' lives. This is one of the first studies on app communication on Instagram. We contribute to research in social media, app communication, and branding addressing Instagram as an intimate media that is suitable for engaging a human brand into followers' everyday lives.*

## **1. Instagram as a visual communication app**

Communication in social media has exploded in recent years. Especially communication using smartphone applications (apps), which we call app communication, has gained more interest among marketers. Social media has several channels through which users can communicate within themselves, as well as, with companies. Facebook and Twitter are established social media platforms, however, in recent years a number of new social media channels have emerged (Walter and Gioglio, 2014). In this paper, we focus on Instagram as a social media channel for visual communication

Instagram is a social media platform for sharing pictures and short videos. Launched in October 2010, Instagram has emerged as one of the top social media platforms boasting of 300 million users in December 2014 (Albergotti, 2014). Available as web and mobile application versions, Instagram has facilitated sharing of more than 20 billion photos since its inception (Instagram, 2015). As a mobile app, Instagram is

free to download to its users and is available as Apple's iOS, Android and Windows Phone operating system versions.

Instagram allows its users to post photos or short videos (not more than 15 seconds) on Instagram, as well as other social media networks (such as Facebook and Tumblr), at the same time. Instagram is a short-form of the combination of the two words 'Instant' and 'Telegram' (Instagram FAQ, 2015) to reflect the ease of use and quickness ('instant') of sharing visual material over the internet (a networking medium, such as wired communication for telegrams). When using Instagram as a mobile app, photos and videos can be clicked directly with the phone camera, or, they can be uploaded from existing data on the phone to Instagram. One of the most essential use properties of Instagram is that it edits all the photos to acquire a square shape thus creating a uniform 'Instagram' photo specification.

Users can add more information to their photos by naming the location where the photo was taken, a short description of the photo and provide a specific theme or topic to the photo by adding a 'hashtag' keyword. The 'hashtag' keywords are used for structuring the multiple themes that users classify their photos in Instagram and is similar to the structuring mechanism used on other social media sites such as Facebook and Twitter (Pylvänäinen, 2014). With the help of hashtag (#) keywords, any user on Instagram can search and look for photos or short videos under a particular theme that is represented by the hashtag keyword. Thus, if twitter facilitates user-to-user discussions with text and other media (such as photos) under specific hashtags, Instagram is specifically used for visual user-to-user communication through photos and hashtag classifications.

The unique feature of Instagram is the availability of a number of photo filters that users can utilize to modify their pictures. The filters add special effects and/or various color tones to the original picture and are used for adding specific experiential aspects to the pictures, such as 'warmth', 'brightness' or 'sepia' (for evoking memories of black and white photo era).

Assessing the growing potential and future popularity of Instagram among social media users, the largest social media network Facebook acquired Instagram for a value of \$1 billion in April 2012, just after Instagram had launched its Android mobile app. (BBC News Technology, 2012). Among several strategic reasons, social media experts have often cited the strength of Instagram in the field of photo sharing as one of the key reasons for this acquisition (Hill, 2012).

On Instagram, each user can create a personalized Instagram profile that functions as the personal 'photo folder'. The photos in the folder can be shared to friends or be made public, where the users who can see the photos can both 'like' and/or comment on the photos. Users who wish to have a more private profile can choose their settings to a specific privacy level.

Users exhibit specific and distinct Instagram use profiles. Hu et al. (2014) have identified five distinct types of users based on their Instagram use patterns including the types of photos shared, frequency of sharing, and groups where photos are shared. They also concluded that the number of followers that an Instagram user has is independent of his/her photos that are shared.

In a similar attempt to classify Instagram users based on age, Jang et al. (2015) have investigated teenage users and they have concluded that teenagers post more self-photos (selfies) and express their self-identities through Instagram photos, as compared to adult users. Thus, Instagram is instrumental in the expression of self-identities of its users primarily through two methods: a) By sharing photos that reflect the user identity, and b) by commenting and liking other user photos, in turn exhibiting personal evaluations and opinions.

## **2. Celebrity branding**

One of the key characteristic of Instagram users is that it is the top social media preferred channel for celebrities to connect with their fans. Out of the top 100 accounts on Instagram, around 75 are owned by celebrity users such as sport celebrities, music celebrities and actors (Albergotti, 2014). To facilitate the celebrity-to-fan relationship authenticity, Instagram announced in December 2014 that it would start offering verified 'badges' for celebrity users, in order to verify the identity of celebrities to their followers on Instagram (Albergotti, 2014).

Several celebrities use Instagram to share images of their personal and professional everyday life events with their fans. For instance, Instagram is a popular social media channel to inform and promote music concerts, sports games, special events as well as everyday life mundane events in the life of celebrities. In his analysis of the phenomenon of artist-consumption in social media, Victorzon (2014) argues Instagram to be an appropriate medium through which it is possible to get a personal glimpse into an artist's life. This is important in facilitating artist-consumption in social media as Instagram is instrumental in forming a personal bond between social media/Instagram users and the artists they follow.

Whether the brand refers to an artifact, service or idol, a brand is determined by brand knowledge created in customers' minds by marketing programs and activities. Brand knowledge includes all thoughts, aspirations, feelings, perceptions, images and experiences that are linked to the brand in the minds of customers.

In this paper, we focus on celebrity brands. In the past decade, the number of celebrities and celebrity brands has increased dramatically due to the social media landscape. As a result, celebrity branding has emerged as a clear trend among audiences, who seek to be noticed in the entertainment field. A celebrity brand is defined as "a clearly defined personality and reputation of a well-known or a famous person who professionally labels, manages, or promotes him- or herself to consumers and other stakeholders for the purpose of commercially leveraging this unique image" (Kowalczyk and Royne, 2013:212). In the brand context, academic research has somewhat neglected the recognition of celebrity branding by limiting its efforts to celebrities as endorsers. Today many celebrities are brands themselves and offer brand extensions of their personal images. (Kowalczyk and Royne, 2013).

Likewise, the amount of so-called human brands has increased due to the digital entertainment market. A human brand refers to "any well-known persona who is the

subject of marketing communication efforts” (Kowalczyk and Royne, 2013:213). A celebrity can be conceptualized as a human brand and at times, the concepts are used interchangeably (Thomson, 2006; Moulard et al., 2015). Human brands or celebrities are introduced as both exceptionally special and very ordinary. Their value of celebrity is based on their unique personality and attractive qualities, but at the same time, they are treated as ordinary people facing the disappointments, problems, enjoyment and delights of everyday life. By doing so, the social and cultural barriers between the customer and the celebrity are removed leading to a strong attachment of familiarity and a relationship of intimacy between the celebrity and the customer. A strong emotional bond between the two is created. As a result, contemporary celebrity culture has succeeded to transform the so-called sophisticated and well-known into familiar, ordinary and intimate figures, which everyone knows or ought to know. The distance between the public and the famous is faded away and equally, the celebrity experiences the routines of everyday life of ordinary people. (Furedi, 2010)

In the customers’ world, brands acts as symbols for psychological and social purposes to express personal identities and to facilitate interactions with others. The customers’ self-concept influences their consumption behavior and acts as the sum of thoughts and feelings about themselves with respect to others. The self-concept contains two sides; actual self is the way how an individual perceives him-/herself, whereas ideal self reflects to how the individual would like to perceive him-/herself. Based on the self-concept, the customer acts in various ways to reach a condition, where the actual matches the ideal, influenced by self-esteem (or self-enhancement) and self-consistency (or self-knowledge). (Choi and Rifon, 2012)

Customers move constantly symbolic propensities out of brands into their personal lives for forming aspects of their self-concept and the world. Younger customers even borrow from a celebrity they admire in their identity construction. The celebrity becomes an exemplary, inspirational figure of cultural meanings relevant to their own personal development. A celebrity can represent a reference group, either actual or imaginary, that has a significant relevance on the younger customers’ evaluations, aspirations and behavior. (Choi and Rifon, 2012)

Typically, customers form strong attachment in the relationships of human brands. Thomson (2006) states that “attachments are a type of strong relationship that people usually first experience as children with their parents; later in life, these attachments routinely develop with other targets, such as human brands” (Thomson, 2006:105). Relationships involving human brands are similar to interpersonal relationships in many aspects. Customers experience these “seeming face-to-face” relationships with human brands as “as if they were in the circle of one’s peers” (Thomson, 2006,105). The human brand relationships have the same expectations, cognitions, emotions and behavior than so-called normal interrelationships and the customers consider a human brand as a pleasant companion, a good friend or even a romantic mate. However, these human brand relationships are not as truly interactive as normal interrelationships. (Thomson, 2006)

In this study we focus on an image sharing app, Instagram, where people can share images with friends and other followers with no or minimal text. Instagram was the fastest growing social network in 2014 (Techcrunch, 2014) Image sharing apps have

also started to interest companies, and many brands have created accounts and used Instagram (FastCompany, 2014; Walter and Gioglio, 2014).

Despite the success of image-based app communication, to date, it has gained little interest in marketing research. As a result, there is a somewhat continuous chaos among practitioners and a small amount of academic studies emphasizing image-based app communication. (Kaplan and Haenlein, 2010; 2012; Davis et al., 2014; Enginkaya and Yilmaz, 2014). To address this gap, and to the best of our knowledge, this is among the first papers to focus on app communication on Instagram.

The specific purpose of this research is to analyze app communication addressing how human brands engage followers on Instagram. Today many celebrities are brands themselves and offer brand extensions of their personal images. The amount of so-called human brands has increased due to the digital entertainment market. A human brand refers to “any well-known persona who is the subject of marketing communication efforts” (Kowalczyk and Royne, 2013:213).

We draw on Thompson (2006), who identifies that the human brand relationships have the same expectations, cognitions, emotions and behavior than so-called normal interrelationships and customers may consider a human brand as a pleasant companion, a good friend or even a romantic mate.

### **3. Engagement**

In an increasingly fragmented media society, brand communication is a challenging activity as there are several sources of information competing for the customers' minds (Hanna et.al., 2011; Solis 2011). The primary motive of social media users is to communicate and engage with fellow users (Lin and Lu, 2011; WeAreSocial 2015b). There are, however, significant number of users, who follow brands and share brand-related content on social media (Solis, 2011).

Customers who follow brands on social media are found to be more aware of brand news and activities (de Vries, Gensler and Leeftang, 2012). Brand communication content plays a vital role in attracting customer attention on social media, where specific efforts are made to attract deeper attention of the customers (Solis, 2011; Walter and Gioglio 2014). One of the key features of social media is that brands can utilize social media channels for deeper attention as customer engagement platforms. Brodie et. al (2011) define customer engagement as:

"Customer engagement (CE) is a psychological state that occurs by virtue of interactive, cocreative customer experiences with a focal agent/object (e.g., a brand) in focal service relationships. It occurs under a specific set of context-dependent conditions generating differing CE levels; and exists as a dynamic, iterative process within service relationships that cocreate value."

Social media users are classified into different types according to the level of engagement (Hellberg, 2015). Users, who engage the most, are labelled as influencers (Peters et.al., 2012) and they are followed by other users in social media communities. On the other end of the scale are users who watch, read, and consume

content online, yet do not engage in a discernible way. Such users are labelled as lurkers (Chen and Chang 2013; Crawford 2009; Heinonen 2011; Schneider, von Krogh and Jäger, 2012). Lurkers do not engage sufficiently with brands because of several reasons – such as, shyness, inability to devote time, desire to remain anonymous, or the volumes of content being unsuitable (Schneider et.al., 2012). Thus, brand managers strive to have as many influencers as possible to engage on social media, whereas at the same time making efforts that users do not fall into the lurkers category.

Instagram followers engage at different levels as the channel and app facilitates several levels of engagement. Through Instagram, simplest engagement activity is liking a picture, whereas a high engagement activity would be to post and share an original picture with hashtags. Instagram is a visual content social media channel, therefore the engagement of followers is dependent on the visual content that users will like to engage with. Engagement on Instagram would thus require the visual content to be appealing and specifically engaging to the target audience. A user may take or share a screenshot of another user's image and post it as his/her image. This action reflects an even higher level of engagement for the brand associated with the image.

Attaining customer engagement on social media has no standard recipes for brand managers (Brodie, Hollebeek, Juric and Ilic, 2011; Hollebeek, Glynn and Brodie, 2014; Solis, 2011) and an overarching engagement approach is difficult to develop. Hollebeek et. Al., (2014) presents a consumer brand engagement conceptualization and measurement scale, developed with the help of Facebook, Twitter and LinkedIn users. The conceptualization, however, does not explain the underlying motives for users to engage with specific content more than others, and is channel dependent. Thus, customer engagement for visual social media channels like Instagram is not yet adequately researched.

## **4. Method and findings**

The human brand in this study is a Finnish school boy, a young pop artist, singer Isac Elliot Lundén, with an artist name Isac Elliot. He published his first record in 2013 when he was thirteen years old. He has active fans in addition to his home country in Norway and Sweden. In 2014 he was nominated to be the "Innovator of The Year" by Spotify in the Finnish Emma Gala for using digital media to be in contact with his followers. Currently Isac Elliot is trying to access the U.S. market. In just couple of years, he has transformed from a teenager schoolboy into a human brand.

We used netnography (Kozinets, 2002) and one researcher observed for one year (2013) how Isac Elliot as a human brand engages his followers on Instagram. The target was Isac Elliot's Instagram page, and all pictures and videos he had published. In order to answer our research question how human brands engage followers on Instagram, we addressed the following sub-research questions in our netnographic study: 1. What kind of pictures/videos does Isac Elliot post to his followers?, and 2. What type of app communication does he use in his postings?.

First all 522 pictures and videos (in 2013) were categorized based on their character. The accompanying brief text descriptions were used as a supporting criterion for our categorization. The analysis resulted in three main categories: (1) artist pictures/videos, (2) pictures/videos of Isac Elliot's everyday life, and (3) fan pictures/videos. The first category included all pictures related to his music career (promotion pictures, pictures of instruments, concert/ studio/interview pictures, pictures of shooting a music video, pictures of film shooting trips etc.). This category also includes such pictures that don't directly show his music career, but where the relation to career is described in text, for example "Now I will go to New York to shoot my new music video". Second category, pictures/videos of Isac Elliot's everyday life, expresses him as a 'normal person' and doesn't relate to his music or career. They are pictures of his family members, friends and his dog, pictures of what he eats, his home, school etc. The third category, fan picture/videos, shows Isac Elliots fans, fan post and pictures that fans have sent him.

In the send phase, all pictures and videos were categorized into two categories: (i) pictures with an explicit purpose, and (ii) pictures without an explicit purpose. Pictures with an explicit purpose included pictures, where he in a way or another communicate with fans or is marketing himself. Some pictures were presented with a question to the fans, a competition to engage his followers, advertisement for his new music, concert, tours, videos, products, events etc., often posted with a hashtag. In addition, such pictures are included into the explicit purpose category, where Isac Elliot specifically addresses his fans, for example thanks them for one million views in Youtube. The second category, pictures without an explicit purpose, includes pictures where Isac Elliot for example tells his followers what he has done or where he has been, but doesn't call for any kind of response, and there is no explicit marketing or information of future events, his music or career.

Table 1 summarizes findings and shows that the most pictures in Isac Elliot's Instagram profile are about his artist career (383 pictures/videos, ca 73% of all pictures/ videos in 2013). However, 124 pictures/videos he published in 2013 present his everyday life, which counts for 24 % of all pictures/videos. Only 16 pictures/videos of all 522 are fan pictures.

Table 1 Different types of pictures/videos that Isac Elliot has published in his Instagram profile in 2013.

| Type of pictures/videos              | No of artist pictures / videos | No of pictures/ videos of his daily life | No of fan pictures/ videos | Total |
|--------------------------------------|--------------------------------|--|----------------------------|-------|
| Pictures with an explicit purpose    | 214                            | 42                                       | 7                          | 263   |
| Pictures without an explicit purpose | 168                            | 82                                       | 9                          | 259   |
| Total                                | 382                            | 124                                      | 16                         | 522   |

The findings reveal that Isac Elliot actively engages his followers on Instagram. He distributes approximately two postings per day. We did a thematic analysis, and two

main themes emerged from the data: 1. Promotion with an explicit, intended outcome and 2. Pictures creating social contact without an explicit, intended outcome. We further analyzed what kind of app communication is used in the promotion pictures with an explicit, intended outcome. We identified six categories: 1. Marketing promotion of concerts, music, products, events etc. (42%), 2. Use of a hashtag (#) that directly links to Isac Elliot (32%), 3. A specified message to his followers (10%), 4. Questions to his fans (7%), 5. Competitions or promotion of competitions (5%), and 6. Voting or promotion to vote (4%).

Isac Elliot frequently uses hashtags in his postings. 85 pictures/videos (32%) of the pictures/videos with an explicit purpose include hashtags. Hashtags may also engage followers into direct action, but not as directly as a call for voting or competing.

Even if Isac Elliot actively promotes his human celebrity career on Instagram, over 40 % of the pictures/videos are presented without an explicit, intended outcome. We further analyzed such pictures/videos and found that ca 50 % of the pictures without an explicit, direct outcome focus on Isac Elliot's everyday life. Many pictures were taken at his home, such as chilling with his dog or getting ready for school. The findings portray a young human celebrity, who using app communication, up to some extent shares his everyday life with his followers and becomes part of his followers' daily lives as they check his postings on a daily bases.

## 5. Discussion

In today's media density, the challenge is to draw people's attention and in specific to engage them to a brand. Brand managers require information about the ways in which users engage with brand content. A high brand engagement causes the rband to remain relevant for its followers and creates strong word-of-mouth, positive attitude, and strong brand loyalty (Peters et.al., 2012).

Instagram is a specific type of social media channel that facilitates visual user-to-user communication. Kaplan and Haenlein (2010) have proposed a social media classification matrix under the categories of 'self-presentation' and 'media richness' (Table 1).

Table 1: Social Media Classification ( Kaplan and Haenlein, 2010)

|                                       |      | Social presence/ Media richness             |   |  |
|---------------------------------------|------|---|---|--|
|                                       |      | Low   | Medium                                      | High   |
| Self-presentation/<br>Self-disclosure | High | Blogs                                       | Social networking sites<br>(e.g., Facebook) | Virtual social worlds<br>(e.g., Second Life)     |
|                                       | Low  | Collaborative projects<br>(e.g., Wikipedia) | Content communities<br>(e.g., YouTube)      | Virtual game worlds<br>(e.g., World of Warcraft) |

In this classification schema, Instagram would occupy a similar position as Facebook that is characterized by high degree of self-disclosure to other users and a medium degree of media richness. The unique feature with Instagram is that it is specifically positioned as an application for photo sharing, in contrast to Facebook and Twitter. Facebook is a multiple media sharing environment and supports sharing of text, videos (of considerable length) and even virtual games. On the other extreme, Twitter facilitates a succinct textual conversation restricted to 140 characters among users. Instagram possesses the agility of Twitter combined with the visual richness associated with Facebook.

One of the key characteristic of Instagram users is that it is the top social media preferred channel for celebrities to connect with their fans. Out of the top 100 accounts on Instagram, around 75 are owned by celebrity users, such as sport celebrities, music celebrities and actors (Albergotti, 2014). To facilitate the celebrity-to-fan relationship authenticity, Instagram announced in December 2014 that it would start offering verified 'badges' for celebrity users, in order to verify the identity of celebrities to their followers on Instagram (Albergotti, 2014).

Several celebrities use Instagram to share images of their personal and professional everyday life events with their fans. For instance, Instagram is a popular social media channel to inform and promote music concerts, sports games, special events, as well as everyday life mundane events in the life of celebrities. In his analysis of the phenomenon of artist-consumption in social media, Victorzon (2014) argues Instagram to be an appropriate medium through which it is possible to get a personal glimpse into an artist's life. This is important in facilitating artist-consumption in social media as Instagram is instrumental in forming a personal bond between social media/Instagram users and the artists they follow.

Our findings indicating that a human brand may become an everyday partner in followers' lives are supported by Thompson (2006), who identifies that the human brand relationships have the same expectations, cognitions, emotions and behavior than so-called normal interrelationships and that customers consider a human brand as a pleasant companion, a good friend or even a romantic mate. The findings show that in Isac Elliot's Instagram postings are close to as many pictures/videos with an explicit (214), and without an explicit purpose (168). In the pictures/videos without and explicit purpose, he more presents his identity as a "friend". We contribute to research in social media and branding addressing Instagram as an intimate media that is suitable for engaging a human brand into followers' everyday lives.

The study has implications for researchers and managers. While Instagram is a potential media to engage followers in the media communication jungle, its character and potential media effects are currently a gap in app communication and brand engagement research. This offers avenues for celebrity-follower one-to-one engagement studies, as well as future studies on other types of brands that are keen to intimately engage with their followers.

We have limited our study on human brands, and to one celebrity on Instagram, who is popular among teenagers, and especially girls. Therefore, we encourage

researchers to address celebrities for different target groups and different visual social media channels, such as Pinterest and Tumblr, which are both emerging visual apps especially targeted for teenagers. While app communication opens up interesting research questions for brand research, we encourage future research to extend to other types of brands on Instagram. Furthermore, even if recent research indicates that lurkers interact with brand content on social media (Chen and Chang, 2013), their engagement is not manifested in any discernible form, and current research has addressed limited attention on engagement of lurkers.

# Electronic Auctioning of Services

***Ute Reuter***

VWA-Hochschule Stuttgart, Germany

*In times of high financial pressure on business units, electronic auctioning devices are a viable possibility to save costs in purchasing services but meet resistance in business practice. This resistance is subject of a quantitative-empirical survey. Results show that hindrances are mostly based on management team, human capital and external resources. Considering the importance of external resources, the relational resource-based perspective is an especially appropriate theoretical background for this scientific paper. In addition, case study research identifies ways to overcome these hindrances. The creation of 'magical moments' and communication between stakeholders prove to be acceptable solutions.*

## Key Words

Electronic auction; purchasing services; services procurement; electronic procurement; service auction; electronic marketplace; digitalization.

## 1. Introduction

In times of ever increasing financial pressure on business units, the utilization of electronic purchasing devices such as electronic auctioning, electronic catalogue management and electronic marketplaces is a viable possibility to achieve cost savings in purchasing, especially in purchasing of material. A large share of this cost savings potential is achievable in purchasing services as well, even if considering the characteristic features of services. Of the three mentioned ways of electronic purchasing, electronic auctioning is the one with the highest cost savings potential. Therefore, this scientific paper concentrates on electronic auctioning.

However, electronic auctioning of services is a concept which meets resistance in business practice. This research paper highlights several hindrances in electronic auctioning of services. Three different problem areas are tackled: obstacles within the company purchasing the services itself, obstacles grounded in the relationship between the company purchasing the services and the company offering the respective services and also obstacles based on the involvement of the intermediary who provides the electronic auctioning devices.

Furthermore, this research paper shows ways to overcome these resisting forces in business practice in general and in the facility management branch in particular. Especially important prove the creation of 'magical moments' for the company's own employees as well as the improvement of communication between the company's own employees with the employees of the intermediaries and with the employees of the companies offering the procured services.

Hence, this research paper provides an overview over business practice in electronic auctioning devices and offers guidance in what concerns their actual implementation. Theoretical Background and Research Question

The actual implementation of ICT in the procurement process leaves much to be desired (Quale, 2005). Improvements can only be achieved if a so-called “internal customer satisfaction” (Croom and Brandon-Jones, 2007: 295) with the (potential) implementation is reached. Ellram and Zsidisin (2002) propose that the degree of closeness between the purchasing company and the (potential) subcontractor strongly determines the tendency to use e-procurement. This means that purchasing partners which implicitly trust each other are more likely to use e-procurement in general and electronic auctioning of services in particular. Arnold and Schnabel (2007) researched the role of reverse auctions in purchasing material and Kumar and Chang (2007) analyzed the cost savings potential of reverse auctioning. Laumer (2011) gave an overview over recent ‘resistance to change’-publications with information and communication technology (ICT) component. Rajkumar (2001) for example elaborated on the importance of system integration for e-procurement and concluded that the ICT systems of purchasing company and subcontractors have to be compatible for successful e-procurement implementation. Emphasizing a more theory-based approach, Bartezzaghi (2007: 195) proposed that “it is necessary to consider the state of the art in innovation adoption and diffusion models, with a specific focus on ICT” in order to explain e-procurement adoption. This argument should furthermore be expanded by resource-based theory and the relational view (van Weele and van Raaij, 2014) as well as the resources of the purchasing company and the external resources from subcontractors and intermediaries are of utmost importance for the whole procurement business. Reuter (2013) for example offered insights into electronic procurement of services from a relational resource-based perspective. Relational resource-based perspective in this case means the integration of the relational view (Dyer and Singh, 1998) into the resource-based view (Lavie, 2004). This line of theory integration is especially apt as purchasing and supply management research is, at the moment, not considered to be able to provide insights into the management of subcontractors as external resources (van Weele and van Raaij, 2014).

Croom and Brandon-Jones (2007) stated that there are very few empirical studies which tackle the problem of e-procurement implementation. This is even more so for specific questions such as the topic of hindrances in electronic auctioning of services. First, purchasing of services is not adequately investigated in literature (Bensch and Schrödl, 2011). Especially under-researched is business-to-business service exchange (van der Valk and Wynstra, 2012). Second, electronic purchasing of services is even less well studied. And third, no research projects in electronic auctioning of services other than Reuter (2013) are known to the author.

In this paper, one important influence factor in electronic auctioning of services is scrutinized: the hindrances. If a company thinks about implementing electronic auctioning, it is very important to know which hindrances exist and how resistance can be overcome. Ronchi et al. (2010) asked for the barriers of e-procurement implementation. In their research, they concentrated on barriers related to IT-categories only and did not consider other resource categories. This shortcoming is amended in my paper as human capital, management team, financial resources, organizational capital and external resources are considered.

Figure 1 provides an overview over the different stakeholders in electronic auctioning of services (Reuter, 2013). Central institution is the purchasing company itself which is supported by the intermediary and various subcontractors (1 to n).

To clarify the wording in this paper, different categories of members of the purchasing company are allocated according to relational resource-based argumentation. Members of the management team are referred to as ‘management team’ and members of staff are referred to as ‘employees’ or ‘human capital’. Employees of the sub-contractors and of the intermediary are referred to as ‘external resources’.

**Figure 1: Relationship between subcontractor, intermediary, purchasing company and ultimate buyer**

## 2. Resource-based hindrances

Impeding forces influence the powers which normally would impel the implementation of innovative ICT devices such as electronic auctioning. Seen from a resource-based perspective, the main hindrances can be categorized into hindrances based on human capital, management team, financial resources, organizational capital and external resources.

First of all, the human capital of the company purchasing services can embody obstacles for electronic auctioning of services. The implementation and utilization of ICT in the purchasing of services is often subject to resistance of employees within the company in which the process change takes place (Johnson and Real, 2007). They do not automatically view changes in a positive light only because the management team does so (Reuter, 2015a).

Different causes of human capital's resistance can be isolated. Transformation readiness is a critical factor in electronic procurement in general and in electronic procurement of services in particular (Monczka and Trent, 1991). Advanced knowledge in conventional procurement vests authority within the procurement department. An employee who is equipped with such advanced knowledge tends to hold onto his or her authority. Therefore, the implementation of electronic auctioning devices evokes resistance unless the employee sees some benefit in the change as well. This is even more so if the process change is imposed upon the employee in a top-down way. Then, his so-called 'power of usual practice' turns out to be a mighty hindrance (Aladwani, 2001) for electronic purchasing in general and electronic auctioning in particular.

Resistance to change is often motivation-induced. Motivation can originate from positive stimuli and team development activities. Focusing solely on incremental process improvement tends to blight radical process innovation initiatives (Reuter, 2013 and

2015a). Employees fear to loose competencies. Most employees do not fear new processes but fear to lose power and knowledge. Even clearly positive changes can provoke such fears and insecurities (Kotter and Schlesinger, 1979). Application of Sheth's (1981) argumentation on risk perceptance leads to the following conclusion: The more pronounced these fears are, the more important becomes the employees' resistance against electronic auctioning of services and the more intensive is the employees' risk perceptance.

Apart from the discussion about transformation readiness and transformation ability of the employees, a purely pragmatic reason can hamper the utilization of electronic auctioning of services. In pre-ICT times, each and every company purchased its services from subcontractors without using electronic auctioning devices. Hence, most companies with a few years of company history have already developed purchasing processes which do not integrate electronic auctioning. The implementation of electronic auctioning of services is a time-consuming process. Especially small and medium-sized companies spare the effort to implement new devices as the employees concerned with purchasing services have other important topics on their mind. The clincher in this case not to think about electronic auctioning of services is a pure lack of manpower.

A second important category of obstacles within the company purchasing services goes back to the members of the management team. On the one hand, the management team decides on the importance of purchasing services - in other words: the buy-quota of services - within a company. This buy-quota, however, influences the implementation of electronic auctioning. If the purchasing of services is a single sensation within a company, the incentive for the management team to think about improving the efficiency or the costs of this onetime experience is near zero. This will not change until the number of purchased services rises significantly. Then, the necessity to define a concise service purchasing process arises. In the course of this service purchasing process definition, an ICT-inclined management team will certainly think about ways to alleviate purchasing services. Hence, the influence of the management team on the buy-quota and therewith on electronic auctioning of services should not be disregarded.

On the other hand, the management team often overlooks resistance in its 'technocratic euphoria' (Reuter, 2013) or otherwise, completely opposes electronic auctioning of services. Such complete opposition nips electronic auctioning initiatives in the bud. Without management team support, electronic auctioning initiatives cannot succeed within the purchasing company (Reuter, 2015a).

Furthermore, hindrances can be based on financial resources, or more correctly, the lack of these. A high buy-quota goes along with the need to maintain relationships with subcontractors. This is a costly thing. Theoretically, utilizing electronic purchasing devices such as electronic auctioning reduces these costs (Brynjolfsson and Hitt, 2000). In practice, however, the implementation of electronic auctioning devices is costly itself and the positive, cost diminishing effects come across not until some time has passed. Hence, practitioners see the short-term costs and tend to overlook the long-term benefits. Hindrances based on financial deliberations could therefore be that the utilization of electronic auctioning is thought of as not profitable and that the initial procurement of the electronic auctioning device itself seems to be too expensive even to consider the implementation.

Sometimes, the existing organizational capital within the purchasing company can be problematic as well. High expectations placed on the procurement function within the company need to manifest themselves in adapted organizational structures (Schneider and Wallenburg, 2013). Each company with experiences in service purchasing

has a more or less well described service procurement process. Hence, the better the description of the service procurement process is, the higher is the incentive for the respective employees with expert knowledge to preserve this well-known and easy-to-handle procurement process. The already existing 'normal' procurement process can be classified as organizational capital of the company with the tendency to hinder the implementation of electronic auctioning. In this case, the service procurement process does not support electronic auctioning easily.

Last but not least, electronic auctioning implies that the purchasing company has a need of services which they cannot provide with their own employees (in resource-based terms: they need the support of external resources). The employees of the sub-contractor are forced to deal with electronic auctioning devices as well, if the procuring company uses electronic auctioning. The utilization of electronic service auctions often requires cooperation between offering and procuring company and an intermediary as well. In this case, the intermediary is a company offering ICT-based auctioning devices and support in their utilization. All three companies in question consist of many different employees. Most of them lack the awareness that changes are a necessary and unavoidable by-product of process improvement. Hence, all the employee-based causes of resistance which were discussed for hindrances based on human capital (see the first few paragraphs of this selfsame chapter) are applicable for the sub-contractor's employees as well.

Furthermore, there are hindrances which arise especially because of the cooperation between purchaser, subcontractor and/or intermediary. Cooperative relationships develop between the company procuring services, the company offering the procured services and/or the intermediary. These relationships can be an impeding force (Monczka and Trent, 1991) as hierarchies within both companies and the network between the companies have to be balanced. This is especially problematic if the employees of the subcontractor see electronic auctioning "as a tool that buyers use to increase and exploit a position of power in the relationship" (Caniels and van Raaij, 2009: 12). Often, in this case, the offering company outright refuses to take part in any kind of electronic auctioning of services.

### **3. Quantitative-empirical research**

#### **3.1. Questionnaire and analysis**

The existence and importance of most of the resisting forces mentioned in section 2 are exemplary proven by a quantitative-empirical survey within the facility management branch in Germany. The questions in the questionnaire were closed questions with five answer alternatives ranging from 'fully accept' to 'do not accept at all'. The consistence of the questions was tested prior to the actual survey. The pretest included 30 facility management or survey experts. The survey itself took part in May and June 2011. All in all, 1,048 facility management companies were asked to participate of which 134 answered questions relevant for research about electronic auctioning of services, resulting in a response quote of 12.79%. Participants were asked per e-mail to answer an online questionnaire.

Figure 2 shows that 16 companies used electronic auctioning of services at the moment of questioning. 96 of the analyzed companies did not use electronic auctioning of services and had no ambition to use it in the near future. 22 of the analyzed companies did not use electronic auctioning of services at the moment of questioning but

plan to use it in the near future. Hence, 88% of the sampled companies provide relevant information for the quantitative-empirical analysis in question.

**Figure 2: Utilization of electronic auctioning of services**

Table 1 summarizes the main hindrances in electronic auctioning of services from the viewpoint of those companies which did not use electronic auctioning at the moment of questioning.

| <i>Hindrances</i>         | <i>Item</i>  | <i>Abbreviation</i> |
|---------------------------|--|---------------------|
| 1. management team        | refusal of electronic auctioning of services by management team    | REFU                |
| 2. human capital          | not enough manpower  | MANP                |
| 3. financial resource     | utilization of electronic auctioning is not profitable             | PROF                |
|                           | procurement of electronic auctioning device is too expensive       | EXPE                |
| 4. organizational capital | service procurement process does not support electronic auctioning | SUPP                |
| 5. external resources     | refusal by offering company (subcontractor)                        | OFFE                |

**Table 1: Hindrances from the viewpoint of companies which did not use electronic auctioning**

### 3.2. Results and discussion

A different number of companies provided answers to each relevant question (see table 2). As the quantitative-empirical research project is explorative in nature, this does not diminish the relevancy of possible findings.

In each column of table 2, three different numbers are given. ALL (the first number on the left) informs about statistical data concerning all companies which did not use electronic auctioning of services at the moment of questioning. PLAN (the left number in brackets) gives statistical data about the group of companies which did not use electronic auctioning of services at the moment of questioning, but plan to do so in the future. NO (right number in brackets) tells about the companies which did not use

electronic auctioning of services at the moment of questioning and have no intention to use it in the near future.

| <i>Abbreviation</i> | <i>Quantity*</i> | <i>Mean*</i>     | <i>Standard deviation*</i> | <i>Variance*</i>    |
|---------------------|------------------|------------------|----------------------------|---------------------|
| REFU                | 103 (21/82)      | 3.19 (3.76/3.05) | 1.401 (0.944/1.465)        | 1.962 (0.890/2.146) |
| MANP                | 45 (11/34)       | 3.76 (3.45/3.85) | 1.209 (0.820/1.306)        | 1.462 (0.673/1.705) |
| PROF                | 90 (19/71)       | 2.98 (3.58/2.82) | 1.349 (0.961/1.397)        | 1.82 (0.924/1.952)  |
| EXPE                | 78 (18/60)       | 3.29 (3.67/3.18) | 1.359 (1.085/1.420)        | 1.847 (1.176/2.017) |
| SUPP                | 86 (19/67)       | 3.13 (3.21/3.10) | 1.282 (0.918/1.372)        | 1.642 (0.842/1.883) |
| OFFE                | 86 (19/67)       | 3.26 (3.84/3.09) | 1.16 (0.898/1.177)         | 1.346 (0.807/1.386) |

\* ALL (PLAN/NO)

**Table 2: Statistical data concerning these hindrances**

Table 3 gives an overview over the correlation between items concerning the observed main hindrances for all companies in question. For the majority of correlations, Pearson's  $r$  surpasses 0.3. Hence, correlation analysis indicates that there is a common structure within the analyzed data. According to Field (2011), explorative factor analysis is applicable in this case. Principal component analysis and the ensuing scree plots show that it is possible to describe the relevant items in one component. Table 4 shows the results of explorative factor analysis. The Bartlett-test is highly significant (Field, 2011) for ALL, PLAN and NO alike and Cronbach's alpha, which is much higher than the requested 0.35, strongly confirms the construct's reliability (Van de Ven and Ferry, 1980).

| Pearson's $r$ | REFU   | MANP   | PROF   | EXPE   | SUPP   | OFFE |
|---------------|--------|--------|--------|--------|--------|------|
| REFU          | 1      |        |        |        |        |      |
| MANP          | .227   | 1      |        |        |        |      |
| PROF          | .531** | .190   | 1      |        |        |      |
| EXPE          | .268** | .249   | .665** | 1      |        |      |
| SUPP          | .270** | .378** | .362** | .528** | 1      |      |
| OFFE          | .357** | .346*  | .488** | .502** | .353** | 1    |

\*\* Statistically significant at the 0.01 level; \* statistically significant at the 0.05 level

**Table 3: Correlation between items concerning main hindrances for ALL**

In case of ALL, factor loadings are above 0.5 for each of the tested items. All items are applicable in the description of the respective component. Only the item EXPE could be problematic because of the extracted communality which surpasses 0.5 only slightly. However, as either the extracted communality or the factor loading can be used as arbitration criterion (Hair et al., 2010), the relatively low extracted communality is not important after all. The value of the Kaiser-Meyer-Olkin criterion

(K-M-O) > 0.7 indicates that the construct is quite good in measuring the sample (Brosius, 2006).

| Item | Extracted Commu-<br>nality* | Factor Loading*     | Con-<br>struct | Cronbach's<br>alpha*       | K-M-O*                     | Bartlett*                  |
|------|-----------------------------|---------------------|----------------|----------------------------|----------------------------|----------------------------|
| REFU | 0.622 (0.547/0.370)         | 0.660 (0.678/0.560) | HINDRANCES     | 0,648<br>(0,661/<br>0,636) | 0,717<br>(0,669/<br>0,684) | 0,000<br>(0,000/<br>0,000) |
| MANP | 0.688 (0.523/0.817)         | 0.593 (0.282/0.218) |                |                            |                            |                            |
| PROF | 0.820 (0.558/0.704)         | 0.783 (0.712/0.768) |                |                            |                            |                            |
| EXPE | 0.513 (0.532/0.592)         | 0.706 (0.707/0.768) |                |                            |                            |                            |
| SUPP | 0.663 (0.716/0.403)         | 0.621 (0.551/0.549) |                |                            |                            |                            |
| OFFE | 0.539 (0.532/0.429)         | 0.731 (0.724/0.650) |                |                            |                            |                            |

\* ALL (PLAN/NO)

**Table 4: Explorative factor analysis and test results**

In case of PLAN, table 4 shows a few differences. Extracted communalities and factor loadings are significantly lower. Especially the item MANP seems to be problematic with its really low factor loading. However, the value of the extracted communality > 0.5 allows to continue the analysis with this item. It has to be noted that the construct's ability to measure the sample of the PLAN-companies is lower, but still in a medium range (Brosius, 2006). In case of NO, extracted communalities are well below 0.5 for REFU, SUPP and OFFE. But as factor loadings are above 0.5 for these items, they can be integrated nonetheless. The same is true for MANP but for different reasons. For this item, factor loading is too low, but the extracted communality is sufficient. To sum this up, HINDRANCES including the items REFU, MANP, PROF, EXPE, SUPP and OFFE is a reliable construct to measure the whole sample (ALL) as well as the sample groups PLAN and NO.

| Item | Wilks Lambda | F      | df1 | df2 | Significance |
|------|--------------|--------|-----|-----|--------------|
| REFU | .957         | 25.099 | 1   | 560 | .000         |
| MANP | .994         | 3.145  | 1   | 560 | .077         |
| PROF | .969         | 17.670 | 1   | 560 | .000         |
| EXPE | .975         | 14.384 | 1   | 560 | .000         |
| SUPP | .997         | 1.593  | 1   | 560 | .207         |
| OFFE | .950         | 29.736 | 1   | 560 | .000         |

**Table 5: Equality test of group mean values**

However, explorative factor analysis has also shown that there are certain differences between the sample groups PLAN and NO. In order to observe these differences in a more convincing and statistically adequate way, stepwise discriminant analysis was carried out.

Wilk's Lambda is quite high for all tested items (see table 5). That means that the predictive value of the items in what concerns their explanatory power could be better (Klecka, 1982). The significance is high or very high for all items except SUPP, thus indicating that the item SUPP will probably be excluded as important variable during the following analysis. This proves to be true as can be seen in table 6.

| <i>Step</i> | <i>Item</i> | <i>Tolerance</i> | <i>F-Value of exclusion</i> | <i>Min. D-square</i> |
|-------------|-------------|------------------|-----------------------------|----------------------|
| 1           | OFFE        | 1.000            | 29.736                      |                      |
| 2           | OFFE        | .953             | 19.078                      | .278                 |
|             | REFU        | .953             | 14.533                      | .329                 |
| 3           | OFFE        | .935             | 21.848                      | .329                 |
|             | REFU        | .951             | 15.183                      | .405                 |
|             | MANP        | .976             | 7.118                       | .499                 |

**Table 6: Stepwise discriminant analysis**

Table 6 shows that of the six tested main hindrances (items), three are included in the stepwise discriminant analysis: OFFE, REFU and MANP. These items offer the highest discriminatory power. The following canonic discriminant functions emerge:

$$Y_{\text{non-standardized}} = -2.333 + 0.415 X_{\text{REFU}} - 0.267 X_{\text{MANP}} + 0.567 X_{\text{OFFE}}$$

$$Y_{\text{standardized}} = 0.569 X_{\text{REFU}} - 0.387 X_{\text{MANP}} + 0.684 X_{\text{OFFE}}$$

With the non-standardized canonic discriminant function, the group centroid for PLAN is 0.611 and the group centroid for NO is -0.154. The negative algebraic sign in the case of MANP shows that this item is more important for the NO-group whereas the positive algebraic signs in the cases of REFU and OFFE indicate that these items have a higher importance for the PLAN-group.

| <i>Wilks Lambda</i> | <i>Chi-square</i> | <i>df</i> | <i>Significance</i> | <i>Eigenvalue</i> | <i>% of variance</i> | <i>Accumulated variance (in %)</i> | <i>Canonic correlation C</i> |
|---------------------|-------------------|-----------|---------------------|-------------------|----------------------|------------------------------------|------------------------------|
| .914                | 50.309            | 3         | .000                | .094              | 100.0                | 100.0                              | .293                         |

**Table 7: Statistical data about the canonic discriminant function**

The higher the canonic correlation (C), the better is the explanatory power of the respective discriminant function (Klecka, 1982). In this case, the explanatory power of the canonic discriminant function is in the medium range. However, the function is highly significant (see table 7) and 67.8% of the originally grouped cases are classified correctly.

As a result, discriminant analysis shows that there are certain differences between the two groups PLAN and NO. The differences within the items MANP, REFU and

OFFE are most important. For companies which do not use electronic auctioning of services and have no intention to do so in the near future (group NO), the lack of manpower (MANP) is the main hindrance in implementing electronic service auctions. Companies with the intention to use electronic auctioning in the near future (group PLAN) put more importance on the negative attitude of management team (REFU) and subcontractors (OFFE) towards electronic auctioning of services when the question arises why they do not procure via electronic auctioning. Statistically speaking, however, these differences are not as pronounced as first assumed.

## **4. Qualitative-empirical research**

Several hindrances in the implementation of electronic auctioning of services were identified in section 4. Successful ways to overcome these hindrances, however, cannot be found in analyzing companies which do not use electronic auctioning of services themselves. Instead, companies which have already overcome these hindrances and have found successful ways to reduce resistance are of interest. Therefore, methods to reduce resistance are described in detail in two in-depth case studies with companies which already use electronic auctioning of services. Following van der Valk and Wynstra (2012), case study research is used to test the assumptions in question.

### **4.1. Case study selection, methodology of case study execution and a short overview over the selected companies**

The success of qualitative-empirical analysis is determined by the selection of the case study companies (Eisenhardt, 1989). As a sampling strategy, criterion sampling was used. Selection criteria to find the most suitable case study companies were the following.

First, the leading facility management companies concerning their volume of sales were identified. Ten facility management companies had a volume of sales of 350 Mio. Euro or more in Germany at the moment of case study selection. Three of these ten companies volunteered to take part in an extensive, longitudinal case study research: M+W Zander D.I.B. Facility Management GmbH (M+W), Bilfinger Berger Facility Services GmbH (BBFS), and a third company which declined to see their company name published. Therefore, this third company is labelled Full Service Provider GmbH (FSP).

Second, experts within these three companies were asked if the procurement department was taking part in electronic auctioning of services or not. If not, they were asked if they had any intention of implementing electronic procurement of services in the near future or not.

M+W had utilized electronic auctioning of services since 2002. Therefore, M+W was a clear candidate for case study integration in this research project. As for M+W, the firm's development at the time of the first case study interview was determined by continual growth. The company showed a very high subcontract quota (buy component) while its share of in-house services (make component) was comparatively low. The organization of strategic procurement was highly centralized, but operational procurement showed tendencies of decentralization.

BBFS answered that they did not auction services electronically but had an inclination to do so in the near future. Therefore, they were a viable candidate for integra-

tion as case study partner in this research project as well. In 2009, during the case study execution, they started implementing electronic catalogue management of services. In 2010, BBFS had risen to be first of the high-selling facility management companies in Germany (e.g. Hossenfelder, 2010). BBFS's subcontract quota was slightly lower than that of M+W. Meanwhile, the organization of strategic procurement at BBFS was centralized whereas operational procurement was increasingly decentralized.

FSP did not auction services electronically. The interview partners indicated that the company had no inclination to start procuring services electronically in the near future. During the timeframe of case study execution, they did not start procuring electronically. Therefore, the case study I did in this third company does not provide relevant information for the research project on hand.

All in all, five in-depth expert interviews per case were conducted with different employees of the respective procurement departments. Each expert interview lasted at least two hours.

At M+W, mostly closed auctions were used. Participation at electronic auctions was restricted to offering companies which had beforehand passed through an extensive evaluation process. The electronic auction did not serve as a device to unearth adequate offering companies but as a price finding mechanism only. The electronic auctioning software was provided by a neutral intermediary. M+W was very content with the software functions and the support of this intermediary. From the start of electronic auctioning in 2002 until the conclusion of the last case study interview, the same intermediary provided the electronic auctioning software. Hence, the employees of M+W's procurement department showed experience in electronic auctioning of services.

In contrast, BBFS started procuring via electronic auctioning as late as 2010. Hence, the employees of the procurement department had not much practical experience with electronic auctioning at BBFS. But most of the interviewed employees had already gained practical experience with electronic auctioning on the job at other facility management companies, for example at M+W. BBFS used the same electronic auctioning software as M+W. Therefore, especially the employees who had worked at M+W in the past could easily transfer their knowledge in electronic auctioning to BBFS. Mostly closed electronic auctions were utilized and electronic auctioning functioned as negotiation support in pricing.

## **4.2. Qualitative analysis and discussion**

Two questions dominate the following case study analysis:

- (1) Were (or are) the identified hindrances in electronic auctioning of services of importance within the case study companies?
- (2) How did the case study companies succeed in overcoming these hindrances?

Discriminant analysis has shown that management team (REFU), human capital (MANP) and external resources (OFFE) are the most important hindrances in electronic auctioning of services. Therefore, the ways to overcome these hindrances are looked at in detail in the following.

It proved difficult to differentiate between management team and human capital within the case studies. Most of the interviewed experts had experiences at being part of the human capital of their company (in the resource-based meaning) and willingly shared these experiences, but had risen to the status of management team during

their career and offered insights in their viewpoints as well. Therefore, the arguments concerning management team and human capital are jointly presented.

At M+W, management team (the head of the procurement department) and human capital (the employees of the procurement department) worked together in a very close and un-hierarchical fashion. Most of the procurement-related questions and tasks within the company were consequently tackled by the procurement department. This very high degree of centralization of procurement led to a close-knit working atmosphere in purchasing in general and of services in particular. At BBFS, centralization of procurement was less distinctive. Therefore, the procurement department had more supporting tasks related to employees of the company who had no or few experiences in purchasing services. Depending on the attitude of these other employees, electronic auctioning was already a question or otherwise, it was necessary to do a lot of persuading. One expert for example stated that it was really hard to convince a certain facility manager with a need to advertise fire prevention services for bids of the utilization of electronic auctioning. A good deal of communication was necessary to make this certain facility manager come around. Both case studies show that communication between employees is as helpful to overcome attitude-induced opposition as communication between management team members and employees. This is also backed up by the argumentation of Kotter and Schlesinger (1979).

However, the communicability of information rises if the information is adequately customized. Customization works best if so-called 'magical moments' are created (Nowak and Neubert-Liehm, 2011). Both case studies highlight that 'magical moments' emerge if digital and analog communication channels are reasonably connected. This connection helps employees to remember the incident in question in a positive light. For further information on 'magical moments' see Reuter (2013, 2015a and b). At M+W, for example, the first electronic auction was commemorated as a real happening. Written invitations were dispatched to management team members of other departments and to several employees with known purchasing requirements. The actual electronic auction was broadcasted on a big viewing screen, so that each guest could see what was happening and could follow the auction process in real-time. Canapés were served and the successful conclusion of the auction was celebrated with a glass of sparkling wine. Even years after this happening, most employees remembered this very first electronic auction of services with pleasure and spoke positively about electronic auctioning in general. The first electronic auction at BBFS was also seen as a special event, but not to the same extent as at M+W.

At BBFS, only the employees of the procurement department and the employees with purchasing requirements who were directly connected to this special auction took part. Furthermore, the author of this paper was invited to take part. In the final stages of the electronic auction, the head of the procurement department dropped in as well. The electronic auction was broadcasted on a big screen and the employee of the procurement department who was responsible for this auction commented on the progression of the bidding. The auction was actually divided into two lots, each with different service bundles in the context of fire protection services. All the services which formed the two lots had been on the market beforehand. Therefore, it was possible to judge potentially realizable prices before the auction actually started. As the electronic auction proceeded, the mood of the participants changed from skeptical at first to exuberant in the end. The auction was a convincing success from the perspective of BBFS as the partaking subcontractors went into a downward price-spiral. All in all, price savings of approximately 65% were realized. Even the head of the procurement department and the employee with the purchasing requirement, who had both been not really convinced of the cost-savings potential of electronic auction-

ing of services, were exalted. The employees with the purchasing requirement even promised to look into all the other pending warranty contracts and to let the offered prices be confirmed in electronic auctions.

Motivation-induced opposition has proven to be important in both case studies as well. Helpful in this context is if the employees know about the application of electronic auctioning devices as soon as possible. Employees should experience that the implementation of electronic auctioning changes the procurement process for the better. This experience can be brought along by qualification. At M+W, many employees saw only the extra amount of work connected with electronic auctioning (especially during the preliminary stages of the auction itself) and did not realize the benefits (such as high cost savings). This changed after the procurement department had started a qualification campaign for electronic procurement. Each employee with known purchasing requirements was asked to take part in a qualification program offered by the employees of the procurement department and additionally could take part in qualification courses offered by the software provider who allocates the electronic auctioning device. At BBFS, such a qualification process was also under way at the time of case study execution, but had not been sufficiently finished. For both case studies holds true that if the necessary prowess and skills to handle the ICT devices are conveyed to the employees, resistance is minimized. This backs up Kotter and Schlesinger's (1979) argumentation on the reduction of resistance via qualification in general.

Coaching also seems to be an effective way to reduce employees' fears. The slogan "The earlier, the better!" (Gros, 2011, p. 717; author's translation) is very true in the context of the case studies. If a negative opinion about electronic auctioning already started to form, it is always harder to convince such then preoccupied employees or members of the management team. In the latest, the members of the management team should raise the employees' awareness for this process change (Freiling, 2008) when the implementation of electronic auctioning of services is certain. At M+W for example, the employees and management team members were integrated in the process of implementing electronic auctioning from the start, as has been shown in the 'magical moments' section above. Employees and management team were all informed about the intention to procure services electronically before the first electronic auction of services ever took place. Hence, the affected employees and management team members felt integrated in the process change and learned early on about the positive effects and the high cost savings potential of electronic auctioning of services.

Furthermore, conflict management is a means of easing resistance, especially if some employees are 'winners of change' and some are (or see themselves as) 'losers of change'. Some employees associate restructuring of the purchasing process with high costs, high time exposure and low improvement of outcome. If these critical employees can be convinced of potential cost savings and gains in the course of the implementation of electronic auctioning of services, their resistance is reduced. This affirms the argumentation of Szmigin and Foxall (1998) on innovation resistance in general.

At M+W and BBFS, the initiative to implement electronic auctioning of services came from the employees at the respective procurement department. Both were so-called bottom-up initiatives (By, 2005). Therefore, there were no employees of the procurement departments who thought about themselves as 'losers of change'. Conflict management was not necessary in the case of M+W and BBFS. Hence, the better the process change is grounded in organizational practice, the higher is the sustainability of change. There is no compensation for a lack of transformation readiness,

however. Both case studies show that the members of the management team and the employees are equally inclined to change. The transformation readiness does not differ subject to the status of the respective participant.

Furthermore, a cooperation in procurement works out if employees support the co-operation-induced changes. External resources, such as the employees of the intermediary, can compensate for a lack of transformation ability. This compensation normally works better for members of the management team than for employees. At M+W for example, the head of the procurement department already had a very high transformation ability. Therefore, no compensation was necessary on his part, but new employees of the procurement department always had to be instructed on electronic auctioning and several showed a lack of transformation ability at first. In this case, the cooperation with the employees of the intermediary compensated for the missing transformation ability of the rookie employees. At BBFS, the subcontractors participated willingly in the electronic auctioning process. Beforehand, they always had problems in assessing reasons for not getting a certain assignment. With electronic auctioning, documentation is, according to the purchasing experts, really accurate and the transparency of the auctioning process is very high.

In sum, the case studies confirm Ford and Ford (2009) in their assumption that it is reasonable to view resistance as a chance to reach better performance and be more successful.

## **5. Contribution, limitations and future research paths**

From an empirical perspective, the paper's main contribution is twofold. Quantitative-empirical analysis showed that the main hindrances in electronic auctioning of services are management team, human capital and external resources. According to qualitative-empirical analysis, these hindrances can be overcome by communication, the creation of 'magical moments', coaching, qualification, conflict management and compensation. The qualitative-empirical results are also important from a managerial perspective as practitioners can use them as guidelines to overcome resistance in their own company. From a theoretical perspective, the paper's main contribution is to show that the relational resource-based perspective is a theory very well suited to be used in purchasing and supply management research.

As are all research projects, this project is subject to certain limitations. In what concerns the ways to overcome resistance, the small number of case studies impedes generalizability. Also, the fact that only companies with activities on the German facility market were integrated in the survey is a constraint, as Caniels and van Raij (2009) found country of origin and liking of electronic reverse auctions to be closely correlated.

Furthermore, one aspect which has not been discussed in this paper emerged during the case study at BBFS: Reputation is also an important hindrance in electronic auctioning of services. One of the interviewed experts stated that the implementation and utilization of electronic auctioning devices is especially problematic for a facility management full service provider. The argumentation in this case was as follows (translation of the author):

"Especially employees with sales experience have problems with the utilization of electronic auctioning of services. Our sales department strongly opposes that our facility management full services are auctioned electronically. They think that facility management full services cannot be auc-

tioned as the quality of the services is the most important aspect and not the price. If we conduct electronic auctions of services ourselves in order to lower the prices of services from our subcontractors, we cannot argue that our own services should not be auctioned. If we did this, our reputation would suffer severely.”

Hence, the influence of reputational aspects on the utilization of electronic auctioning has been neglected in this study.

A methodological limitation of this paper is that the questions concerning hindrances in electronic auctioning of services were part of a much bigger online questionnaire. Hence, only a few questions were actually dedicated to the mentioned hindrances. In further studies, the influence of reputation on electronic auctioning of services seems worthwhile to explore. And in order to bolster statistical significance and improve eigenvalue and canonic correlation, a questionnaire could be designed which solely tackles the paper's topic as well as the ways to overcome these hindrances.

# ICT use in delivery of uncertain and complex project services: the case of building refurbishment

Ahmet Anil Sezer<sup>1</sup>, Jan Bröchner<sup>1</sup>

<sup>1</sup>Chalmers University of Technology,  
Department of Technology Management and Economics

*Auto repair, industrial maintenance and surgical services share with building refurbishment an uncertainty associated with the condition of the object that is to be serviced. Here, the aim is to study how the use of various types of ICT support for service delivery depends on the ability to determine the state of artefacts subject to intervention. Relying on theories of technology acceptance, a survey of ICT support in refurbishment covers 16 managers. These were found to prefer usefulness to ease-of-use. 3D scanning of existing buildings was unusual, and this limits the application of integrated digital models in co-production with clients. Simultaneously relying on virtual media and face-to-face contacts appears to be important.*

## 1. Introduction

Whereas the relation between providers and customers for many types of consumer services has its focus on service encounters and their balance between face-to-face interaction and various media, there is a group of project based business services with more extensive and recurrent encounters (cf. Gutek et al., 1999; Sundbo et al., 2015). Among the project based business services, there are relations where innovation is less important than joint problem solving. Here there is a range of services, from those with a strong creative element such as advertising to those which are also depending only partially on fixed routines, while nevertheless considered to be less creative, such as building refurbishment. Co-production takes place here starting from a contract which does not specify the service outcome in detail. Instead, discoveries are made during the project and a number of solutions are found successively.

Construction projects in general and building refurbishment in particular are produced by service systems that typically include at least one knowledge-intensive business service firm (e.g., architects, engineering consultants) and at least one firm belonging to operational business services, according to the services classification by Glückler and Hammer (2011). Here it should be noted that the construction industry is not officially classified as part of the services sector in national accounts, although it is easy to argue that building refurbishment is a service activity (Holm, 2000).

Using the classification of services developed by Silvestro et al. (1992), building refurbishment can be characterized according to its equipment/people focus (more equipment than people), customer contact time per transaction (high), degree of customization (high), degree of discretion (high), value added back office/front office

(both) and product/process focus (product). Refurbishment appears to fall mostly in their 'service shop' category, somewhere between professional and mass services. Auto repair, industrial maintenance and surgical services share with building refurbishment an uncertainty associated with the condition of the object that is to be serviced. Therefore, IT use for services that intervene in clients' complex artefacts is twofold: as for most other types of services IT will support more efficient delivery, but there is also a potential for more efficiency in diagnosing the initial condition.

For many types of services, not only mass produced, the trend has been over decades to narrow the gap between routine driven manufacturing processes and service production, partly by breaking down services into modules and introducing more detailed control systems (Sundbo, 1994). This development is slower or difficult to identify for more complex services where delivery is subject to uncertainties and a high degree of unique customer adaptation, such as the majority of building refurbishment projects. It is then probable that project control systems will be incomplete and to be explained within the framework formulated by Modell (1996) for analysing management accounting and control in services. Fundamental in his first proposition is that

the higher the degree of task uncertainty in services: the lower the emphasis top management places on accounting-based and other formal controls; the lower the acceptance and use of accounting information by operating level managers, and the lower the weight assigned to formal controls in relation to informal ones.

Also, his fifth proposition should be particularly relevant for ICT use in construction and refurbishment site operations:

when the delivery of services is geographically constrained, the weight assigned to informal controls in addition to formal ones [...] is enhanced by greater geographical distance of operating level units from the administrative core of the organization.

The aim of the present investigation is to study how the use of various types of ICT support for service delivery depends on the ability to determine the state of artefacts subject to intervention at the client's site. As a case, actual use and attitudes to IT support in monitoring residential and office refurbishment projects are investigated.

This paper is structured so that it begins by reviewing the co-produced business services, media choice, technology acceptance, as well as ICT use in construction firms and in refurbishment projects. Next, the survey methods relied on are discussed followed by the survey results. Finally, we discuss the findings and identify conclusions from the investigation.

## **2. Literature review**

This investigation draws on several bodies of literature. Basically, theories of co-produced business services are relevant. Media choice and technology acceptance have attracted numerous researchers, and only a few aspects can be brought up here. Over the years, there has been research on the introduction and diffusion of

various types of ICT in construction firms, and more recently also specialized studies of ICT use for building refurbishment projects.

## **2.1. Co-produced business services**

Many consulting services are characterized by co-production with the client, incomplete contracts and information stickiness (impeding transfer of information) (Xue and Field, 2008). Contracts can be incomplete in several ways: for creative services, it is counterproductive to specify outcomes in detail; the state of nature, or the state of an existing structure or system may be too costly to investigate in detail before a contract is signed. Technologies that alleviate information transfer are clearly relevant in the co-production context. There is a parallel with employee and user driven service innovation (Sundbo et al., 2015), although it is unknown how the existence of company systems and platforms might inhibit creativity in IT use on lower hierarchical levels in service organizations.

The advantages of new ICT tools appear to depend greatly on service provision contexts, as is obvious from the retrospective view offered by Miles et al. (2014). Ambrose et al. (2008), who included a construction case in their empirical material, emphasized that projects have phases and that media selection shifts through these phases. Their study concentrated on the choice between telephone and e-mail, in addition to face-to-face meetings. Studies of consumer services include varieties of virtual interactions as opposed to face-to-face interactions (Seck and Philippe, 2013). Co-production relations in knowledge-intensive business service projects are often structured with regular face-to-face meetings, formal digital communication although informal communication over a range of media can also be important. Visualization of schedules and designs can support face-to-face meetings, where provider and client may discuss and evaluate alternatives jointly (Baark, 2005). In a services project context where joint problem solving occurs repeatedly, combinations of virtual media and face-to-face encounters can be of particular relevance.

## **2.2. Media choice**

Initially (Daft and Lengel, 1986), media choice theory was related to equivocality and uncertainty reduction, leading to predictions of the contexts for using e-mail versus telephone communications. However, contextual constraints such as urgency, confidentiality, accountability, social interaction and information integrity should not be overlooked when explaining actual media choice (Palvia et al., 2011). Two of these constraints (accountability and social interaction) can be expected to be especially relevant for media choice in refurbishment projects.

## **2.3. Technology acceptance**

While media choice theory concentrates on the ability to communicate messages, technology acceptance is associated with a different conceptual structure. In a pioneer study (Davis, 1989), the determinants of individual-level technology acceptance were reduced to two, perceived usefulness and perceived ease of use.

The information systems literature separates 'perceived usefulness' from 'ease-of-use' (Karahanna and Straub, 1999). Beliefs about systems are thought to lead users to (i) positive attitudes toward systems; (ii) intentions to use systems, and (iii) actual system use. In their empirical study, availability of training and support from an IS (information systems) department has less effect than expected.

In a study of bank employees comparing TAM and the related TPB (theory of planned behaviour) model, Brown et al. (2002) found that staff attitudes to 'mandated technology' might reflect influences of 'keeping one's job', which lies outside standard theories of IT use. When interviewing managers about their ICT use and requirements on ICT tools, it is necessary to consider that they are expressing beliefs. Lewis et al. (2003) analysed beliefs concerning ease of use and perceived usefulness according to individual, social and institutional influences. Institutional influences emanate from top management and corporate systems; social factors include peer pressure in the organization, whereas individual factors include computer self-efficacy and personal innovativeness with technology.

## **2.4. ICT in construction firms**

Earlier studies of the growing use of ICT in construction projects and construction firms have clarified typical applications as well as drivers and constraints for the implementation of new tools. An analysis of the literature on IT applications in the construction industry including articles published between 1992 and 2001 revealed that frequent applications were in the areas of estimating, cost control, document management, planning, resources management, equipment management, quality management, productivity management, risk management, safety management, bidding and contracting, performance evaluation and financial planning (El-Ghandour and Al-Hussein, 2004).

Drivers for IT use among contractors were identified by Mitropoulos and Tatum (2000) as competitive advantage (winning the contract), process problems (costs, project delays), technological capabilities and external demands (from clients, competitors and government agencies). Having one system to facilitate ease of understanding, end-user focus, training and commitment of all project participants was emphasized by Weippert et al. (2003). Stewart et al. (2004) grouped barriers to IT adoption in the industry at three levels: industry level (clients are misinformed and are cost driven and there is poor interoperability between actors), organizational level (limited resources are available to smaller firms) and project level (low technology literacy of project participants). Another Australian study (Peansupap and Walker, 2006) identified ICT implementation constraints at three slightly different levels: personal, organizational and group. At the personal level, there were budget limits for ICT investment, lack of commitment from other project participants, lack of ICT standards and security problems. Organizational constraints were related to computer experience, time for learning, and furthermore the identification of benefits from ICT use. Group level constraints were seen as relating to the time available for information sharing, the quality of personal contacts and the effects of geographical distances.

How ICT supports client-contractor co-production is thus only touched upon in most construction studies. Developing a firm level index for contractor IT use is no less

than 48 work functions, El-Mashaleh et al. (2006) did not reach a significant correlation with customer satisfaction, which they measured only as percentage of repeat business customers; their US questionnaire survey, however, revealed that 81 per cent of respondents agreed (or slightly agreed) that IT had an impact on customer satisfaction in general.

In a longitudinal study, Samuelson and Björk (2014) have tracked IT adoption in the Swedish building sector, relying on surveys carried out between 1998 and 2011. Their results indicate that all sites had computers and Internet access already in 2007. Mobile connectivity had brought significant benefits including Internet access alternatives to temporary work places such as construction sites. Improving communication and sharing information were highlighted as strong drivers for IT use, while use of more complex applications, namely the implementation of building information modelling (BIM) (cf. Azhar, 2011), was found to be unusual. Compared to other firms in the building sector, not least technical consultants, contractors appeared to use electronic document management and BIM less and they generally presented a lower degree of IT maturity. Although contractors were found to increasingly use IT for materials management and purchasing, they do not use more IT for scheduling and cost estimating purposes, again compared to other firms in the sector.

BIM is an example of an advanced interorganizational use of ICT, involving both clients and other participants of construction projects. Adriaanse et al. (2010) developed a theoretical model explaining interorganizational use in US construction, assuming that intention to use lies behind actual use. The intention arises from personal and external motivation, although actual use is also influenced by knowledge and skills as well as acting opportunities. Analysing the adoption of BIM in construction, Singh and Holmström (2015) rely on Maslow's motivational theory of needs to explain adoption of new technologies by actors at both individual and organizational levels. The study highlights the role of organizational change management, primary and secondary needs of individuals and external perturbations. This and other studies of the slow uptake of BIM appear to have underestimated the effect of positive network externalities, in other words that the profitability for a contractor of engaging in integrated models for project communication depends on acceptance of BIM among a sufficiently large number of business partners in the sector.

According to Nourbakhsh et al. (2012), who developed a mobile application prototype, usability is the critical determinant for unsophisticated users who may lack experience with, e.g., touch screens. Their study is based on an analysis of how clients, consultants and contractors need information from each other. For new construction, they identified contractor needs for on-site information management: schedule updates, reporting violations, reporting quality control and assurance problems, accident reporting, productivity information, report inspection results, progress photos and change orders.

In principle, we should expect ICT on construction and refurbishment sites to serve one or more of three purposes: (i) to offer immediate data and information support for carrying out the core production process itself, (ii) to measure performance (or at least for accounting), (iii) to support the customer dialogue. To some extent, these three purposes can be expected to give rise to similar requirements on ICT tools. In

addition, there could be purpose-specific site user requirements that would influence ICT use as far it can be observed in reality.

## **2.5. Refurbishment projects**

Refurbishment is a service that is delivered at the customer's place; ICT is used by the provider service system – at least by design service providers – to translate customer needs (Sundbo et al., 2015), and it is used by refurbishment contractors for internal purposes of monitoring the service project. The role of co-production extends beyond an element of participatory design (Sørensen and Henten, 2014) and can be observed throughout a typical refurbishment project. The usual distinction between service encounters and service relationships is blurred in the case of most building refurbishment projects, as well as in many new construction projects. While repeat business with the same client may be unlikely or only happening after an interval of years or decades, there is a succession of contacts between the service provider (refurbishment contractor) and the client (building owner) during the project, which might last several months. Within the project, there is clearly a service relationship in the sense of having repeated contacts (Gutek et al., 1999).

In this sense, refurbishment is similar to co-production in any construction project and is partly to be interpreted as renegotiation of an original contract. Such changes in contracts may arise from a variety of sources (Bröchner and Badenfelt, 2011). For refurbishment, the successive discoveries of the true nature of the existing structure, which is the client's imperfectly understood artefact, can give rise to multiple adjustments which have to be negotiated. New infrastructure construction projects, in particular tunnels, are often characterized by a related process of successive discoveries of rock properties as tunnelling reveals the state of nature.

Refurbishment includes a number of site activities or processes which are partly tied to company processes. Singh et al. (2014) have listed nine typical site processes:

- (i) preparation of plans and specifications,
- (ii) site investigation by contractor,
- (iii) preparation of site logistics plan,
- (iv) mobilization and demobilization,
- (v) temporary construction,
- (vi) selective demolition,
- (vii) material and equipment procurement,
- (viii) demolition waste management,
- (ix) mechanical, electrical, and plumbing roughins (installation).

Most of these site processes depend on ICT tool use, and for some of the processes, there will be little or no latitude for site staff to deviate from company systems.

Compared to new construction, refurbishment projects suffer from a higher degree of technical risk and uncertainty, making them less predictable (Egbu, 1999).

Decentralization gives refurbishment production managers flexibility and allows quick decisions to respond to the higher risks and uncertainties associated with the refurbishment works. In Egbu's survey of refurbishment organizations in England, financial management of refurbishment projects was more stressed by managers in senior positions, whereas junior (typically production managers) and middle

management were more interested in the planning and programming of the works. Communicative skills were ranked highly throughout the organizations. Skills of decision making, required by the need for impromptu solutions to be found during projects.

Different applications and customization are needed for different groups of employees; two main groups to be distinguished are mobile knowledge workers and mobile field workers. Stieglitz et al. (2015) include real-estate restoration workers in the group of mobile field workers and define the characteristics of mobile field workers as that they deal with simple-structured, recurring, urgent, hands-on and coordinating tasks. Given these characteristics, permanent access to internal corporate information is not identified as a necessity for field workers, and information flow among them focuses more on coordination than collaboration. It is argued that there might be technical problems for field workers such as finding wireless networks. Besides technical issues, Stieglitz et al. (2015) see it as difficult for organizations to adopt mobile applications in daily work routines in the presence of information overload, to convince employees to use the mobile application and also dealing with security concerns. It should be noted that production managers, compared to refurbishment workers, may have to deal with more complex situations and uncertainties while some of their tasks are seldom repeated.

More recently, integrated digital models for the entire life cycle of facilities have been developed and increasingly for new construction of (complex) facilities. Early and late stages of a facility life cycle are of obvious interest to clients, and efficient digital models would serve as a good medium for communication between clients and contractors. Nevertheless, in the context of refurbishment projects, the implementation of building information modelling (BIM) has been more of an exception (Ali, 2010; Cheng and Ma, 2013; Kim and Park, 2013; Volk et al., 2014). Early reports indicate strong positive effects of BIM on labor productivity in subcontractor renovation activities, mostly due to increased reliance on prefabricated components (Poirier et al., 2015).

In principle, BIM for refurbishment can be integrated with geometrical data obtained by 3D laser scanning (Brilakis et al., 2010). Industry experiences reveal that the efforts involved in modelling even simple buildings are costly, because of the manual effort to convert surface data (such as are obtained by 3D laser scanning) into a parametric BIM model. In addition, there is the issue of technical features (such as rotting timber, asbestos and other hazardous substances) hidden from sight, but which might appear in broad daylight as refurbishment proceeds.

Closer to the issue of how ICT supports client-contractor co-production is the use of digital decision support systems for housing condition assessment and refurbishment strategies. Such systems can be seen as useful for residents, providing information about trade-offs between cost and quality including life cycle cost, renovation cost and improved quality and therefore decreasing conflicts between residents and contractors (Juan et al., 2009).

### 3. Methods

The study is based on a Swedish survey of 16 production managers with experiences of housing and office refurbishment projects as well as experience of working in projects of different sizes. These production managers belong to two of the largest contractors in Sweden. Production managers are site managers, coordinating refurbishment work on site. A questionnaire has been combined with face-to-face semi-structured interviews. The survey covers use of various ICT tools on refurbishment sites, managers' views on ease of ICT tool use, access to support and linkage to life-cycle design (BIM) software, as well as the relation to clients' databases.

### 4. Results

Questionnaire results concern hardware use by refurbishment project managers (Table 1), as well as their perceived requirements on ICT tools and systems (Table 2). The interview results allow an understanding of how the project managers reason more in detail and an understanding of causal relationships.

#### 4.1. Hardware use

The questionnaire responses indicate that laptops, mobile telephones, printers and scanners are IT tools used commonly on refurbishment sites while tablets are rare (Table 1). The standard deviation for use of tablets is relatively high. Production managers either do not use tablets at all or use them seldom compared to other IT tools.

| Hardware         | Average | Standard deviation |
|------------------|---------|--------------------|
| Laptop           | 4.9     | 0.34               |
| Tablet           | 2.2     | 1.05               |
| Mobile telephone | 5.0     | 0.25               |
| Printer          | 5.0     | 0.25               |
| Scanner          | 4.8     | 0.40               |

Table 1: Hardware use among refurbishment production managers

The interview responses agree with the questionnaire results where use of mobile telephones and laptops was acknowledged by everyone. Only half of the interviewees, however, said that they use tablets and the other half thought that tablets would be used in the future at refurbishment sites. One of the interviewees mentioned their organizational policy where production managers have access to tablets when a project budget exceeds a certain limit. Besides these types of hardware, interviewees also mentioned printers, wireless Internet and scanners. One

of the interviewees pointed out monitor screens on sites, where they share information about the project.

Based on the interview results, different kinds of hardware can be seen to be used for different purposes. Laptops are used for planning, e-mailing, handling invoices, following resources, writing protocols, purchasing, cost management, monitoring of quality, staff management, information searches, networking within the organization, managing drawings, scheduling and safety rounds. Mobile telephones are used for basic purposes as telephoning and messaging, and for more advanced purposes as e-mailing, taking pictures and sharing, scheduling, reading documents, looking at drawing details, safety rounds, reminders, entering project data to the system via an application and checking calendars. Tablets are often used for visualization including checking drawings on the actual site, taking pictures during safety and quality rounds and attaching them to the drawings, environmental rounds and 3D models. One interviewee said: "Well, I believe that we shall have tablets with much more 3D models within a few years", while another interviewee described the need for tablets on refurbishment sites as:

Pads, on site, just for handling drawings; to avoid having drawings out on the site, you should be able to extract the drawing, scale it up and down and then be able to view and explain to the craftsmen then and there, simply and flexibly. And also for inspections, safety rounds, environmental rounds....

Distributed visualization of documents is important. Another interviewee mentioned that there were a computer and a projector at a higher level of the building undergoing refurbishment:

with a cable going down here so that we are able to run PowerPoint presentations up there where the workers are sitting, if there is any information or [...] or for waste handling, an information sheet, in that case we can just mirror the desktop view from down here. Though we haven't used that yet, but there it is, nevertheless.

## **4.2. User requirements on ICT tools and systems**

Returning to the results of the questionnaire survey, the average and standard deviation of all statements are presented in Table 2. For their mobile phones or tablets, the interviewees identified several functions they would like to have, mainly related to accessibility, including: having a portal where drawings are constantly updated, having tablet software which allows easy linking and comparing reality with a drawing, accessing the security camera monitoring of the construction site via mobile phones and being alerted if anything suspicious is going on, accessing all files at any time, an application that facilitates keeping track of different projects, and accessing information about projects and pictures during meetings. Automatic updates was emphasized by one of the interviewees: "that the drawings are automatically downloaded to a tablet overnight, that is the future, new drawings will be on the portal in daytime, and your tablet will be updated during the night."

| Statement  | Average | Standard deviation |
|--|---------|--------------------|
| It must be easy to enter data to the IT support  | 4.4     | 0.49               |
| It must be easy to update project information in the IT support  | 4.5     | 0.50               |
| IT support must allow easy connections to the BIM (3D) models  | 2.6     | 0.95               |
| IT support must be available without interruption which lasts longer than 30 seconds                             | 3.8     | 1.24               |
| If I have IT related questions, I must be able to get help within two minutes, even outside normal working hours | 2.6     | 0.88               |
| It must be easy to interpret what I see on my screen   | 4.4     | 0.61               |
| IT support must be able to connect to the client system  | 2.4     | 0.88               |
| IT support must be available on my smartphone  | 3.6     | 1.02               |
| I must be able to reach all the digital drawings quickly   | 3.8     | 1.24               |

Table 2: Site user requirements on ICT tools for refurbishment projects

The interviewees reflected that it is important to be able to use IT tools on the actual construction site. Besides the technical capabilities of providing flexibility to the users, production managers use IT support tools depending on the level of value it creates for the user. It should not take more time to use an IT tool to complete a task compared to the traditional way. Nevertheless, one interviewee gave an example of visualizing time plans which took considerable time to produce and update, but they were very useful. Sources of added value can be different, for instance according to one interviewee, project data were entered directly to a portal by using mobile phones and tablets, and thus they avoided paper use and worked in a more sustainable way. There was also a more dubious example where the organization introduced a new application linking mobile phones and printers so that production managers can print directly. However the interviewed production manager was dissatisfied since he did not understand why such a connection was needed. Clearly, interviewees appreciate if they see a value from the use of IT support tools and that the particular type of IT support possesses useful technical capacities.

## 5. Discussion and Conclusions

The results showed that production managers assert that they replace or refine traditional methods with IT support tools when they find them useful, although it might take them more time than before. Interpreted in terms of the technology acceptance model, it is the perceived usefulness of an IT support tool that production managers primarily consider rather than ease of use, since they were willing to spend more time on new IT tools than they did traditionally.

While applying a technology acceptance model to production managers, it is crucial to consider organizational hierarchies, routines and policies. This is particularly relevant here, given that all respondents were employees of large organizations. One of the production managers acknowledged that they are mandated to use tablets and BIM models for refurbishment projects over a certain budget. The modelling even of simple existing buildings is costly, but the contractor clearly saw profits of using BIM and 3D modelling for larger projects, making project size one determinant of the level

of IT use. This might explain why BIM use is more often seen in new construction projects rather than in refurbishment, where the typical project budget is lower.

According to Lewis et al. (2003), peer pressure influences IT use among knowledge workers, but this source of external pressures was not acknowledged by the interviewees in the present survey. Instead they would emphasize the usefulness of IT support tools and perceived self-efficacy as influences on adoption. This pattern of attitudes can be explained by the fact that refurbishment organizations are decentralized which gives flexibility to production managers who are empowered to make quick decisions when responding to the higher risks and uncertainties associated with refurbishing buildings (Egbu, 1999). It is also what can be expected along with Modell's (1996) argumentation concerning the effects of task uncertainty in services.

Whereas there are elements of client/contractor co-production in refurbishment projects, the questionnaire survey results showed that production managers failed to see any need for connecting to a client's IT system. Furthermore, none of the production managers acknowledged the importance of clients and co-production during face-to-face interviews. Establishment of BIM models with joint databases can be seen as creating a platform enabling more efficient routines for co-production between contractors and clients. BIM is not used for small refurbishment projects which can be explained by the observation that neither clients nor contractors see profits of using BIM in smaller refurbishment projects. Nevertheless, it is reasonable to expect that developing database that allow easy visualizing of refurbishment projects can make the service relationship with client interaction during formal meetings more efficient. As in the relation between the production manager and the refurbishment workers, it is the simultaneous combination of IT interfaces with face-to-face encounters that is important.

More extensive use of ICT tools, advanced or simple, is associated with the project scale. It is possible to spread the cost of stronger ICT support in large refurbishment projects, reducing technical uncertainties and establishing a platform to enhance co-production with clients.

The reluctance among production managers to engage in integrated IT models of buildings and linking to clients' IT systems can be understood as caused by the difficulty of assessing structural and other problems that are often encountered during refurbishment. Experiments have been made with 3D laser scanning to provide geometrical models that are compatible with BIM, but the IT support possibilities for discovering in advance what is hidden under wall and floor surfaces are still insignificant. This is a major reason why traditional craftsmanship remains important in building refurbishment. Innovative and effective diagnostic methods are necessary for enjoying the benefits of IT model integration, supporting co-production dialogues, while also making it possible to monitor productivity and sustainability effects more closely for ongoing projects.

<sup>b</sup> University of Strathclyde, Scotland

## Abstract

This paper explores the online customer experience (OCE) in relation to a utilitarian search for government provided business support services. The aim of this research is to understand the variables that can influence customers searching for business support services online and to explore the potential role of online customer support via social interaction during a customer's online experience. Through the use of in-depth interviews and structural equation modeling, this study establishes a theoretical framework outlining the variables that have the potential to influence the online customer experience within the business support environment. This paper provides further theoretical understanding of the OCE through the introduction of information quality, website credibility and the length of time spent on the website, as variables influencing the OCE. In addition, this paper establishes the need for online customer support during a utilitarian search for business support information and services.

## 1. Introduction

Recently, services researchers have developed an interest in the online customer experience, most often centred on the online retail environment (Hoffman; Novak, 2009; Luo et al; 2011; Rose et al, 2012). Researchers, marketing practitioners and consultants have long expressed an interest in the customer experience and have agreed on its importance in producing outcomes of satisfaction, revisit intention and trust (Shobeiri et al, 2014). However, empirical research on the online customer experience (OCE) remains scant (Ahmed, 2011; Bigne et al, 2008), thus it is important for both academia and industry to understand how the customer experience can affect the online customer in a number of different searching and buying contexts.

Additionally, online social interaction through the use of web 2.0 functionality and social media has received much attention from marketing researchers as tools that allow customers to collaborate, communicate, share and connect with each other, (Kaplan; Haenlein, 2010; Mayfield, 2008; O'Reilly's, 2005) yet researchers have not explored the role of social interaction (synchronised communication) between customers and customer representatives in providing online customer support in relation to the customer experience. Given the recent technological developments providing online social interaction, this paper advances our understanding of the role of social

interaction in providing online customer support in relation to the customer experience.

Recently, studies have investigated some of the drivers of a positive customer experience. This study steps outwith the online retail shopping environment and explores the customer experience in a utilitarian context of searching for Government provided business support information and services. Government economic development agencies provide business support services on business growth, leadership, developing employees, funding and day-to-day advice on running a business. Large proportions of public money are spent on the development of web services to provide business support, yet little research has explored the variables that may influence a customer's experience interacting with such services. The main objectives of this study are as follows:

- 1) Examine the variables influencing the online customer experience while searching for business support information and services.
- 2) Investigate the role of customer emotions while searching for Government provided business support services online.
- 3) Establish the role of customer support through social interaction in relation to a customer's experience.
- 4) Develop a comprehensive online customer experience model incorporating variables influencing the customer experience during a utilitarian search.

Through exploring these objectives this paper makes several contributions to services literature by adding and extending knowledge through developing and testing a new online customer experience model within a novel context. The paper first of all discusses the theoretical background of searching for information online and the customer experience. In the next section the research method is outlined, followed by the findings of the research. Lastly, a discussion of the findings, theoretical contribution, managerial implications, limitations and suggestions for future research are provided.

## **2.0 Theoretical Background**

### **2.1 Information search**

Within the area of marketing, research to date has somewhat neglected information search. Most research papers have been aiming to understand a customer's overall decision-making process in the context of purchasing a product (Engel et al, 1978). Within Engel et al's (1978) decision-making model, information search is a key part of the decision making process. Thus, it is important that marketers have an understanding of the underlying information search process. Like the customer experience, information search is regarded as a holistic process, involving the psychological constructs of cognition and affect (Kuhlthau, 1991). Kuhlthau (1991) research was the first to outline the role of emotions in searching for information. More recent

research conducted by Flavian-Blanco et al (2010) found that emotions are prevalent when searching in the online environment prior, during and post search. Kuhlthau's (2004) influential research suggests that if customers do not have positive emotions during search and instead experience emotions of frustration, anxiety and uncertainty, they are likely to abandon their search. As a result researchers have aptly outlined the importance of emotions in the customer experience.

## **2.2 Customer experience**

The customer experience has been extensively discussed in the offline environment (Schmitt, 1999; Edvardsson et al, 2005). Meyer and Schwager's (2007) suggest the customer experience is the "internal and subjective response that customers have to any direct or indirect contact with a company" (Meyer; Schwager, 2007, p.118). The customer experience is often theorised as a psychological construct, which is holistic and the subjective response resulting from touch-points with an organisation (Gentile et al, 2007). The psychological constructs of cognition and affect have been identified in numerous aspects of customer experience (Edvardsson, 2005),

According to Carbone and Haeckel (1994) the outcome of a customer experience is the creation of takeaway impressions that are subsequently stored in the memory of the customer. Numerous research studies have outlined that the customer experience is an important area of research due to the outcomes of a positive customer experience (Meyer; Schwager, 2007), namely satisfaction, trust, re-visit intention, re-purchase intention and loyalty (Schmitt, 1999; Edvardsson, 2005). Verhoef et al (2009) outline that a focus on the customer experience is of the upmost importance to organisations in order to have a competitive advantage, moving beyond that of assessing service quality.

## **2.3 Online Customer Experience**

Empirical research on the online customer experience remains somewhat limited. Customers operating in the online environment encounter numerous components capable of influencing their experience with the website (Rose et al, 2012). Gentile et al (2007) found that customers interoperate different types of information on a website (text, imagery, video and audio) from both a cognitive and affective perspective. Novak et al's (2000) research suggested that customers are only influenced by their cognitive thoughts online. However, subsequent research (Rose et al, 2012; Wang et al, 2012; Verhoef et al, 2009; Ethier et al, 2006) outline emotions as playing a significant role with regard to the customer experience. As a result, in line with the search process (Kuhlthau, 1989), Rose et al (2012, p.309) suggest that the online customer experience is a "psychological state manifested as a subjective response to the website". Therefore, the customer can be seen as engaging in cognitive and affective processing due to the influence of stimulus material and characteristics of a website, which as a result forms an impression in the memory of the customer.

A comprehensive review of the literature outlines 14 variables capable of influencing the online customer experience. These variables include information quality, credibility, flow, telepresence, enjoyment, concentration, engagement, web skills, challenge, interactivity, interactive speed, control (ease of use, customisation, connectedness), website aesthetics and emotions. (See Rose et al, 2012; Hoffman; Novak, 2009; Ding et al, 2009; Mollen; Wilson, 2010; Faiola et al, 2013; Brodie et al, 2013; Mathwick et al, 2005; Macmillan; Hwang, 2002; Song; Zinkhan, 2008; Hilligoss; Rieh, 2008; Van Noort et al, 2012; Wu et al, 2013; Liu; Shrum, 2002; Lee; Jeong, 2010; Harris; Goode, 2010.) While these variables have been outlined individually many have overlapping features and can be deemed as antecedents of variables within various research studies. It is important that this study further explores the relevance of each of these variables.

## **2.4 Customer Support**

However, often regarded as one of the fundamental differences within online and offline service environments is the element of social interaction, i.e. synchronised two-way communication (Nass; Moon, 2000). Within the offline environment, customers interact with service personnel in a face-to-face manner and in some instances may even make an effort to maintain a relationship with key service staff (Macintosh; Lockshin, 1997). In the online environment, the experience is often comprised by the inaccessibility of service staff along with machine responses (Yang; Jun, 2002). Over recent years however, technological advancements through web 2.0 functionality and social media have enabled the development of a more interactive social environment that provides B2B, B2C and C2C communication (Renard, 2013). The introduction of online social functions has developed what we see as the 'social customer' raising the expectation on being able to communicate online (Greenberg, 2010).

Many service providers are now utilising technology in order to provide customer service and support online (Truel et al, 2013). Research has shown that in the offline environment, encounters with other customers and with service staff have an influence on the customers experience during and after the service encounter (Tombs; McColl-Kennedy, 2003). Tombs and McColl-Kennedy's (2003) research finds that social interactions can give rise to individual's emotions and emotional displays, which in turn can influence the individual's behaviour. Truel et al (2013) discuss live chat technology that allows website users to seek 'service related information' from a real human representative who provide answers through the synchronous media (Truel; Connelly, 2013). Additionally, Chattaraman et al (2012) highlight three key purposes of live chat technology, firstly to serve as a search support function, secondly to serve as a basic decision support function and thirdly to serve as a navigational/procedural support function. Such support as highlighted by Tombs and McColl-Kennedy (2003) is often required in the offline environment and subsequently has an effect on the customer's experience. Kuhlthau's (1994) work on the zone of intervention highlighted the importance of social interaction with others in order to move through the search process.

According to Rafaeli's (1988) interactivity theory, a role exists for communication in providing customer support.

### **3.0 Methodology**

The method used in this study is in two parts. First of all in-depth interviews are conducted to explore the research area, followed by an online experiment using Structural Equation Modelling to produce a new online customer experience model.

#### **3.1 Interviews**

Due to the limited research within the study's context and the little attention paid to the online customer experience, in-depth interviews were conducted with 16 SMEs from an array of industries (creative industries, financial services, technology and manufacturing) lasting approximately one hour. 94 businesses were approached to take part in the in-depth interviews, of which all had searched for business support information on a Government funded economic development agency's website within the last 30 days. The in-depth interviews helped to provide comprehensiveness and parsimony (Whetten, 1989), therefore deleting those variables that were not relevant to the study. Each interview was recorded using a digital recorder and fully transcribed. The data from the transcripts were colour coded for particular topics and then categorised into relevant themes so that the data can be easily analysed.

#### **3.2 Online Experiment**

An online experiment was conducted on three selected Government funded business support websites with a sample size of 160 participants. Three tasks were set up for participants to complete on each website experiment (3x3). Participants were then given a business scenario and information to find, three mini tasks existed within the three main experiments. Participants were given 6 minutes for the tasks on each website, 18 minutes in total, with the experiment and questionnaire taking 36 minutes on average to complete. Figure 1.0 provides a graphical representation of the experiment procedure.

**Figure 1.0 Online Experiment Procedure**

Using an online experiment provided each respondent with the experience of searching for business support services across three different business support websites. Data were collected through a web-based questionnaire immediately after the completion of each experiment.

In order to test the hypothesised relationships in the study, structural equation modelling (SEM) was adopted using AMOS Graphics 22. Due to the online questionnaires being research administered, all 160 responses were usable with no missing data, which is consistent with the sample required for SEM (Byrne, 2013). The benefit of structural equation modeling is that the hypothesised model can be tested statistically in a simultaneous analysis of the whole model of variables (Byrne, 2013). The sampling frame consisted of a mix of business people, undergraduate and postgraduate business students with the UK. The sample achieved a relatively even split between males (47%) and females (53%). In terms of age group, the study achieved a good representation of ages, 18-25 (37%), 26-34 (28%), 35-42 (18%), 43-50 (14%) and 50+ (4%). On average participants were fairly knowledgeable and relatively confident at using the Internet.

### **3.3 Measure Development**

The questionnaire consisted of 49 scale items measuring the variables outlined from the in-depth interviews. All scale items were measured on a 5-point Likert scale ranging from (1) Strongly Disagree to (5) Strongly Agree. The session length for each task was recorded in order to aid in categorising successful or unsuccessful search. The average time for a successful search was worked out for each task (x3) in each experiment (x3). Those searchers who were faster than the average time to successfully complete the task were allocated 2 points. Those searchers who were slower than the average successful searcher were allocated 1 point and those who did not complete the task were allocated 0 points. In total the maximum number of points a participant could receive was 18 points (3 tasks x 3 experiments). In order to

work within a 5 point scale, like all other scales within the study, the total points for each participant was divided by 3.6. Using the recorded time for completing a successful search allowed the researcher to measure how successful a customer was in searching for their tasks. Additionally, as appropriate existing scales could not be found for the variable 'time spent on the website' a new scale was developed in line with scale development procedures (Churchill, 1979). See appendix 1 for all scale items and their corresponding sources where applicable.

## 4.0 Results

### 4.1 In-depth Interviews

This study finds ten attributes that influence the online customer experience some of which can be considered antecedent variables of other higher order variables, thus we are presented with 6 variables capable of influencing the customer experience during an online utilitarian search for business support information; namely, website aesthetics, control, information quality, website credibility, flow and the length of time spent on the website.

- *Website Aesthetics*

Respondents commented on the need for a well designed website that looked aesthetically pleasing and offered a logical layout in turn making navigation simple for the user. The concept of control was found to be an important variable with the potential to influence the customer's experience.

Respondents commented on the need for a site to be easy to use (not challenging), customisable and have the feeling of being able to do what the user requires, thus providing the customer with a level of control over what they are able to do.

- *Control*

The concept of control emerged as an important variable with the potential to influence the customer's experience. Respondents commented on the need for a site to be easy to use, thus providing the user with a level of control over what they are able to do. In addition, respondents outlined the need to be able to identify their own business when searching for support information, as a result being able to receive content that is customised or customisable for businesses may provide the experience required. Respondents pointed out that they want to be able to narrow down their search and find content that is relevant to them. Some respondents explicitly commented that being in control of what they are doing is important to them. Respondents wanted to be able to go to parts of the site that they wanted to see and not have the website dictate what they do. Thus, it is important that control is further explored in the experimental stage of the research and included in the theoretical framework.

- *Information Quality*

The quality of the information provided by a business support site is quite clearly essential to businesses. Respondents commented that key business decisions may be made from the information that is provided to them, as a result it can be expected that the quality of the information needs to be high. While the quality of the information was seen as being important to businesses, respondents further commented on the problem of information overload. Many respondents suggested that the quality of information could be affected by the mass of information that is often provided. Respondents further discussed the time-constraints of searching through such information. Some respondents outlined the need to try and confirm facts through their own knowledge or from other websites. Respondents also discussed the need for information to be accurate in terms of spelling and grammar; such mistakes can leave businesses questioning the professionalism and quality of the information provided by the organisation, as well as the information being current and easily understandable. Respondents aptly highlighted that if the quality of information provided is not good, you simply move on to the next website which is only a click away. Thus, it can be determined that Information Quality is another important variable to explore further in this study and shall be included in the theoretical framework.

- *Website Credibility*

Many respondents commented that the credibility of the website is important to them when conducting a search for business support information. Respondents outlined that in order to evaluate the credibility of the website, respondents look to the surface characteristics of the website such as the look of the site, the brand name, URL, navigation and the ability to contact the organisation. Respondents also commented on the need to confirm the information with information from another source or person within the field. This can be seen as an element of factual accuracy confirmation. Respondents outlined that anyone can simply create a website or a blog offering business support, however, respondents commented that the credibility of that website needs to be brought into consideration. Respondents highlighted the importance of decisions made from the information sought; as a result credibility as well as the information quality appear to be a priority for businesses.

- *Flow*

Further exploration outlined that being able to focus on the customer's task without distraction and becoming absorbed in what the user is doing is an important element in searching for business support information, thus being in the state of flow. However, conversely to other studies, respondents outlined that having a level of enjoyment, which is often seen as a part of flow, is not important to them in the context of searching for business support services, rather being able to focus on the task at hand is seen as more important.

- *Time spent on the website*

The variable of time became very apparent through each individual in-depth interview. Each respondent discussed the issue of time-constraints when searching for business support information. Respondents discussed the importance of being able to find information quickly without wasting any time. Respondents highlighted that they do not have the time to spend 20mins - 1 hour searching for information, the running of the business needs to be taken care of and thus, time can not be wasted. During discussions around other variables that have the potential to influence a customer's experience, the variable of time resonated each conversation. It is clear to see from the findings of the in-depth interviews that businesses are unwilling to spend time searching for business support information. Respondents further commented that any means that can be provided to help them find information in a timely manner is beneficial. Respondents discussed the goal directed nature of their search and therefore highlighted the need to find the information they are looking for and then leave. This for respondents can be seen as the optimum experience.

- *Customer Support*

Respondents illustrated that searching for online business support information is not a day-to-day task and therefore may only be carried out once or even twice per year, thus, respondents suggest that assistance is often required in an unfamiliar environment. Respondents suggested that being able to interact with a company representative, having the ability to talk to someone about their needs and the information they are looking for can help to reduce the level of frustration, anxiety and uncertainty over their information seeking experience. Respondents commented that being able to communicate with someone to seek support provides the experience that they are looking for and somewhat expect.

- *Search Success*

Respondents of the depth interviews illustrated that if they are unable to find the information or services they require they will abandon their search and thus result in an unsuccessful search. Respondents commented that searching online can become a frustrating task. Therefore, should customers encounter negative emotions of frustration, confusion and disappointment, customers will not have a positive experience and will be dissatisfied with their search. Further to this, respondents suggested that if they are required to spend longer than perceived necessary searching for information or services they will likely abandon their search on the website and move to an alternate service provider.

Following the insights from the in-depth interviews, we have reached the conceptual model in figure 2.

**Figure 2: Hypothesised Customer Experience Model**

## 4.2 Preliminary Analysis

Several analyses were performed before going on to estimate the research model using SEM. First of all a repeated measures ANOVA was conducted between business people and postgraduate/undergraduate business students across the three experiments to identify if any differences existed between the responses of the two groups on the variables within the study. The results of this test showed that there was no statistical significant difference between business people and business students, Wilks' Lambda = .40,  $f(20.00, 20.00) = 1.514$ ,  $p = .181$ . Thus, as a non-significant result was achieved  $p > .05$  (.181), it can be concluded that there is no difference in responses to the questions within the questionnaire between business people and business students across all 3 experiments. Therefore, the sample used in the study can be deemed as being appropriate. Additionally, a second repeated measures ANOVA was conducted to identify if any differences existed between the three websites used in the study. The results showed, Wilks' Lambda = .19,  $f(20.00, 140.00) = 29.920$ ,  $p = .000$ , which can therefore be concluded as a significant statistical difference as the  $p$  value is  $< .05$ . As a result, this provides the study with a broad and representative set of websites that can produce generalisable results for economic development agencies operating business support websites.

Secondly, the study tested for the potential influence of four control variables, age, gender, usage of the Internet and confidence using the Internet. In order to carry out such tests a Multivariate Analysis of Variance (MANOVA) was conducted for each control variable. The results of the MANOVA test showed no significant difference with regard to age group (Wilks' Lambda = .67,  $f(40, 596.000) = 1.723$ ,  $p = .069$ ). In addition, the MANOVA test showed no significant difference with regard to gender (Wilks' Lambda = .937,  $f(10, 149) = 1.000$ ,  $p = .447$ ). Again the result of the third MANOVA test showed no significant difference with regard to how often participants use the Internet (Wilks' Lambda = .76,  $f(30, 432.150) = 1.498$ ,  $p = .073$ ). The last MANOVA test conducted found that there was a significant difference between the level of Internet Confidence a customer has on the variables within the study (Wilks' Lambda = .55,  $f(30, 432.150) = 3.404$ ,  $p = .000$ ). Thus, only one

control variable is included in the structural model (Level of Internet Confidence) as all other control variables produced non-significant results from the MANOVA tests.

Thirdly, scale reliability tests and data normality tests were conducted prior to structural modelling. In order to conduct reliability tests cronbach's alpha coefficient was calculated. The value for each scale was above the critical value of .7 (Pallant, 2013). Thus the scales offer discriminant validity. Appendix 1 outlines the Cronbach's alpha values. In order to determine if the data are normally distributed, a z-score from the skewness and kurtosis values need to be calculated, this is done by dividing the skewness and kurtosis values by their standard error. The z-score for each variable falls between the values of -2.58 and +2.58 after a conservative statistical significance level of .01 is set, therefore the data can be considered as normally distributed.

### 4.3 Structural Equation Modelling

Structural Equation Modelling (SEM) was adopted in this study with the use of AMOS 22. Structural equation modelling with an analysis of moment structures is one of the most commonly used statistical techniques that is adopted in order to conduct analysis on structural theory through a confirmatory approach (Tabachnick and Fidell, 2007). Structural Equation Modelling involves two important aspects (1) that the casual process that is being studied is represented by a series of structural (regression) equations and (2) the structural relationships can be modelled pictorially to provide a clear representation of the theory being studied.

Structural equation modelling is conducted in two steps, first the measurement model and second the structural model. Therefore in the first step of the structural equation modelling, the CFA measurement model was specified and estimated. The fit statistics of the model were good ( $\chi^2 = 2.65$ , CFI = .960, NFI = .954, GFI = .949, SRMR = .040, RMSEA = .047, RMR = .015). Further to the fit statistics all loadings were adequate and significant at  $p = .000$ .

Thus, due to a good fitting measurement model, the study can proceed to the second step, which involves the specification and estimation of the hypothesised structural model as shown in figure 1. The fit statistics of the structural model showed goodness of fit ( $\chi^2 = 2.61$ , CFI = .973, NFI = .964, GFI = .969, SRMR = .019, RMSEA = .047, RMR = .010), in addition the standardised path coefficient regression weights,  $R^2$  values and statistical significance are shown in table 2 and figure 3.

|                       |      |                     | Estimate | P   |

| Search Success        | <--- | Level of Internet Confidence | -.125    | .017 |

\*\*\* ≤ .000

**Table 1 Structural Path Regression Weights**

|                         | Estimate |
|-------------------------|----------|
| Website Characteristics | .260     |
| Time Spent on Site      | .291     |
| Customer Experience     | .791     |
| Seek Customer Support   | .592     |
| Search Success          | .629     |
| Aesthetics              | .438     |
| Control                 | .831     |
| Info Quality            | .581     |
| Credibility             | .479     |
| Flow                    | .768     |
| Satisfaction            | .710     |
| Positive Emotions       | .828     |

**Table 2 R<sup>2</sup> Values**

### **Figure 3 Structural Equation Model**

Thus, significant relationships can be seen in table 1 and figure 2 in relation to the hypotheses previously outlined in figure 1. All hypothesised relationships show high regression weights all of which are significant at the .000 value. Therefore, the study concludes that the proposed model with its mediating structure has supporting statistical and theoretical evidence.

## **5.0 Discussion**

The aim of this study was to explore the variables capable of influencing a customer's experience while searching for Government provided business support information and services through developing a new online customer experience model. Additionally, the study aimed to explore the role of customer support through synchronised social interaction online, a phenomenon unexplored in relation to the customer experience. Insights into the findings of the research will now be provided along with a discussion on the theoretical and managerial implications of the research.

### **5.1 Theoretical contributions**

This paper makes a number of theoretical contributions to enhance our understanding of the online customer experience. The first contribution is the introduction of exploring the online customer experience within a utilitarian context of online business support. Past research has explored the customer experience in relation to the online shopping environment (Ha et al, 2010; Khalifa; Liu, 2007; Hoffman; Novak, 2009) and investigating outcomes of repurchase intention (Rose et al, 2012). This paper has provided theoretical insight into a utilitarian search for online information during the customer's journey to finding information.

Secondly, the findings of the research establish that the variables of information quality and website credibility influence the customer experience during a utilitarian search for business support information, both of these variables have been overlooked in previous studies. In addition, this paper finds that an underlying latent variable named 'website characteristics' encompassing website aesthetics, level of control, information quality, website credibility and flow together effect the online customer experience. The findings of the in-depth interviews and the online experiment highlighted the overlapping features of each of the variables. Previous studies (Khalifa; Liu, 2007; Song; Zinkhan, 2008; Hoffman; Novak, 2009; Ha et al, 2010; Rose et al, 2012) have outlined that numerous variables are capable of influencing the customer experience, however this study extends the current body of literature by introducing a new higher order variable and asserting the equal importance of each of these variables together influencing the customer's experience, proving hypothesis H1(a-e). The findings of this research show that the combined variable of 'website characteristics' has a direct and indirect effect on the customer experience through the length of time spent on the

website, requiring to seek customer support and through the success of the search.

This paper has furthered our theoretical understanding of the online customer experience through establishing the unidentified variable of the length of 'time spent on the website' in influencing the customer experience, the need to seek customer support and the success of the search, proving hypothesis H3, H4 and H5. Previous studies exploring the online customer experience have overlooked the variable of the length of time spent on the website. Limited research from Ludin and Cheng (2014) and Luo et al (2010) acknowledge that the length of time spent searching online may be influenced by the quality of the information provided. The findings highlight that the website characteristics (including: website aesthetics, level of control, information quality, website credibility and flow) influence how long customers are willing to spend on the website, poor website characteristics result in customers spending longer searching on the website, proving hypothesis H2. In turn, the longer customers perceive to spend searching for information or services on the website results in customers having a negative experience, resulting in negative emotions and dissatisfaction with the experience. Additionally, the structural model finds that the length of time spent on the website effects the customers likelihood in having a successful search. Thus, the longer customers are required to spend searching on the website the less likely they are to have a successful search.

Due to the emergence of the variable time spent on the website, this paper made a further theoretical contribution through developing and validating a new five point likert scale to measure 'time spent on the website' with four measurement items derived from the in-depth interviews. Following a further review of the literature and due to the fact 'time spent on the website' is a new variable to be introduced to marketing literature, no relevant scale could be obtained to measure the variable. Thus, in line with Churchill's (1979) scale development procedures as previously discussed a new validated scale has been introduced to the literature.

Moreover, this paper outlined the collection of positive customer emotions as well as a level of customer satisfaction as a measure of the customer experience. This is in line with previous studies suggesting that the customer experience is made up of cognitive (Novak et al, 2000; Hoffman; Novak, 2009) and affective (Rose et al, 2012) processes. The results showed high regression weights with statistical significance at .000. Therefore this study further confirms previous studies measures and theoretical underpinning of the online customer experience.

An important objective of this study is to examine the role of social interaction in providing customer support in relation to the online customer experience. This paper found multiple significant relationships with regard to the online customer experience and online customer support. The findings outlined that should customers feel they are spending more time on the website than they feel necessary they will require online customer support through one to one interaction with a company representative. The findings also showed that if

customers perceive the website characteristics (including website aesthetics, level of control, information quality, website credibility and the level of flow) positively then customers will not require online customer support. However, as previously discussed this relationship is mediated by the length of time spent on the website. Therefore while the website characteristics may be perceived positively, the length of time spent searching on the website can result in customers requiring to seek customer support. Conversely, where customers perceive the website characteristics as being poor, customers will require online customer support with a company representative.

In addition, the online experiment identified that customers who have an unsuccessful search require customer support in order to help them find the information or services they require, proving hypothesis H8. Respondents of the online experiment and in-depth interviews suggested that searching for business support information is not a day-to-day task and therefore it can be difficult to find the information required and thus support is often needed. Finally, the structural model illustrates that customers who need to seek customer support do so as they are having a poor experience, with negative emotions of frustration, anxiety and disappointment as well as being dissatisfied with the experience, thus proving the hypothesised relationship of hypothesis H6. The findings illustrated that when customers do not have a level of control over the website, being able to move through the website with ease and customise the website to their own individual needs then they are likely to require customer support in order to find the services they require.

Furthermore, respondents also elaborated on the aesthetics of the website as a fundamental reason for requiring customer support, where a poor design, look and feel of the website gives off the impression that the website may be difficult to use as well as a negative judgement on the credibility of the website. The comments from the respondents further support the rationale of the higher order variable of website characteristics and therefore the reason why each of the variables combining to create 'website characteristics' should be considered together with equal importance. The literature to date has not explored the need for online customer support in the form of synchronised social interaction in relation to the customer experience. This paper specifically establishes this requirement in the context of a utilitarian search for business support information and services. These findings add significant value to research within the domain of the online customer experience.

The findings further elaborate that the success of the search has an effect on the customer's experience. A strong relationship between the search success and the customer experience was found, where if a customer was successful in their search the customer experience would increase by .54 having a significant effect increasing positive emotions and the level of satisfaction with the experience. Therefore it is important to acknowledge the variables of website characteristics encompassing website aesthetics, level of control, information quality, website credibility and flow as well as time spent on the website influencing the success of the search in order for customers to have a positive experience eliciting positive emotions and satisfaction with the experience.

In addition, this paper found that the customer's level of Internet confidence has an effect on the length of time customers are willing to spend on the website. The more confidence the customer has in using the Internet will result in the confident searcher being unwilling to spend longer than they perceive necessary searching for information or services. Thus, confident searchers are even more time sensitive than less confident searchers. Further results showed that the level of confidence a customer has in using the Internet has a relationship with the success of the search. Interestingly, the results find that those who are confident in searching are likely to abandon their search on a business support website. Participants of the in-depth interviews and the online experiment elaborated that using a business support website was not a familiar activity, thus while those participants may be confident in using the Internet in general, the confidence in using a business support website may actually be low in comparison and therefore result in customers having an unsuccessful search. However, based on the psychological reactance theory (Brehm, 1966) where past experiences create expectations, confident searchers appear to become frustrated and disappointed in the website than those less confident searchers, thus confident searchers are quicker to abandon their search and seek customer support than those less confident searchers.

## **5.2 Managerial Implications**

This study offers economic development agencies offering online business support services numerous managerial implications. The findings suggest that the website aesthetics, the level of control the website provides customers, the quality of the information on the website and the websites provision to customers to allow them to concentrate on their task (flow) altogether have an influence on the customer's experience. The website aesthetics refer to the design, look and layout of the website. The level of control refers to how easy the site is to use and the ability to customise the experience by filtering and controlling content relevant to the customer. The quality of the information refers to the accuracy, relevance, how current and the usefulness of information provided on a website. Website credibility refers to the assessment of key surface characteristics of the site, including an assessment of the sources, checking accreditation or company credentials, the brand of the website, the URL and the websites aesthetics. Lastly, flow refers to the extent to which the website allows the customer to concentrate and focus, while feeling absorbed and engrossed in the task. Thus managers and marketing professionals within economic development agencies ought to pay close attention to each of these variables in providing customers with a positive experience.

Much industry research refers to the importance of customers spending a longer length of time on the website as a benchmark of a successful website. This research highlights to marketers and managers of economic development agencies to use such a benchmark with caution as this research finds that the longer customers spend searching on a website, the less likely they are to have a positive experience as well as being less likely in having a

successful search. Thus, marketers should offer business support websites that allow customers to complete their tasks in a timely manner.

As has been previously discussed, a distinctive difference between the online and offline environment is the ability to socially interact with a customer representative. With the advancements of recent technology, new features such as live chat technology and online customer helpdesks allow organisations to offer synchronised customer support online. The research findings suggest that online customer support is required via synchronised social interaction when the website characteristics are poor, the customer is required to spend longer than perceived necessary and when the customer does not have a successful search. Thus, a further implication for marketers and managers of economic development agencies is to provide customers with online support, simply providing customers with information and self-service functions may be a disservice to customers. An introduction of online customer support may help to prevent customers abandoning their search.

### **5.3 Limitations and recommendations for future research**

The findings and the contributions of this study are somewhat constrained by certain limitations, of which opportunities for future research arise. While the online experiment outlined actual behaviour, in order to further explore customer support online via synchronised social interaction, researchers could develop a website with a form of customer support such as a 'live chat' function and one without to compare the difference on the customer's experience. This would help to advance the research undertaken in this study.

Additionally, it would be insightful for economic development agencies to identify if the same variables influence the customer experience on mobile devices. This study conducted the research in the situation of searching on desktop and laptop devices. With the rise of customers using mobile devices to access the Internet for information and services it would be prudent to investigate if differences exist.

Finally, while managerial implications apply for economic development agencies, this research has found that online customer support is required if a customer perceives to spend longer than necessary on the website or if the customer perceives the website characteristics as being poor or if the customer is having an unsuccessful search. It would be valuable for future research studies to explore if a role for online customer support exists within other contexts including the popular online shopping context.

## *Abstract*

*This study explores future digital value creation in service business. The aim is to create understanding about future digital services and business opportunities with the aid of four complementary theoretical approaches: customer experience, reverse use of customer data, different channels (omnichannel) and digital business models. Based on multidimensional theoretical framework of future digital value creation, we suggest empirical research methods and practically-oriented propositions that can be used to capture the specificities of the phenomenon under examination.*

## **1. Introduction**

Continuous growth of new mobile devices and digital services has dramatically changed both b2c and b2b customers' behavior in recent years. The most visible change relates to the role of customers in the value creation; the power is shifting from companies to customers (e.g. Vargo; Lusch 2008) and most of the decision-making currently takes place out of vendors' reach in social networks and search engines. Also, the customers' decision-making is more and more guided by emotional and experiential factors, not only rational criteria (e.g. Verhoef et al., 2009). Marketing Science Institute (2014) has suggested that understanding customer and the customer experiences will be the most important research priority in the following years. In understanding customers essential issue is to identify changed behavioral models and value creation processes through which the customers satisfy their needs.

In most industries, majority of the companies have not really understood the consequences of digitalization for customer behavior (Forrester, 2014). In order to succeed in the new digitalization era, the firms need to get to know their customers more carefully and they need to tailor appropriate service packages for each customer type. It

is therefore important to create profound understanding of how digital value creation can be understood and used in developing new service businesses. Our study approaches future digital value creation by focusing on the four key theoretical approaches (i.e. customer experience, reverse use of customer data, omnichannel and digital business models) and a variety of empirical research methods that are able to capture the specificities of the phenomenon. The research questions are: 1) How can digital value creation be understood theoretically? 2) What kind of research methods are needed to create understanding of the future digital value creation within service business? 3) What are the key aspects to focus on in the future when exploring digital value creation?

In relation to the first research question we will explore the possibilities of digitalization with the aid of four complementary theoretical approaches: customer experience (e.g. Verhoef et al. 2009), reverse use of customer data (e.g. Saarijärvi; Grönroos; Kuusela, 2014), omnichannel (e.g. Karjaluoto et al., 2014) and digital business models (e.g. Zott; Amitt; Massa, 2011). They are tools that aid us to understand digital revolution of value creation and to harness its business potential for the benefit of service firms. These approaches have gained scientific attention only recently and linking them to research digital value creation has been scarce. Based on these four interrelated approaches we suggest a multidimensional theoretical framework linking these perspectives together towards understanding on how to unlock new business potential in digital service field. Secondly, this framework of digital value creation aids in identifying the diverse set of research methods that are suitable for exploring this future-oriented phenomenon. Existing research is mostly based on conventional research methods such as case studies (e.g. Yin, 2009) or surveys (e.g. Kahneman et al., 2004) but when the aim is to really understand new digital opportunities in service business in the future, these methods used individually do not provide much help. We will fill this gap by suggesting innovative research methods that can be used to create in-depth understanding of the research phenomenon as well as proposing how different research methods could be combined to provide more comprehensive understanding. Finally, based on the framework we present practically-oriented research propositions that will guide future research towards unravelling new business potential in digital service business.

The theoretical and practical contribution of the study relates to linking four relevant, yet under-researched theoretical approaches together to create comprehensive understanding of how to utilize digital value creation in developing new service businesses. Suggested versatile and innovative research methods will aid forthcoming research to find out ways to better understand digital value creation and related possibilities and challenges. Finally, practically-oriented propositions focus on relevant aspects to be explored in the future and point out several possible pathways to guide both academics and businesses involved in digital service business. Consequently, in the next section a brief discussion on the related literature streams is provided after which the theoretical framework is presented. Then, the methodology of the study is presented and finally we discuss the findings and conclusions of the study.

## **2. Theoretical background**

Customer value creation processes are changing radically. In order to succeed in the turbulent environment, companies must learn to understand and identify differences between their customers more deeply to be able to offer tailored services in accordance with customer needs. In this study we aim to advance knowledge and understanding of digital services in the future with focus on four key approaches: customer experience, reversed data usage, omnichannel strategies, and digital business models. These are next discussed in detail to form a basis for our multidimensional theoretical framework of digital value creation.

### **2.1. Customer experience**

The importance of understanding customer experiences has recently been recognized in academic marketing literature. The concept of customer experience (Verhoef et al., 2009) shifts the focus from the characteristics of products and services towards holistic understanding of value creation and value perceived by different actors (e.g. Komulainen et al., 2006). Verhoef et al. (2009, p. 32) define customer experience as being holistic in nature and involving the customer's cognitive, affective, emotional, social and physical responses to the retailer and suggest that "experience is created not only by those factors that the retailer can control (e.g. service interface, retail atmosphere, assortment, price) but also by factors outside of the retailer's control (e.g. influence of others, purpose of shopping). Pine and Gilmore (1998, p. 98) define a customer experience to occur "when a company intentionally uses the services at the stage, and goods as props, to engage individual customers in a way that creates a memorable event". Although customer experience has been defined as the customer's individual and subjective response and therefore internal, hedonic and extraordinary experience of the individual has been emphasized, the perspective has recently evolved towards a greater emphasis on experience as a collective, co-created phenomenon relevant to both consumers and business actors (Helkkula et al., 2012; Jaakkola; Helkkula; Aarikka-Stenroos 2015).

Each customer experience is a potential source of customer value (Saarijärvi; Kuusela; Rintamäki, 2013) and the creation of superior customer experience is considered key to attaining loyal and satisfied customers (Grewal et al., 2009). The importance of customer experience is in line with the service-dominant logic that emphasizes the experiential nature of value (Vargo; Lusch 2008). Accordingly, value is embedded in the customer experiences created through value co-creation between different actors.

Previous studies suggest that perceived value is not based purely on economic or functional aspects but encompasses both emotional and symbolic dimensions (Rintamäki et al., 2007). Perceived value usually is not rational or objective but very subjective and influenced by time and context (Corsaro; Snehota, 2010). Also past experiences and future expectations are integral parts of value perception (Komulainen; Mainela; Tähtinen, 2013). There are some studies focusing on value of digital

services (e.g. Komulainen, 2010) but in order to develop new digital services with real business potential, more research is needed about holistic customer experience.

## **2.2. Reverse use of customer data**

Traditionally customer data usage – often referred to as customer relationship management (CRM) – supports firm's internal processes, including segmentation, cross-selling, identification of the most profitable customers, supply chain management and rewards for the most loyal or profitable consumers (Payne; Froh 2005). Through the use of this customer data, firms have been able to adapt to fluctuating market demand, understand rising consumption patterns and manage their customer loyalty programs (Saarijärvi et al., 2014). In other words, customer data offer important sources of information that helps firms manage their everyday business activities. Companies' traditional use of customer data can also be useful for customers in an indirect way through, e.g. category management (better fit between customers' needs and the company's product categories) or direct marketing campaigns (customers are provided with targeted promotions of products that they find relevant). However, the current CRM framework has been inherently very firm-centric and focused on using customer data for the benefit of a company (see Thaler, 2011).

The traditional role of customer data is not in tune with the current service because of its inherent focus of selling more products. Increasing number of private and public initiatives challenge conventional CRM activities and suggest new, innovative ways of using customer data by shifting attention towards sharing data with customers rather than using it for firm purposes (Saarijärvi; Karjaluoto; Kuusela, 2013). As the amount of customer data is growing explosively, the customers are becoming more and more aware that firms are collecting data about them. Therefore, firms need to consider how to use the customer data for the benefit of their customers. *Reverse use of customer data* means that firms are converting their customer data into information to directly support customers' value creation (Saarijärvi et al., 2014). This can be seen as the major future development specifically in service oriented business environment.

As suggested by Saarijärvi et al. (2013), moving towards customer data sharing opens up many new business and service opportunities. For example, healthcare actors could return data about customers (i.e. patients) back for customers' own use and local authorities can provide geographical data to customers to modify, refine and apply in their own processes. Also an increasing number of social media applications enables to use customer data to support customers' processes. Therefore, customer data should not be viewed as solely owned or by solely useful for the firm but a way to provide customers with additional resources, for the purpose of better serving those customers. Shifting the focus from internal to external use of customer data finds also theoretical support in recent discussion about service logics (e.g. Grönroos, 2008; Maglio; Spohrer, 2008; Vargo; Lusch, 2004). Accordingly, value is co-created between the actors thus benefitting all the parties involved in exchange.

Understanding the opportunities involved with the reconfigured role of customer data has major implications for practice as it aids in creating new ways to serve customers better which in the long run results in equal benefits for the company. Reverse use of customer data combined with digitalization opens up new ways to support customers' value creation. Most importantly, it enables companies to get involved in their customers' everyday life and thus better responding to their continuously changing needs.

### **2.3. Omnichannel / Mobile channel**

Mobile technology is well on its way to changing both consumer behavior and expectations, and business opportunities for the companies. For example, in the context of retailing, Brynjolfsson, Hu and Rahman (2013) suggest that recent technological advances in mobile computing and augmented reality are blurring the boundaries between traditional and Internet retailing, enabling retailers to interact with consumers through multiple touch points and expose them to a blend of offline and online content. Thus, retailing industry is evolving toward a seamless "omnichannel retailing" which gives consumers more channels from which they can obtain information during the purchase decision process. Decisions can be shaped by information e.g. from the store channel, store websites, mobile apps or social media. This allows consumers to accumulate product knowledge in one channel and then purchase from another channel. As omnichannel enables collecting huge amount of new data from social, mobile and local channels it provides an opportunity for companies to understand not just customer transactions but also customer interactions such as visits to the store, likes on Facebook, searches on websites, and check-ins at nearby establishments (see Brynjolfsson et al., 2013).

Omnichannel is increasingly a part of consumers' and business customers' everyday life. For example, 71% of consumers expect to view in-store inventory online, while 50% expect to buy online and pick up in-store (Forrester, 2014). The greatest change in omnichannel has been the explosive growth of mobile devices (e.g. smart phones, tablets) that has been said to change firms' processes remarkably in next few years (Forrester, 2014). It is clear that today's consumers are focused on convenience, and they expect their retailer of choice to provide this convenience across all channels. However, according to recent market research, only a third of retailers have sufficiently prepared for these changed customer expectations and operationalized even the basics such as store pickup, cross-channel inventory visibility, and store based fulfillment.

Research on service logics (e.g. Grönroos, 2008; Vargo; Lusch, 2008) emphasizes the need to understand customer's everyday life as a starting point for value creation. Digitalization and omnichannel provide new possibilities to develop such services that connect value creation to the customers' routines (Kallio; Lappalainen, 2014). Omnichannel and digital services can be seen as important value creating mechanisms that firms can use to support customers' value creation processes (Karjaluoto et al., 2014). Different kinds of mobile services are a significant way to transfer firm's knowledge to serve customer's value creating processes regardless of location or

time. It is critical for the success of the new mobile services to understand the value it creates to all parties involved.

## **2.4. Digital business model**

The concept of business model has been used to describe, understand and model a firm's business (e.g. Chesbrough; Rosenbloom, 2002) and it can be seen as the mode for generating revenues. In other words, it is stressed that the right business model or 'the architecture of revenue' needs to be found if companies wish to create revenues from new technologies (Chesbrough; Rosenbloom, 2002). The business model concept has also been used as a general construct explaining how a firm is interacting with suppliers, customers and partners (Amitt; Zott, 2003). Although there are numerous different definitions for business model concept, it is possible to identify certain similarities between them. First, customer value creation can be seen as one of the core elements: the business model needs to explain how the firm creates value for its customers. Secondly, revenue logic or earnings logic refers to how the firm yields a profit from its operations and the exchanges between different actors. Finally, business model construct also incorporates the relationships that the firm has with various actors in its value network (see Komulainen et al., 2006; Nenonen; Storbacka, 2009).

In developing digital services there is a risk that the firms are investing in service development without clear and defined digital business model. For example, in retailing context digital services are usually seen as a tool to develop customer relationship. Identifying and understanding the digital revenue logic needs to be in the central role when the firms aim to harness the opportunities provided by digitalization.

## **2.5. Theoretical framework**

Based on the above discussion we suggest a multidimensional framework of future digital value creation (see Figure 1). Linking the four theoretical approaches (customer experience, reverse use of customer data, omnichannel and digital business model) together in a model forms a basis for both new practical and theoretical understanding as well as creating scientifically interesting research settings and using innovative future-oriented research methods. In relation to these approaches we identify four involved concepts, i.e. *co-creation*, *engagement*, *customer journey* and *digital service design* as complementing the big picture. They can be seen as tying the four key approaches together and are thus needed to for a comprehensive picture of the influence of digitalization on future value creation in service business.

Figure 1. Multidimensional theoretical framework of future digital value creation

Next, we will use the framework as a basis for identifying different types of innovative and future-oriented research methods suitable for in-depth exploration of future opportunities in digital value creation.

### 3. Methodology

This is a conceptual study that is a part of a larger research project. The objective of the project is to 1) understand how users/consumers/customers create value in mobile context, 2) transform this information to companies and finally 3) identify sources of key competitive advantage rooting from the mobile context and value creation in it. The project involves universities and a research center, as well as industry representatives i.e. companies that strive for better understanding of digitalization in service development. Therefore, it represents a new kind of interaction between digital service providers, technology providers, end users and research institutes. The research project has been ongoing from the beginning of 2015 and it is still in an initial phase. However, we will next discuss the data collection methods that we have either already used or will be using as the project proceeds. In line with Dube and Helkkula (2015) who claim that research should use variety of methods to gain understanding of the influence of individual everyday lives on app use experiences, also this study investigates digitalized value creation using multiple methods.

This research project is divided in four phases (see table 1). The phases are partly overlapping and inter-related. In the first phase, we investigate our partner companies' (i.e. service providers') customers and use multiple data gathering methods for understanding customers' everyday life, and how their value creation processes are and could be connected to companies' businesses. We explore both B2B and B2C customers with the aim of creating a comprehensive understanding of their value creation processes.

In this phase we use many different methods: thematic interviews with partner companies, digitalized storytelling and group discussions conducted in various focus groups, trend analysis, and diary method in parallel with thematic interviews of mobile application users. In addition to qualitative methods also quantitative surveys and web analytics will be used in order to form a comprehensive picture of the customer journeys.

The research project began with altogether 11 initial interviews with research partners (service providers) that were conducted to find out the current state of their service development and expectations for the project. Interview data provides us a starting point for targeting further research efforts towards relevant and interesting directions.

Our focus group working includes both group discussions and digitalized storytelling method. A focus group is according to Thomas et al. (1995) "a technique involving the use of in-depth group interviews in which participants are selected because they are a purposive, although not necessarily representative, sampling of a specific population, this group being 'focused' on a given topic". The main aim of using focus groups is to understand, and explain, the meanings, beliefs and cultures that influence the feelings, attitudes and behaviours of individuals (Rabiee, 2004). Therefore, it is ideally suited for our study as we explore the everyday life of individuals within the context of their experiences. In our study, there were altogether three focus groups with four persons in each group. In addition, three researchers were involved as encouraging discussions and organizing different phases of working. Duration of the focus group working varied from 2 hours to 2,5 hours and all the discussions and material produced were collected and videotaped as well as transcribed afterwards.

During the focus groups the participants discussed about their current use of different mobile services and envisioned their possible lifestyles and behavior in the future in relation to different types of mobile services or applications. In addition to group discussions, a digitalized storytelling method was used to create visions and scenarios about possible future developments. According to Meadows (2003) digital stories are "short, personal, multimedia tales, told from the heart". Anyone can make them and

publish them on screens anywhere. Typically digital stories are personal stories in which sound, pictures and text are combined together to form a small-scale multimedia composition. We decided to use this method as these personal stories may reveal very interesting ideas, thoughts and trends of future behavior and lifestyles of individuals, thus aiding in forming innovative scenarios of how digital services could be used in the future. The analysis of the focus group data has been tentatively started and will be continued with a narrative analysis.

In order to study customer experiences and value perceptions in mobile applications we use a diary method in parallel with thematic interviews in the specific case study of mobile wallet application. The diary research method has emerged as one of the preferred qualitative research methods (see Dube; Helkkula, 2015) and it aims to explore a phenomenon by recording the process elements as they happen (Patterson, 2005). The diary research method provides an in-depth understanding of use experiences in real time, which is not possible by other qualitative methods (Bolger et al., 2003). In the data collected by using a diary method, users of the mobile application were asked to describe and write a diary of their experiences of using the mobile wallet every day during two weeks time period. In addition to the diaries the users are also interviewed to get a comprehensive picture of their experiences and value perceptions. The data collection is still in progress.

From the quantitative angle, we are interested in e.g. continuous use of mobile service. A large survey will be conducted for the users of mobile bank application (i.e. consumers) to find out how their perceived value, engagement with the bank and the continuous use of the application influence their everyday life and the relationship with the bank that is one of our partner companies in the research project.

In the second phase of the project, we will identify *future customers' value creating scenarios* through linking multiple data collected earlier in the first phase. As suggested by Peterson, Cumming and Carpenter (2003) scenario planning is a systemic method for thinking creatively about possible complex and uncertain futures. The central idea is to consider a variety of possible futures that include many of the important uncertainties in the system rather than to focus on the accurate prediction of a single outcome. Scenario planning can incorporate a variety of quantitative and qualitative information and the participation of a diverse group of people in a systemic process of collecting, discussing, and analyzing scenarios builds shared understanding. The scenarios created in this research project enable us to communicate and discuss identified value creating elements with technology providers such as start-ups and SMEs.

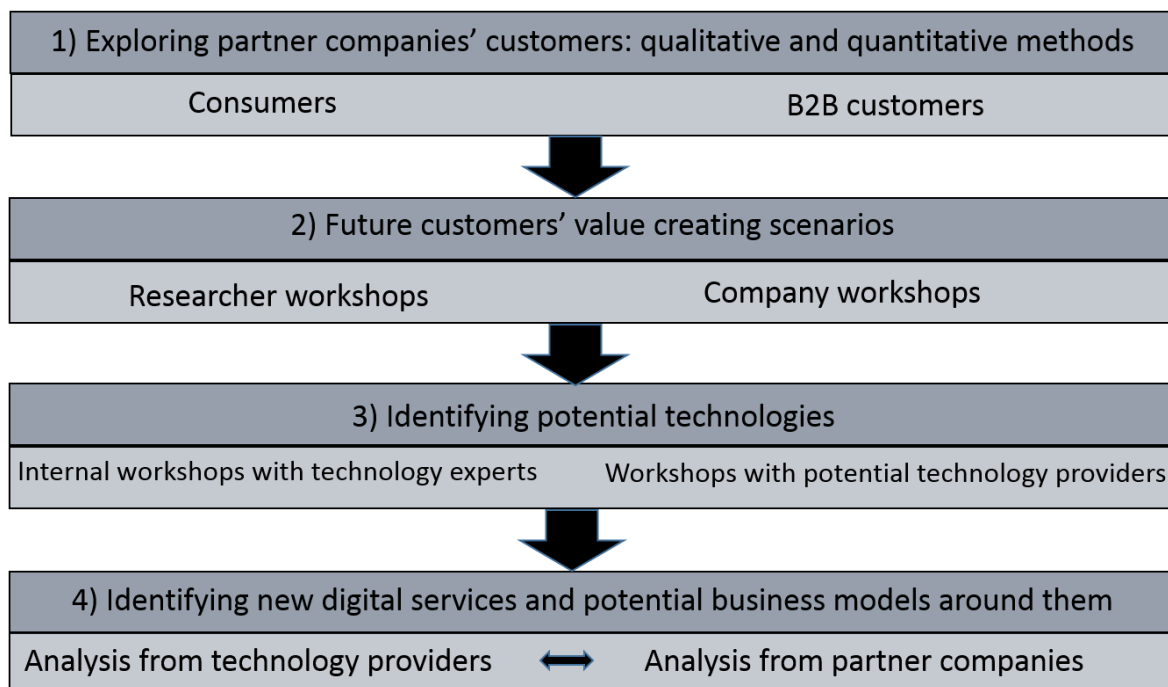

In the third phase the focus is on *identifying potential technologies to support digital value creation*. Following the scenarios identified in the previous stage, needed technologies supporting customer's value creating processes will be suggested. In this phase, thought leaders within the digitalized business will be interviewed and their expertise will be utilized. Thought leaders in this study refer to informed opinion lea-

ders in their field of expertise. They are trusted sources who move and inspire people with innovative ideas; turn ideas into reality, and know and show how to replicate their success (Brosseau, 2014). Klavans & Boyack (2008) suggest that thought leaders have two characteristics. First, they are committed to participating at the forefront of science rather than on older science. Second, they are willing to shift their emphasis from older ideas to newer ideas when warranted. In this research, thought leaders provide us important information and ideas on how to develop new, innovative digital services that create value for both the technology companies, service providers and end users.

Furthermore, we will arrange workshops for company representatives and selected technology providers interested in customer oriented innovation work. Within these workshops, using for example service design methods, participants are encouraged to innovate new digitalized services based on identified customer needs and their everyday life processes. The aim is to facilitate co-created value creation between workshop participants. This also enables us to observe and interview the participants during workshops.

In the last phase, *new digitalized services and the potential business models around them* will be investigated. Here interaction between technology providers and technology users (service providers) is in the focus. In this phase, we will explore and identify possible new digital services and the development of digitalized revenue and business models within partner companies by using qualitative methods, e.g. interviews and observations.

Table 1. Phases of the research project

## 4. Findings and discussion

Although still in its early phases, this research makes valuable insights both into the theory and practice. It contributes to existing research by linking together the four under-researched theoretical approaches on digital value creation and presents a theoretical framework that aids in understanding and developing new digital opportunities in service business. The concepts of customer experience, reverse use of customer data, omnichannel and digital business models are connected to each other by related concepts of co-creation, engagement, customer journey and digital service design. Altogether they form a comprehensive picture of digital value creation and aid in creating new research settings and identifying innovative research methods for developing future-oriented services.

Secondly, based on the framework we suggest a diverse set of research methods to explore digital value creation. More specifically, we identify different qualitative and quantitative methods that can be used to examine future possibilities and challenges in the field of digital services. These methods aim at in-depth understanding and utilization of customer experiences, reverse use of customer data, use of omnichannel and digital business models as a basis for developing new kinds of digital services. The identified methods include e.g. focus group discussions, digitalized storytelling, thematic interviews, observations, trend analysis, diary method, surveys and web analytics. We suggest that these methods are most useful when used innovatively in novel ways and if possible, as complementing each other.

Finally, based on the above discussion, we present four overall themes and related nine practically-oriented research propositions that will guide future research towards unlocking new business potential in digital services. We hence suggest that the forthcoming research (including this research project) needs to focus on the following themes and related questions:

### *1. Customer experience and future digital customer journey*

P1a: How is customer experience formed in diverse B2C service contexts?

P1b: To what kinds of customer value creation processes will firm's business be connected in the future?

### *2. Reverse use of customer data and customer value formation enabled by new technologies*

P2a: How could digital services be used to transfer firms' knowledge to support customers' processes?

P2b: How is customer value formed now and in the future?

### *3. Omnichannel / Mobile channel*

P3a: What kinds of services will future technologies make possible to create?

P3b: What kinds of technological possibilities are already available to support customers' everyday life?

#### *4. Digital business/revenue model*

P4a: How can digital services create value for firms and their customers?

P4b: What kind of business models will be developed as a result of digital value creation?

P4c: What kind of digital earnings logics will be developed around new services?

## **I4: Unlocking new potentials of ICT**

*Chair: Jørn Kjølseth Møller*

# **XXV. International RESER Conference: Use of equipment lifecycle data in industrial services**

*Moramay Ocaña Flores and Miia Martinsuo*

Tampere University of Technology

*Manufacturing firms can use equipment lifecycle data to enable industrial services. With the increased centrality of information technology, they may need cooperation with software providers, and this cooperation is still poorly understood. This study pursues increased understanding on the use of equipment lifecycle data in industrial services. An exploratory study with four software providers and two manufacturing firms reveals unexploited opportunities for industrial services through intensified triadic cooperation and clarifies the task division between manufacturing firms and software providers. A framework is suggested, on the conditions enabling and promoting success in the services based on equipment lifecycle data.*

## **1. Introduction**

### **1.1. Background**

As the competition increases, manufacturing firms need to find ways to stay in business and differentiate from other players in the industry. These firms often need to seek for competitive advantage by extending their offering to services, besides the delivery of industrial goods (Gebauer, 2007). Services can involve the customers as co-producers of added value and quality (Edvardsson & Olsson, 1996) while the supplier gets a better understanding of its customer and is capable of turning that value into revenues. This demands more flexible responses to changing business and the collection and analysis of lifecycle data from the equipment in the customers' use. Software-based services and modern technologies have enabled manufacturing firms to transform from data-driven to more cooperative knowledge-driven environments, by analyzing data gathered throughout the whole lifecycle of their products (Camarinha-Matos et al., 2009).

During servitization, manufacturing firms often take over some of the customer's processes, e.g., through remote access handling inventory and spare parts (Mezgár & Rauschecker, 2014). As the equipment's lifecycle data becomes available, the possibility to offer new services based on use patterns and better customer's understanding becomes real (Yang et al., 2009). Processing the lifecycle data requires specialized skills that servitizing manufacturing firms do not necessarily possess. Consequently, manufacturing firms can use their knowledge of the customers' needs to integrate other service suppliers into their processes (Finne & Holmström, 2013). In spite of the advantages of exploiting this possibility, the use of lifecycle data is challenged by various issues in inter-organizational cooperation, such as agility, security, privacy and interoperability aspects (Mezgár & Rauschecker, 2014).

The literature has already addressed the technical capabilities and challenges of data collection of remote monitoring systems. Westergren and Holmström (2012) presented applications of sensor-based solutions in a real industrial case and mentioned different value drivers for the stakeholders in a network. Their study focuses on the open innovation paradigm and establishes the importance of ICT (Information and Communication Technology) and trust to overcome security issues. It does not focus on the positions and tasks of each player of the network nor provide more details about how to utilize the collected remote data. Technical literature regarding the resources needed to ensure data security and privacy is also available as in Mezgár & Rauschecker (2014), but it has not been broadly studied from a business perspective. Similarly in the technical stand point, Vezzetti (2009) presented Web3D software tools to visualize lifecycle data as part of a Product Lifecycle Management (PLM) initiative. These software tools can benefit network partners with integration and interoperability issues but details about the tasks and business opportunities for industrial suppliers are not explained. Based on these studies and other recent empirical research, it was found that the collaboration between manufacturers and software providers to offer new industrial services has not been studied as much as the more traditional cooperation between supplier and customer in value co-creation.

Particularly, this study is focused on exploring the possibilities of industrial services based on equipment lifecycle data (ELD) and ways of cooperation between the manufacturer and software-based service provider in enabling industrial services. For this study, issues such as security and privacy have raised interest amongst the target companies, therefore the expectations on how to overcome these initial challenges will be addressed. Our contribution is based on offering a combination of two different points of view towards the use of equipment lifecycle data. By combining the perspective of the manufacturing firms and the software-based service providers new business models can be developed based on a triadic cooperation between suppliers of complex systems, software firms and their customers.

## **1.2. Research objectives**

The objective of this study is increased understanding on the use of equipment lifecycle data in industrial services. We explore the use of equipment lifecycle data particularly through supplier's different network positions, tasks and cooperation in the context of manufacturing firms and their prospective software service providers. We also explore the ways in which the companies can enhance the use of equipment lifecycle data, to promote success in their industrial services. We believe the software service providers can design new business models in cooperation with manufacturing firms to deliver the ultimate customer value and at the same time manage the possible risks. To fulfill the objectives, two main research questions are stated:

1. What is the task division between companies (particularly manufacturing firms and software providers) when using equipment lifecycle data in service delivery?
2. How do companies in the network enable and promote the use of equipment lifecycle data for successful service delivery?

The combination of equipment lifecycle data collection and software-based services provides a possibility to improve the service offering of manufacturing companies. In

this study, we explore the perspectives of both manufacturing firms and software firms in the context of industrial services offered for corporate customers. The focus is on industrial equipment, i.e., complex systems, and related industrial services. Consumer services are not covered, and also other parts of the supply chain are excluded. This study does not cover the customer's point of view as we did not have access to them directly. The long lifespan of the equipment is characteristic to the manufacturing firms: as the purchases of the manufacturing firm's equipment are scattered in time, the relation with their customers is almost transactional and in most cases dealt via distributors around the globe.

As a result of this study, we report conclusions on the task division between manufacturing firms and software providers in their triadic relationship with customers, emphasizing the enhanced use of equipment lifecycle data in industrial services. We will report key challenges in the use of equipment lifecycle data, and respective enablers and promoters that can drive forthcoming success in industrial services based on ELD use.

## **2. Literature review**

### **2.1. Supplier's use of equipment lifecycle data**

Manufacturing firms are looking for possibilities to enable more business opportunities by offering product-related services (Gebauer, 2007). Sandin (2015) expressed the importance for the customer and supplier to know the basics of each other's businesses to co-create value supported by various networks. In a traditional approach of product-related services, the offering is limited to the lifecycle of the physical product (Oliva & Kallenberg, 2003). The lifecycle of industrial equipment creates big amounts of data that can be of value for both the supplier and the customer or end user. Equipment lifecycle data refers to the data that can be collected through all the lifecycle phases of an intelligent product, from the market requirements to the disposal or decommissioning (Qureshi et al., 2014). Previous literature discusses the concept of "product lifecycle data", but the word equipment has been selected to emphasize the industrial context in this particular study, and to create a clear distinction from the business-to-consumer market.

Traditionally there are three phases in the lifecycle of industrial equipment: design, manufacturing and service or operational phases (Brunssman et al., 2011). Modern technologies based on ICT have enabled automatic data collection from these different phases in intelligent products. Especially when companies collaborate with suppliers or partners, data management practices increase their relevance (Kropsu-Vehkaperä et al., 2009). Nevertheless, despite the increasing possibilities enabled by remote monitoring systems and the Internet, data collection from the supplier's point of view often ends once the equipment leaves the factory and is delivered to the end customer.

According to Yang et al. (2009), the intelligent product's data can be classified into static and dynamic, depending on the stage of the lifecycle it is collected. The static data is related to the specifications of the product and is collected from the first stages of its lifecycle. These data can include the specifications of the product such as

the materials, components, suppliers and how it operates, and it is often studied under the concept of product data management (PDM). On the other hand, the dynamic data is created during the operational phase of the product and is studied as product lifecycle management (PLM). (Yang et al., 2009; Kropsu-Vehkaperä et al., 2009)

Previous research has frequently looked into the customer's (i.e. equipment users) viewpoint regarding how equipment lifecycle data is used, and the benefits for the manufacturer are often overlooked. Generally, identifying bottlenecks in the operations as well as analyzing possible break downs to minimize negative cost impact are mentioned as benefits for the customers (Brunssman et al., 2011). Most of the benefits of the equipment lifecycle data are connected to the customer's satisfaction and supporting them by taking over some of their operations. Manufacturing firms as suppliers could also benefit from the equipment lifecycle data by forecasting better spare parts stock needed to fulfill customer's demand and decrease warehouse costs. R&D processes can be also improved by knowing exactly how the equipment is being used (Kucza & Gebauer, 2011; Yang et al., 2009). It is necessary for the manufacturers to offer attractive industrial services to get access to the data in the first place. The possibilities are presented in the following section.

## **2.2. Industrial services based on equipment lifecycle data**

The manufacturing firms' interest is to utilize the equipment data to identify service opportunities, and develop and deliver appropriate industrial services in line with the customers' needs (Edvardsson & Olsson, 1996). The previous literature makes evident that just collecting the data is not sufficient to offer more services, but it is necessary to analyze and store it too. Unfortunately the collection of equipment data is not easy in practice and the challenges related to ownership, maintenance and relevant processes have not been widely studied as the academic research areas of PDM and PLM are relatively new (Kropsu-Vehkaperä et al., 2009).

Manufacturing firms utilize different kinds of software tools to handle internal information such as ERP systems (Enterprise Resource Planning), CRM systems (Customer Relationship Management) and supply chain management information systems. These systems can facilitate tasks related to resource optimization, marketing and supply chain management, but there are processes linked to R&D, product provision and support services that are not solved with them (Yang et al., 2007). PLM (Product Lifecycle Management) systems have emerged as a solution to manage the equipment lifecycle data generated during the distribution, use, maintenance and end-of-life stages. Yang et al. (2007) presented a PLM model where the dynamic data flows from the intelligent product to the PLM system through a communication's support infrastructure; after it has been manipulated and stored, the knowledge and information is used to enable industrial services for the stakeholders.

Yang et al. (2009) also proposed a series of services that manufacturing companies can provide to their customers based on the processed data, such as remote management of spare parts, preventive maintenance, as well as modernization services at the end of life of the equipment. Similarly, internal processes - based on dynamic data related to equipment usage and distribution - are possible, such as remote diagnosis and monitoring. Deeper knowledge about use patterns can give the supplier a better understanding of the customers' needs to develop the equipment (Yang et al., 2009).

By relying on external software tools, Kucza and Gebauer (2011) proposed a classification of services in different sorts of operations based on the level of knowledge intensity gained through the data collection. Those operations can be divided in four: customer service, basic services for the installed based, maintenance services and R&D oriented services (Kucza & Gebauer, 2011). This classification is shown in Figure 1.

|           |  |
|-----------|--|
| 1st level | <ul style="list-style-type: none"> <li>▪ Electronic order placement</li> <li>▪ Spare part forecasting.</li> </ul>  |
| 2nd level | <ul style="list-style-type: none"> <li>▪ Cost-benefit analysis</li> <li>▪ Benefit visualization</li> <li>▪ Preventive maintenance services</li> <li>▪ Product and software upgrades</li> <li>▪ Viability studies/problem analysis</li> </ul>   |
| 3rd level | <ul style="list-style-type: none"> <li>▪ Full preventive maintenance and spare parts handling.</li> <li>▪ Process-optimization through continuous maintenance.</li> <li>▪ Technical consulting and advice.</li> <li>▪ R&amp;D support</li> <li>▪ Process-oriented design</li> <li>▪ Business consulting in product and process development.</li> </ul> |

**Figure 1:** Software-based services based on knowledge intensity, adapted from Kucza & Gebauer (2011).

In the first level, customer services are addressed by providing basic software-based services that include electronic communication. In the second level of knowledge intensity the services are more oriented to provide extra value for the installed base and also some general customer services. The higher level of knowledge intensity deals with all the kinds of service operations, including maintenance and R&D oriented services. This level of intensity implies a stronger relation between the manufacturer and the end customer. (Kucza & Gebauer, 2011)

The software systems used in industrial service delivery such as PLM systems require not only the technical competences, but also an understanding of what data can be generated and how it can be enriched. By sharing knowledge, resources and experiences, firms in a collaborative network could complement their core capabilities (Camarinha-Matos et al., 2009) and fulfill the technical competences and the potential of the generated data. The following section explains the roles that each stakeholder has when handling the data generated by the equipment in a B2B context.

### **2.3. Companies' network position and tasks in industrial service delivery**

Information and communication technologies may drive changes in the stakeholder configurations of industrial service delivery. Previous studies have focused on the dyadic cooperation between supplier and end user (Finne & Holmström, 2013), and their diverse supply-chain collaboration strategies. In some cases, suppliers adopt the role of value process organizers to support unexperienced customers and they go through all the processes of identifying, activating, collecting and integrating resources to make the value creation possible (Sandin, 2015). On the other hand,

manufacturing firms may also work as systems integrators since they have the best understanding of the service needs of their customers, while subsystem suppliers possess the resources and capabilities to fulfill those needs (Finne & Holmström, 2013). This last example fits the scenario we are studying, as a software-based service supplier can fulfill the service needs from the customers of a manufacturing firm. In any case, when a cooperative network exists and combines experience and knowledge from different industries, value co-creation during servitization is possible.

In a more traditional view, value was created with minimal interaction with the customers, but nowadays it is possible to integrate the customers in any step of the value creation process (Mejtoft, 2011). Despite this evolution, the interaction with customers and a support service supplier has not yet been widely considered. The triadic collaboration between software firm–manufacturing firm–customer can be facilitated by different technologies such as wireless communication and analytical software tools. The use of external software tools is already considered in previous literature and the possibilities of remote monitoring of data collection have been analyzed. Nevertheless, there is not a clear path towards acquiring, developing and implementing this kind of tools. It was also noted that the focus has not included data ownership issues neither other clear benefits for the supplier besides increasing revenue through adding customer value. A few studies have covered the network positions, tasks and cooperation of the firms in the service supply chain as summarized in Table 1.

**Table 1.** *Summary of previous research on manufacturing firms' and software firms' network position in industrial service delivery.*

| <b>Author(s)</b>                | <b>Sandin (2015)</b>   | <b>Kucza &amp; Gebauer (2011)</b>  | <b>Finne &amp; Holmström (2013)</b>  |

The tasks associated to the network positions of manufacturing and software firms in industrial service delivery and their cooperation with each other and customers have been studied in separate contexts. Mezgár and Rauschecker (2014) covered the concept of a networked enterprise in manufacturing industry, but specifics on the partners involved in the network were not presented as the study had more of a technical focus looking to the benefits of cloud computing. The position of manufacturing firms pursuing service development has been analyzed jointly with that of their customers, as the needs and requirements are established. For example Sandin (2015) talks about the role of manufacturing firms and their customers in the aviation industry, where the services are built upon products already in use. Kucza and Gebauer (2011) studied in a multi-case setting the service organization and the implications of separating it from the strategy organization within the manufacturing firm, which helped them understand how to respond to the customer's needs in a global setup.

Yang et al. (2009) and Vezzetti (2009) focused on the software capabilities and tools needed to analyze lifecycle data in a manufacturing context, but as such the role of the software tool provider is not presented. The most evident gap in previous research is in evaluating and understanding the role of a software service provider in the network of industrial services. The closest study to address this study's concerns is that of Finne & Holmström (2013), as the triadic relation in the service supply chain is considered in a case study, which showed how a subsystem supplier can provide services to the end user controlled by the integrator. This particular case could be applied in the context of a manufacturing firm being an integrator between the end customer and a software service provider.

A comprehensive study of the network, considering a software service provider as a subsystem supplier to enable services utilizing ICT to process equipment lifecycle data in a manufacturing context is missing. As the wider network is not yet considered thoroughly, the network positions, tasks and cooperation of the different stakeholders are not clear. The service possibilities enabled by equipment lifecycle data have been considered in previous literature but the expectations from the manufacturing firms' point of view are not evident; neither has been the actual added value from software-based services provider. This study will try to answer the research questions by filling the gaps left in the existing literature.

### **3. Research methodology**

#### **3.1. Research design**

A qualitative interpretive study was conducted to understand the processes, possibilities, concerns and limitations of the use of lifecycle data in industrial services. As part of a broader study, we gained access to four companies offering software-based services and two manufacturing firms, all with an interest to get involved in data-oriented industrial services. The names and specific information about the companies is kept confidential to protect their privacy, therefore they are referred to as Company A-F.

The software companies to which we gained access varied in size and types of offers, allowing us to identify the opportunities and challenges of their participation in

a collaborative network according to their situation. Company A offers a broad range of products and services in a multinational context, serving small to big customers all over the world. Company B and D are medium size companies offering software solutions and services based on their own technologies, but also acquiring support technologies from other providers. Company E on the other hand offers a solution based on the technology of a secondary source but adds value by offering intensive consultancy services. The first three companies mentioned are used to work in partnerships with their customers and the latter one tends to work in a more transactional way.

Companies C and F in this study are big manufacturing firms with an international presence, delivering high-tech equipment and support services to offer innovative solutions to their customers. Both have developed and adapted technologies to acquire data from their equipment and are currently looking for business cases to develop new services for their customers. The participation of Company C is linked to a very particular business unit with a standardized piece of equipment, characterized by having a long life span and being idle most of the operational time, acting as a protection in case of anomalies in the system it is part of. The focus in Company F is on a product that enables manufacturing automation and allows online and offline data collection, depending on the customers' policies. Unlike Company C's case, Company F's product is constantly used and the products can be tailored to the customers' needs via the embedded software.

### 3.2. Data collection and analysis

The method for data collection utilized in this study consisted primarily of semi-structured interviews with manager level personnel in the software and manufacturing firms. There were two different outlines for the interviews to better fit the industry's context, although they covered the same topics. Depending on the respondent's background and information the questions had to be adapted and differed to some extent from session to session. Altogether seventeen semi-structured interviews were held with the companies' personnel, exploring their experiences with industrial services, the use of lifecycle data, experiences with software-based services, and cooperation with different stakeholders. A brief summary of the sources of the data collection is presented in Table 2.

*Table 2. Summary of data collection sources.*

| <b>Company</b>   | <b>Industry</b> | <b>Interviews</b> | <b>Respondents</b> | <b>Average duration</b> |
|------------------|-----------------|-------------------|--------------------|-------------------------|
| <b>Company A</b> | Software        | 4                 | 4                  | 39 min                  |
| <b>Company B</b> | Software        | 1                 | 1                  | 34 min                  |
| <b>Company C</b> | Manufacturing   | 8                 | 8                  | 37 min                  |
| <b>Company D</b> | Software        | 1                 | 1                  | 68 min                  |
| <b>Company E</b> | Software        | 1                 | 1                  | 68 min                  |
| <b>Company F</b> | Manufacturing   | 2                 | 2                  | 33 min                  |

The interviews took place in the companies' offices, allowing the interviewer to also observe the manufacturing firm's products and get a better understanding of how they function and their characteristics. Each one of the interviews had one interviewee per session, them being personnel from different areas such as: product devel-

opment, research and development, sales, lifecycle costs and risk assessment specialists, service developers and business analysts. Since the respondents held managerial positions they were able to provide deep insight about different operations and expectations in each of their departments related to the interests of this study. The current situation was assessed, as well as the expectations and plans for the future regarding services based on equipment lifecycle data.

More specifically, the answers provided by the manufacturing firms came from general area managers to line managers. Product and project managers answered the questions from both service and product's points of view. The focus of the personnel was on servitization, R&D and also software tools and development, despite the fact that the companies were considered as manufacturing firms for the purposes of this study. On the other hand, in the software firms there was a relatively smaller sample compared to the respondents in the manufacturing firms due to the size of the companies. The interviewees held positions related to Internet of Things or Industrial Internet, business analytics, consulting and business solutions. All were somehow related to data analytics and servitization.

The interviews were audio recorded and sent to an external service provider to be transcribed. The first author, who was also the interviewer, revised the transcriptions and compared them to the notes made in each session. After the review, the concepts that were mistaken or misunderstood by the external transcriber were corrected and the gaps left in the transcriptions were filled in. The data were content analyzed in an inductive manner, with focus on three main themes: services based on equipment lifecycle data (ELD), manufacturers' and software providers' network position, tasks and cooperation, and the challenges in implement ELD use in industrial services. To draw conclusions from the analysis, the general tendencies and key differences among respondents will be reported, some illustrative excerpts from the interviews will be used, and the manufacturing firms' and software firms' viewpoints are compared with each other.

## **4. Results**

The interviews revealed versatile current and potential industrial services, rather clear task expectations in the service triad, and key challenges to be overcome in the use of equipment lifecycle data. Slight differences are found between the experiences of interviewees in the manufacturing firms and software providers. The results are presented thematically rather than case specifically.

### **4.1. Services based on Equipment Lifecycle Data**

Most of the service expectations based on ELD from the manufacturing firms are connected to preventive maintenance, which was a recurrent topic in the majority of the interviews. One of the benefits for the manufacturing firms can be the cost reduction when maintenance is planned based on the collected data and failures can be prevented, as they would not need to send a technician to analyze what is the situation but instead could get that information remotely. On the customer side, they could reduce breakdown costs and time if they could know when a component or piece of

equipment is more likely to fail and act accordingly. As said by one of the managers in Company C:

*“Now we more or less give just an error message and contact the customer support or the service organization, and then there’s a man or woman travelling to the site and fixing the problem and then travelling back... more self-service oriented information could be implemented.”*

The interviewees in Company C and F thought it would bring more benefits to everyone if the services were more proactive instead to reactive. Enabling ELD sharing could benefit both the customers and the suppliers in terms of time and costs allocated to support services. Similarly services related to changes on the configuration or components of the equipment could be enabled too. For example, tracking changes in the lifecycle of the equipment could benefit not only the support and maintenance, but also the update of its components and future service offerings based on the latest status.

Offering reports based on the usage and events related to the equipment was also pointed out, i.e. a potential service could be the analysis of the events to inform the condition of the installation. It could also be possible to know the status of the installed base, for instance reporting what kind of products are in use, their health and possibly also foresee when will be the decommissioning time of a device. By allowing the harmonization of the customer’s installed base of equipment based on the needs understood with the actual equipment data, it would be possible to sell the newest upgrades for the equipment and to keep the customer’s installed base up to date, possibly reducing future maintenance costs and operation issues between equipment in the same system.

Interviewees in the software firms had further experiences based on earlier cooperation with manufacturing companies and they gave examples of services that could be enabled by data. As each company differed in the type of solutions they had, their services ideas were slightly different. Three main categories of services were found: Customer service, Analytics and Quality assurance. Table 3 sums up the service possibilities suggested by the interviewees in the software firms.

**Table 3.** *Services based on data according to interviews in the software firms.*

| <b><i>Analytics</i></b>           | <b><i>Customer service</i></b>                | <b><i>Quality Assurance</i></b> |
|-----------------------------------|---|---------------------------------|
| Risk assessment                   | Operation support                             | Predictive maintenance          |
| Process optimization              | Monitoring of the installed base of equipment | Product quality feedback        |
| Maintenance schedule optimization | Traceability to facilitate decommissioning.   | Product development             |
| Performance indicators            | Configurations storage (cloud services)       |                                 |
|                                   | Use patterns report                           |                                 |

These three categories seemed to have evident benefits for the customers, but the realization of new revenue streams based on them still represents a challenge for the

service developers in the manufacturing firms. For instance, in some of the services already implemented in manufacturing firm C, there was no monetary benefit as the services are given away for free or bundled with the equipment. However, this was used as a differentiator from the competition. For company F, the services are oriented to support and maintenance, therefore the revenues are constrained to the failure or upgrades of the equipment.

In each kind of industry, the environment and operation conditions play an important role too when there is an interest to implement new services. For Company C, the safety in the operations of their equipment as part of a critical process is one of the top priorities. Their equipment is not often active and the lifecycle is very long, thereby restricting the possibilities of the service offering. Therefore, companies may have different positions and tasks in the network, and there are diverse conditions that need to be fulfilled before the implementation of services based in ELD becomes successful. These topics are covered next.

## **4.2. Firms' position and tasks service delivery, based on ELD**

Currently the manufacturing firms are heavily investing to understand and create new business cases related to services based on ELD. The challenge is to find benefits beyond the customer's satisfaction that can also represent a new revenue stream for the manufacturing firms. Related to this, interviewees particularly in Company C agreed that when they seek for the software partner's expertise, they expect them to provide new input and ideas based on what they have seen in other industries or cases.

During the interviews it was asked "what are the expectations on the potential software partners for the manufacturing firms?" and "what are the roles each actor played in a triadic network?" The recurrent answer was that software firms provide solutions that can enable the manufacturing firms to offer services based on their products. They do not necessarily need to operate jointly over the long term, as they can provide the tools and knowledge until the manufacturing firms have succeeded building their own capabilities supported by the software service providers. Company A's business analytics responsible stated...

*"They [the manufacturing firms] go out and say, we need you to help us build the capability. Typically they don't want to outsource it all because they still feel that it's part of their core value creation. They see the importance of the data, and the software based model. So what they use us for, is help them build their internal capability and accelerate it, so they will be quicker. So it would mean that we might run for instance analytic services for them for a year or two, helping them at the same time build their own capabilities."*

The manufacturing firms' interviewees expect much from the software firms, as their experience in the service business is wider and concerns different industries. The majority of the software firms' interviewees shared this opinion, as they believe they can support the manufacturing firms rather than take over their operations related to services based on data. The collaborative network is based on understanding the capabilities and needs from the partners. From the perspective of the manufacturing firms, the knowledge about their customers' needs and their own systems and products is the key for a successful collaboration. It was suggested that even though the

manufacturing firms have strong software development knowledge, they are constrained to a single industry, limiting their experience to their own field and not allowing them to see what the trends in other industries are. As the Business Development Director from Company E said, *“In every five years, you need to renew your own model and renew all your skills. Those lifecycles with these technologies are actually quite short, especially compared to the industrial systems that might have 30 years”*. It was also noted in one interview in Company F, that the industrial customers they serve tend to be more conservative than customers from other firms. This also influences the changes that can be done according to the trends in other areas and the experiences they have.

Furthermore, software firms’ interviewees believe according to their experience that they can build capabilities and optimize the industrial processes to support the manufacturing firms and their customers. Optimization is not merely about reducing costs, but also about getting more out of the existing systems and processes. Nonetheless, costs can be positively affected as the software firms absorb the costs of long development of service capabilities in manufacturing firms by using pre-built solutions and tailoring them for the specific needs their partners have. Those costs primarily are allocated in the intellectual capital as said in all of the software firms’ interviews, either by the software developers or the service and analytics consultants. In terms of physical infrastructure, the manufacturing firms have the possibility to build their own if desired i.e. servers to support the cloud services, but they can also rely on external partners to take care of that. This allows them to share the risk and take care of the investment costs. Table 4 summarizes the roles positions and key tasks of the manufacturing and software firms in a triadic collaboration network to provide services based on ELD.

**Table 4.** *Key tasks of the suppliers in a triadic cooperation for services based on ELD, according to the interviews.*

| <b>Software firms</b>   | <b>Manufacturing firms</b>   |
|---|--|
| Create solutions based on software tools<br>(i.e. visualization, reports, analysis, etc.) | Understand the customer’s needs  |
| Help building capabilities  | Provide equipment lifecycle data   |
| Provide insight from different industries   | Serve as an integrator, bring together software and equipment capabilities |
| Enable new services’ business models  |  |

Building a cooperative network was considered as relevant by a couple of respondents and was seen as a larger network than just a triad. Having different providers with different expertise areas can enhance the service offering and improve the business possibilities of the manufacturing firms, while they also serve their customers better. As given in one interview from Company A: *“from the industrial manufacturer’s point of view, they could be collecting data and then looking at their wider value chain, taking and providing some of that data for use of their partners who could then utilize that somehow to create more value, added to the value chain”*. The focus on the suggested added value was in enabling new services based on data, where all the firms involved had experience in a specific field and then they could exploit it to create services.

#### **4.3. Conditions for enabling and promoting industrial services, based on ELD**

The equipment manufacturing firms are selling carry the most value to the customers and that has been the case for many years, making the transition to a product-service organization more complex. Different challenges were brought up during the interview sessions, where the most difficult was the realization of revenue via services when they are not the core offer from the firm. The pricing of services in the two manufacturing firms participating in this study has been an issue through time. As said by one of the managers in Company C *“How do we package all these services and put a price tag on it?”* It was then highlighted that the implementation of different services based on data was not due to lack of technological resources or motivation, but depended on the conditions specified by the customers and the difficulty to set an attractive price for the services.

Often the challenges about servitization rely on the lack of direct input from the customers, as their opinions and expectations come from the product and project managers instead of straight from the equipment and service users. On the other hand, if distributors and third channels are involved, the collection of customers' expectations is even more complicated. A solution would be having an online connection to the equipment to collect data to understand what the current status from the device is, helping the development and delivery of new features and upgrades.

As said by the software and services manager in Company A: whenever possible, data should be collected so it can be used in the future as historical data and improve forecasts or whatever services are designed. A challenge then becomes the integration of different sources of data in all sorts of formats. This has been an issue from the manufacturing and software firms' perspective. But as mentioned in Company C, if they had a standard for the information some competitive advantage would be lost. It seems that there is currently no way around that challenge. From the technological point of view, it is possible to integrate different data sources but it may slow down the process for their customers.

On the same technical line, issues regarding the security of the data were mentioned. During the interviews it was asked from the manufacturing firms' respondents what were they thoughts related to the data security and ownership, as they showed their interest since the beginning of the study. For the whole sample, the data ownership was clear: the customer owns the data that is generated by their equipment. Therefore the challenge on the industrial services based on the analysis of lifecycle data relies on the possibility to get that information from the customers.

This then connects to the security issue, as the customers seem reluctant to provide any kind of data to their suppliers when requested. From the manufacturing point of view it was said that as a basic principle *“information shouldn't be available to other people, as a customer I would like to be in charge of who can access the data”*. Nevertheless, it was mentioned that when the support service teams of Companies C and F asked for a log or other kind of information of the equipment, the customers did not hesitate to share the data as they knew the objective. When that is the situation, customers do not mind sending the information via email or through some other cloud service that may not count with enough security measures. Particularly in Company F's case, customers enable the online connection to the equipment for as long as the support team requires it, sometimes taking days.

*"I'm not really sure about if that's kind of sensitive information. Because anyway, quite often they [the customers] are sending their configurations to us also over mail if they want to show that okay, 'we have some issue with this application, could you help us to get this correctly configured?' They send the configuration files to us, so I don't see that as a really critical."*

For instance, with the current software tools of Company C, some services based on data have been enabled but there are still expectations to increase the offer if the customers were more willing to share their information. Nowadays the collection of data is technically possible, but human factors have slowed the servitization process. Personally, the majority of the interviewees were not comfortable sharing information through the Internet, therefore they understood why in a business-to-business context the customer firms would not allow their information to be shared with their supplier.

Company C had a specific case where data could be collected already from the equipment and stored in a cloud service if the customer activated it, but it was not very appealing for the customers as they could not see where it would be used on. In Company F, there is a possibility to be always connected and sharing data to the support team, but it is often disabled until there is a malfunction and the customers require assistance due to security concerns

In short, the interviewees agreed that sharing the information may not be that critical if there is trust in what the company is going to do with it and if the customer does not have to do any extra effort. Customers are also willing to compromise in a way their security when the breakdown costs are higher than the risk of opening the connection for some time while the support teams work to fix their problems. This is strongly connected with the first issue mentioned in this section, as the price tag that is connected to the service package needs to be good enough for both the supplier and customer. As the interviewee in Company B mentioned, it is a cost vs. benefit analysis for both the customer and the supplier, which is the manufacturing firm in this case:

*"The customer is thinking about the potential 'pain and gain' if they give the data or access to the data. What do we get if we give it? If that ratio is enough, meaning that they feel they get more benefit than, like negative things when they give it. That's typically so big problem as it is seen in the market... (for the manufacturing firm) you need to give something, especially in the beginning, you need to be giving something even if it is for free, to get access to the data, because everything starts from that."*

That opinion was shared at least to a certain level in the software services context, as the interviewees suggest starting by sacrificing something or giving a service for free to then gain access to the data and build business cases on top of that. It was still remaining to know what kind of sacrifices are the manufacturing firms willing to do to get access to the data, as they have not yet seen the full potential of the servitization.

To sum up, the involved interviewees in both types of firms mentioned four main challenges: revenues realization of the services based on equipment data, equipment data acquisition (ownership), equipment data management (integration) and data security. It was also a shared opinion that these are issues related to perception rather than technical capabilities, therefore the creation of an attractive business model would help them overcome the challenges.

## 5. Discussion

This study focused on manufacturing firms and software providers pursuing service-oriented business through enhanced use of equipment lifecycle data. The results show that the manufacturing firms' current services dominantly cover preventive maintenance, R&D processes of product development and process optimization inside the firms and for the customer, and such services are located in the second and third level when compared with the ones proposed by Kucza and Gebauer (2011) based on the knowledge intensity of services. Visualization and analysis tools were mentioned to create cost-benefit analysis, present performance indicators and visualize benefits. When compared with the services proposed by Yang et al. (2009), the preventive maintenance was again mentioned, as well as the use patterns report and better forecast to optimize the maintenance schedule.

Both the interviews and earlier literature emphasize that there are more possibilities than only preventive maintenance, in services based on ELD. Primarily the software providers emphasized many kinds of services (e.g. Risk assessment; Operation support; Monitoring of the installed base of equipment; Traceability to facilitate decommissioning; Configurations storage (cloud services); e.g. Oliva & Kallenberg 2003; Kucza & Gebauer, 2011, Yang et al., 2009). Product quality feedback) that are not, yet actively used by manufacturing firms.

By identifying the service possibilities, this study sets a starting point for more detailed studies oriented towards understanding the specific needs of each of those services and the possibilities to extending the service offering beyond the lifespan of the equipment, as originally suggested by Oliva & Kallenberg (2003).

### 5.1. Division of tasks in ELD-based service delivery

The first research question dealt with the division of tasks between the manufacturing firm and the software provider, in the delivery of services based on equipment lifecycle data. The results showed that the expectations on the network position and tasks of the manufacturing firms are generally consistent with the key findings presented earlier in the literature but novelty lies in the empirical evidence about the positions and tasks of the different companies in the service triad. As a contrast to the findings presented by Finne & Holmström (2013), the results in this study propose that the manufacturing firm acts as the **integrator** between the customer sharing ELD and the software firm, while also acting as the only direct service supplier to the customer. The results in this study also suggest that the subsystem supplier (i.e. software firm) acts as a partner in the co-creation of services besides providing the ICT tools for ELD processing. Due to the nature of the manufacturing firms' environment, software firms act as **enablers**, meaning their cooperation can end when the capabilities to provide services based on ELD have been built. Previous studies considering the analysis of data to enable services do not analyze the tasks that each company has in the delivery network. The previous literature covers the dyadic cooperation between manufacturer and customer (Sandin, 2015; Kucza and Gebauer, 2011) but do not look into the cooperation of a support service supplier (Finne & Holmström, 2013), even when talking about software tools to analyze the data (Yang et al., 2009; Vezzetti, 2009). This study contributes with the perspective of the software firm as a prospective subsystem supplier, differentiating this paper from the previous literature.

As mentioned in Mejtoft (2011), in a more traditional view value was created with minimal interaction with the customers. The triadic setting presented in Figure 2 positions manufacturing firms as integrators and they not only interact with customers, but also with a support service supplier in the successful use of equipment lifecycle data in industrial services.

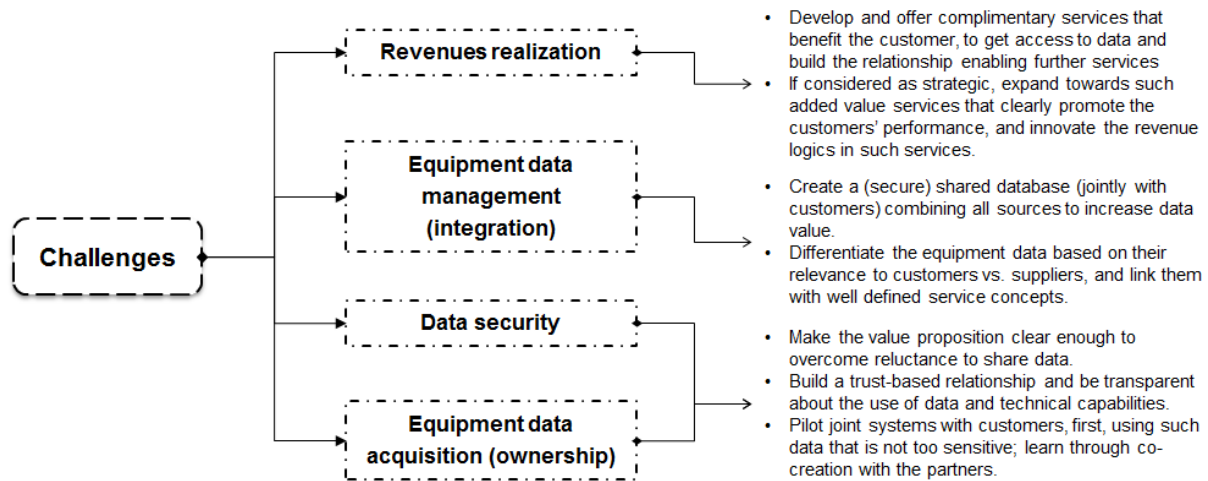

**Figure 2:** Triadic collaboration model between service suppliers and customer.

Deviating from the findings of Finne & Holmström (2013) where manufacturing providers cooperated with service providers in a direct supply chain toward the customers, the subsystem (software) supplier does not need to aim to keep in touch with the end customer, as the manufacturing firm integrates the software services and the customer needs. The triadic collaboration between software firm, manufacturing firm and customer is facilitated by different technologies such as wireless communication and analytical software tools, like the PLM system explained by Yang et al. (2007). The customer's equipment lifecycle data is collected and sent to the manufacturing firm that shares it with the software-based services supplier according to the customer needs. The software-based service supplier analyzes the data based on its experience in other industries and environments and can propose new services, different to the traditional approach of preventive maintenance.

## 5.2. Promoting the use of ELD for successful service delivery

The second research question asked about the ways in which companies in the network enable and promote the use of equipment lifecycle data toward successful service delivery. As seen from the empirical research, manufacturing firms have good potential to promote the ELD-based services even more widely. Various conditions need to be met to enable the use of ELD in services and ensure service business success. While the technical capabilities and requirements have been analyzed as in Vezzetti (2009), it is needed to overcome some other issues too. Mezgár & Rauschecker (2014) presented the main issues but did not proposed steps to solve them. In this study we identified four main challenges to be solved to enable and promote services based on ELD in a service delivery network successfully. These challenges and potential solutions are presented in Figure 3.

**Figure 3.** Implementation challenges and potential solutions (particularly for manufacturing firms).

It has been emphasized that the technical capabilities to keep the data secure are already available and previous studies can confirm that. Therefore the limitations to offer services based on ELD are due to human preferences and decisions, meaning that the security issues could be overcome when there is an attractive business offer from the manufacturing firm based on which data that could enable further business cases could be utilized. To make the implementation of services based on ELD possible it is essential that the customers are convinced that the communication channels are secure but more importantly, that they understand the benefit of sharing their data.

In Sandin (2015) a key finding was that monetary benefits are hard to measure in a partnership such as the one needed in this triadic collaboration. We argue that it is possible to measure the monetary benefits, for example when processes are being optimized through data analysis and costs are saved when R&D utilized historical data to update the equipment. Manufacturing firms may need to be willing to give away something to attain greater benefits and get the end customers on board to share their data. During a couple of software firms interviews, there were specific examples given from electricity and media industries where the companies started by giving away some services based on data to ensure customer loyalty, which later on enabled them to build more services on top of them. Giving the opportunity for the final customers to monitor their equipment or processes can enable the suppliers to get access to data and also understand the real use of their equipment without making big investments. Through these kinds of examples in other industries and their successful implementation of services based on data, software partners can provide a company-specific offer to the manufacturing firms to develop a new service business based on their equipment lifecycle.

## 6. Conclusions

Servitization in manufacturing companies has become a challenging trend, as the commercialization of products is not enough to differentiate from the competitors. In a traditional view, services related to products in manufacturing firms relate to maintenance and spare parts handling. With the use of ELD the service possibilities increase and could allow the manufacturing firms to realize new revenues from differ-

ent streams and have more satisfied customers. ELD use can also help the manufacturing firms to offer services even after the lifespan of the equipment has ended.

The first research question referred to the task division when delivering services based on equipment lifecycle data. With the idea of the importance of ICT evolution and possibilities for servitization in mind, we integrated the software service suppliers in the service delivery network of manufacturing firms. By relying in the software service suppliers' knowledge and experience, manufacturing firms can increase their service offering based on equipment lifecycle data. We studied the different points of view of manufacturing firms and software service providers and identified their position and tasks in a triadic cooperation network. The network is based on the idea where the customers utilizing the manufacturing firms' equipment provide the lifecycle data to the manufacturing firms to process and enrich it, enabled by a software subsystem supplier.

The empirical study allowed us to compare and consolidate the different perspectives of the manufacturing and software firms. By doing this, we answered the second objective of understanding how the firms in the service delivery network can enable and promote the use of ELD. Four main challenges were identified based on the experience of the manufacturing firms and existing literature: revenues realization, equipment data management, data security and equipment data acquisition. With the input from the software firms, potential solutions to improve the conditions for servitization based on ELD were suggested.

It is concluded that the participation of external software suppliers can benefit the service delivery in the manufacturing industry. Despite the high technological development in manufacturing firms, the lack of experience in a larger context from different industries may narrow the view of service possibilities. Software firms can add fresh ideas to the service delivery network to enable and promote services based on ELD. With a clear and attractive service offer of the manufacturing firms, customers might be willing to oversee the security and ownership concerns related to sharing their equipment's data.

This study was limited to the interpretation of the different stakeholders in a small sample of companies; therefore it would be recommended that a more thorough empirical case study be done to analyze the viability of these suggestions. Another recommendation is to integrate the customer's point of view in the study, to test and verify the assumptions of the suppliers related to what they expect and to what extent they are willing to share their data.

## **Acknowledgements**

This research has been conducted as part of the Service Solutions for Fleet Management (S4Fleet) research program funded by the Finnish Technology and Innovation Agency Tekes, companies and research institutes, and coordinated by FIMECC (Finnish Metals and Engineering Competence Cluster). We gratefully acknowledge the support of the financiers and the companies that participated in this study.

# Actor roles in the Internet of Things ecosystems

*Seppo Leminen<sup>1,2</sup>, Mervi Rajahonka<sup>1,2</sup>, Mika Westerlund<sup>3</sup>*

This study investigates actor roles in the ecosystems of the Internet of Things (IoT). Previous studies suggest that unstructured ecosystems make one of the greatest challenges for creating business models for the IoT. Based on a literature review and analysis of data from five cases, we show how actors take and make different roles in the emerging IoT ecosystems, and address how they choose the business model and the type of ecosystem they want to get involved. We identify four diverse actor roles in IoT ecosystems: butterfly, ant and greenfly, spider, and the swarm of bees. The findings contribute to our understanding of the IoT by suggesting that emerging IoT ecosystems are structured in accordance with actor role behavior.

## 1. Introduction

In the near future, many kinds of everyday objects from cars to toothbrushes and buildings to baby monitors will be connected to the Internet and with each other. The Internet of Things (IoT) can be defined as a world where physical objects are seamlessly connected to the information network, and where these objects can take actively part in business processes (Haller et al., 2009). It integrates diverse technologies and systems (Fleisch et al., 2009) and creates a significant potential for companies, their customers and other stakeholders to produce, co-create and get better services cost-effectively. The networked infrastructure of the IoT enables incremental and radical innovation and business development (Bucherer and Uckelmann, 2011).

Despite the vast potential the IoT holds, the business promise has not yet been realised (Bucherer and Uckelmann, 2011). The diversity of objects, the immaturity of innovation, and the unstructured ecosystems are proposed to be primary challenges for developing business models for the IoT (Westerlund et al., 2014). Thus, more research is needed on how the technological opportunities can be realised from the business perspective (Haller et al., 2009; Leminen et al., 2012; Leminen et al., 2014). New business models will be needed for this emerging highly-connected world. Previous literature on the IoT has underlined technological issues, but IoT business models have been discussed sparsely. In fact, prior literature calls for more research on the emerging IoT ecosystems from the business perspective (Leminen et al., 2012), and argues that studies on IoT business models should be widened from a single company point of view to an ecosystem perspective (Westerlund et al., 2014).

This study investigates the actor roles, and adjacent business models, in emerging IoT ecosystems. Our research questions include: i) which roles can actors take and

make in emerging IoT ecosystems?, ii) how are these ecosystems built?, and iii) how are the role options linked to the emergence of IoT ecosystems?

The paper is organised as follows. After this introduction, we review previous theories on ecosystems, particularly the IoT ecosystem, and actor roles. Thereafter, we explain the methodology and present key findings. Finally, we conclude by discussing the key implications of our research both to practice and the theory, and provide avenues for future research.

## **2. Literature review**

Next, we briefly review literature on IoT ecosystems, particularly related to IoT ecosystems and their business models, as well as actor roles in those ecosystems.

### **2.1. The IoT ecosystems**

The concept of business ecosystem originates from James F. Moore in 1993. He emphasises that innovative businesses cannot succeed alone, but they must rely on various resources. Businesses need capital, partners, suppliers, and customers to create cooperative networks. According to the ecosystem view, a company is not just a member in a single industry, but a part of an ecosystem crossing multiple industries. In ecosystems, companies act cooperatively and competitively developing new products and satisfying customer needs together. Since Moore, ecosystems have been a popular topic in business and technology research. Burström et al. (2014) point out that the ecosystem studies focus on large companies. Hence, there is a lack of studies on the roles of small and medium sized organisations in ecosystems. Tukiainen et al. (2014, 9) classify ecosystem research into four streams: product studies, company studies, industrial studies and meta-studies. Product studies refer to research on ecosystems as e.g. “mobile phone ecosystem” or “microprocessor ecosystem”, whereas company studies describe e.g. “Amazon’s web service ecosystem” or “Google’s innovation ecosystem”. Industrial ecosystems may be, for example, “ICT ecosystems” or “automotive ecosystems”. Meta-studies refer to wider studies of “business based ecosystems” or “technology based ecosystems”.

In the future, a large number of small and specialised “things” (devices and sensors) will be connected to each other and to the Internet, expanding existing Internet applications and services and enabling new ones (Leminen et al., 2012). The IoT increases complexity of communications. Complexity is increasing and network structures are transforming from centralised structures towards decentralised and distributed structures when businesses become participants of complex business ecosystems (Barabasi, 2002; Möller et al., 2005). Actors are increasingly interdependent through technical and business ties, and thus developing their roles. The ecosystem view and actor roles will be more and more important. Tarkoma and Katanov (2011) argue that an IoT ecosystem is a community of interacting companies and individuals where the companies use a common pool of core assets, based on linkages of physical world of things with virtual world of the Internet.

Leminen et al. (2012) note that the existing literature lacks sufficient understanding and empirical research on IoT business models and their connections to the underlying ecosystem. The authors (ibid.) propose a framework to visualise a variety of existing and potential IoT business models and to distinguish four diverse IoT business model categories. Prior research on IoT business models has identified versatile challenges related to the IoT ecosystems (Haller et al., 2009). For instance, Westerlund et al. (2014) mention the diversity of objects, the immaturity of innovation, and the unstructured ecosystems as challenges. The latter challenge refers to the fact that participants and their roles are not yet clear in the emerging IoT ecosystems. Thus, by focusing on the ecosystem approach of doing business it is possible to overcome the challenges and design successful IoT-enabled business models.

Given the rapid development of IoT, increasingly complex ties between things and actors highlight the importance of ecosystem view on studies of IoT business models. Westerlund et al. (2011) discuss business model management and propose that various business models and their differences in the ecosystem context can be studied by linking business models with the firm's external strategy and relationships. They also suggest a shift from business model of a firm to ecosystem business models (i.e. value designs). Westerlund et al. (2014) argue that further business model frameworks are needed to understand these value designs because existing frameworks focus on the architecture of the business model rather than capturing the dynamics of the model. The value design demonstrates how value is created and captured in an ecosystem, and it can be conceptualised by four pillars: value drivers, value nodes, value exchanges, and value extracts. Value drivers are motivations of participants to generate value, realize innovation, and make money. Involving stakeholders in a "win-win" relationship is important for designing viable IoT business models (Bucherer and Uckelmann, 2011; Westerlund et al., 2014). Value nodes can be actors, activities, processes, or networks of organisations linked with other nodes to create value. Value exchanges describe an exchange of value, i.e. resources, knowledge, and information. Value extract refers to a part of ecosystem that extracts value. Any part of the ecosystem's business model can be described with the value design. This part may be single activities, individuals, organisations, networks and value flows between these nodes.

## 2.2. Actor roles in ecosystems

A role refers to expected behaviour of parties in particular positions (cf. Allen; van de Vliert, 1984). As actors pursue role-taking or role-making, Nyström et al. (2014) argue that in open innovation networks this '*role ambidexterity*' means that actors (individuals or organisations) must both *take and make roles* that benefit them and the network. One example is that if users in living labs wish to solve problems in their everyday life, they need to change their "taken" tester roles into co-creator roles, and thus "make" their role. '*Role temporality*' suggests that actors should avoid getting stuck in their roles and pursue to their best possible roles. It is important also for the network that participants can adjust and adapt to the structural changes in the network. However, role transitions are always challenging.

Nyström et al. (2014) argue that previous role theory research has three approaches: the structuralist, symbolic interactionist, and resource-based views. The structuralist approach proposes that a firm comes into an established social structure and fills a particular position. Symbolic interactionist roles are dynamic, describing what actors

intend to do; in other words, actors in networks are active in constructing their operating environment. The resource-based approach argues that a role is a resource, so that it means a membership and acceptance in a social community, and access to different kinds of capital – social, cultural, and material. Based on innovation research, Nyström et al. (2014) suggest a fourth theoretical view to roles; an action-based approach. They claim that the prior literature sees the innovator roles and tasks as actions that should be taken for innovation to occur. This can be seen as normative approach to roles. Heikkinen et al. (2007) identify roles by mapping actors' tasks in innovation networks. They (ibid.) find several role-related tasks: 1) the webber decides which actors should be contacted, 2) the instigator guides the actors' decision making, 3) the gatekeeper makes decisions and owns significant resources, 4) the advocate distributes positive information, 5) the producer contributes to development, 6) the planner gives resources for development, 7) the entrant interferes in development, and 8) the auxiliary takes an active part in the end of the process, 9) the compromiser balances actions and relationships, 10) the facilitator provides resources but does not interfere, 11) the aspirant aims at becoming a part of the network, and 12) the accessory provider promotes its products, services, and expertise. The actors' actions determine their roles, and some of the roles are more incremental or radical, or more expected or emerging (Heikkinen et al., 2007).

In their study on open innovation networks, Nyström et al. (2014) confirmed seven previously identified roles (cf. Heikkinen et al., 2007), but also proposed ten new roles characterised by openness and user involvement: 1) the coordinator who is a focal network actor, acting as a “focal network hub”, 2) the builder promotes close relationships between participants, 3) the messenger forwards and disseminates information, 4) the facilitator directs and motivates the users towards a specific direction, and provides them with intangible resources, 5) the orchestrator orchestrates the whole network of actors, 6) the integrator integrates knowledge, development ideas, technologies, and outputs of different living lab actors into a functional entity, 7) the informant is a user that brings users' knowledge and opinions to the living lab, 8) the tester is a user testing innovations in real-life environments, 9) the contributor is a user collaborating with other actors to develop new products, services, processes, and technologies, 10) the co-creator is a user that co-designs a service, product, or process together with firms and other living lab actors. However, it is not required that all roles are active for a network to operate satisfactorily.

Ecosystem literature documents different actors in ecosystems rather than focuses on actor roles. Burström et al. (2014) argue that the post-Moore (1993) research has not brought up too much knowledge about leadership and control of ecosystems. The main body of studies propose close links between technology development, platform leadership and ecosystem leadership. The ecosystem approach relies on an analogy with biological ecosystems (Moore, 1993; Lansiti and Levien, 2004). As in biological ecosystems, participants in business ecosystems are interdependent with each other for their development and survival. Although some actors are stronger than others, a single actor cannot control the entire ecosystem. In fact, the ecosystem can be understood as relationships between actors where they take different roles as keystone, dominators, or niche players. Ecosystems also typically reach several domains, and they also may have shared domains with other ecosystems (Lansiti and Levien, 2004; Burström et al., 2014). Burström (2010) emphasises the importance of an inter-firm platform for firms' strategy, operations, and functions. Therefore he claims that platform development should be seen critical for the development of various business ecosystems. Huang et al. (2009) in turn submit that small and medium-

sized enterprises (SMEs) may need strong intellectual property rights and/or the possession of complementary capabilities that protect them from being overrun by platform owners in the ecosystem. Moreover, Burström et al. (2014) urge more research on issues such as what roles SMEs play in business ecosystems, and whether and how SMEs can collaborate and compete at the same time in business ecosystems.

Tukiainen et al. (2014, 15) suggest that there are both key actors and supporting actors in ecosystems. The key actors are large firms and SMEs, as the SMEs mainly work as partners or complementors for large firms that are, or want to be, platform leaders in business ecosystems. Tukiainen et al. (ibid.) also argue that besides these key actors there are supporting functions in ecosystems that can be served by universities, governments and funding agencies. They (ibid, 39) also note that companies may have different strategies related to ecosystems: in single ecosystem strategy, a company concentrates acting in one ecosystem only, for example as an application provider using ecosystem leader's distribution channels; in multiple ecosystem strategy, a company connects across ecosystem boundaries, but the boundary is not changed. For example, a system supplier could connect to various ecosystems without changing the rules of game in a particular ecosystem. In a multiple ecosystem strategy with boundary spanning, a company presents new ways of doing business that change the rules of game and boundaries of the ecosystems. The example of the last mentioned case include Apple and its iOS ecosystem.

Tukiainen et al. (ibid., 23) use Gawer's (2009) framework for platform innovation and competition to categorise ecosystem companies into four groups based on low versus high autonomy to innovate and low versus high likelihood of competition in the ecosystem (see ibid, 37-38). Group 1 companies produce software products in low technical and low or medium market uncertainty. The business is easy to start and based on exploitation, and the rules are known and followed. Group 2 includes platform wannabes acting in high market and technological uncertainty. There is no clear market, and rules of the game are unknown. Huge investments are needed for starting a business based on exploration; there are also huge risks and opportunities. Group 3 consists of service or system integrators. There is a low technical and medium market uncertainty and the business is easy to start based on exploitation, but it is difficult to internationalise. The rules of the game are known, but the company needs good customer relationships and various kinds of expertise. Group 4 comprise solution providers acting in medium to high technical and market uncertainty. Some of the rules are known, but not all. The business is based on exploration, and there are huge risks and opportunities.

Given our review on the role theory and research on actor types in ecosystems, the extant studies fail to integrate ecosystems and the role theory. In particular, more research on actor roles is needed in ecosystems.

### **3. Methodology**

This study drew empirical data from semi-structured interviews with eight interviewees in five different organisations in the emerging IoT ecosystem.

### 3.1. Research setting and research design

We draw on a multiple-case study design approach with cross-sectional data from different industries to generate evidence on actor roles in the emerging IoT ecosystem. As suggested by Jensen and Rodgers (2001), we deploy snapshot studies on cases. We focus on case comparisons because each analysed case share similar elements, allowing us for typifying role characteristics, as well as different business models in the context of the IoT ecosystem.

### 3.2. Data collection

The empirical data were collected from 2012 through 2014. The original data set included a three-round Delphi study and sixteen interviews. The Delphi study aimed at mapping Finnish experts' views on current and future IoT business models. The first round of the study was launched in early 2012, and the 3rd round took place in mid-2013. From the sixteen in-depth interviews we selected interviews that in particular dealt with actor roles in the emerging ecosystems. Thus our empirical data comprised eight in-depth interviews representing five key organisations in the emerging IoT ecosystems. The interviews were conducted to understand different types of IoT ecosystems and roles that actors can have in them. We followed an interview guide suggested by Patton (1990), and collected information on various themes. The interviews were carried out face-to-face, and each interview lasted between 60 and 120 minutes. The interviews were recorded and transcribed for the purpose of analysis. The interviewees offered different views organisations have in building or joining the IoT ecosystem, which enabled broader perspectives to actor roles in the IoT ecosystem. Table 1 gives an overview of the empirical material.

| In-depth interviews |  |
|---------------------|--|
| Topics discussed    | IoT in general; interviewee's organisational aims and views regarding it. Table 1: Overview of the empirical material of the study.

### 3.3. Data analysis

The empirical data were organised according to the informant, the date of interview, and the type of informant. Two researchers independently analysed and coded the interviews. They searched for words associated with business networks, ecosystems, business models, actor roles, role expectations and role activities by using the con-

tent analysis technique. The aim of the coding and content analysis was to better understand the cases (Roberts, 1997; Neuendorf, 2002). The empirical material was first coded by two authors, and the identified business models, networks, ecosystems, roles, expectations and activities were compared and discussed in the team. In the second phase, we analysed more thoroughly the actor roles in the emerging IoT ecosystem. This involved a second round of coding using content analysis with the aim of understanding the emerging ecosystem, different types of ecosystems and related actor roles, expectations and activities. At this stage, we analysed case-specific roles in detail, particularly from the point of view of role theories presented by Heikkinen et al. (2007) and Nyström et al. (2014), and ecosystem theories presented by Burström et al. (2014) and Tukiainen et al. (2014). We also wanted to identify the emerging value designs in the IoT ecosystem as represented by Westerlund et al. (2014), i.e. value drivers, value nodes, value exchanges, and value extracts. After comparing our interpretations with prior research, we identified new approaches to actor roles in the IoT ecosystem. Table 2 gives an overview on our data analysis and the phases of the study.

| Data analysis phases                         | Task   | Outcome  |
|--|--|--|

Table 2: Data analysis process.

## 4. Findings

Previous studies suggest that unstructured ecosystems make one of the greatest challenges for creating business models for the IoT. Our literature review on the role theory illustrates how actors make or take roles in ecosystems. Based on our data

analysis from eight in-depth interviews, we identified four diverse roles for actors in IoT ecosystems. Our case study shows that these roles are typical in four distinct types of ecosystems. We label the roles as: (i) *butterfly*, (ii) *ant* and *greenfly*, (iii) *spider* and (iv) *the swarm of bees*. We also suggest that a company can choose the type of ecosystem it wants to be part of, and, consequently, its role in the ecosystem. Therefore, companies benefit IoT by different roles. Next, we will discuss the findings of this research. First, we will briefly describe the case companies, and then present our findings on the role configurations in the emerging IoT ecosystem.

#### **4.1. Case companies**

Case A is a Finland-based component supplier for the construction industry. The company is interested in opportunities of the IoT in connected buildings, and is developing their product and service offering. However, they are aware that being unable to add connectivity to the products, the company probably will lose deals to competitors that may be ahead in satisfying high-end customers' advanced needs. Case A has a role configuration of a butterfly.

Case B is a multinational company offering network solutions. The company sees both opportunities and enormous threats in the IoT, and has not yet found significant business opportunities or lucrative roles to position itself in the IoT ecosystem. Although Case B is used to offering services to multiple business ecosystems, it is either unable or reluctant to become an active actor in building new business networks. We describe the role configuration of Case B as an ant and greenfly.

Case C is a multinational telecom operator enthusiastic of being actively involved in building business networks to employ opportunities of the IoT. The company is already offering machine-to-machine (M2M) communication services to their business partners, but aims to be more proactive in regards to the IoT due to the threats coming from large global actors such as Google. However, Case C perceives challenges in understanding the differences between building business relationships in the M2M vis-à-vis the IoT context. The role configuration of Case is termed as a spider.

Case D is a Finland-based telecom operator operating on a local market. The company is considered to be as an active business network developer or accelerator in the local community. Moreover, they aim to build networks and business models that can be replicated in other contexts. Similarly to Case C, we describe the role configuration of Case D as a spider.

Case E is a small, Finland-based technology start-up developing sensor-based solutions. The company wants to be closely connected to users and user communities with whom the company wants to develop IoT-based products and services. In terms of role configuration, we view that Case E is involved in a swarm of bees.

#### **4.2. Role configurations and ecosystems**

In our empirical study, we found four roles that actors can have in the emerging IoT ecosystems. A *butterfly* focuses on relatively compact issues, and this role configuration leads to limited but rather safe business model choices. Case A recognises the nodes (customers) and flows (possible products and services.) of the new business

model. No specific IoT ecosystem is needed because the IoT solutions are add-ons offered in prevailing ecosystems (cf. Fig. 1, butterfly, point of time 1 and 2). The company concentrates on one customer relationship at a time, and in providing IoT-enabled products and services in these relationships. This is an example of role-taking: the butterfly takes a predefined organisational role in an existing product ecosystem. It focuses on creating links (value designs) with single nodes in the network, and on replicating these links into as many relationships or networks it can. Referring to Tukiainen et al. (2014), we argue that the rules of the game are known or easy to learn in this kind of “*Product ecosystem*”: There are only minor technical or market risks. No large investments are needed, and the actors can easily take a predefined organisational role in an existing product ecosystem.

”It is very important for us that we don’t compete with our customers.” (Case Company A, Supplier of Construction Components)

“We have a number of partners worldwide. Our value chain has several steps, wholesales, installation etc. There are many kinds of integrators involved – it is a very multifaceted model. After we have managed to specify our products into a project, after that it is quite straightforward. Preparations are crucial. Our competitors don’t use our components.” (Case Company A, Supplier of Construction Components)

Fig. 1: Role configurations and emerging networks and ecosystems, part 1.

*An ant and a greenfly* refers to a role configuration in which a company may lock itself into larger “company ecosystems”, similarly to an ant sucking sap from a greenfly. The ant can start sucking sap as soon as the network (the greenfly) has been established (cf. Fig. 1, Ant and Greenfly, point of time 2). Ant views and compares a variety of supplementary nodes and links between companies that are not utilised at a particular moment. It wants to define (make) its role so that it can easily take a similar role in as many future networks as possible. Case B wants to understand the motivations and business logics of different actors, but the company thinks that several actors, and particularly intermediaries, are still missing in the emerging networks. Case B wants to grasp the opportunities by offering infrastructure services for actors in several networks, but for the moment they feel a bit frustrated because the company cannot do anything else but wait until the company ecosystems have been built by the focal actors. As soon as the challenges have been overcome and the IoT-based networks start to mature, the ant may offer boundary crossing services for several networks. The ant takes the roles that open up for it in the emerging ecosystem, but at the organisational level the company makes (defines) its role itself. Apple and Google ecosystems make good examples of “*Company ecosystems*”. The rules of the game are known, but given by the ecosystem owner. Other actors can only take roles that open up for them in the ecosystem.

"We cannot sell networks if we don't know how they are used." (Case Company B, Network Solution Company)

"The telecom operators don't want to develop IoT services. That is why we now have to discuss directly with their customers. Probably there is an actor missing, an intermediate." (Case Company B, Network Solution Company)

"Did the revolution already happen, but we just do not know it yet? If big companies don't wake up, small companies will take over." (Case Company B, Network Solution Company)

A *spider* weaves its own network in the IoT ecosystem. It may aim to become a key, hub, or leading part of the network. In this case, it could be described as a "platform wannabe" (cf. Tukiainen et al., 2014, 38). However, the spider can also take a minor role after the network has matured. Cases C and D wish to take active roles and build IoT-based company networks (cf. Fig. 2, Spider types 1 and 2, point of time 1). Case C also pursues becoming a focal actor in the ecosystem (Spider type 1, point of time 2). On the contrary, the most important driver for Case D is to get the network going, after which the company can take any role that is suitable for it (Spider type 2, point of time 2). The case companies aim at replicating their network models into different contexts, either geographically or into other industries. Thus, the spider concentrates in building a viable network, and in replicating this network structure with all its value designs into different contexts. The rules of the game are at least partly unknown, investments are needed, and there are risks related to technology and market. However, by being active in building the ecosystem, Cases C and D try to manage the risks and guarantee that the emerging rules of the game will be beneficial for them. Cases C and D cannot cooperate, rather consider each other as competitors. For the time being there are many open opportunities, and genuine IoT-based new networks crossing multiple current industries (for example health, wellbeing and IT) are still emerging. We call these "*IoT-based industry ecosystems*". Some of the rules are known, but not all. The business is based on exploration, and there are huge risks and opportunities. The ecosystem roles are all emerging, and the actors can offer their expertise (or roles) to be taken part of the emerging ecosystem.

"We have a big partner network. We have asked them to build applications for us. So, our partners build the solutions. We also have a partner who has built us the platform and we sell it to our customers." (Case Company C, Multinational Telecom Operator)

"The model will be same in every country. Services cannot stop in the border of the country." (Case Company C, Multinational Telecom Operator)

"We can build business models, where we use local actors as partners. In our region there is knowhow related to sensor technology in universities, and there are small software companies, etc. Partnering with them will guarantee that knowhow stays in the region. However, these should be concepts that we can replicate to other similar regions. For this purpose we have started to build a developer business model and a piloting environment" (Case Company D, Local Telecom Operator)

"We have to test things at local level first. Then we can go forward." (Case Company D, Local Telecom Operator)

Fig 2. Role configurations and emerging networks and ecosystems, part 2.

New kinds of value designs may emerge for a *swarm of bees*. For example, bottom-up models may arise from the IoT user and developer communities, where users share their own expertise and knowhow and become producing actors (Fleisch, 2010; Kortuem et al., 2010). The case companies were not yet actively involved in these kinds of networks, but our interviewees mentioned some examples. Case E, a small technology start-up, was very interested in involving user community in its product development processes. Actors in these networks have “swarm intelligence” which can be described as collective behaviour of decentralised, self-organised systems. This concept was introduced by Beni and Wang (1989) in the context of cellular robotic systems. The actors in a swarm follow very simple rules, but local interactions lead to the emergence of “intelligent” global behaviour, and the swarm being able to adapt to changes in the environment. There may also be some division of work (roles) between the bees of the swarm, i.e. explorative work can be done by scout bees in addition to local exploitative work done by other bees (cf. Pham et al., 2005, Karaboga, 2010). In “*peer-to-peer ecosystems*”, technological and market uncertainties are great, but at least part of the risks can be shared with collaborative models by the community. As each actor makes its own role by defining the role at the organisational level, the actors configure the ecosystem and make the roles of the ecosystem together and evenhandedly. As mentioned earlier, in order to succeed, the IoT business models need to motivate all actors, including customers and end-users. Therefore, this landscape of cooperative ecosystems is not easy for big companies. However, they can build their business models around cooperative ecosystems. For example, Über and AirBnB have built their business models so that they involve the community in the value creation process, and at the same time distribute a share of the profit to the community members.

”People will have more knowhow, so that in the future they will be able to build IoT devices for themselves. However, you cannot assume that everybody who has a personal problem, say a heart condition, is a technology wizard; therefore there is a challenge, how we can offer easy enough tools for every possible user, not just for the nerds.” (Case Company E, Technology Start-Up)

”The culture of open hardware and open software is getting stronger. People want to become “makers”. There are many bottom-up opportunities in the IoT, and if you can provide a good solution to a particular user group, you can easily replicate it to a different group. This is difficult for big companies, and therefore there are many opportunities for small companies.” (Case Company E, Technology Start-Up)

"There are services in the internet where people can do things themselves for free. This could have been a business opportunity for somebody, but when people learn to do things themselves, these business opportunities become extinct." (Case Company E, Technology Start-Up)

"Even if you have scarce people resources, you can reach the right resources through the peer-to-peer network. We don't want to get involved in high volume business, because top-down models don't work in a high cost country. We have started from the open hardware culture, and it is a rather strong trend globally. The main point is openness." (Case Company E, Technology Start-Up)

In our interviews, although the interviewees thought that there is a great potential in the development of new cross-industry services and value creation based on the IoT, efficiency was mentioned as the most common driver of adapting IoT at company level. For developing new cross-sectoral IoT-enabled products and services, the actors must step out of their current roles. Companies that mention efficiency as the greatest driver for developing IoT-enabled products and services, generally deploy the role of a butterfly, or, in some cases, the ant and greenfly. Companies' current organisational structures create challenges, because they are designed to support current business models and for delivering products and services for present customers or sectors efficiently. Therefore nobody has responsibilities to develop new cross-sectoral IoT solutions, and nobody has incentives to sell them. IoT solutions are not easy to sell because nobody knows yet exactly the real benefits of using these solutions. Some of the experts we interviewed perceived the IoT as 'business as usual' for their company, as M2M solutions have been around since the 1990s. Companies that try to add IoT into their current products and services, deploy the butterfly's role.

However, at least some of the interviewed experts saw possible disruption in their own networks due to the global nature of the IoT business. We interviewed both local and multinational actors who want to build IoT solutions together with partners (thus, themselves working as spiders in the emerging ecosystem). In particular, they want to find smaller firms who develop IoT services in close cooperation with the customers. The local telecom operator (Case D) we interviewed pursues for a role as a local business developing company working with local partners (thus, a role of a spider). It is especially interested in offering services for municipalities. However, there are challenges for the telecom operators, because there are not enough promising IoT service developers available for their networks. Furthermore, in the IoT field, there will be also global actors who act according to their own logics and rules. Thus, there will not be lack of wannabe spiders. In our interviews the experts claimed that some industries have factors that slow down the development; for example, there may be regulation that creates barriers for entering the market, or there are strong incumbents, or the market structure is fragmented. One of the most interesting, but also problematic areas is the health sector, where all the factors mentioned above are valid. There are strong incumbents, fragmented markets, and strict regulation.

"Regulation in the public sector makes it fragmented, and it is very difficult to develop services or to get customers there." (Case Company D, Local Telecom Operator)

Bottom-up models of the IoT will emerge, because peer-to-peer communication becomes easier and cheaper, but also because big companies have certain inertias that slow down their innovations. The experts we interviewed mentioned some examples of bottom-up models; for example after the disaster at the Fukushima nuclear

plant a group of citizens who did not trust information provided by authorities, organised radiation follow-up with their own sensors and published their observations in the Internet. Other examples referred by the experts are weather detection networks, e.g. Lightningmaps ([www.lightningmaps.org](http://www.lightningmaps.org)), which are communities of volunteers. The value drivers for an individual bee taking part to these bottom-up swarm models can be getting trust-worthy information services cost-efficiently, or getting money by selling their own expertise or resources to other users. This means that users may share their own expertise and knowhow and become producing actors (Fleisch, 2010; Kortuem et al., 2010).

## 5. Conclusions

This research aimed to investigate actor roles in the ecosystems of the Internet of Things (IoT). The findings contribute to our understanding of the IoT by suggesting that actor roles are limited by the type of an ecosystem, and, subsequently, emerging IoT ecosystems are structured in accordance with actor role behavior. Furthermore, this study highlights the following four contributions to the ecosystem and role theories.

First, designing and analysing business models for the IoT ecosystem require new methods. Actors in the emerging ecosystem are still searching for their roles, and the ecosystem lacks many actors, especially new kinds of intermediates. By using the role theory as a tool for analysing the emerging IoT ecosystems, we show that there may be many roles that actors can have in the IoT ecosystems.

Next, the study identified four new actor roles companies can use in IoT ecosystems namely: *butterfly*, *ant* and *greenfly*, *spider*, and the *swarm of bees*. A *butterfly* focuses on compact issues, leading to limited but rather safe business model choices for a company. An *ant* may attach itself into a larger “company ecosystem” (*greenfly*), as soon as it has been formed. A *spider* weaves its own network in the IoT ecosystem. It may aim to become a key actor (spider type 1), or it can take a more modest role in the network (spider type 2). New kinds of value designs, bottom-up models, may emerge for a *swarm of bees*, in which the users share their own expertise and knowhow and become producing actors.

Third, the study suggests that a company can choose the type of network or ecosystem it wants to be part of, and its role in it. It can also decide how active it is, and it can either make or take its role in the network. The results show that each of these four roles is associated with a specific type of ecosystem. We distinguish between four types of ecosystems: *product-*, *company-*, *industry-*, and *peer to peer*. This study demonstrates that these types of ecosystems have different value design logics, and different logics of taking and making roles.

Fourth, this study showed how actors can aim to *replicate* their role-based value designs (*butterfly* and *ant*) or whole network structures containing value designs (*spider*).

For managers, this study increases understanding of the role configurations that companies can have in the emerging IoT ecosystem; more specific, how companies

can make or take their roles, and how the roles are connected to business model opportunities and challenges in the ecosystems on the organizational and ecosystem levels. The global nature of the IoT may bring forth new global actors, but also user-centric bottom-up models emerge. Thus, there are many possibilities for disruption of the current models. We argue that the major challenges in emerging technology fields and in emerging business ecosystems, such as the IoT environment, do not lie at the company level, but at business network or ecosystem levels. It is challenging to design business models based on new radical technologies, because the technologies have not yet matured into products and services, and the actors and their roles are not yet formed in the evolving ecosystem (cf. Westerlund et al., 2014). This study offers some tools for analysing these issues.

In this study, we give examples on how to analyse actor roles and ecosystem business models with the role theoretical and ecosystem approaches. We have also employed the value design tool in analysing IoT-enabled business models. The data covered the emerging IoT ecosystem from the Finnish perspective, in its early stages. However, due to several research gaps, ecosystem business models and actor roles in the IoT ecosystems should be studied more in the future. Also there is a need for more research on the dynamics of ecosystems, and development of actor roles over time. The analysis methods presented and tested in this paper constitute first attempts to show how ecosystem business models and actor roles in ecosystems can be analysed.

# Utilization of Text Analytics in Service Development

Eugen Molnár<sup>1</sup>, Rastislav Molnár<sup>2</sup>

<sup>1</sup>Comenius University Bratislava, <sup>2</sup>Imperial College London

## **Abstract**

*Unstructured information, distributed via different channels are becoming more and more important for the business and service development. Customer create a number of different data about the company and its services. Channels like blogs, social media, emails or customer calls are few of sources of these data. Companies are relatively easily able to obtain these information. The challenge for them is to utilize these data for the improvement of its operations and services. We believe the knowledge-based intelligent system can play an important role for the service development, for the improvement of existing and creation of new services alike. We propose and explain such system in this research*

**Key words:** Service development, ICT, Knowledge management, Information Extraction, Big Data

## **1. Information technologies in service development**

Business today utilize modern information technologies more and more often. In this section, we aim to illustrate the importance of these technologies for the servitization and service development. Our approach is to aggregate a large body of literature and examine whether authors discuss information technologies (ICT) in their research.

### **1.1. Literature search and selection**

We were searching for academic publications on the Google Scholar with a clear set of criteria. The full list of criteria we have established:

- Search on the Google scholar (scholar.google.com)
- The most cited articles (sort articles by number of citations)
- Only full articles published in English
- Only papers published between 2011 and 2015
- The following keywords research strings have been used, obtaining the following results: “servitization” AND “service development”

Originally 534 items were displayed with the number of citations in ranges 0-112. In the next step we selected 50 the most cited available articles.

Articles were then searched for keywords in the body of the article not in their references. Terms “Information” and “Technology” were analysed independently of their instances in the phrase “information technology” or “information and communication technology”. Table 1 reports findings of our analysis. It is important to point out all 50

articles contained string “customer” which is not a surprise as the topics of these articles are servitization and service development. On the other hand it is interesting a relatively large number of articles contain phrases “information” and “technology”, while relatively small number of articles contained terms “information technology” (IT) and “information system” (IS). Same results are reported in a graphic way in the Figure 1.

| <b>servitization AND service development AND</b> | <b># of articles</b> |
|--|----------------------|
| ICT / Inf. & comm. technology                    | 14                   |
| Information                                      | 47                   |
| Technology                                       | 45                   |
| Information technology                           | 17                   |
| Information system                               | 18                   |
| Customer   | 50                   |
| Customer centric / focused / centricity          | 10                   |
| Customer oriented / orientation                  | 11                   |
| Consumer   | 31                   |

Table 1: Number of articles with keywords in the text of the article (out of 50)

Figure 1. Amount of articles with the instance of particular keywords

Figure 2 shows 50 most cited selected articles in terms of where they were published or presented. The most frequent journals were in this case The Industrial Marketing Management, The Journal of Cleaner Production and The Service Industries Journal.

Figure 2. Number of analysed articles per journal

## 1.2. Deep analysis

On the top of a simple reference collection and search for keywords in the text of selected articles, we have done more detailed analysis of their content. The goal of this deep analysis all selected articles is to identify relationships between specified concepts:

service development & customer & information & ICT/IS/IT

From obtained results we can see that although term “ICT” is widely used term in the servitization, only 14 times (28%) was directly mentioned in analysed articles. When analysing a combination of terms ICT & IT & IS we can observe that as minimum one of these three terms exists in 30 articles what represent 60%. Similar situation is with phrases “customer centric” and “customer oriented/orientation”. As minimum one of these two phrases exists in 18 articles (36%).

Practically all articles highlight role of information in service development process and in the servitization as whole. The information technologies became an integral

element of 21<sup>st</sup> century consumer experiences (Baron et al., 2014). Technology plays a crucial role in the service development nowadays (Park et al., 2012).

For first stages of the service development is important to set up process of assessment customer perceived value to meet a customer's business needs and to be customer centric (Cavalieri and Pezzotta, 2012), (Macdonald et al., 2011), (Sojung and Yoon, 2012). In addition, there is an idea to include the customer as an input in the production function (Djellal and Gallouj, 2013), (Raja et al., 2013). To obtain clear customer requirements is a complex process requiring a lot of experience. These activities are often supported by specialized IT tools (Lee et al., 2013)). Such tools usually provide additional useful capabilities such as mapping customer requirements, service attributes to determine a priority based on the customer orientation, Product Lifecycle Management systems, and applications to process of information feedback (Tukker, 2013). The next common idea expressed in many of analysed articles is the importance of usage IT solutions for listening to the 'voice of the customer' and for product distribution (Belvedere et al., 2013), especially because the identification of customer needs is an essential part of the service development (Lim et al., 2012), (Meier et al., 2011), (Raja et al., 2013), (Sojung and Yoon, 2012).

To be able to meet customer needs, first the relevant information have to be collected. Gathering customer information is complex process which is unimaginable without of ICTs (de Jong and Vermeulen, 2003). Sometimes, it is useful to gather information directly from citizens (Lee et al., 2013) or observe behaviour and habits of customers (Reim et al., 2015). It is necessary to point out not all companies are able effectively utilize collected information (Barquet et al., 2013).

There are different ways of acquiring customer information (Turunen and Toivonen, 2011). Information gathering from different customers can be anonymised and generally used (Kujala et al., 2013). Most frequently, different types of questionnaires and feedback mechanisms are used (Turunen and Toivonen, 2011), (Phumbua and Tjahjono, 2012). Interactive web form can be amended by text analytics capabilities (Molnár et al., 2014). Such solutions often help the customer to find relevant information promptly and increase of her/his satisfaction at the same time.

One of key drivers of service innovation are IT and collaborative communication with customer (Santamaría et al., 2012). Another work suggests intense interactions with customers and increased service levels can affect characteristics of the Product-service systems (Phumbua and Tjahjono, 2012).

This is enhanced when there is offered "integrated combinations of products and services that meet specific demands of customers" (Velamuri et al., 2011). Service provider needs to be informed how customers use their product, what difficulties they meet, what is the condition of using the product, and what is the relationship between the core product and related products (He and Lai, 2012). A very important is specify contemporary issues related to service research (Baron et al., 2014).

The requirements collection, follows an evaluation phase when requirements are evaluated from both formal and business sides (Tukker, 2013). An important part of requirement management is sharing gathered information (Beuren et al., 2013), (Macdonald et al., 2011), (Reim et al., 2015) what is also relevant for service supply chain (Finne et al., 2013).

A very important part is played by the customer satisfaction, especially in the service delivery stage (Beuren et al., 2013), (Boehm and Thomas, 2013), (Candi et al., 2013), (Kastalli et al.2013), (Pardo et al.. 2012), (Saccani et al., 2014). There are cases when customers are willing to pay a premium, which reflects the added value of satisfaction that usually arises from service personalization (Gaiardelli et al., 2014), (Zhen, 2012). Often it is the information system as business supporter, which adds the main value to provided service (Pardo et al., 2012).

Although findings of this literature review confirmed irreplaceable role of the ICT in service development, necessity of automatic processing the customer needs (demands, requirements) by the utilization of specific tools with original capabilities is not clearly specified. In the next section we have processed another portion of selected literature directly related to ICT in service development with a goal to specify requirements for ICT capabilities as accurately as possible, enabling us to propose the framework for such tools.

## **2. Service Development – an Information view**

### **2.1. Service development and ICT**

Developing new services has become crucial for many service providers including servitizing organizations. Major part of them implement a rule saying by Edvardsson and Olsson that the customer is a co-producer of the service has wide-reaching implications to new service development (Edvardsson and Olsson, 1996).

When manufacturer introduces a new service he is in a new position. According to the (Edvardsson and Olsson, 1996), services are much more dependent on ICT as products. The role of ICT is significantly higher and ICT enables the increase of the efficiency of communication, co-operation and interaction. This happens both inside of the project team and also with customer. ICT capabilities therefore support the development of new services (Bullinger et al., 2003). The important role in service development is played by the front office. The front office personnel represents an essential part of service development team. In the first line, they can acquire valuable insights on customer needs and match it with what company offers (Alam, 2006).

The key aspect of the new service development is the orientation on customer needs, which is especially important when developing the service by alliance (Valkeapää et al., 2006). The following requirements on ICT capabilities used during service development process can be identified: 1) interaction with customers must be allowed for service developers and customer servants, 2) to collect, store and process the content of the interaction, 3) to allow to execute the market research and observation, and 4) to acquire the knowledge about customer needs (Valkeapää et al., 2006).

According to Shekar (Shekar, 2007) Service development stages are 1) Problem Identification, 2) Idea Generation, 3) Concept Development and Evaluation, 4) Business Analysis, 5) Development and Testing, 6) Market Testing, 7) Commercialisation, and 8) Post evaluation. From the point of the quality of service and hence the customer satisfaction it is the most important to analyse and evaluate a customer satisfaction surveys collected during the last stage of service development process.

Another approach is also presented by (Shekar, 2007) who points out the „Customer is part of the production phase“.

Nowadays, customers express their experience and needs via a number of channels (including social media, discussions, blogs etc.). To automate this process, it is necessary to identify and utilize related ICT capabilities systematically. Another challenge are activities banded with study and analysis of gathered information. In order to analyse unstructured data from customers, the Text Analytics and NLP capabilities are required to be implemented by the company. Companies with such capabilities dramatically improve their customer relationship, enhance customer experience and enable more informed service development.

The customer communication can be massively supported by new capabilities of ICT (Molnár et al., 2015). In addition communication with customer is getting very important tool for improving of customer satisfaction with a possibilities targeted leverage on customer. (Posselt and Förstl, 2011) defines “a supportive culture as a construct of complementary dimensions consisting of innovative supportive culture, market orientation culture, learning culture, and customer communication culture.”

(Belvedere et al., 2013) describes and demonstrates the essence of the impact of ICT on value creation in servitizing organization. They highlight “superior responsiveness of operating processes” and “improvements in the product offering”. In addition, it is claimed that a new product development is more powerful when utilizing new decision support systems “with better support for the decision-making process”.

Orme (Orme, 2014) points that the most important for service is the integration of new ICT systems with existing business systems and establishing a 360-degree view of a customer. He adds new position for servitizing organization it is the position of the service provider which is required not only to provide service but also to keep required service quality including service reliability and relationship with customers.

ICT provides not only the support for the employees of the company but also useful insights on customer opinions and their needs. In (Bains and Lightfoot, 2013) are specified extended ICT capabilities into five functions applicable for advanced services: 1) Monitor, 2) Transmit, 3) Store, 4) Analyse, and 5) Respond.

The most important flow of Data for servitizing company is data from sensors (often thousands). Bains & Lightfoot (Bains and Lightfoot, 2013) introduce that “advanced services frequently require a wide portfolio of additional data” which is transmitted to the manufacturer. Another important part of data flows in Servitization is customer feedback which is mainly used to improve of Manufacturer’s operation but is a valuable source of information for service development and improvement as well.

Sanders et al mention the first three steps of service research and development process (“generating an idea for a product or services, gathering and synthesizing information on the idea, and designing the product or services”) are directly connected with the utilization of ICT (Sanders, 2012). A very important part of these service development’ activities is learning-about or search process (Sanders, 2012) which represents search and synthesis with the goal “to gain insight and understand the potential of an emerging technology or a new idea”.

## 2.2. Requested ICT capabilities

The companies could profit from a capability to collect and analyse data and use it to improve key features of their service development – strong customer orientation. Besides, understanding of the human-generated information including feeling or sentiment, requires a fundamentally new approach that uses technology to deliver insight, ideas, and intuition into the rapidly growing and diverse data that we deal with every day. This approach takes all processed data and evaluates its meaning within the context of the entire knowledge pool (Molnár et al., 2014). This is a successfully story of Rolls Royce which has leveraged digital innovations around analytics and the “Internet of Things.” (Barrett et al., 2015).

Service innovation is closely related with ICTs (Barras, 1986). In these traditional approaches to the utilization of ICTs within service innovation process (Baines and Howard, 2013). ICTs have been understood as sophisticated tools which contribute to increasing of productivity and efficiency of service delivery process. Against those perspectives, there are new views on ITC's role in service innovation (Lusch and Vargo 2014). These underline the importance ICT and assign it directly into resources for service innovation.

(Barrett et al., 2015) suggests “that service innovation is a critical area for Information System research contribution to knowledge.” In addition (Barrett et al., 2015) claims that information should be placed at the centre of service innovation and knowledge is its “key operant resources”.

Often the changes in ICTs are related to service innovation recognized implicitly instead of explicit manner (Barrett et al., 2015).

Based on the previous and this section of our paper, we can clearly identify following key findings in existing literature:

- The importance of customer orientation and interaction was confirmed by literature review of articles related to the Service Development. From this point we can conclude: customer communicate via several different channels directly with the organization or indirectly posting his/her message on web (pages, blogs, discussions, social media...).
- There is a gap between the traditional perception of ICT's utilization within servitizing organizations and real needs of the business of these companies (unstructured data processing). This implies Big Data technologies enhanced by Text mining, NLP, Analytics and Knowledge Management are key ICT needed by those organizations.

These findings accompanies the development of knowledge based systems with strong focus on Text Analytics and NLP capabilities. Utilization of these capabilities allows organizations to obtain insight from gathering unstructured data from customers or potential customers. It allows companies to keep focus on customer centric service development. In order to achieve that, organizations have to implement a complex knowledge based solution.

### 3. Our Approach

Customer centric (oriented) service development supposes to process unstructured mainly textual data. It is also a common practice companies want to track their customers through their lifecycle. The retrieval and analysis of unstructured textual data is a big challenge for companies. According to Miner (Miner, 2012) “Text mining and text analytics are broad umbrella terms describing a range of technologies for analysing and pro-cessing semistructured and unstructured text data.”, they also split text mining into seven areas: 1) Search and information retrieval, 2) Document clustering, 3) Document classification, 4) Web mining, 5) Information extraction, 6) Natural language processing, and 7) Concept extraction.

We propose the architecture combining several of these areas, first we need the search and information retrieval in order to get raw information from customer, than we use the natural language processing and information extraction and concept extraction to extract all relevant information from it. Then we visualize the data. This architecture can be then easily utilized for the service improvement. Company can monitor and track how customers react on a number of aspects of their services and any changes made to them. Company can also identify and fix weak spots of their services using data from customers.

In this chapter we first theoretically introduce the information and knowledge, then we propose the architecture for information retrieval and processing and then we illustrate the architecture on a particular example.

#### 3.1. Information and Knowledge

The usual form of the communication between the organization and its customers is “Information - Information”, where customers supply some information and company replies with another information. These interactions are important and often recorded by the company (for example calls on the customer service line). Another form of the communication is “Data - Information”, where customer provides or publishes some unstructured data and the aim of the company is to respond as promptly and as accurately as possible in order to satisfy him. The example of latter are customer reviews on specialized websites.

We propose the architecture with the ability to understand different inputs from customers and automatically accumulate and report the knowledge and the information contained there. This way company can provide better and timely response to customers, but what is more important, it can use accumulated knowledge for the service development and improvement. In this case the communication becomes “Information – Knowledge - Information” and the Knowledge base is used for the service development. Whole process is described in the Figure 3.

Figure 3: The Data – Information – Knowledge Flow

Traditional information flow is direct from the customer to the company. It is then recognized by the company on a certain level, but a large part of the information available on the internet would remain unknown. In these settings the company does not have all relevant information to improve or alter their services. We propose a model in which company retrieves the information from both, the communication with customers and internet, and creates the knowledge base. The knowledge base can be then used to improve the communication with customers and more importantly to improve existing services, or create new services.

### 3.2. Proposed architecture

In order to implement the Knowledge base (and/or the “Information – Knowledge – Information” communication), a company has to be able to retrieve, process and understand a large quantities of unstructured data. We propose a following model enabling company to cope with these requirements (as shown in Figure 4):

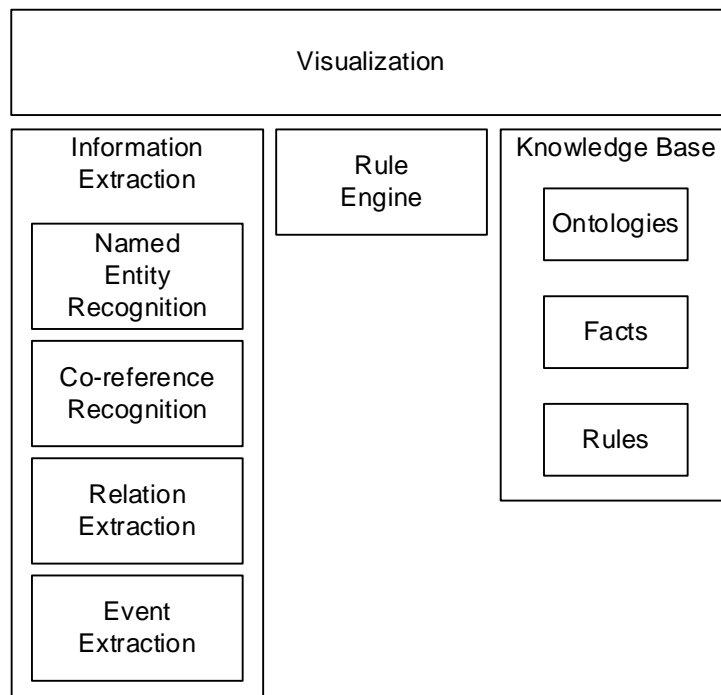

Figure 4: The functional blocks of proposed Knowledge-Based System

Proposed system uses unstructured data as the input, then it extracts the information from them using the rule engine. The main parts of this solution are Knowledge based represented by lightweight ontology and facts enrolled in POSL (POSL – Positional Slotted Language), Rule based system and the Reasoning engine. We also propose the use of retrieved data in order to provide more insights using the visualization in order to display the comprehensive information more clearly to the company and employees.

The input of this system is raw text, it is downloaded from the internet and other sources for example from the customer-company email communication. Raw information is then processed using the information extraction system. This system performs also, among other tasks, the entity recognition and relation extraction. Please refer to (Cowie and Lehnert, 1996) or (Piskorski and Yangarber, 2013) for more information about the information extraction. How are the information extraction systems implemented for web is described in (Chang et al., 2006).

After the information extraction step is the information passed to the rules engine. This engine uses a set of pre-defined rules to process these information and extract structures (or items). Examples of rule based systems are (Skeppstedt et al., 2012) who used it for the entity recognition in health records or (Folorunso et al., 2012) who used it for mineral identification. All structured data (items) as well as other information (for example ontologies and rules) are stored in the knowledge base. They are then retrieved and visualised as needed. An example of this system is a system visualising the most important issues customers create information about and what their attitude is. Such system is then used by the customer care and product departments in order to improve existing or create a new product. Another example would be an autonomic responding system that automatically responds on customer queries (for example online and e-mail support).

### 3.3. Example

Here we present an example of proposed architecture and its application for the service development and service improvement. The example is textual customer review of the service, which is publicly available on a specialized website. Using proposed architecture, the review is retrieved as a raw text, then processed and visualized in order to enable the company to act on it.

Example customer review goes as:

*"We were planning to migrate to XY's cloud, we have tried to contact them 5 times but they never contact us back. We used the form in their webpage, we have received an email that said that customer care should be in touch with us in the next 24 hours but they never called us. They do not offer chat assistance or telephone assistance. They have very serious problems in this area as they have lost a big client and they do not even know."*

Parsed, but still raw text is processed and displayed following the approach described in the previous sub-chapter. First is the text split to sentences and then the topics of individual items (sentences) are identified using pre-defined set of rules. On the top of that, the sentiment analysis is performed to reveal the attitude of customer. The last step is the visualization of retrieved data using dashboards. It is crucial to

display the data in a correct way in order to make it clearly visible for company to act based on them.

The example of how is the text split into sentences and sentences analysed is shown in the Table 2. You can see the information extraction module of our architecture split the text to sentences and calculate the sentiment.

| Raw sentences:  | Sentiment: |
|---|------------|
| said that customer care should be in touch with us in the next 24 hours | 0.718      |
| they have lost a big client and they do not even know                   | -0.647     |
| We were planning to migrate to XY's cloud                               | 0          |

Table 2: Raw sentences and identified sentiment<sup>1</sup>

This provides some insight on what is expressed in the text, however it does not identify to what are these sentences related (topic identification). While it does not matter for relatively small amounts of data, should there be hundreds of texts and thousands of sentences, it would be hard to extract any insight without the topic identification and clustering sentences to similar topics. We proposed to use the rule engine<sup>2</sup> and pre-defined set of rules to identify topics in individual sentences. The example of structures extracted from sentences using the rule engine is shown in the Table 3.

| Raw sentence:   | Identified structure:  |
|---|--|
| said that customer care should be in touch with us in the next 24 hours | <b>CONTENT (of CONTACT)</b><br>WHO = company<br>WHAT = contact client<br>WHEN = in 1 day |
| they have lost a big client and they do not even know                   | <b>ATTITUDE</b><br>WHO = company<br>WHOM = client<br>WHAT = lost<br>WHEN = past          |
| We were planning to migrate to XY's cloud                               | <b>MIGRATE</b><br>WHO = client<br>FROM = ?<br>TO= cloud<br>WHEN = past                   |

Table 3: Raw sentences and related identified structures

<sup>1</sup> The sentiment was identified using HP Idol available at: <http://www.idolondemand.com/>

<sup>2</sup> For more information on rule-based systems please refer to (Buchanan and Shortliffe, 1984)

As it is visible in the Table 3, once raw and unstructured text becomes structured. These structures are then stored in the knowledge base and used for different visualizations and reports.

Processed data are visualized using the combination of visualization techniques. A nice review of different visualization techniques was created by (Kucher and Kerren, 2014) and the overview of more than 200 methods is available at <http://textvis.lnu.se/>. Our visualization methods are based on the combination of BLEWS method by (Gamon et al., 2008), LDAExplore method by (Ganesan et al., 2015) and ShakerVis method by (Geng et al., 2013). Our goal was to display information retrieved from different sources, parsed into text and then analysed into meaningful dashboards to enable company's employees to act on these information.

Figures 5a through 5d show all visualization screens, on the first screen there is a complete overview of all company's services, number of identified items and overall sentiment. Services are then sorted from lowest sentiment. Second screen provides more detailed view as it shows number of items and their sentiment per topic. In our case all 9 items identified from the review were related to the customer support. Third picture shows even greater detail that reveals 8 items were from the Interaction topic and one was Complaints, in this case are individual topics sorted by number of items. The last picture shows Interactions topic, to be precise Interactions with Customer support related to the cloud service of the company. In this view it is possible to spot trends in number of items and overall sentiment (upper part of the Figure 5d), this enables to observe how customers communicate about an particular topic (in this case Interactions of the Customer support). Bottom part of the last view displays whole user's text with highlighted items and coloured by the sentiment and individual items related to given user's text.

Figure 5a: Home page with all services

Figure 5b: Details of the Cloud Service

Figure 5c: Details for the Customer support of the Cloud Service

Figure 5d: Detailed view with individual items for Interactions with Customer support

Visualizations, similar to one presented above are crucial tools for the interpretation of retrieved and analysed information. Companies can utilize them for the improvement of their services. They can simply implement changes and then see the reaction of customers on the internet and in the communication with the company in several, clear and straight dashboards without any need to go through thousands of documents.

## 4. Conclusion

In this research we present a model of the knowledge-based system for the evaluation and analysis of company's services. The system collects, processes and displays unstructured, customer-created data. Conceptually this system utilizes the information extraction base on the rules and knowledge management. It helps to understand what are customers saying and it reveals patterns in their opinions. This enables company to see not only the communication with customers but also information available via public sources. Clear and simple visualization system helps to present processed information in a meaningful way, enabling company to act prompt-

ly on any issues raised about their services. Moreover, this tool can be utilized to analyse products and services of competitors as well.

Unstructured data are more and more important and customers are producing more and more information and express their opinions on services they use. This implies the architecture similar to proposed will become a crucial tool for the service development for any company.

# Transaction costs and the sharing economy

Anders Henten, Iwona Windekilde

CMI, Electronic Systems, AAU, Denmark

*The paper discusses the so-called sharing economy from an industrial structure perspective. The illustrative cases examined are Airbnb and Uber. The research question raised is concerned with the extent to which transaction cost theory can be used to explain the changing industrial structures in the application areas that the Internet-based platforms are addressing and how other theoretical frameworks can be helpful in understanding these developments. The paper concludes by proposing a theoretical framework for analyzing the structural implications of the sharing economy based on theories on multi-sided platforms, transaction costs, and substitution and complementation.*

## 1. Introduction

During the past couple of decades, a wide variety of Internet-based platforms have sprung up – some of them extremely successful. eBay is a prominent example of one of the platforms established before the dotcom crash. Airbnb (accommodation) and Uber (transportation) are successful examples of platforms established during the past 5-10 years. Airbnb and Uber are seen as examples of the emergence of a sharing economy (Hamari, et al., 2013), (Zervas & Byers, 2013) where people share human and physical resources. Indeed, sharing includes many different forms of activities – some of which are non-commercial and others commercial. The paper examines the commercial kinds of developments and discusses the possible foundations and implications in terms of economic reasons and industrial structures. The research question is concerned with the extent to which transaction cost theory can be used to explain the changing industrial structures in the application areas that the Internet-based platforms are addressing and how other theoretical frameworks can be helpful in understanding these developments.

The obvious explanatory framework is transaction cost theory taking its point of departure in Ronald Coase's seminal paper from 1937, as the digital platforms allow for decreasing transaction costs – in the eBay case between sellers and buyers of all the items and services sold via eBay; in the Airbnb case, between those offering and those buying accommodation; in the Uber case, between those offering and buying transportation. Without the digital platforms, the transaction costs of searching, contacting, contracting, etc. would generally be much too high for such commercial markets to develop. However, this obvious explanatory framework has only been little elaborated upon academically and analytically (Benkler, 2004). The aim of this paper is, therefore, to take a more analytical approach, using a transaction cost framework for examining prominent examples of the sharing economy. The examples examined are Airbnb and Uber.

In 1937, Coase had his paper entitled 'The Nature of the Firm' (Coase, 1937) published, which presented the basics of the transaction cost approach, and he used it

as a theoretical framework for explaining industrial structures. Basically, he used transaction costs as the explanation for the existence of firms: Were there no costs of transacting between the agents in markets, the structure of industries would be composed of individuals (or only very small companies). The explanation for larger companies to be created is the existence of transaction costs, which can be minimized by the establishment of larger entities, is the argument in the Coase paper. The 1937 paper is, in a sense, a position paper, where Coase boldly advances transaction costs as the primary basis for industrial structures with large companies. He even discards other explanations, for instance the divisions of labor and the specialization efficiency effects. The goal was to put transaction costs on the agenda of studies of industrial structures.

In the present paper, the transaction cost approach is seen as a crucial element in explaining the development of sharing on a mass-scale. However, this approach cannot stand on its own. It does, for instance, not explain the limits of the encroachment of sharing-services on established markets (e.g. hoteling and taxi driving). It actually does, in an inverse manner, contribute to explaining the establishment of new large companies in the Internet world. There have always been companies that live on transaction costs. Business lawyers are good examples, as their function is to see to the contracting and enforcement of business agreements. So are real estate brokers, establishing the connections between the sellers and buyers of real estate property. But the Internet has created a foundation for a large variety of new businesses that live on providing services lowering transaction costs. It may be that some of the explanatory frameworks that Coase discarded so quickly and other theoretical frameworks can offer elements of explanations for the structure of market developments.

In the paper, case analyses of the new Internet-based platform services, exemplified by Airbnb and Uber, are provided as well as an analysis of the implications for the markets they are addressing. This analysis will be used for discussing theoretical approaches that are needed in order to explain these developments. First, the paper examines the concept of sharing and its different forms. This is followed by a theory section, where Coase's approach to transaction costs and ideas on substitution are presented. Thereafter, an overview of the different types of Internet-based platforms is put forward, followed by case analyses of Airbnb and Uber. Before the conclusion, implications for theory and analysis are discussed.

## **2. Review of literature on sharing economy**

### *Going back to collaborative consumption (1978)*

The sharing economy concept is said to build on the concept of collaborative consumption (Hamari, et al., 2013). Actually, the concept of collaborative consumption, as it was first put forward by Felson and Spaeth (Felson & Spaeth, 1978) had a different meaning, namely 'events in which one or more persons consume economic goods or services in the process of engaging in joint activities' (Felson & Spaeth, 1978). The examples were 'drinking beer with friends, eating meals with relatives', etc. (Felson & Spaeth, 1978).

From 1978 until 2007, there were only few publications on collaborative consumption within the context of sharing or renting goods. In 2007, Russell Belk described sharing as an alternative form of distribution to commodity exchange and gift giving. The author pointed out that sharing can foster community, save resources, and create certain synergies. His article addresses impediments to sharing as well as incentives that may encourage more sharing of both tangible and intangible goods (Belk, 2007).

In subsequent publications, Belk provides an extensive theoretical review of the concept of sharing and distinguishes 'sharing in' and 'sharing out' in terms of gift giving and exchange. He suggests that 'sharing in' dissolves interpersonal boundaries posed by materialism and possession attachment through expanding the aggregate extended self. However, such sharing is challenged by growing market commoditization (Belk, 2010).

In 2014, Belk published a paper, 'You are what you can access: Sharing and collaborative consumption online', where he pointed out that "sharing is a phenomenon as old as human kind, while collaborative consumption and the sharing economy are phenomena born of the Internet age". He concluded his paper by the modifying the former wisdom, 'You are what you own', converting it to a new wisdom, 'You are what you share', indicating that we just may be entering the post-ownership economy (Belk, 2014).

Furthermore, Rachel Botsman and Roo Rogers have redefined collaborative consumption as an activity which 'is enabling people to realise the enormous benefits of access to products and services over ownership, and at the same time save money, space, and time; make new friends; and become active citizens again' (Botsman & Rogers, 2010).

#### *Some people make allusions to transaction costs*

Relatively few papers have studied transaction cost aspects of the sharing economy. Yochai Benkler in his essay 'Sharing Nicely' (Benkler, 2004) seeks to define a particular class of physical goods as 'shareable goods' that systematically have excess capacity, and to combine comparative transaction cost and motivation analysis to suggest that this excess capacity may better be harnessed through sharing relations than through secondary markets.

Benkler pointed out that the primary systematic differences between the transaction costs of markets and sharing are related to information and enforcement costs. 'Markets use a combination of the price system and managerial hierarchical reporting and command flows to manage information about the universe of potential actions on resources in the world. Social frameworks use social cues that are usually less formal and less focused on crisply delineating the alternative courses of action open to participants in these frameworks' (Benkler, 2004). In regards to enforcement cost he emphasize that 'markets rely more heavily (though not exclusively) on formal enforcement, while social relations rely on informal enforcement mechanisms studied in the literature on social norms and reciprocity'.

#### *Discussions regarding non-profit and for-profit sharing*

There is also a discussion regarding non-profit and for-profit sharing – that the new for-profit sharing encroaches on already existing non-profit sharing. This consideration corresponds to the rise of numerous for-profit and non-profit activities that are booming thanks to the rise of the sharing economy, for example Airbnb and Uber.

Neal Gorenflo (Gorenflo, 2013) talks about how money is ruining what started out as a transformative concept. In his post, he emphasizes that collaborative consumption is suffering growing pains. 'As collaborative consumption goes mainstream, it risks losing the very thing that attracted people in the first place, the unique and even transformative social experiences made possible when you interact with helpful strangers' (Gorenflo, 2013). He stresses that with this potential loss goes an important part of the positive impact of non-profit sharing. Erin Griffith (Griffith, 2013) has a similar point of view. She provides examples of Airbnb, which basically took the model of Couchsurfing and turned it into a for-profit enterprise, and car sharing which is just a more organized car-pooling. She argues that a transaction that involves money is not actually sharing, its renting or selling. At the same time, alternative approaches rise. Juliet B. Schor (Schor, 2014) points out that while the for-profit companies may be 'acting badly', these new technologies facilitating peer-to-peer economic activity are potentially powerful tools for building a social movement centered on genuine practices of sharing and cooperation in the production and consumption of goods and services. But achieving that potential will require democratizing the ownership and governance of the platforms. Erin Griffith (Griffith, 2013) admits that without money many sharing economy sites would not have gotten to the size they are today. 'The sites required money to offer services that are effective and, as a result, their services have impacted more people than they might have otherwise. That's how, in most cases, for-profit sharing economy companies have outgrown their free counterparts' (Griffith, 2013).

*Similarly, there is a discussion regarding how sharing affects users' protection but also workers' rights*

New platforms such as Uber and Airbnb have drawn significant criticism from established operators and concerns from governments about fair competition, workers' rights and consumer protection. Brishen Rogers in his research focuses on the relationship between employment regulations and liberal distributive justice and on the influence of information technology on the world of low-wage work. In his paper, 'The Social Costs of Uber', Brishen (2015) pointed out that 'Uber's longer-term impact on labor standards is quite unclear, however, and it may have dark implications for the future of low-wage work more generally'. He assesses Uber's effects on safety, privacy, discrimination, and labor standards and outlines how law makers might adapt existing laws to reach Uber and other ride-sharing companies.

*The sharing economy is also a result of the economic crisis, where people lose their jobs and need to find other means of income*

The macro-economic factors seem to play an important role in driving the growth of the sharing economy. Many researchers point out that the new trend towards collaborative consumption started to gain momentum as a response to the global financial crisis and an attempt to fight over consumption. According to the European Economic and Social Committee (EESC) (EU, 2014), a consultative body of the EU, collaborative consumption, such as car sharing, room rental, and digital communities for learning languages, represents great alternatives in times of crisis. Many believe that the sharing economy is an appealing alternative for consumers due to its economic benefits (i.e., low cost, new income opportunities), which have been considered important following the global economic crisis. It is also suggested that collaborative consumption will continue to grow even when the economy is fully recovered (Bardhi & Eckhardt, 2012), (Walsh, 2011), (EU, 2014).

*But first and foremost, sharing has always existed, but technology provides a new platform*

The Internet has made it much easier for people to connect with one another and to coordinate their activities. People use platforms to rent, sell, or share things with others. It is an obvious approach and many researchers suggest the importance of digital technologies, facilitating the emergence of the sharing economy in overcoming the transaction costs, the trust and reputational barriers that once restricted sharing activities (Schor, et al., 2015), (Stokes, et al., 2014), (Benkler, 2004), (Forum, 2014).

### **3. Transaction cost theory and theory on substitution**

In the present paper, theory on transaction costs is the basic explanatory framework for understanding the development of services like Airbnb and Uber. However, in order to understand the potentials for the costs of transaction to have an influence on the use of the new Internet-based platforms, the degrees of substitutability between traditional services and the new services have to be discussed. Two different but interrelated frameworks will briefly be dealt with: Transaction cost theory and the issue of substitution.

Transaction cost theory was first presented in a succinct manner by Ronald Coase in his 1937 paper, 'The Nature of the Firm' (Coase, 1973). In the basic assumptions in neo-classical economics, there is full information for all economic agents in all markets, and the only costs to be considered are the costs of production and transportation. There are no transaction costs, as all economic agents are fully informed of qualities and prices of all products and of all production and consumption possibilities.

What Coase did was to modify this assumption by including the real-world view that economic agents have only limited information, and that there are many costs associated with transacting in markets. This realistic view has a host of different implications for how markets work, however, Coase wanted to put emphasis on its implications for industrial organization. He used it for explaining why we have firms, where many people co-operate in smaller or larger entities in the production and marketing processes, and not only a vast array of individual economic agents transacting with one another. The reason he indicated was that because of the many different costs of transactions, economic agents would join up and create larger economic entities in order to lower transaction costs. However, he recognized that there are also costs of managing companies (internal transaction costs), but that the external transaction costs are powerful economic mechanisms that lead to the establishment of firms.

These initial ideas on transaction costs were later further developed, first and foremost, by Oliver Williamson (Williamson, 1979), (Williamson, 1981). Building partly on Herbert Simon's bounded rationality concept (Simon, 1957), Williamson developed a framework for understanding transaction costs including the concepts of bounded rationality, uncertainty, opportunism, asset specificity, and transaction frequency. These are the kinds of factors that create transaction costs in the economy: The fact that there is uncertainty in markets and that all economic agents have bounded rationality and act opportunistically, and that assets to a large extent are specific and that transactions may take place more or less frequently will create transaction costs.

Similar ideas and concepts are relevant for the discussions on substitution. In basic neo-classical economics, taking the foundational assumptions for granted, there is in principle full substitution between all products and services to the extent that different bundles of products and services can deliver utility to the users in ways that may satisfy the needs of users in similar manners. In reality, substitution is discussed in relation to products and services that fulfill comparable needs of users. In our examples, hotels and private accommodation both deliver accommodation services, and taxis and private transportation both deliver transportation services. The discussion is the extent to which the different services are fully substitutable. Is there full substitution between hotels and private accommodation and between taxis and private transportation?

The answer to these questions can build on, e.g., a value proposition approach and an approach that takes into account the different reasons for transaction costs and the different elements in the business processes, where there are transaction costs. In a value proposition approach it will be discussed what the different elements in the value propositions of the different services are. A hotel stay, for instance, offers a room and bed at some known standard quality (in most cases), solitude, several rooms at the same time if being a group of people, breakfast, etc. Private accommodation via Airbnb offers a room and bed at more unknown standards, the chance of meeting new people, etc. The value propositions are to a large extent similar, but also differ at some points.

If looking at the issue from the point of view of the reasons behind transaction costs and the processes of transaction, uncertainty, bounded rationality, and opportunism may play a role, as the service users will have less knowledge on the services provided because of the lower degree of standardization. The processes of searching, contacting, contracting, etc. would previously be much more difficult for private accommodation and transportation than for hotels and taxis. However, this is exactly where the new digital platforms come in and change the basic conditions for substitution. When it becomes easy to search for the right place or the right means of transportation, to contact and to contract for getting access to the services, the degree of substitution will increase. The potential substitutability between services becomes a real possibility for substitution.

## **4. Internet based platforms**

With the diffusion of the World Wide Web from the mid-1990s, an interest in categorizing the different types of new Internet-based business models was initiated. One of the first most cited contributions at the time was the paper 'Business models for electronic market' by Paul Timmers (Timmers, 1998). Another important contribution was the website maintained by Michael Rappa (Rappa, 2010), which included a taxonomical categorization of 'Business models on the Web'. This taxonomy included the following business model categories: Brokerage, advertising, infomediary, merchant, manufacturer, affiliate, community, subscription, and utility.

Later, during the first years of the new millennium, came an increasing interest in ontologies of business models, i.e. the interplay between the different elements of business models including the technological, organizational etc. aspects. One of the major contributions in this field came from ICT researchers from the Netherlands and

Belgium, see, e.g. Faber et al. (2003), 'Designing business models for mobile ICT services'. Other major contributions came from Alexander Osterwalder and Yves Pigneur, with Osterwalder's doctoral thesis, 'The business model ontology', (Osterwalder, 2004) as an important landmark.

The development of science in this field thus follows the traditional path from taxonomies to ontologies – and back again with more specified taxonomies on the basis of increased knowledge on the interplay between the different elements and facets of business models. The interest in the present paper is on a type of brokerage model that not only has become the object of steeply increasing research attention during the past decade (Rochet & Tirole, 2006); (Gawer & Cusamano, 2002); (Hagiu & Wright, 2011), but also has spread quickly in actual business developments, namely multi-sided platforms (MSPs).

The MSP concept is an extension of the two-sided market concept (Rochet & Tirole, 2006) with more than two different kinds of customers, who are interdependent and are being served by the same platform. In a paper by Hagiu and Wright (2011), they differentiate between MSPs, re-sellers and input suppliers, where MSPs are distinguished by the direct interaction between the different customer groups. In the two cases analyzed in the present paper, Airbnb organizes the direct interaction between accommodation providers and users and Uber organizes the direct interaction between transportation providers and users. Airbnb and Uber are thus basically two-sided markets - which may be further developed into multi-sided platforms with, for instance, advertisers as a third kind of platform customers, if considered strategically desirable by the platform owners.

Airbnb and Uber are certainly not the first Internet-based platforms in the accommodation and transportation areas. Other commercial as well as non-commercial platforms have preceded them. In as well the accommodation and the transportation areas, there are many non-commercial platforms, where people can find free accommodation and transportation. These kinds of arrangements have contributed to the air of sharing, which the commercial platforms build upon. However, while the non-commercial platforms are altruistic sharing platforms, the commercial platforms are 'in it for the money' both with respect to the revenue derived by the platform owners and the payments to the accommodation and transportation providers.

Other commercial platforms have also existed before the large international ones with Airbnb and Uber as the archetypes. Renting of accommodation, especially vacation accommodation, via agencies has been taking place for a very long time. Internet has certainly provided such commercial operations with a new and much more efficient platform but has, in many cases, basically been an extension of an existing business model. With Airbnb and Uber and other similar operations, these kinds of old-fashioned two-sided market operations have been taken to a whole new international dimension. Airbnb and Uber have vastly extended the markets for residential accommodation and transportation.

As mentioned in the introduction to the paper, businesses living on transaction costs have existed 'as long as business itself'. Lawyers and real estate brokers were mentioned. However, Internet with its vastly improved capabilities for communication between and among individuals and businesses establishes a basis for markets to expand and be created. Internet allows for considerable decreases of transaction costs,

but just for this reason, it also in a paradoxical manner creates the basis for new businesses based on handling transaction costs.

## **5. The cases of Airbnb and Uber**

### **5.1. Airbnb**

Airbnb, originally called Airbed & Breakfast, is an Internet company founded in August 2008, based in San Francisco, California. The idea of renting out free space in their apartment came up in 2007. Airbnb founders, Nathan Blecharczyk, Joe Gebbia and Brian Chesky, rented out three airbeds on their living room floor and provided breakfast for their guests. On March 1st 2015, Bloomberg announced that Airbnb was raising money from investors in a financing round that would value the room sharing service at \$20 billion (Bloomberg, 2015).

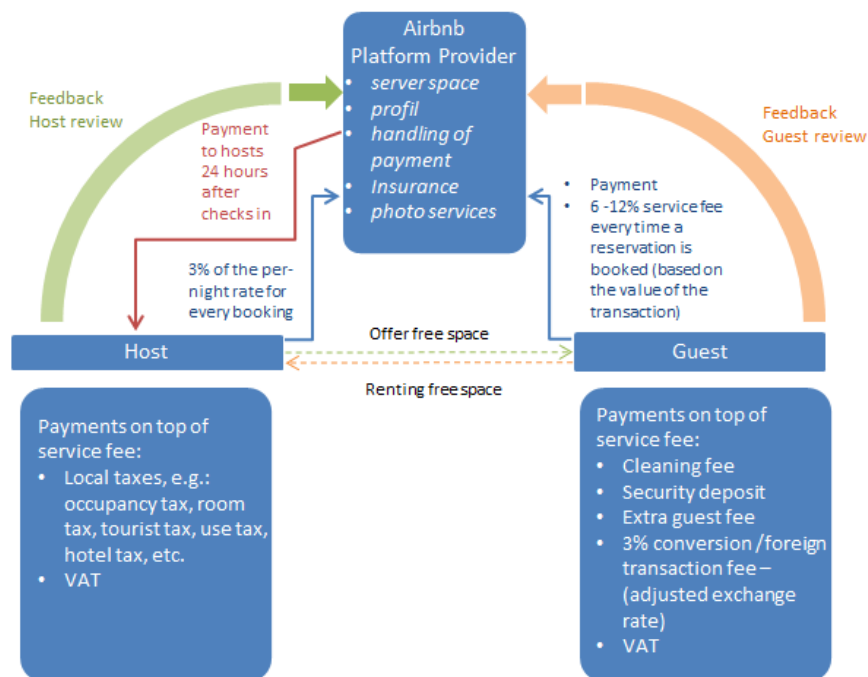

Since 2008, Airbnb provides an online platform that connects hosts who have places to rent with guests seeking to rent such places. The business has grown exceptionally, and in 2015 Airbnb is representing 1,000,000 listings in 34,000 cities and 192 countries (Airbnb, 2015). Airbnb has acquired several of its competitors and has surpassed the InterContinental Hotels Group and Hilton Worldwide as the world's largest room service provider.

Airbnb states clearly in their 'Terms of Service, Host Guarantee Terms and Conditions' that Airbnb does not own, sell, resell, furnish, provide, rent, re-rent, manage and/or control properties. Airbnb's responsibilities are limited to facilitating the availability of the site, application and services and serving as the limited payment collection agent of each host for the purpose of accepting payments from guests on behalf of the hosts. Guests pay Airbnb when they book a place and Airbnb releases the money to hosts 24 hours after the guests check in.

Airbnb charges hosts as well as guests for the use of their online platform. Both fees are calculated as a percentage of the applicable accommodation fee:

- Guests are charged a 6-12% service fee on top of the reservation every time a reservation is booked (Airbnb, 2015). The exact percentage of the guest service fee depends on the reservation subtotal. It falls steadily from 12% to 6% when the reservation amount is increased so that guests can save money by booking large reservations. The company claims that fees cover the cost of running the Airbnb platform.
- Hosts are charged 3% of the per-night rate for every booking. This fee covers the cost of processing guest payments and is deducted from the host payout. Hosts are responsible for setting their per-night rates, cleaning fees, and security deposits. Furthermore, hosts are responsible for following all laws and regulations, including paying any local taxes that apply to their accommodations.

**Figure 1: Airbnb platform**

The total fee may include taxes and cleaning fees. Airbnb charges VAT on its service fees for users (applicable to hosts and guests) from the European Union, Switzerland, Norway, Iceland, and South Africa. In some locations, Airbnb has made agreements with governments to collect and remit local taxes on behalf of hosts. Currently, Airbnb is collecting and remitting taxes in the following locations: Multnomah County and Portland, Oregon USA, San Francisco, CA USA, San Jose, CA USA, Chicago, IL USA, District of Columbia USA, Malibu, CA USA, Amsterdam NL.

If the guest pays for a booking in a currency different than the one the host has chosen in the listing, guest will be subject to varying Airbnb exchange rates which may not be identical to the real-time market rate. Furthermore, Airbnb charges 3% conversion/foreign transaction fees when booking is done in foreign currency. This accounts for Airbnb holding costs and currency risks. The conversion/foreign transaction fee is separate from and in addition to the Airbnb guest service fee. The conversion fee is applied to the reservation total after guest service fees have been added (Airbnb, 2015).

Depending on the host, the actual costs can vary due to cleaning fees, extra guest charges and security deposit. Moreover, it is very difficult for guests to estimate the total costs during a searching process because of the variation in local tax levels which makes the Airbnb pricing scheme less transparent than in the hotel industry.

Despite the fact that Airbnb has its own million dollars insurance policy, it is necessary to have a property-owner's insurance. Airbnb will cover the property and general furnishings but only after the property's own insurance policy is exhausted (Airbnb, 2015)

Even though Airbnb has left pricing decisions in the hands of hosts, they have recently started working on a predictive pricing algorithm which will provide hosts with a recommended price for their space depending on many factors including room style, property type, number of reviews, capacity, location, seasonality, pricing of other list-

ings, hotel and airline demand, and even temperature changes at the destination. However, it still allows the host to ultimately set the final price.

Airbnb is a prominent example of a company which is part of the sharing economy. In 2014, Airbnb was named 'company of the year' by Inc. magazine which claimed year 2014 to be the year of the sharing economy (Fox, 2014). During the last few years, the company has grown exponentially but also has faced many problems with regulators in regards to tax requirements and unfair competition.

### 5.1.1 Present and future implications for the hotel industry

Few years ago, nobody expected that the Airbnb platform would threaten the traditional hotel industry. Hotels have failed to predict the growing scale of Airbnb's activities. Airbnb's platform has scaled quickly in terms of users and numbers of transactions. A strong network effect has influenced the constant growth of hosts and guests. Through its platform, Airbnb has not just created new user behaviours but has changed the supply side of the hotel industry as well.

Since 2014, big hotel chains have started realizing that the Airbnb platform is affecting their business, but it is very difficult for them to quantify the impact. Hotel News Now Report has examined how new platform businesses are impacting hotel demand, with analyses of 10 Largest hotel companies by room count as illustrative case studies. In table 1, Airbnb is compared to four large hotel chains.

**Table 1: Largest hotel companies by room count**

| Company                                  | Existing Hotels | Existing rooms | Rooms in development pipeline |
|--|-----------------|----------------|-------------------------------|
| <b>IHG InterContinental Hotels Group</b> | 4840            | 710,295        | 193,772                       |
| <b>Hilton Worldwide</b>                  | 4278            | 708,268        | 230,000                       |
| <b>Marriott</b>                          | 4044            | 692,801        | 240,000                       |
| <b>Wyndham Hotel Group</b>               | 7645            | 660,826        | 117,000                       |
| <b>Airbnb</b>                            |                 | 1,000,000      |                               |

Source: (The 2015 Big Brands Report)

Until recently, the luxury hotels haven't considered Airbnb as a direct competitor. This has changed due to a fact that Airbnb is expanding its offers into the business and luxury travellers' segments which are critical groups of customers to the hotel industry. In 2014, Airbnb entered the business segment, teaming up with Concur – an American travel management company, providing travel and expense management services to businesses. The agreement with Concur allows Airbnb charges to appear directly on travellers' expense forms. By 2015, Airbnb reports that just below 10% of its guests are business travellers (Weed, 2015).

Even though Airbnb provides an alternative to traditional hotels, there is a new trend among small and luxury hotel owners which are joining the Airbnb platform to list their rooms alongside with booking.com, trivago and other websites.

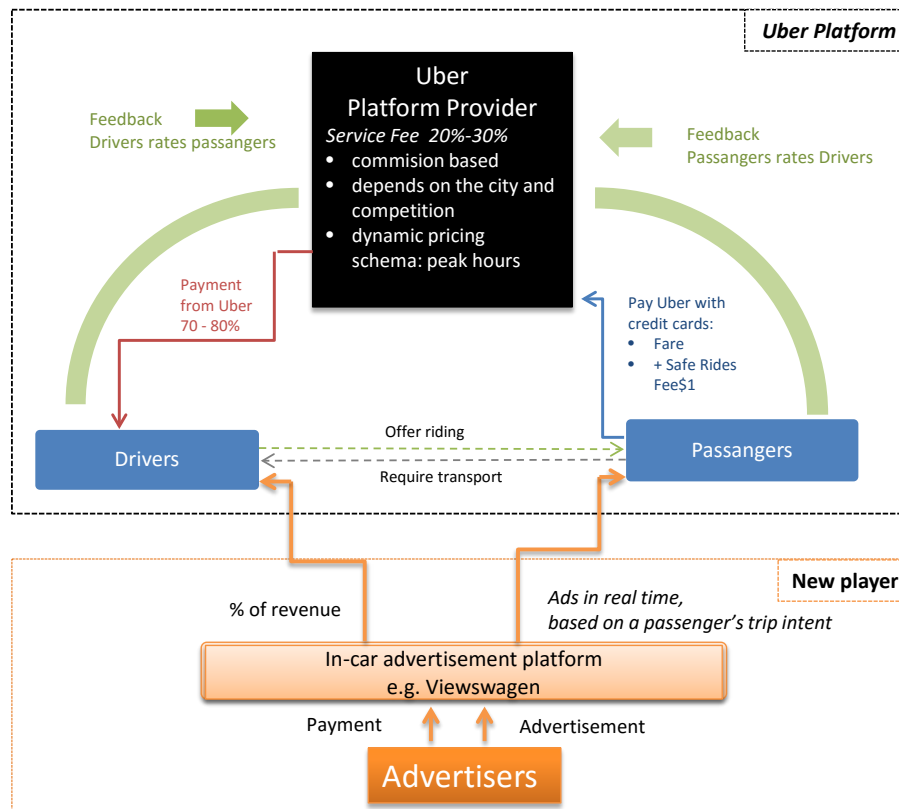

## **5.2. Uber**

Uber is an US-based online transportation network company founded in 2009. On December 4 2014, Bloomberg announced that Uber was worth more than \$40 billion (Bloomberg, 2014). Uber does not own cars and does not employ drivers. Uber claims to be a marketplace where Uber's drivers as independent agents meet Uber's customers. Uber states in 'Terms and Conditions' that their services constitute a technology platform that enables users of Uber's mobile applications or websites to arrange and schedule transportation and/or logistics services with third party providers of such services, including independent third party transportation providers and third party logistics providers under agreement with Uber or certain of Uber's affiliates (Uber, 2015).

Uber represents a platform business and provides more opportunities for growth of a sharing economy. The core value that Uber delivers is a reduction of search and transaction costs for both drivers and passengers. The Uber platform can be classified as an exchange platform due to the fact that Uber creates value primarily by enabling direct exchange between actors. The Uber platform manages a network of drivers and passengers through apps and provides real-time ride sharing options. Uber provides also various options associated with transportation or logistics, including the transportation brands: Uber, uberX, uberXL, UberBLACK, UberSUV and UberLUX and the logistics brands: UberRUSH, UberFRESH and UberEATS.

Worldwide, the company now facilitates 1 million rides per day and is adding 50,000 new drivers per month. As of March 26 2015, the service was available in 55 countries and more than 200 cities worldwide (Uber, 2015). Uber, in contrast to Airbnb, is setting prices for rides. Payment is done directly to Uber not to the drivers. Uber's commission-based pricing structure means that the company will take a percentage of a driver's fee every time the driver gives a ride. Uber fares include a base fee as well as rates based on time and mileage, which vary from city to city. UberX, for instance, charges \$1.63 per mile and \$0.30 per minute in Seattle, along with a \$2.14 base fare and a \$6 minimum fee. On average, 70-80% of gross fares go to the independent drivers. Uber has stated that charges will be inclusive of applicable taxes where required by law. Some portion of the percentage that is retained by Uber goes to cover payment processing, payment fraud, refunds, customer service, dispute resolution, cellular handsets and local regulatory efforts.

**Figure 2: Uber platform**

In 2012, Uber introduced a dynamic pricing scheme due to the fact that there was a supply and demand imbalance during Friday and Saturday evenings. Uber offered the drivers higher prices during weekends. By offering more money to drivers, they were able to increase the road supply of drivers by 70-80% in Boston.

Dynamic pricing changes are calculated algorithmically when wait-times are increasing dramatically, and 'unfulfilled requests' start to rise. Prices are changed if utilization rates fall below 60% or are above 80% (Uber, 2013). In essence, there are two functions of the increased price model. One is to increase supply. The second function of the price increase is to temporarily intentionally reduce demand. Through these two mechanisms, the company is able to increase supply, assure reliability which is a key tenet of the company, and maximize the number of completed rides (Gurley, 2014). Uber has informed platform users that charges applicable in certain geographical areas may increase substantially during times of high demand.

In 2014, Uber introduced a \$1 Safe Rides Fee, paid for by riders. The new fee, which applies nationwide in the US, will cover the company's costs related to 'background checks, ongoing safety monitoring, education, insurance and safety features (e.g. an in-app emergency button)'. This new fee is for UberX — which lets everyday drivers shuttle people around town — and not for the more expensive UberBLACK service, which uses professional chauffeurs (Soper, 2014).

On top of the Uber platform, other companies are trying to build their business model. Viewswagen has recently launched an advertising platform inside Uber and Lyft vehicles that allows drivers to show promotions on tablet screens in cars' backseats. It uses GPS to generate specific ads targeted toward passengers as they ride.

### **5.2.1. Present and future implications for taxi industry**

Uber, as the world's largest ride-hailing service operator, is directly affecting taxi companies' businesses. The taxi business is indeed sensitive to the fact that Uber and taxi drivers operate in the same markets subject to different rules: safety, privacy, fares, etc. Until now, taxi companies' response has been to demand more regulations for ridesharing. But taking into consideration that 70% of the world's population is expected to live in urban areas by 2050 and faces congestion problem, the view point has been put forward that a better alternative for taxis and customers would be deregulation for both - taxis and ridesharing (Beyer, 2015).

Felix Salomon has pointed out that Uber can actually raise taxi drivers' income over time, not lower them, due to the possibilities to sell their services to either taxi-fleet owners or to companies like Uber. Looking from this perspective, more competition on the market means higher income for drivers (Salomon, 2013).

Presently, however, the Uber platform is disrupting the status quo of the taxi industry around the world. The San Francisco Municipal Transit Agency has noticed a sharp and steady downturn in taxi use in San Francisco from 1,424 average trips per month in March 2012 to 504 in July 2014, a steep 65% decline (Agency, 2014). Uber already has and will increasingly have implications on the structure of the taxi industry, on jobs and on wages.

## **6. Implications for theory and analysis**

In a paper from 2014, Belk (Belk, 2014) seeks to align the concepts of sharing economy and collaborative consumption by characterizing the Felson and Spaeth definition and the definition by Botsman and Rogers (Botsman & Rogers, 2010), which sees collaborative consumption as including 'traditional sharing, bartering, lending, trading, renting, gifting and swapping', as 'miss-specifications' (Belk, 2014). Belk (Belk, 2014) in contrast seeks to promote a definition of collaborative consumption as 'people coordinating the acquisition and distribution of a resource for a fee or other compensation'.

Such a definition puts collaborative consumption on par with the commercial versions of sharing. One of the most prominent discussions on sharing and collaborative consumption is on the commercial versions and aspects (for-profit) vs. the non-commercial (non-profit) versions and aspects. Criticism has been raised against the commercial versions for piggy-backing on all the non-commercial initiatives, where people share resources without charging any fees. Another line of inquiry is represented by, for instance, Rifkin (Rifkin, 2014) who in his book on 'The zero marginal cost society' among a multitude of other issues also writes about the sharing economy. The basic thought of the book is that in a growing part of the central sectors of society, there is a trend towards zero marginal costs. The clearest example is information and communication where the marginal costs of one additional person using a piece of information or communicating are (at least close to) zero (Rifkin, 2014). Other examples that he uses is sustainable energy and even transportation, and the idea is that if the marginal costs are zero then it will not be possible to charge for consumption and then eventually the economic foundations of capitalism will fall

apart – as is epitomized in the sub-heading of the book: ‘The Internet of things, the collaborative commons, and the eclipse of capitalism’ (Rifkin, 2014).

In this paper, we do not venture into such a discussion but stay with the shorter term (and maybe more realist) industrial organization implications of the sharing economy trends. These implications mainly relate to the issues of transaction costs, substitution (and complementation), and multi-sided markets. The lowering of transaction costs facilitated by Internet-based platforms allow for the exchange of goods and services between people that would not otherwise have been possible – simply because of the very high costs of searching, contacting and contracting that this would require. In a sense, new markets are created – we are dealing with market creation, as markets for private accommodation and private transportation are created. Also, new markets for intermediaries are created. The Ubers and Airbnbs are becoming gigantic business operations, where there formerly were no possibilities for such operations to be erected. At the same time, these new markets and market operators also substitute for existing business operations. As the new markets and operators do not service entirely new human needs (e.g. accommodation and transportation), there is a degree of substitution – but also complementation.

The examples of Uber and Airbnb discussed in this paper show that there can be a relatively large degree of substitution and a considerable derived competition between the old business models and the new ones. It is not likely, however, that the new business models in foreseeable time will entirely eradicate the old models (e.g. hoteling and taxi driving). But they can do serious harm to the existing business models. And, the question raised by Rifkin (Rifkin, 2014) is whether just a share of the market for the new operators will be able to tip the market in favor of the new operators. 10% is the figure cited by Rifkin. The reason should be that the margins in some industries are low and that losing just a share of the turnover may cause the market to tip.

This, however, is a slightly strange argument, as it presupposes that the exiting industries are not able to adapt and shrink if needed. The most likely scenario is that there will be a degree of substitution, but also a degree of complementation – on the demand side as well as the supply side. On the demand side, the new operators may attract users that did not previously use the services of the existing industries. On the supply side, as is shown with respect to hoteling as well as taxi driving, some of the existing operators may offer their services through the new platforms. Furthermore, it’s not only a struggle between incumbents and newcomers. The disruption of markets also leads to incumbents entering the markets of other incumbents. Once a relatively stable division of labor is shaken up in one industry, it will have repercussions in a number of surrounding industries.

In discussions on the sharing economy, many different trends and issues are now and then blended. This applies, for instance, to mixing the sharing economy issue with the presently very popular concept of co-creation (Prahalad & Ramaswamy, 2004). Obviously, there is co-creation in the sharing of facilities. However, the focus of the co-creation issue is different from the issue of sharing. Co-creation is about the joint creation of value and also of innovation (Sundbo et al., 2015) in the interaction between providers and users, while the commercial aspects of the sharing economy are basically about the creation of new markets. Also, it’s about the creation of new companies providing the platforms for the exchange of goods and services – the companies living on transaction costs.

In order to analyze these new sharing developments, we suggest using an analytical framework comprising theories on multi-sided platforms, transaction costs, and substitution and complementation. The new commercial sharing platforms are either two-sided markets or may develop into multi-sided markets. The primary function of such platforms is to deal with the transaction cost issue that has previously hindered such markets from developing to any great extent. The new markets will, to different degrees, substitute for existing providers and business models but will also enter into an interaction with existing business models in a complementary manner.

## **7. Conclusion**

Current discussions in public media on issues relating to the sharing economy are mostly very enthusiastic about the new ways of sharing and transacting goods and services or rather critical concerning commercial sharing arrangements and businesses piggy-backing on the non-commercial activities and concerning labor conditions for those delivering the services and service quality for those receiving the services being downgraded – or rather the conditions for those working in the traditional industries being undermined by the newcomers. These are very important issues and will also, in different manners, affect the industrial developments and structures, for instance regulatory measures promoted by the taxi industry in order to defend the working and service conditions in traditional taxi businesses – and obviously also protect the existing markets from new entrants.

In the present paper, we focus on the implications for the industrial structures in the affected industries. The research question being asked has been concerned with the extent to which transaction cost theory can be used to explain the changing industrial structures in the application areas that the Internet-based platforms are addressing and how other theoretical frameworks can be helpful in understanding these developments.

The conclusion is that transaction cost theory is a central theoretical tool to understand the sharing economy. Internet-based platforms facilitate drastic reductions in the transaction costs between users and providers of, for instance, private accommodation and transportation. This creates whole new markets, which were previously only possible to a very limited extent. However, these new markets also substitute for existing accommodation and transportation markets. Theories regarding substitution and complementation must thus be added to transaction cost theory in order to analyze industrial developments. As has been shown with the Airbnb and Uber cases, there is not only substitution but also complementation.

An obvious question could be whether the new business models will entirely substitute for the old ones. The degree of substitution is obviously subject to concrete analyses in the different industries, but it seems that there could be considerable possibilities for substitution based partly on lower prices of the new sharing arrangements. However, there are also limitations, which are related to the fact that there are differences in value propositions, for instance, between a hotel room and private accommodation. Limitations are also related to the regulatory measures that will be taken in relation to the new business models, but also the adaptability of the existing industries and their competitive capabilities.

An interesting side effect is that the reduction in transaction costs is facilitated by business operations that in a number of cases become extremely highly valued huge international business companies. The reduction in transaction costs, which leads to increased possibilities for smaller business operations to function, at the same time leads to the creation of large business companies thriving on transaction costs. This is, in a sense, a paradox, which also bears witness to the strength of the capitalist economy. Rifkin (Rifkin, 2014) advances the idea that zero marginal costs will undermine the capitalist economy. However, the information and communication industries, which are core examples of the 'zero marginal cost economy', have shown the great adaptability of the capitalist economy. The industries thriving on transaction costs underline this.

The platforms that facilitate the lowering of transaction costs create two-sided markets or develop into multi-sided platforms. These kinds of business models become increasingly widespread facilitated by the Internet. On the basis of the abovementioned different theoretical approaches, the present paper proposes a theoretical framework for analyzing the sharing economy based on theories on multi-sided platforms, transaction costs, and substitution and complementation.

# Analysis on Collaborative Development of Meaningful Technologies in Services

Kentaro Watanabe<sup>1</sup>, Masaaki Mochimaru<sup>1</sup>

<sup>1</sup>National Institute of Advanced Industrial Science and Technology

*ICT is an important element in successful services. It is becoming more integrated in service processes and the collaborative technology development with stakeholders in service fields is a promising approach to realize meaningful technologies for services. However, such collaborative development of early-phase technologies has not been studied sufficiently. In this study, we conducted case studies of collaborative technology development with service firms. We clarified features in the development process and roles and capabilities of stakeholders.*

## 1. Introduction

The role of ICT is becoming more important in services. The evolution of technologies including performance enhancement, downsizing and new algorithms enables service providers to apply ICT to various issues such as customer analysis and cognitive support for employees. For the development of meaningful technologies in services, collaborative development with stakeholders in workplaces is a promising approach (Greenbaum; Kyng, 1991, Bødker et al., 2009, Sanders; Stappers, 2008). A number of ICT development projects have been conducted and studied in collaboration with stakeholders in various workplaces (Fitzpatrick; Ellingsen, 2013, Kleinberger et al., 2007; Mumford, 2000). However, there are few studies that focus on the development processes of early-phase technologies in collaboration with service firms. To clarify effectiveness and success factors of such a development approach, a study on actual technology development projects is required.

In this paper, we analyse collaborative technology development projects with service firms. The research questions are 1) how the technology development process in collaboration with service firms should be and 2) what kinds of roles and capabilities are required in this technology development. The following contents of this article start from the literature study on ICT for service fields and its development approach in section 2. In section 3, we introduce two cases of technology development for services. In section 4, results and key findings of case studies are presented. In section 5, we explain several implications from these results and conclude this paper in section 6.

## **2. Background**

### **2.1. ICT's role in service fields**

Technologies, especially ICT have been affecting the way of providing services strongly. The typical purpose of applying technologies is substitution of human tasks and automation. In 1960-70's, automation technologies nurtured in the manufacturing industry were adapted to service workplaces. The Levitt's well-known article "the industrialization of service" (Levitt, 1976) presented various technologies to replace human tasks such as consumer credit card system, automatic car wash and automatic coin receptacles, and standardized supermarket and fast-food service systems.

In collaborative workplaces for services, communication technologies to support interaction and collaboration help workers. The research field on Computer-Supported Cooperative Work (CSCW) became prominent in the 1980's (Bannon; Schmidt, 1989). CSCW is an interdisciplinary research topic of organizational science and information science. To understand the nature of cooperation in workplaces and the role of technologies there, various workplaces such as hospitals (Reddy et al., 2001, Schmidt et al., 2007, Zhou, 2011), airport control (Fields et al., 2005, Halverson; Ackerman, 2008) and call centre (Ackerman; Halverson, 1999) have been studied. Based on the knowledge from these studies, several applications of communication support systems, groupware and social software have been developed (Ackerman; McDonald, 1986, Boland et al., 1992, Koch, 2008).

Then, ubiquitous technologies were proposed to assist employees and customers with small ICT devices. Mobile devices enable employees and customers to access information whenever they need. Sensors such as Radio-Frequency IDentification (RFID) and video monitoring and wireless networks to connect these devices also realize gathering data for services in real-time. As an example of applied research projects of ubiquitous technologies, Ambient Assisted Living (AAL) is a well-known research project to realize independent lives of elderly people with ICT devices (Kleinberger et al., 2007). Recently, ubiquitous technologies have been further sophisticated and integrated in daily life and work environments as Internet of Things (IoT) technologies (Aztori et al., 2010). IoT devices and "big data" collected from them are expected to innovate services with data analysis techniques (Zaslavsky et al., 2013).

Furthermore, robotics technology is gaining attentions as a new type of automation in industries including services. There have already been a number of cases to apply robotics technologies to service fields such as health care facility (Pineau et al., 2003, Wada et al., 2005) and they would be implemented more in services.

In summary, new types of ICT have been adopted in service industries continuously and they have been changing services.

### **2.2. Development approach of ICT for services**

To realize effective use of ICT in services, how to develop ICT is an important issue. A systematic approach to formalize requirements for technologies in the systems engineering and requirement engineering domain (Kotonya; Sommerville, 1996) has

been commonly applied in industries. Meanwhile, the adaptation of technologies changes the way of work and service activities. Therefore, service processes must be considered and even redesigned in parallel to technology development. Business Process Reengineering (BPR) or Business Process Management (BPM) provides a methodology to formalize and improve business processes in companies (Childe et al., 1994). In this view, technologies are developed to substitute parts of the processes in a service system (Qiu, 2009). This approach is effective to the systematization of service processes and its concept suits the industrialization of services. In the early studies of New Service Development (Johnson et al., 2000), such systematic approaches were preferred.

A participatory approach is another important approach in developing technologies for services. Concerning complex services, especially with various interactions among stakeholders, it is difficult to apply the aforementioned systematic approach. In the research of CSCW, participatory design (Greenbaum; Kyng, 1991) to involve users in the development process of technologies is a dominant approach (Pilemalm; Timpka, 2007). In innovation studies, user-driven innovation (von Hippel, 2001) is an important topic in developing services (Sundbo; Toivonen, 2011). The basic idea of these studies is succeeded to studies on recent employee-driven innovation (Høyrup, 2010) and service design (Steen et al., 2011; Watanabe et al, 2015).

There have been a number of studies on technology-oriented service development (Tuunanen et al., 2011, Dominguez-Péry et al., 2013, Wallin et al., 2015). These development cases highlighted the participation of stakeholders such as technology developers, service providers and customers based on the several concepts of co-creation (Prahalad; Ramaswamy, 2004, Vargo; Lusch, 2004). Meanwhile, there have not been few analyses on technology development for services especially in the research phase or early development phase. In addition, how developed technologies can be disseminated beyond a single case study is necessary for delivering innovations in services broadly.

### **3. Case studies**

#### **3.1. Methods**

In this study, we analysed two research projects which include early-phase technology development for services. Both of the projects were conducted by researchers of National Institute of Advanced Industrial Science and Technologies (AIST) in Japan as parts of the research project on service engineering from 2009 to 2012. We selected these cases with two reasons; 1) these cases included technology development from its early phase and 2) the developed technologies were disseminated to other service fields after the project ended.

As a research methodology, we conducted semi-structured interviews with the researchers who participated in the research projects. Two researchers from each case were interviewed. We mainly asked about the research processes (activities, events and important decision-making) and the stakeholders (concerns, roles, characteristics and their change) in the project period and later. As supplement of these inter-

view results, we also analysed internal research records and public project reports (CfSR/AIST, 2012).

### **3.2. Case 1: development of analysis and visualization technologies of employees' movement**

The first case is an R&D project of human sensing technologies for the analysis of employees' movement. This project was conducted in collaboration with a restaurant company, elderly-care facilities and several other service companies. The research team developed a set of technologies to measure, estimate and visualize employees' movement and activities to improve work efficiency and customer satisfaction continuously.

### **3.3. Case 2: development of consumer behaviour analysis methods for the management of service operations**

The second case is an R&D project of consumer behaviour analysis methods mainly for the management of service operations. Some retail companies and a restaurant company were the main partners of this project. In this project, category mining and demand forecasting methods were developed to support the decision making of store managers.

## **4. Results**

### **4.1. Overview of Case 1**

We first summarized the results of case studies. Table 1 shows the overview of case 1.

In FY2009, the research group started applying their basic technologies to measure and visualize human movement to several service fields such as restaurant and elderly-care facilities. Through this application, a manager of the restaurant service focused on this technology as a tool for continuous improvement.

In FY2010, the measurement technology was utilized as a support tool for continuous improvement. The research team applied the technology to three fields: traditional Japanese hotels, a restaurant and an elderly-care facility. The technology was accepted mainly in a restaurant service which originally had a bottom-up improvement activity known as the Quality Control (QC) circle (Watanabe, 1991). While applying the basic technology, the research team continued developing new technologies such as service operation estimation and reduction of the measurement device size.

In FY2011, the research team applied a developed new service operation estimation technology to the restaurant and the elderly-care facility in addition to the basic movement measurement. Through the experience in the past two years, the research team learnt how to represent and explain the results of measurement. The research team had been improving the visualization tool to represent the data to employees.

The research team also started systematizing a part of the technology application process such as automatically collecting data from devices.

In FY2012, the research team combined financial data with measurement data and evaluated the technology from the management perspective. In this phase, the technologies and their application process were almost established. The research team started the discussion to develop a new business to adapt technologies to service fields as business.

The start-up company was launched in 2014. Various kinds of workplaces such as not only other kinds of service fields but also manufacturing workplaces became targets of technology application. Another interesting change was that the visualization tool became major strength of the research team. Instead of using the research team's own measurement technology, it became possible for them to combine different kinds of measurement technologies with their visualization tool to evaluate workplaces.

Table 1 Overview of case 1

| (Fiscal) year | Main topics   |
|---------------|---|
| 2009          | - The research team explored applicable fields of their basic measurement technology.   |
| 2010          | - The measurement technology was used in some service fields as a tool of continuous improvement.<br>- The research team developed new technologies (service operation estimation, etc.) in parallel. |
| 2011          | - The research team applied the developed service operation estimation to the service fields.<br>- The research team improved skills and a tool to explain the capability of the technologies.        |
| 2012          | - The research team evaluated the financial benefit of the measurement technologies.<br>- The research team started discussion to develop a new business for the measurement service.                 |
| Later         | - A new company to provide the measurement service was launched.<br>- The visualization tool became a major technology for the research team.   |

## 4.2. Overview of Case 2

In Table 2, we presented the overview of the case 2.

In FY2009, the research team started the study on service fields by utilizing quantitative, numerical data to analyse services. They focused on Point-Of-Sales (POS) data that represent the usage situation of services. Though the POS data analysis had been already a well-known approach, they considered that the diversity of prefer-

ences of consumers was not taken into consideration sufficiently. They started analysing a retail service and a restaurant service and developed a new classification method of customers by numerical analysis.

In FY2010, the research team focused on a new issue to be tackled from the interviews with store managers. In the store operation of store managers, how to determine work shift and procurement was the major issue. To support this, the research team studied demand forecasting that is important for both operations. The research team interviewed store managers on possible causal information which affects demands of customers and established a demand forecasting method. They applied the developed technology to both retail and restaurant services and gained significant results.

In FY2011, the research team added work shift design support and communication support with customers, and developed a management support technology package. The licensing of this package also started and has been applied to different kinds of services. The research team has been continuing a study on management support, especially focusing on benchmarking with other service providers.

Table 2 Overview of case 2

## 4.3. Findings

### 4.3.1. Technology development process

From case studies, we figured out three phases of the technology development process.

#### 1) Exploration phase

In both cases, the research teams started their research with rather the technology-push approach. They also applied some other approaches in addition to the success-

ful one shown above. After the trials of these approaches, the applied technologies and application fields were eliminated. We call this phase “exploration phase.”

## 2) Maturation phase

After the exploration phase, the research teams focused on specific problems and approaches to tackle them in service fields. Through the interactions with stakeholders in service fields, the problem and its solution were gradually clarified. As a parallel activity, technology development was conducted in both cases. Through the process of development, application and evaluation of technologies several times, the technologies and the application processes became established. We call this phase “maturation phase.”

## 3) Dissemination phase

The research team standardized their own solution including technologies and application processes to disseminate to various service fields. This solution was implemented, in one case as a start-up company and in the other case as a technology package. These solutions were adapted to various fields, some of which were not related to the original application fields. For example, the measurement technology in case 1 was applied also to manufacturing workplaces which had difficulty in analysing their work processes. We call this phase “dissemination phase.”

### **4.3.2. Roles and capabilities in research teams**

We figured out three kinds of roles in the research teams.

#### - Research manager

Research manager is a role to manage the research process and resources of the project. They determined which technologies and service fields should be studied. The relationship building with the management of research fields was also an important role of the research managers.

#### - Field researcher

Field researcher is a role to have a direct contact to service fields. Field researcher clarified requirements and situations in service fields and applied technologies. The relationship building with service employees was also an important issue. In case 1, one researcher mainly communicated with members in QC circles to explain the meaning of measurement data. Field researcher was required to understand the concerns and objectives of stakeholders in the service fields and aligned them with the research objectives. Communication skills to explain the meaning of projects and technologies were also important.

#### - Technology development researcher

Technology development researcher is a role to develop concrete technologies. Since the technology development took a long period, its process was conducted in parallel. In case 1, a new technology of service operation estimation developed in 2010 was actually applied to the service field in the next year.

Some researchers in the research teams took multiple roles. While most researchers in the research team took a single role in case 1, the interviewed researchers in case

2 took multiple roles; one as a manager and a field researcher and the other as a field researcher and a technology development researcher.

### 4.3.3. Roles and capabilities in service fields

In the cases, the following roles were observed in the service fields.

#### - Executive

Executive was not necessarily related to the research activities directly. However, whether they had concrete objectives toward the research projects affected their results. Some interviewees mentioned that projects with companies whose executives did not have clear goals to the research projects were difficult to continue.

#### - In-charge manager

In-charge manager who directly took care of a research project was a key role. As was required for executives, in-charge managers also needed a concrete objective toward the research project. Their objective directly related to problems in service fields. In case 1, the in-charge managers were interested in the productivity of service operations from the experience of activities in QC circles. In case 2, the in-charge managers as store managers had concerns in improving their store operations.

#### - Employees

Employees were directly affected by the research project. They were also required to be at least positive to participate in the project. In case 1, employees who had experiences of QC circles were able to accept the research project and technologies. According to one interviewee, one employee said that she or he felt lonesome to work without a measurement device on the last day of measurement. This implied the acceptance of the technology by employees in case 1.

### 4.3.4. Interactions and mutual learning in projects

The members with the aforementioned roles in the research teams and service fields interacted and affected one another. Figure 1 shows their relations.

Figure 1 Interactions between the research team and the service field

The aforementioned capabilities of both the research teams and the service fields did not necessarily exist when they started a collaborative study. In the cases, they learnt their concerns and required capabilities mutually through continuous interactions. In case 1, employees in the service field got accustomed to putting devices to them through several experiences. In-charge managers needed some time to understand the actual potential of technologies.

Meanwhile, the field researcher also learnt how to explain the purpose of the research and the meaning of technologies through several trials. Through the projects, the research teams and the service fields developed mutual understanding. In addition, new technologies and solutions were created through the interaction with the service field. In case 1, the visualization tool for communication with the members in the service fields was developed and became one of the core technologies to conduct their research. In this view, the interactions between the research teams and the service fields were the co-creative problem solving process.

## **5. Discussion**

### **5.1. Technology development process**

We figured out three phases in the technology development process for services. In the exploration phase, the research teams conducted several trials to apply different kinds of technologies in several service fields. We consider that this process could be more sophisticated by conducting the prior field study to understand requirements and situations of target service fields. In the cases, the research teams also put more efforts on observation and field study for further understanding of service fields in the later phase of the research projects. Meanwhile, a certain amount of trial-and-error processes are unavoidable since the technologies which research teams aim at developing do not necessarily fit to situations and requirements of service fields. To reduce risks of mismatch between brand-new technologies and their usages, it is important to have several fields to conduct research in parallel.

In the maturation phase, the research team needs to manage the technology development and its adaptation to service fields. Since the technology development requires a long-term period, its process tends to be several years and should be in parallel with the requirement analysis and problem solving in the service fields. The coordination between field researchers and technology development researchers is important to realize meaningful technologies to service fields shown in Figure 1. Another important point is to gain positive attitudes and participation of stakeholders in service fields. In both cases, the interviewees put efforts to develop good relationship with service fields.

After the maturation of technology and its application process in one or some service fields, the dissemination phase started. The success in at least one service field is important in disseminating its result to a numbers of service fields.

## **5.2. Roles and capabilities in research teams**

According to the aforementioned requirement in the exploration phase, research managers are expected to manage relations with several service fields. In the cases, two research teams shared one service field. The collaboration among researchers is effective to respond to the requirements of service fields flexibly. In addition, it is preferable that research managers can develop the long-term relationship with service fields.

In the other two roles of researchers, field researchers especially take an important role in collaborative technology development. Field researchers need a skill to communicate, understand and assess service fields. The techniques and experiences in social studies are expected to field researchers. In both cases, the field researchers had such basic skills. In addition, field researchers also need to understand the technologies for collaboration with technology development researchers. To develop the researchers who have both skills, specialized education for that is necessary.

## **5.3. Roles and capabilities in service fields**

From the findings in the case studies, the concrete objectives of members in service fields toward technology development are necessary. The importance of in-charge managers' willingness and technology acceptance of employees was pointed out in the existing study, also (Wallin et al., 2015). In addition, in-charge managers need to manage the balance between research and business practices. Human resource development of in-charge managers is important to promote collaborative technology development for services.

## **5.4. Interactions and mutual learning in projects**

There are several implications for the success of learning process in collaboration. First, workplaces with QC activities successfully utilized technologies in their work. This could be because employees had already had sufficient concerns in their performance. To let employees feel the effectiveness of technologies, it is also important to provide proper feedbacks or to assess the effectiveness with evaluation standards for service fields. In case 1, visualization technology took an important role to provide feedbacks to employees. In case 2, the research team developed evaluation standards and an interface to show them in the technology package.

Meanwhile, it could harm overall performance of service systems to evaluate them only with a single viewpoint or evaluation standard. The reflection of technologies and evaluation standards is essential. In Case 2, the research team reflected the results of their research every year and changed their approach.

## **5.5. Other issues**

In addition to the development of technologies for certain problems, the classification of problems and correspondent technologies is important to provide adequate solutions for new cases. For this purpose, the meta-analysis of technology development cases is necessary. For example, Watanabe et al. (2013) classified service process-

es into categories and correlated them with technological solutions. The further study on such a meta-analysis is required.

## **6. Conclusion**

In this study, we first figured out ICT's roles in services in the past from the substitution of human tasks to the support of collaboration. Technologies are becoming more ubiquitous and important in service systems. As a result, the development of new technologies for services should be more integrated to service development. Through two case studies to develop new technologies for services, we clarified the development process with three phases; exploration phase, maturation phase and dissemination phase. We also figured out three kinds of roles and their required capabilities for both research teams (research manager, field researcher and technology development researcher) and service fields (executive, in-charge manager and employee). Especially, field researchers in research teams and in-charge managers in service fields are required to collaborate with each other for managing research and practical issues and also technological and socio-technical issues. The collaborative relationship between research teams and service fields created a dynamic process of mutual learning and co-creative problem solving.

The result of this study is based on two cases studies. To obtain more general remarks, more cases should be considered. In addition, the interviews of stakeholders in service fields should be also conducted. These are the remaining issues in the future study. In addition, the meta-analysis of various cases to classify problems and solutions in services is necessary.

## **Acknowledgement**

We appreciate sincere supports of the researchers who participated in the case projects. The cases in this paper were partly supported by The Japanese Ministry of Economy, Trade and Industry in the project on service engineering (2009–2012).

# Governance and innovation in public sector services: The case of digital library

*Ada Scupola<sup>1</sup>, Antonello Zanze<sup>2</sup>*

*<sup>1</sup> Roskilde University, <sup>2</sup> University of Urbino*

## Abstract

Based on a longitudinal case study of ICT adoption and e-services development in a Danish library, we examine how governance modes affect technical and organizational change in the public sector. We contribute to extant literature on the links between governance and innovation by highlighting three important aspects that characterize such links. First, our case study shows that the transition from what could be considered as a spurious New Public Management approach towards a “networked model” implies important organizational innovations and more emphasis on bottom-up decision making. Second, we provide evidence of increasing involvement of end users in innovation and co-creation activities. Third, the increasing involvement of users has created important innovation opportunities that are more and more characterized by their frugal/bricolage nature, hence more localized but not necessarily trivial and relatively easy to diffuse to different contexts.

Key Words: Governance, Innovation, Public Sector, Services, ICT, Virtual Library

## 1. Introduction

The public sector has long been considered as characterized by low levels of innovation, largely lagging behind the business sector. This perception is partly motivated by the existence of some structural features of public sector that may hinder innovation, but does not correspond to the state of affairs in general, and is largely misleading in some areas.

Indeed, one might argue that innovation has always been present in the public sector, what changes in different circumstances and over time are the nature and intensity of innovation itself, as well as the role of actors involved. Circumstances that may affect innovation in the public sector include: technological factors, and particularly the massive introduction of ICTs in public services; economic factors, as public administrations (PAs) are increasingly forced to do better with less resources; and socio-demographic factors, ranging from ageing population, increasing needs to invest in knowledge intensive activities and in green technologies. This set of factors combines with changing ideological perspectives that have emerged and dominated in different phases of recent history. One way to characterise such perspectives is to distinguish: a) the “traditional” public administration model, dominating in the post-World War II (WWII) for more than three decades, that can be broadly sketched as state and producer centred and based on largely hierarchical relations within PAs; b) the “New Public Management” that has been pervading PAs since the mid-1980s and relies on the idea of emulating the private sector and of introducing market selection mechanism within PAs; c) the “Networked Governance” model, emerged in the early 2000’s, which is much more attentive to civil society and is largely shaped by its

pressures, for example by directly involving the users in the service development process (see Bennington and Hartley 2001 and Roste 2005 for more on this distinction). It has been argued that these paradigms can be associated with a very different nature of innovation, and with different roles of key players in innovative activities, including policy makers, public managers and users (Hartley 2005). The purpose of this paper is to evaluate whether and how the nature and organization of innovation and the roles of the actors involved have changed over time in relation to these paradigms in a specific public sector domain, i.e. university library services. The focus is here on the transition from a New Public Management approach (with elements from the Traditional Model still embodied in it) to the Networked Governance perspective.

Using a longitudinal case study of the introduction of new services with special focus on ICT related services at Roskilde University Library since the end of the 1990's through 2014, we will show how the nature and organization of innovation and the roles of the actors involved has changed in the transition from one paradigm to the other. We will highlight that while the distinction between paradigms is still rather blurred in the examined case, one can indeed detect some remarkable changes in the nature and intensity of ICT related innovations being developed and up taken over time. In general terms, we will observe more and more emphasis on organizational innovation, a decreasing role played by radical technological innovation and increasing incremental, "bricolage" type of improvements in services, and a greater involvement of users in the co-creation of new services. It is suggested that analysing this experience in a long run perspective may help understand future avenues for innovation in both public and business services.

The remainder of this paper is organised as follows. Sections 2 and 3 illustrate different models to characterise the links between public sector governance and innovation, building on Hartley's seminal contribution and taxonomy. In section 4 we provide some introductory evidence on Roskilde University Library and describe the case study methodology we shall follow to shed some light on the evolution of governance and innovation in this specific institution. Section 5 will illustrate the transition from what could be roughly identified as a NPM phase, embodying elements from the traditional hierarchical approach, to the emergence of a networked approach to public sector innovation, with specific reference to the case of Roskilde University Library. Section 6 will provide some concluding remarks.

## **2. Public sector governance and innovation**

Hartley (2005) identifies three different phases in the evolution of public sector innovative activities in recent history, reflecting different governance models:

(a) a "traditional" model wherein innovation is initiated by political decisions at the highest level (policy makers as "commanders"), imposed to the public management, perceived as "clerks and martyrs", and delivered to passive users seen as "clients". This view is consistent with big technical changes and large purchases of technology, as visible efforts to innovate that can be used by policy makers as assets in political markets;

(b) a "new public management (NPM)" perspective that takes on board the issues of efficiency and the need to customize services to improve performance. Policy makers

indicate objectives of improved performance, public managers are perceived as efficiency maximizers, and the emphasis is on organizational change and on the need to increase involvement of different organizational layers within PAs. Users are considered as “customers” whose needs must be explored and dealt with, as their satisfaction becomes a key element of public sector performance to be monitored;

(c) a “networked governance” view of innovation characterized by an involvement of innovators at both the local and central level, with a particular emphasis on incremental changes at the front-line level. Policy makers play the role of interpreting emerging technological and social innovation opportunities, thus “inspiring” innovation, public managers are key to exploring technologies and new avenues. This model is more consistent with a bottom-up approach to innovation, and users are increasingly seen as co-creators of new services and processes.

These different conceptions and related patterns of innovation in PAs indeed correspond to specific historical phases: the traditional model has dominated in the early decades of the post WWII period; the NPM approach has become a key reference in the late 1980s, while the emergence of the networked model can be observed in the early 2000s. However, such models can also co-exist in various ways in any given moment in time. On the one hand, elements of previous approaches tend to persist and mitigate the emergence of new models, thus blurring distinctions in the real world. On the other hand, the three approaches can be perceived as competing paradigms that tend to prevail according to the nature and intensity of changes in the (economic and technological) contexts in which PAs are active.

Hartley’s framework (Table 1) has the merit of being rather comprehensive and systematic, and helps integrate different insights from the literature, and interpret ongoing developments in many public service fields. Some evidence on patterns of innovation in the public sector appears to be roughly consistent with this conceptualization. Examples cited by Hartley herself illustrate the emergence of these three models of public sector governance and innovation. Several studies have documented the wide diffusion of top-down approach to innovation in PAs, providing indirect evidence of the fact that elements of the both the Traditional and of NPM approaches tend to persist in spite of important changes in technological paradigms (the ICT revolution) and in the presence of new and increasing pressures from civil society (EC 2011, Epsis 2013). Nevertheless, there are some signals of the emergence of networked governance innovation offered by other studies, such as the Trends and Challenges Report (Rivera and Leon, 2012), and the Tech4i2 SMART report on eGovernment (Osimo et al 2013).

**Table 1. Innovation and improvement in different conceptions of governance and public management. A synthesis of Hartley’s approach (Hartley 2005)**

|                    | <i>‘Traditional’ Public administration</i>           | <i>‘New’ public Management</i>                       | <i>Networked governance</i>                  |
|--------------------|--|--|--|
| <i>Innovation</i>  | Some large-scale national and universal innovations. | Innovations in organizational form more than content | Innovation at both national and local levels |
| <i>Improvement</i> | Large step-change                                    | Improvements in manage-                              | Aiming for both trans-                       |

|                                |   |   |   |
|--------------------------------|---|---|---|
|                                | improvements initially, but less capability for continuous improvements | rial processes and systems. Customer focus produces quality improvements in some services | formational and continuous improvement in front-line services |
| <i>Role of policy-makers</i>   | Commanders  | Announcers/commissioners  | Leaders and interpreters                                      |
| <i>Role of public managers</i> | "Clerks and martyrs"  | Efficiency and market maximizers  | 'Explorers'   |
| <i>Role of the population</i>  | Clients   | Customers   | Co-producers  |

Even though Hartley's framework provides a helpful and stimulating distinction of the different phases in the evolution of public sector innovative activities, it might be useful to identify some issues that are not fully considered in this approach and would need to be dealt with. First, Hartley's model does not fully account for the *complexities within PAs*. In particular it articulates the vertical process from policy makers to managers down to users, without considering the further distinctions between different layers of managers and employees involved in the design, development and provision of new services. This equals to underestimating the role of barriers, conflicts and interactions across these different levels which severely affect performance and effectiveness of services. Second, Hartley's model leaves the *role of users* rather underdetermined, even if identified with standard labels such as "clients", "customers" and "co-creators". One needs better clarify what could be beyond these labels, and show how these roles change in the presence of new technology and of emerging pressures from civil society. Third, Hartley's framework appears to oversimplify the links between governance and the *nature of innovation*. The underlying assumption is that radical innovation is favored by the traditional governance approach, whereas organizational innovation is required by NPM and both radical and "bricolage" innovation are relevant in networked approach. It appears that such a distinction might be too sharp and that innovation patterns are becoming more and more complex in the transition from one model to the other.

### 3. Elements for improving the framework

To overcome these limitations it might be useful to recall some ideas from the literature which help improve Hartley's framework.

As for the first set of issues (*complexities within PAs*), one could refer to Jane Fountain (2001, 2007), who has focused particularly on eGov in the US and was perhaps the first who emphasized that it is not only nor primarily a matter of technology being implemented from the top down, but a matter of technology "enactment" involving all different levels of PAs. Indeed she largely disregards the user, but develops an extensive analysis of the different actors involved on the supply side. See Arduini, Denini, Lucchese and Zanfei (2013) for a review of Fountain's approach and derivations. This set of issues connects to the literature on the distinctions between front office

and back office innovation. More generally, these contributions of Fountain's are broadly consistent with the stream of literature on the coevolution of ICT, organizational change and human capital development. See Seri and Zanfei (2013) for a review on this topic. The latter strand of literature has so far been explored mainly in the area of private business, but has received some limited attention in the case of public sector too. There are links to the wide literature on Solow's paradox (that ICT can be seen everywhere but in productivity statistics). See inter alia Brynjolfsson and Hitt, (2000).

As for the second set of issues (going inside the black box of *user driven innovation*), Scupola and Nicolajsen (2010, 2013) help better articulate how the user can be involved at different stages of the innovation process. Among the issues to be introduced, one could emphasize: the different roles played by users at different stages of innovation processes (Alam and Perry 2002), the benefits of face-to-face meeting in user-producer interactions (Magnusson 2013), and the risks and challenges of user involvement in innovation processes (Nicolajsen and Scupola, 2011; Prandelli 2006). What makes this stream of literature important is that: it helps to identify different roles for the user, which go beyond the "co-creator role" mentioned by Hartley; it helps operationalize the different way of involving users in the different phases of the innovation process; and it points out that user involvement is not an easy task, especially in co-creation. From this perspective, one additional line of argument stems from Nathan Rosenberg's research on the role of users in shaping the pace and direction of technical change through their technological expectations (Rosenberg 1978); and on the importance of learning by using in the development of new knowledge especially in the presence of complex technologies (Rosenberg 1982). Even more interesting, Rosenberg (1982) shows that an important part of learning by using takes the form of "disembodied innovation", that is a stimulating category to be taken into account particularly when talking about innovation in services. This line of argument on the circumstances under which users can be fruitfully involved in innovation, has been strengthened by the increasing perception of the revolutionizing role of ICTs and digital economy. Once again, some insights can be drawn from the literature reviewed by Scupola and Nicolajsen (2010, 2013), mainly referring to how ICT changes the role of users in business services. This literature shows that huge advantages are associated with the involvement of users in innovation processes, through ICTs and especially the World Wide Web and social media. The ways to involve users span from web based surveys and 'complaint areas' in the idea generation phase, to 'virtual product tests' in the product test phase (Prandelli et al., 2006, 2008;), to online idea competitions to create user-adjusted design of products (e.g. Ogawa and Piller, 2006; Franke et al., 2008). Virtual communities and social media networks are other examples of customer involvement as a means to help organizations to innovate products or services. Lego Mindstorm and online gaming are well known examples in this respect (Jeppesen and Molin, 2003). Virtual communities may be initiated either by user or by producing firms. However, in both cases user involvement is based on their own interest and prestige in the community. In a different context, Osimo et al (2012) also emphasise the role of end users as promoters of web based innovation. In fact, with reference to eGovernment, they make a big argument of the importance of users initiating innovation in public service provision in the age of web 2.0.

As for the third issue (*nature of innovation* involved according to the innovation governance model), we could agree on the general statement that the 3 approaches singled out by Hartley do have different implications on the characteristics of

innovation being undertaken (scale of investment, different emphasis on organizational change, incremental vs. radical innovation). Nevertheless one needs to emphasise that these characteristics of innovation are not exogenous, but are largely affected by the role of actors involved. Once again, some reference can be drawn from Scupola and Nicolajsen (2010, 2013). By reviewing the literature on customer involvement and type of innovation, they conclude that innovations initiated by the users or developed with the involvement of the user are mostly incremental in nature. From this perspective, it should be emphasized that web 2.0 seems to favour incremental innovation and reputation, more than drastic technical change. In addition, there are insights on the importance of bricolage innovation in services (Fuglsang 2010) and in public service innovation in particular. 'Bricolage' innovation can be conceptualized as problem solving on the spot using existing resources. Changes occurring through bricolage in everyday situations can be building blocks to gradually and slowly create new solutions and structures. However, the question is how bricolage can be understood in an organizational context and how can bricolage activities integrate with more structured innovation planning within an organisational context (Fuglsang 2010).

An additional insight is that innovation requires a higher concentration of competences in the first approach of Hartley's framework (the traditional, hierarchical one) as it presupposes that lower level management and employees are mere executors; then it implies a higher diffusion of competencies in the second approach (new public management perspective) as it requires public managers at all level to be efficient in the use and implementation of new technology; and it benefits from an even higher dispersion of competencies in the third model (network type of governance) as it involves a strict interaction with users who become more capable to co-create innovation, the more they are themselves skilled.

The analytical framework we have developed here will be used to articulate the case study, to show how different governance models and patterns of innovation have emerged in the recent history of ICT adoption and diffusion within Roskilde University Library. We will rely on qualitative data collected over more than a decade. This time span allows following the transition from a rather spurious New Public Management setting, which embodies several elements of the traditional hierarchical approach to innovation, to the first manifestations of the networked model. Although it might be a rough distinction we shall refer to these as Phase 1 and Phase 2.

In the rest of the paper, we will first illustrate the research method followed, and then we shall examine the changing context in which ICT based innovation have taken place, the different nature and intensity of organizational and technological innovation that have been developed in the library system in the two phases under observation, and the role played by the different actors involved (policy makers, library management and servants, users).

#### **4. Research Method**

To investigate whether and how the nature and organization of innovation and the roles of the involved actors have changed over time in relation to the transition from a New Public Management paradigm to the first manifestations of the networked model in Hartley's framework we conducted a longitudinal case study (Yin, 1994) of Roskil-

de University Library (RUB). The Danish research library sector was chosen as the empirical context of this study since in Denmark libraries have undertaken a huge transformative process since the mid 1990's due to the policy program "IT Society for all" launched in the 90's. In this paragraph we first describe the Danish library sector in general, then present how RUB is organized, and finally present the research method and data collection process and techniques.

## 4.1 Research Context : The Danish Library Sector

There are two types of libraries in Denmark: public libraries and research libraries. The purpose of public libraries is to promote information, education and cultural activity by placing books and other media at the disposal of the public (*Thorhauge*). Research libraries mainly serve higher education and research institutions even though they are also open to the public at large. In Denmark there are 20 major research libraries connected to universities and other higher-level educational institutions and a large number of smaller research libraries connected to other educational institutions. Both public and research library services are free of charge, but libraries can demand payment for special services (Danish National Library Authority <http://www.bs.dk>).

The Danish library system is based on the Danish citizen's fundamental right to knowledge and information. The Danish National Library Authority (DNLA), an agency under the Ministry of Culture, is the Danish government's central administrative and advisory body to the public libraries and the research libraries. DNLA is also the administrative authority for the Danish law no. 340, [Act on library activities](#) (Lov om Biblioteksvirksomhed) of 17 May 2000, and the amendment, law no. 30 of 10 January 2005 (Danish National Library Authority, <http://www.bs.dk>). DNLA is responsible for advising the government on the organisation, co-ordination and strategy for the library service and gives professional advice to ministers and public authorities, as well as local authorities, libraries and information services. In addition, DNLA has an active role in national and international collaboration within the field of libraries, documentation and information. DNLA is also responsible for collecting and providing statistical information about Danish libraries as well as acts as the administrative base for Denmark's Electronic Research Library, a major institutional initiative for the Danish libraries virtualization process (<http://www.bs.dk/>). In fact DNLA's vision in the 21<sup>st</sup> century is "the development of the hybrid library, where an increasing number of electronic services work in unison with the physical library and its particular services, and where the interplay between virtual and real services is forever vibrant" (<http://www.bs.dk/>). In this paper we conceptualize the "virtual library" as a library that facilitates users to search, browse and retrieve selected information from sources worldwide instantly from the users' own network-connected computers, anytime, anywhere as well as to request help at any point in the process. Our definition is close to Maness (2006)'s "library 2.0" definition: according to which the virtual library could be:

- **User-centered.** Users participate in the creation of the content and services they view within the library's web-presence, OPAC, etc. The consumption and creation of content is dynamic.
- **Socially rich.** The library's web-presence includes users' presences. There are both synchronous (e.g. Instant Messaging) and asynchronous (e.g. social networks) ways for users to communicate with one another and with librarians.
- **Communally innovative.** It rests on the foundation of libraries as a communi-

ty service, but understands that as communities change, libraries must not only change with them, but must allow users to change the library. It seeks to continually change its services, to find new ways to allow communities, not just individuals to seek, find, and utilize information.

Such important transformation from physical to virtual and hybrid libraries and relative innovation challenges has been widely dealt with in the literature on innovation (e.g. Scupola and Nicolajsen, 2010; Carr, 2009; Scupola, 2009) as well as library and information science (e.g. Wu and Abdous, 2013).

## **4.2 The Case: Roskilde University Library**

Roskilde University Library (RUB) is a research library serving the students and staff at Roskilde University. Roskilde University accounts for about 9000 students, 650 teaching staff and about 430 employees with technical and administrative tasks. It is located in Roskilde, a city about 35 km. from Copenhagen, the capital City of Denmark. RUB was founded in 1971, as part of Roskilde University. As a research library RUB is responsible for providing Roskilde University staff and students access to information and materials needed for research, teaching and learning. Regional research and educational institutions, businesses and citizens have access to the library as well ([www.ruc.dk](http://www.ruc.dk)). In 2001 RUB moved into a new building, designed by the Danish prestigious Henning Larsen's Architects Company. Today the library counts 36 employees. The library consists of a 8,000 square meters building, of which 4.500 square meters are for public use, 930 for offices and 875 for closed stacks. In 2013 it had a collection of about 944,000 books and 218,000 AV media, and counted about 4 million downloads (See Appendix 1 for a detailed overview of the key figures of RUB over the last 10 years). Over the last decade, RUB has undergone a virtualization process initiated by the government in mid 1990s. This process has substantially changed the organization, the services and the service delivery of many of RUB's library services by substantially increasing self-services. Examples of new services and service delivery processes are access to e-journals and e-books, digital repository of all the student projects, and virtual reference such as "chat with a librarian" service. From an organizational point of view, the library has been reorganized several times over the last decade. In 2015 RUB organization consists of top management (a director and a head of reader services) and 4 lines (departments), each with a dedicated staff and a department head, also called line manager. Some employees might belong to different lines, thus creating a matrix organization. RUB can be defined as a "hybrid library" as it has maintained both its physical buildings and a number of face-to-face services while simultaneously offering a number of electronic services and self-services.

## **4.3 Case Study Design and Data Collection**

A single case study approach was adopted to study the relationship between different governance modes and innovation within the research library sector since single cases allow to investigate phenomena in depth to provide a rich understanding of them ([Walsham, 1995](#)). This choice is also consistent with Yin's suggestion to consider three conditions to choose a proper research method: (1) the type of research

questions posed; (2) the extent of control an investigator has over actual behavioral events; and (3) the degree of focus on contemporary as opposed to historical events ([Yin, 2003](#)). A case study has advantages over other research methods, such as surveys and experiments in answering questions of 'how' and 'why.' Our research deals with explaining how governance modes have influenced innovation at a research library over a period of time. We are interested in a contemporary phenomenon of virtual library innovation within a real-life context as opposed to historical events. In addition, there is broad consensus among researchers that a case study approach is particularly well suited to study the development, adoption and implementation of IT-based innovations in organizational contexts (e.g. [Benbasat et al., 1987](#)).

RUB was selected as single case according to the following criteria: 1) being representative of the Danish research libraries regarding the link between governance, ICT and innovation and 2) been willing to participate to the study. RUB is representative of the virtualization process of the Danish library sector as this process has been enforced top down by policy makers and has involved partnerships and collaboration among all the Danish research libraries mainly through an initiative called DEFF (Denmark's Electronic Research Library Denmark ([www.deff.dk](http://www.deff.dk))). The data were collected in relation to three research projects. The first project (sponsored by the Danish Research Council, 2004-2007) focused on new organizational forms induced by the societal diffusion of services delivered through ICT networks. The second (sponsored by the Danish Research Council, 2008-2012) focused on user driven innovation., The third (sponsored by Velux Foundation, 2014-2015) focused on ICT, service innovation and governance. One of the author was involved in all three projects, the other only in the last one.

Data sources included secondary and primary data (see Table 2). Secondary sources included a range of academic, government and library studies and reports on the Danish library sector and its virtualization process. This material proved invaluable for understanding the societal, political, governance and technological trends that were affecting the library sector mainly nationally, but also internationally. In addition RUB provided the authors with data such as internal reports, strategic plans, minutes of meetings, user surveys, documents concerning library services and e-services provision. about number of books, journals, employees, physical space at the library (provided by the library and retrieved mostly from RUB and DEFF's websites). Finally the authors also collected statistical data about number of books, journals, employees, physical space at the library both from RUB's employees as well as from Rub's and Danish library authority web sites. These documents were used to support and verify interviews and other primary data.

The primary data sources included qualitative explorative and semi-structured interviews conducted over a period of 10 years to follow RUB virtualization process; organization and participation in meetings with RUB personnel over the period 2008-2012; data generated in three future workshops organized by the authors and involving both RUB personnel and library users in the period 2008-2012; contents of a blog established by RUB in collaboration with one of the authors for idea generation and co-creation with the library users; continuous observations and use of RUB services, e-services, self-services, building facilities. A total of 18 interviews were conducted with top management, middle management and librarians at RUB. Two extra interviews were conducted with two different librarians at other two Danish libraries to get an overall picture of the link between governance and innovation at Danish libraries. The first interviews (relating to the first project) were explorative.

The rest were semi-structured. Most of the interviews were individual except for three group interviews with either two or four participants. We generated field notes immediately after each interview to summarize the key content and to suggest possible interpretations. The interviews lasted circa 1.5-2 hours each, they were all tape recorded and most of them were fully transcribed. The three future workshops (Jungk and Müllert, 1987) were conducted simultaneously at the library premises, lasted three hours each and were tape recorded. The posters and post-it produced by the workshops participants were analyzed and summarized in Excel files and the results presented and discussed in a meeting with library managers. The blog was observed for a period of three months and the data analyzed to understand user involvement and co-creation.

| Data Sources (Primary and Secondary)         | Number of Interviews or secondary data | Location of the interview or type of source   |
|--|--|---|
| Interviews                                   |  |   |
| Interview Positions                          | Number of Interviews                   | Organization  |
| Director                                     | 1                                      | RUB   |
| Vice Director                                | 2                                      | RUB   |
| Top Manager                                  | 5                                      | RUB   |
| IT Director                                  | 3                                      | RUB   |
| Front office librarians                      | 3                                      | RUB   |
| Back office librarians                       | 2                                      | RUB   |
| Members of user driven committee (4 members) | 2                                      | RUB   |
| Director                                     | 1                                      | Research Library at Another University  |
| Librarian                                    | 2                                      | Research Library at Another University  |
|  |  | Public Library  |

*Table 2. Data Collection Activities*

At the beginning of each data collection phase (in 2004; 2008; 2014) a contact was established with a top manager of the library. The top manager investigated whether there were other library employees who had an interest in participating in the study. Several managers and librarians expressed their interests to participate. Subse-

quently top management invited other librarians/library managers to participate in the interviews, meetings and workshops with the researchers. The criteria for respondents' selection included involvement in RUB virtualization process at top and middle management level as well as front and back office level (Patton, 1990). Thus the key role that the respondents had in RUB virtualization process gives high level of reliability and validity to the findings. Using our theoretical framework to organize our data, we analyze the case in the transition from New Public Management to Network Governance as well as its implications for innovation activities at RUB with particular focus on service innovation, especially ICT-based innovation. In this process we find some limitations of the theoretical framework and propose some amendments thus making a contribution to theory. The paper has been presented and discussed with one top and one middle level manager at RUB.

## 5. Analysis and Results

By analyzing our data, we find two phases of ICT-based innovation adoption, implementation and development at RUB, roughly corresponding to a New Public Management period (Phase 1) and to the first manifestations of the networked model (Phase 2). We find that these phases may not be as clear-cut as theorized by Hartley. Nevertheless, they can be associated to rather different innovation patterns, and to distinct roles of policy makers, managers and end users.

### 5.1 Phase 1: Public governance and innovation- New Public Management

The beginning of RUB's virtualization process largely coincides with what can be dubbed as the New Public Management period, starting around mid 1990's and spanning through the subsequent decade. This phase incorporates some elements of what Hartley calls the Traditional Public Administration period. These elements can be detected especially by examining the role of policy makers and public officers that respectively appear to resemble very closely the functions of "commanders" and "clerks and martyrs" of Hartley's Traditional model. See Table 3 (a) for an illustration of the innovations and the role played by different actors at RUB in this phase.

| <b>PHASE 1:</b> <i>NPM (mid 1990s-early2000s) with elements of Traditional Public Administration</i>  | <b>PHASE 2:</b> <i>Networked Governance (mid 2000-2014)</i>  |

**Table 3 (a): Public governance and ICT related innovation at Roskilde University Library from mid-1990s to 2014 (part 1)**

## **5.1. Innovation**

### **5.1.1. Technological and Institutional Contexts**

From mid-1990s to early 2000s the innovation context was characterized by a) important technological transformations such as the emergence of Internet and World Wide Web, the diffusion of ICT and broad band technology in the Danish society, made possible by important investment decisions of the Danish government whose vision was formulated in the policy plan "Information Society for All" from 1996. This policy plan has been the main driving governmental force of the Danish information society, including the digitalization of the libraries to provide all the Danish citizens with access to electronic resources. b) Institutional innovations such as Denmark's Electronic Research Library (DEFF) established for the facilitation of the innovation and development of library electronic services and overall objective of improving the use of ICT in support of research and education.

### **5.1.2. Organizational innovation**

At the end of the 1990's -beginning of 2000s RUB starts an organizational innovation process involving several dimensions of change and especially enacted through different major initiatives. First of all, in 2001 RUB moves to a new, modern library building with double the size of the old one providing a more attractive look, as well as much more shelf and office space. The new building facilities allow the increase in the number of open stacks relative to closed stacks, thus increasing the number of library resources that can be accessed directly by the library users, therefore laying the grounds for an increase in library self-services. This period is also characterized by an increase in partnerships and collaboration with several national and local actors. The most important of these initiatives is RUB's participation to the DEFF consortium. This implied the establishment of partnerships with different Danish research libraries with the common purpose to innovate the electronic services and library services both at national level and local RUB level. Such partnerships and service innovations were partly financed by government funding and partly by joint purchase of licenses ([www.deff.dk](http://www.deff.dk)). DEFF's initial strategy was:

"To improve the end user's access to information through cooperation between the Danish special and research libraries. The cooperation includes joint development in cases where cooperation will result in a greater advantage than the sum of local initiatives, including a better and total utilization of the libraries' resources; further development of the joint network of information resources; collective dissemination of the research libraries' information resources to the public"([www.deff.dk](http://www.deff.dk), *retrieved February 2007*).

In this period RUB also starts collaborating with the IT service department (Campus IT) and the department of education at Roskilde University and to start developing e-learning (Scupola, 2009). This collaboration was mainly desired by top management at Roskilde University (but originating from policy statements) due to two major trends: a new vision that research libraries had to become an integral part of the university organization; budget constraints both at Roskilde University and RUB level. These organizational innovations implied changes in staff competencies with heavy

re-training of RUB's staff and changes in front office and back office tasks. In the attempt to cope with these organizational changes, RUB introduced an additional organizational innovation: the establishment of a blog to support the internal communication of RUB employees and to facilitate their knowledge exchange. This was an important change in line with the transformation of RUB towards a virtual library with the benefits and resistance that such ICT-based innovations may generate (Interview with a top manager, Spring 2008).

### **5.1.3. Innovation in service delivery**

The most radical innovation in service delivery at RUB in this period is the introduction of e-services, that is the possibility of searching, browsing and retrieving needed information remotely and instantly from the users' own computers, anytime, anywhere through the use of the World Wide Web, thus providing access to e-journals and e-books 24/7 all the year around. This was perceived as a major change at that time as it implied that the library users could themselves download the journal articles or book chapters from the library web page without necessarily needing to go to the physical library. Simultaneously RUB started innovating its face-to-face services in accordance to a shift to a more market and customer centered strategy and to an increase in the customer focus. For example RUB had conducted 2 user surveys, one before and one after moving to the new building in 2001 in order to measure customer satisfaction with their service provision. Since the survey conducted after the move to the new building showed a decrease in customer satisfaction, RUB at the initiative of 3-4 librarians developed a new service concept, "book a librarian", which can be seen as one of the first examples of services customization at RUB. This service consists of offering the student individual instruction and support in literature and information retrieval within the specific subject/field of the student or project. The librarian can for example offer help in choosing appropriate search strategies, choosing relevant databases, guidance in selecting and evaluating relevant sources and internet resources, advice in keeping track of the literature used in the project ([http://ask-rub.altarama.com/reft100.aspx?key=bookbib\\_en](http://ask-rub.altarama.com/reft100.aspx?key=bookbib_en), retrieved Spring 2013).

### **5.1.4. Role of Policy Makers**

The case shows that in this period policy makers mainly play a role of announcers of societal changes and innovation through the formulation of policy directives, but they also act in a way that much resembles the "commanders" typical of Hartley's Traditional Public Administration model. For example they act as announcers in the Danish government vision and policy plan "IT society for all". However, Danish policy makers act as commanders when in May 1996 the Ministry of Culture, the Ministry of Education and the Ministry of Science established an IT working group to investigate the transformation of the research libraries into electronic research libraries. In 1997, the "DEFF report" was published, creating the basis for potential partnerships for the Danish research libraries' IT development. The "DEFF report" described a model of reference for Denmark's Electronic Research Library including the essential electronic functions and services to be delivered by such libraries. A budget was then allocated by the three ministers involved, a board of directors was appointed, and a vision and a strategy for the DEFF project were developed. In 2003, DEFF became a permanent activity with the objective of improving the use of IT in support of research and education.

Table 3(b): Public governance and ICT related innovation at Roskilde University Library from mid-1990s to 2014 (part 2)

### 5.1.5. Role of Public Officers/Servants (library managers and workers)

The examined period is characterized by a transformation of the role of RUB top management and some librarians into “public managers”. The re-organization of RUB’s organizational structure into a matrix organization implies that some librarians act both as top or middle managers (with related decision power), while simultaneously keeping their role of librarians with front desk responsibilities. In the role of top level managers, such library employees implement at RUB level the changes dictated by the university, government, DEFF and Library Authority. They act both as efficiency maximizers and cost minimizers, especially due to the pressure from cutting costs in the public sector coming from both the Danish government and Roskilde University management. They are also responsible to implement the changes envisioned by DEFF at local RUB level, thus engaging into partnerships or collaborations on specific projects with other Danish Libraries. However, while some librarians take on the roles of top and middle managers, other librarians and library clerks become in a sense “martyrs”. RUB virtualization has imposed substantial changes in competencies, tasks and working procedure placing a remarkable increase of pressure on library employees. that are increasingly required to do more with less. For example from the statistics on the number and types of library employees published on RUB web site (<http://rub.ruc.dk/en/>, retrieved summer 2014), one can see that while the number of librarians and subject specialists has been more or less constant in the decades from 1994-2014, the number of clerks has been cut by half by 2014. This is explained by the following statement: „*The spectrum of work for academic staff is widening and taking on tasks that earlier were done by clerks. ..So there are fewer tasks for clerical staff and therefore less clerical staff.*“ (Top manager, RUB, summer 2015)

In accordance to Hartley’s model, this period is also characterized by emerging competition among top managers of different Danish libraries, as “you want to be a little bit better than your neighbour library” (Director of reader services, RUB, spring 2009).

### 5.1.6. Role of users

The library user in this period is still considered to be fairly homogeneous and a relatively static kind of client, even though some examples of service customization are emerging as in the case of “book a librarian” (see above). This is reflected in the fact that the customer’s wishes and wants do not play a big role in the library innovation activities yet. The only ways in which the library takes into consideration the users’

needs and wants is by conducting a survey every 5 years, and through the customer complaints box. The self-service philosophy introduced in this period is based on the idea of letting the user choose out of a fixed menu of alternatives. The users are not involved in designing the alternatives to choose from. The users are perceived to be mostly generators of smaller, incremental innovation ideas as the following statement shows: “It is limited how much the users may contribute with ideas.. Well it is smaller suggestions, they are not trivial, they can be just as legitimate, but they are not high-flying” (Top manager, RUB, Spring 2008).

## **5.2 Phase 2: Public governance and innovation-Networked Governance**

The Networked Governance period, which for RUB starts in the mid-2000s, is characterized by continuous, still on-going changes.. Such changes concern especially the innovation context as well as an increased focus on customization and co-production of library services. This implies an overall change in library support services as the Danish Library Agency states in a report of 2008:

*“Such library support will entail a shift in focus from supporting the creation of truth to supporting the creation of value. This might mean a stronger focus on supporting inspiration and new ideas as opposed to focusing on quality in support of the search for truth (Danish Library Agency, 2008).”*

Table 3 (b) summarizes the innovations and the role played by the different actors in this phase.

### **5.2. Innovation**

#### **5.2.1. Technological and Institutional Contexts**

The technological context in this period is characterized by a capillary diffusion of the Internet and complementary technologies in the Danish society, government and business organizations. The institutional context, instead, is characterized by a transformation of academic institutions such as universities towards business like organizations, with a board of directors and activity based budget. In this period Danish universities experience an increased focus on strategic management and strategies development. The Danish universities experience a shift from elected to appointed vice-chancellors as well as deans and vice-deans (Danish Library Agency, 2008). Although the emphasis on business like procedures could be seen as a manifestation of the NPM approach, being this institutional change associated with a decentralization of decision making in the innovation area, makes it more consistent with the networked governance model.

### **5.3. Organizational innovation**

RUB’s organizational innovation in this period is focused on how to best understand and meet the customer needs and wants. In this period and especially in response to the policy initiative “User Driven Innovation”, RUB for example establishes the “user

driven innovation committee” with the specific task to understand the user needs and provide ideas on how to innovate the library services accordingly. More recently this committee has been replaced by an information specialist responsible for the service journey and how to improve it. For example this information specialist followed the service journey of the use of the library scanner and came up with suggestions on how to improve it. In addition, RUB has extended its opening hours until midnight all the year around. This is possible because the users can access the library with the library card when the library staff is not in service (). In this period RUB has also implemented a number of organizational changes in the back and front offices (front desk), to meet the organizational requirements dictated by the increasing electronic services and self-services provision. Especially front-desk service innovations are very important in this period. Such innovations are often developed bottom up by the library employees and approved by top management as for example the case of book a librarian or the chat service. However a lot of smaller incremental service innovations (improvements) take place at front desk and middle manager levels without the involvement and/or approval from top management. These continuous small changes in the services and/or service delivery process are mainly based on bricolage and often discussed at lunch time among librarians and front desk employees, thus contributing to their diffusion within RUB (e.g. Fuglsang, 2010). Bricolage innovation takes place as a means to satisfy the users, but also to make employees own work practices easier. Finally RUB has been experimenting with the creative use of social media such as blogs and Facebook in an attempt to get closer to the customer, engage into a two ways communication, and involve them idea generation and co-creation of innovations.

### **5.3.1. Innovation in service delivery**

This period is characterized by radical and incremental innovations in RUB services and service delivery, but also by “new service development” especially in support of teaching, research and students. For example the librarians (subject specialists) can provide assistance to Roskilde University faculty with research applications by helping for example with a literature review. After suggestions from the users (faculty staff), RUB has introduced tailor made courses for teachers and students on how to use reference programs such as End Notes, REFWorks and Mendely. RUB has established a coffee vending machine in response to the user (student) wishes to be able to get a cup of coffee while in the library. Some service innovations are conceptualized, initiated and developed locally at RUB with or without user involvement (as the examples above), others take place within the broader context of DEFF as for example the “Library Call Service” (“Bibliotek vagt”), initiated by DEFF in an attempt to harmonize access to information help across the public and research libraries and successively designed and implemented locally at RUB. In this period the focus gradually shifts towards self-service of e-journals and e-books, self-checkout and self-returns of library material as well as the use of the library physical facilities with access card when the library is not staffed. The content of the service is increasingly driven and co-created by the user as in the case of the “Patron Driven Acquisition Service”, a user driven service allowing immediate access to the user (against a fee charged to RUB) to articles or books that are not in RUB’s collection. This is clearly evidenced by the following RUB’s statement:

“The library service is based on the principle of extensive self-service and access to open stacks. Self-checkout and self-return stations are located near the exit. All users are responsible for observing due dates and renewing and reserving material.

It's possible to pay fees and bills through your library account.” (<http://rub.ruc.dk/en/about-library/the-library-from-a-to-z/>, downloaded summer 2014)

## **5.4. Role of Policy makers**

The policy makers in this period act as “leaders” and “interpreters of the societal trends”. They define the general policies for the continuous innovation of the service provision in the public sector. An important policy initiative that has influenced many sectors of the Danish society including the library sector is the “user driven innovation” policy of the late 2000’s. This initiative has been introduced by the Danish government to encourage public administrations and private organizations to involve the citizen/customer in innovation processes and activities (e.g. Ogawa et al., 2011).

### **5.4.1. Role of Public Servants (Library Managers and Workers)**

In this period RUB managers take on the role of “explorers” by engaging in a number of activities aimed at innovating the library services based on high level of user involvement and co-creation.). Top management, however, still provides inputs to RUB’s strategy and development plans and is the initiator of most radical innovations by implementing at local RUB level the information policies developed by the library authority DEFF and the government. For example Top management has taken the initiative to adopt the “Patron Driven Acquisition Service” described above. RUB’s middle managers and front desk employees develop small incremental innovations (bricolage) that remain at the middle-management-front desk level. Some suggestions are taken to top management through the biweekly meetings of the coordination committee, and sometimes they get approved and get implemented in the whole RUB. Examples of initiatives where RUB managers act as explorers are: the service journey; the use and analysis of the activity data of the users (data analytics) for service management and innovation; the “user driven innovation committee”; the establishment of a blog and conduction of future workshops for the co-creation of new service ideas with the user; the use of supervision and teaching sessions to get inspiration on how to improve the library services and their provision; the use of log files, electronic positive and negative feedback and pop-up windows to understand how to improve RUB’s electronic services.

## **5.5. Role of users**

In this period, RUB experiences a shift in the role of the user from being a static entity to become more active and central in the service innovation process. The role of the user develops from being passive or what Nambisan (2002) defines as “resource” (e.g. mainly answering a survey), to being “a co-creator”. In addition the users contribute to the service innovation process by just using the services (the “user” role) and electronic services as their behavior can be captured by log data or electronic sensors and analyzed with data analytic techniques to make conclusions about service innovations. RUB also involves students working at the library to test a new service or improved service before lunch improvements. Users start being integrated in the New Service Development of library services by taking an active role in ideas generation and co-creation as in the blog and future workshops initiatives. These initiatives have led to innovations such as the coffee vending machine or establishment

of library group rooms. In addition, the continuous improvements of the “book a librarian” service and the “virtual reference” service more and more user-driven; including the electronic chat are driven by the users through their difficulties, complaints and suggestions. , This reveals a fundamental change in perspective: from the choice out of a fixed menu, to the actual design of the menu, i.e. the user is highly involved in the co-creation of the service, by adding new quality and content to the service that is being delivered.

## 6. Conclusions and implications

The paper has taken inspiration from Hartley’s seminal contribution to develop some reflections on how technical and organizational transformations combine with changes in the roles played by policy makers, public managers and users in the development of public sector innovation. Using a case study on the Roskilde University Library to illustrate these patterns, we have highlighted three important aspects that characterize the links between governance and innovation in this field.

First, the examined case shows that the organizational complexities have increased in the transition from what could be considered as a spurious NPM model, incorporating elements of the traditional hierarchical model and elements of market-like competition, towards a “networked model” implying more emphasis on bottom-up decision making and a greater involvement of end users. The variety of government policies and instruments has considerably widened, public managers have increased their relative capacity to take relevant decisions on innovation uptake and new service development, library employees have become more involved in this process with a more active role to play.

Second, we have provided evidence of increasing co-creation activities in which end users are involved not only in choosing out of a given menu of alternative solutions to given problems, but also in the definition of the menu itself, and in shaping and implementing innovative solutions.

Third, the increasing involvement of users has created important innovation opportunities that are more and more characterized by their frugal/bricolage nature, hence more localized but not necessarily trivial and relatively easy to diffuse to different contexts.

As in the case of other case studies, ours can hardly lead to generalizable conclusions. However, it can be expected to provide useful insights on ongoing changes that would be more difficult to capture otherwise. Future research might benefit from a deeper analysis of the issues emerging from this experience of virtual library development.

# Innovation in retail: impact of mobile phone on consumer behaviour

*Zhuo ZHANG* <sup>1</sup>,

<sup>1</sup>Aix Marseille University

## **Abstract**

"...as consumers adopt new technologies, their behaviours change" (Zinkhan & Watson, 1998). With the development rapidly of the smartphone and the wireless network from decades, consumers use more and more frequently their mobile phones to purchase and/or reserve the goods and services, that's why the mobile commerce is growing to a field which cannot be ignored by the managers and the researchers. However, it still remains at the period of his infancy in the retailing industry and there are too many papers concentrate on the technology acceptance model of m-commerce, but few of them pay attention to the context of using the mobile phone. This paper aims to: (1.) discover the context of use of m-commerce for the chain hypermarket clients in France by identifying the critical factors in different phases of m-commerce; (2.) try to understand the importance of the mobile service by analysing the interactions between the retailers and the customers in each phase and (3.) to find out the change of the consumer behaviour in this brand new business model. This study reports an exploratory qualitative method by interviewing the mobile customers in France.

Keywords: Mobile commerce; Mobile service; Mobile context; Interaction; Customer behaviour; Chain hypermarket in France.

# 1. Introduction

Currently there are 6 billion mobile phone users in the world, and 1 billion smart phones, the figure will be DOUBLED in 2015. The mobile phone penetration rate is from Macau in China with 236% and 105% in the United States, 102% in France. With Big Data is collected by the e-commerce, we can understand consumers' behavior such as seeking out its fields of products, scan products to stores, buying, etc.

The products and the services offering by the mobile and the wireless network engage the development of the M-commerce which is becoming a global subject. 'The developments within m-commerce is subject to two major technological advances; the growth surge of smartphones and instant high speed mobile internet access (ZHANG et al, 2013). In France, the possession of smartphones is 55% and the number will grow constantly in the next few years, because the rate of possession is already reached by 69% in USA and 74% in England respectively. And the most impressive phenomena are the m-commerce represent 3.7 billion euro in 2014 and it will increase to 7 billion by 2015 which will be the 12% of the e-commerce (Source: Centre for Retail Research). This drives more and more researchers to focus on this topic, 'Although a large volume of literature is available on mobile commerce (m-commerce), the topic is still underdevelopment and offers potential opportunities for further research and applications' (Ngaia & Gunasekaran, 2007). Even there exist some papers of M-commerce adoption, but 'Context is an inherent part of service use experiences that helps to understand when mobile services generate superior value-in-use for customers and are preferred to other services, but little research exists on the subject'(Gummerus & Pihlström, 2011). The traditional consumers used to purchase in the face to face context and the e-commerce make the context more divers. The online customer experience (OCE) can help managers to raise the consumer's loyalty. (Rose, Hair & Clark, 2011) But, M-commerce will change completely the purchase context by making the channel fragmentally. It's hard to catch the consumers if the retailers don't know the new context. So, we are going to find out the use context of M-commerce and define the different phases of purchasing for the retailing industry because 'To safeguard their existence in the face of harsh competition, food retailers have shifting their attention from goods to service. In this development, mobile services have emerged as suitable venues for intensifying companies' service orientation.' (Saarijärvi, Mitronen & Yrjölä, 2014). Is mobile phone making services of retail become better than before, the Importance of the interactions between the retailer and the consumer will be analyzed in this paper.

Mobile commerce is a new service in the background of the development of information technology innovation. Service output in Europe and developed countries accounted for more than 70% of GDP, and it will be enhance in the future. This caused the interest by a large number of scholars and companies, to carry out the deepening research of the service. One of the most prominent participants is IBM who proposed the concept of SSME (Service Science Management and Engineering). They hope to develop the technologies needed in service industry by combining the cloud computing science; marketing; industrial engineering; business strategy; science of management; social and cognitive research; science of law and so on. However, before that, the academic research on service industry is extremely rare compared to the production industry. So, we are going to present the M-commerce and the service.

## **2. Conceptual Framework**

### **2.1. Use context**

People carry their smart phones or mobile devices (as iPad, etc.) to anywhere they go at any time. Following the data from Compete, 63.2% of shopping activities took place at home, 34.5% consumers use their mobile devices in store to compare the price, watch the comments or download the coupon, and 28.6 of them purchased in their fragmented time such as the bus station, coffee shop and so on. They could search for information, enjoy the entertainment applications, communicate with others, and purchase or reserve the products/services without the limit. All of these new concepts or technologies are becoming a very important part of our daily routine, which means the new context of commerce activities are also coming into our life. The context, especially with regard to mobile applications, is seen as an important variable, and due to the possibility of developing context-aware or location-based services in the mobile domain, the concept of context has received more and more attention (Bouwman & Wijngaert, 2002).

Then, if mobile services are to come up with real added value to the user experience, developers have to understand both the concept of mobility, as well as the context of the use of mobile applications (Bouwman, Bejar & Nikou, 2012). First of all, we have to understand which factors compose the context. To better understand the impact of context on consumers' behavior, particularly in terms of technology-based services, researchers have called for more research on contextual factors (Dabholkar & Bagozzi, 2002). To better understand the contextual factors, the service use outcome in the model of the service production process was discussed, because the relationships between the context and the service use outcomes is important (Chell, 2004). Following the previous research, context can be divided to Computing context, user context, physical context (Schilit, Adams & Want, 1994) and time context (Chen & Kotz, 2000). Computing context refers the basic technologies of mobile commerce such as the Wi-Fi access, the communication costs and so on. User context means normally the social situation of consumers. Physical context refers the environment condition including the temperature, the traffic condition. Time context refers to e.g. day, week, or month (Chen & Kotz, 2000). Some services clearly fit some context while other services do not. It is therefore important to categorize services quite carefully, and to relate them to contextual aspects (Bouwman, Bejar & Nikou, 2012).

In this paper we focus on the retail industry, because traditional retailers are increasingly shifting their strategic focus from goods to service (Saarijärvi, Mitronen & Yrjölä, 2014). As we said, the new daily routine of shopping is coming to us, consumers' comportments and purchasing decisions are now revolutionary changed thanks to the penetration of smartphone. Consumers don't need to go shopping anymore; they are doing it all the time at all the places. They can find and reserve the products or services at many scenes even when they are busy, they can give orders by phone through the purchase process. This revolution has given consumers the right to speak and brings the challenges for retailers to find the new model to meet new customers' behavior. In the context of retailing, they began to realize the situation and tiring to introduce M-service for the new cycle of purchasing.

Varley & Rafiq proposed in (2005) that retail services is customer service, including a variety of additional value-added services through interactive offered by sales staff, the implementation of commercial policy and the facilities provided by retailers. The initial service innovation, mainly through the introduction of advanced technology and equipment, such as fast cash system and convenient bag storage systems, but consumers' demand changes to the spiritual level, the service began to consider the innovation of diversification for the various departments.

Consequently, M-services become more and more important for retailers by provide the personalized shopping experiences to their consumers with the persist information (Nysveen et al., 2005). Current research specific to the retailing context, shows that consumers who own a smartphone perceive social media and other applications provided by the retailer as valuable in the in-store environment (Sands et al., 2011). In conclusion, integrating research on M-services with the recent theoretical discussion around service as business logic offers clear synergic outcomes (Heinonen and Strandvik, 2009).

In retail industry, there are two kinds of mobile apps for the use context. One of them is developed by the independent application developers like 'Shopkick', it was designed by an independent company who offer the service for the retailers like Best Buy, Macys, American eagle, etc. They use the LBS (Location Based System), the coupon which could get from 'kickbucks', scanning function to make consumers purchase easier and funnier. Amazon has the same application which focuses more on the price compare function.

Another kind of apps was developed by retailers themselves. Like Walmart developed his own apps and it could switch to 'in store model' automatically when customers enter into one of Walmart, and they will receive the information of new products or promotions, they could reserve the products if they are sold out. In France, retailers developed also their own apps because they caught the tendency of retail's future. We are going to make a list of these apps with their functions to understand the factors of use context.

| Retailers           |                          | Auchan | Casino | Carrefour | DIA | Monoprix | Leclerc | Lidl | Walmart |
|---------------------|--------------------------|--------|--------|-----------|-----|----------|---------|------|---------|
| Functions           |                          |        |        |           |     |          |         |      |         |
| Information service | Catalogue                | ○      | ○      | ○         | ○   | ○        | ○       | ○    | ○       |
|                     | Promotion                | ○      | ○      | ○         | ○   | ○        | ○       | ○    | ○       |
|                     | Scanning                 | ○      | ○      | ○         |     | ○        |         |      | ○       |
| LBS                 | My store                 | ○      | ○      | ○         | ○   | ○        |         | ○    | ○       |
|                     | Accurate search in store |        |        | ○         |     | ○        |         |      | ○       |
| Personal Assistant  | List of shopping         | ○      |        | ○         |     | ○        |         |      | ○       |

|              |                        |   |   |   |  |   |   |   |   |
|--------------|------------------------|---|---|---|--|---|---|---|---|
|              | Member card management | ○ | ○ | ○ |  | ○ |   |   | ○ |
|              | Contact with seller    | ○ |   | ○ |  | ○ | ○ |   | ○ |
| Payment      |                        | ○ | ○ | ○ |  | ○ |   |   | ○ |
| Social media |                        | ○ |   | ○ |  |   |   | ○ | ○ |

We can observe through the list that information service is the most basic function for the retailers, in the function of LBS, the location for store is used by most of retailers and the accurate search in store is still under developed. The management of member card and payment are also popular in the context, the contact with seller and social media are the factors of interaction, they are popular but not well used by some retailers.

## 2.2. Mobile service

The huge potential in delivering m-services through mobile devices created by the combination of rapidly developing technology and high uptake rates of mobile devices has been recognized for more than a decade (Bitner et al., 2000). M-services are understood here as mechanisms through which food retailers can enable their strategic shift toward serving their customers (Saarijärvi, 2012). As the application of new technology, the M-commerce and his innovative services have a lot of features. The researches of the key factors for the high-quality mobile services with excellent customer perceived, technology platform for mobile services, service model, service delivery methods, as well as the changes of consumers' behavior, make us understand better the value of mobile commerce.

The definition of the service is still a controversial topic, because the services are too complicated, it makes the understanding of the services become blurred and contentious. So far, the service has no precise definition. Services include both the traditional labor-intensive services, and the modern knowledge-intensive and technology-intensive services with the development of information technology. Services can be categorized in many different ways. Some services can be characterized as communication services, and others featured as information, entertainment or transaction services (Bouwman, Bejar, Nikou, 2012).

In addition, there are many different definitions of service. However, the definition above just give some characters of services, these definitions are always unclear for the particular service sector. Especially, the new business model such as mobile commerce needs a more vivid and more targeted description of the service. Thus, this paper tries to analyze the services offered by the retailers in France via mobile phones. Mobile commerce includes not only the products but also the good quality service offered by the retailers, such as the precise information, the products' scanning function, the reservation ubiquity, after-sell service and the social share experi-

ence, etc. In some cases, mobile services are even more useful to attract and keep the consumers than the products.

### 2.2.1. Interaction between customers and retailers

Because of the intangible and uncertainty of services, many scholars doubt innovation of services, they think the service is an adjunct of tangible product and service innovation itself does not exist. In addition, the relations between service innovation and technological innovation was discussed, do they have the same process, nature, mechanisms and effects. Currently, the debate over whether the presence of innovative services to generally agree: innovation in services exist, but the form is very different with technical and organization innovation. It exist almost no services without tangible elements, at the same time, there is little tangible goods don't include the services (Christopher H. Lovelock, 2001).

Retailers need to make the service innovation activity and strategy; they must first clear the basic driving forces of innovation in services. Sundbo & Gallouj (1998) analysed the services with a number of European countries and they proposed a model of the driving forces:

We can see that customers are one part of actors, following Gummerus & Pihlström (2011, pp. 521–522), M-services can be defined as ‘content and transaction services that are accessed and/or delivered via a mobile handheld device (PDA, mobile, cellular or phone, GPS, etc.) based on the interaction/transaction between an organization and a customer’. So, in M-commerce environment, customers participate in the production of service more frequently than before, research on customer participation and their influence to the production and delivery process of service gradually increased (Bendapudi and Leone, 2003; Ennew and Binks, 1999; Hsieh and Yen 2005; McCollough et al, 2000; Yen et al., 2004). Consequently, M-services become more and more important for retailers by provide the personalized shopping experiences to their consumers with the persist information (Nysveen et al., 2005).

## 2.2.2. Service production process in M-commerce

Mills & Moberg (1982) proposed a systems model of the service production process to explain the interactions between the consumers and the service workers through the service production process in the traditional commerce environment.

Service production process and the manufacturing process are very similar. Therefore, the principle of the management of manufacturing operations with some management experience can be used to manage service processes. However, due to the characteristics of the service, management and operations of services have a different process. Like participate of customers, customers could get satisfied by the quality of the relationship with service person, and to determine the quality of service. Through m-services the company can create interactions with its customers, engage with their value-creating processes and deliver additional resources for their use (Grönroos, 2008a; Grönroos and Ravald, 2011).

The purpose of M-service is to find customers current and future needs, then design the programs to meet the customer's needs, including mobile services, service delivery methods and experts support. Then try to provide the faster, more comprehensive services to customers with an unprecedented shopping experience. The company is able to interact with customers via a variety of m-services that assist customers in their everyday processes beyond the traditional boundaries of food stores (Klabjan and Pei, 2011).

Mahatanankoon et al. (2005) define that M-commerce includes information services (google, yellow pages, etc.), transactions, location-based services (e.g. the receipt of discount coupons in a local store, etc.), support services (emergency) and entertainment. If a retailer can offer all these services, they will keep their customers' loyalty.

## **2.3. Consumers' behaviour**

Consumers' behavior in a traditional commerce environment influenced by consumers' internal characteristics (including personalized preferences, interests and emotions) and external environment (including social, cultural, marketing activities, etc.). This behavior is totally different from a mobile commerce environment. So, we are going to present and compare the consumers' behaviors in traditional commerce, E-commerce and M-commerce environment.

### **2.3.1. Consumers' behaviour in traditional commerce**

There exist a lot of theories and models of consumers' behavior in traditional commerce environment such as the Habit Formation theory, Information Processing theory, Risk Reduction theory and Marginal theory which can explain the consumers' buying behavior. Then, the researchers provided some classic models such as:

- Nicosia Model, 1966

Francesco Nicosia proposed this model in his book 'The process of purchase decision of consumers' in 1966. It describes the sequence of the information processing without detailing the different stages that comprise it.

- Lotler Philip model, 1973

It is the basis of purchase decision process of consumers and there are 4 parts: Need recognition, Search for Information, Pre-purchase evaluation, Purchase. The purchase decision is not only influenced by domestic factors but also external, throughout the influence of corporate marketing. In this model, there are two external factors: marketing stimulation and external stimulation.

- Howard-Sheth Model, 1963/1969

Designed in 1969 by John Howard and Jagdish Sheth, it fundamentally enriches the analysis of the formation of attitudes by offering three levels of behavioral responses: cognitive, affective, conative. Thus, the decision process will be different depending on the situation of purchase in which the consumer finds.

- EKB (Engel-Kollat-Blackwell) Model, 1968/1984

This model states that all actions of consumers resulting from internal and external variables. External variables are the social influences (e.g., culture, reference groups and family) and situational influences. Internal variables are individual characteristics (e.g., patterns, values, lifestyle and personality).

- S-O-R (Stimulate-Organism-Response) Model, 1991

The model SOR was developed for consumer purchases in stores. Part of the model is tested with panel data Behavior Scan Information Resources Incorporated. The results show a significant influence on consumer purchases.

- EBM Model, 1995/2001

This model is the basis of EKB model to describe more detailed on consumer buying behavior. It becomes the most model are to analyze consumer buying behavior.

These models could use to explain the relationship between the variables during the purchase processes. Although the processes of purchasing decision are various according to the product, the price and the consumers' abilities. But generally, the process of purchasing decision includes 5 stages (EKB, 1968): Need recognition, Information research, Alternative evaluation, purchase decision and the Post-purchase behavior. And the managers could follow the laws of consumer behavior to make the market strategy: AIDMA, use the advertisement to attract the Attention and Interest, transform them to the Desire and keep the Memory in their brain, then make the Action of purchase.

### **2.3.2. Consumers' behaviour in E-commerce**

In E-commerce environment, consumers' behavior becomes more personality. As e-commerce beyond the limited of time and location, the choices of products were greatly expanded. Consumers of E-commerce generally have a certain cultural level and a certain income level, so they can choose the merchandise with their personal character. Thus, the consumers enjoy more and more their experience of purchasing online. Without the limited of time and location, they can search, compare, share and purchase the products freely.

But they also have the problems facing the massive information from internet, they don't know what course to take because the information from internet is asymmetrical, so consumers cannot analyze effectively the selected products, many consumers purchase the goods by feeling and this increase the possibility of a non-rational choice.

In the E-commerce environment, consumer could get the information through the search engine, online community, social platforms and other ways to share information and experiences. Consumers' behavior has a lot of changes compared to the traditional environment, consumer behavior generally followed AISAS mode.

Consumers are attracted by a good idea or because of a need, they pay Attention to certain products or services, interactive make consumers became Interested in participating, then the consumers go back to the internet to Search for relevant information or information provided by users. They will take the Action after obtaining sufficient information, and sent the experience back to the internet to Share with friends. This makes a complete consumers' behavior in the E-commerce environment.

### **2.3.3. Consumers' behavior in M-commerce**

Consumers' comportments and purchasing decisions are now revolutionary changed thanks to the penetration of smartphone. Consumers no longer need to go shopping since they are doing it at all time and all places. They can find and reserve the products or services at many scenes even when they are busy, they can give orders by phone through the purchase process. This revolution has given consumers the right to speak and brings the challenges for retailers to find the new model to meet new customers' behavior.

The mobile consumer is very different than traditional customer or e-commerce. Consumers no longer need to stay in the shop to make the choice or to seek in front of the computer, they can make the decision by walking, by taking the bus or while watching TV. And then, with the LBS system, consumers can see the rental shops, distance and find the products they need by clicking their mobile phone. In addition, the mobile business is highly customized to different customers; it can offer product or specific services for each consumer.

Due to internet access costs continue to reduce, the popularity of smart phone, smart phones users change their life habits, drive mobile commerce development rapidly. Consumers' behavior in M-commerce is mainly characterized by the following features:

- Anytime, anywhere. Compared to traditional E-commerce, M-commerce environment is more casual and relaxing. Consumers could purchase the products or services at anytime and anywhere constantly. As long as the mobile is in the hands, consumers could browse, compare, order via mobile phone.
- More personalized. Since mobile phones are more personal than fixed computers, each mobile device demonstrates the owner's personality. With the bar codes, two dimensional codes, graphics and voice search and other human-computer interaction technologies, M-commerce allows consumers who have the intent explicit to find the target products quicker and more accurately. If the E-commerce looks like a huge sea, then the M-commerce is the navigator for the consumers.
- More integrity. As the sim card of mobile phone number with user information can determine a user's identity, there is a credit certification basis, so the mobile phone users will pay more attention to their reputation, potentially encourage them become more honest.
- Fragmented. As the mobile phone can be carried easily, consumers use it on the way to work, at the bus station or the metro, in bed, even at the toilet. They could use these fragmented times to make the quick research, compare, fast purchase, social recommendation, reservation and other activities.
- Interactive. Since the transmission of information between mobile devices is one to one, so the M-commerce consumers' behavior shows more interactive features.
- More sensitive with the price. Because the M-commerce is more act at the fragmented times which is limited by the speed and price of internet, so consumers in this case are difficult to make decisions on expensive items, which determine the price is very sensitive for them.

M-commerce environment has the same factors that influence consumers' behaviors in the traditional commerce environment, including the internal factors like motivation, feelings, attitudes, etc. It also contains the extrinsic factors such as social class, family status. Consumers' behavior factors of E-commerce environment are also similar, such as personal characteristics, trading environment, online merchants conduct and Website, etc. But in M-commerce environment, as consumer access to the internet at anytime and anywhere, the factors that influence consum-

ers' behavior are more complex and more diverse. There are some researchers made their contribution in the past decade and we will make a list of them:

Thong, Hong & Tam (2006) discussed the effect of the perceived usefulness, perceived ease of use, perceived entertainment, users' experience difference, customer satisfaction which could influence the use continued with a sample of mobile Internet users. An empirical study confirm the perceived usefulness, perceived ease of use, perceived entertainment have a direct impact to the use continued, customer satisfaction plays the intermediary role has an indirect effects the use continued. The experience difference influence the use continued through the perceived usefulness, perceived ease of use, perceived entertaining and user satisfaction.

Cheong & Park (2005) made a model on the basic of technology acceptance model theory which indicates that the perceived usefulness, perceived entertainment, perceived price level are the important factors of M-commerce. Wu & Yang (2005), Bouwman, Carlsson, Molina-Castillo et al. (2007) have the similar results.

| Authors  | Factors   |
|--|---|
| Wang & al. (2003)                                | Cognitive credibility   |
| Vreehopoulos, Constantiou, Sideris et al. (2003) | Security, terminal equipment, custom support, low price   |
| Knutsen (2004)                                   | Efforts expectations, perceived usefulness, attitude  |
| Anderson (2004)                                  | Efforts expectations, desired effect, convenience, social impact  |
| Cheong & Park (2005)                             | perceived usefulness, perceived entertainment, perceived price level  |
| Wu & Yang (2005)                                 | Users perceived risk, cost, compatibility, perceived usefulness   |
| Jen-Her Wu (2005)                                | Users perceived risk, cost, compatibility, perceived usefulness, perceived ease of use, use intention, the actual use     |
| Thong, Hong & Tam (2006)                         | perceived usefulness, perceived ease of use, perceived entertainment, users' experience difference, customer satisfaction |
| Bouwman, Carlsson, Molina-Castillo et al. (2007) | The factors varied by different M-commerce users  |
| Mahatanankoon (2007)                             | Individual creativity, perceived entertainment, excitement exited level   |

### **3. Research Methodology**

In this section, the paper attempts to discover the mobile services offered by the retailers and to examine the change of the consumers' behavior. The purpose is to find out the context of using the mobile phone to purchase and reserve the products and/or the services. The objective of paper is to draw a conceptual framework of the interactions between the consumers and the service providers. The interviews were focused on the retailing context, as a research context, it offered a global and dynamic business environment to address the emerging research phenomenon and provided the access required to generate the interesting and diverse illustrations of m-services from which a tentative framework could be suggested (Saarijärvi, Mitronen & Yrjölä, 2014).

#### **3.1. Respondents**

To achieve the objective of this paper a set of personal semi-structured interviews with 15 people were conducted in France with European, Asian users. The respondents were selected by different backgrounds such as age, sex, work, family role, etc. And the interviews were carried on in varying situations i.e. in front of the supermarket, fast food store, train or bus station, university, office, and at home to distinct the different context of using mobile phone. Participants were ranging from 20 to 56 years old and were business professions, students, academicians. Irrespective of the interviewee's gender, majority of the participants had a good knowledge of the mobile commerce and consumed frequently via their mobile phones.

#### **3.2. Interview procedures and analysis**

The interviews process was devised to two stages. First, we asked the interviewee when and where they use the apps and what kind of function was most useful for them, so we can determine the context of using mobile applications which designed by the retailers. To capture the entire use context, they were asked to describe

- One situation where they use the mobile apps of retailers
- The reason they use it and what experience they got from that situation
- Which m-service they feel the most useful

Second, we asked them the level of interaction in each stage of their purchase, the objective was to find out the factors of interaction in each stage of mobile commerce environment. In this part, the interviewees were asked to describe

- The stage of their purchasing and
- What interaction they made
- How they feel about these interactions for their shopping experience.

## **4. Result and discussions**

The analysis was made to construct a tentative framework to understand how the retailers change the consumers' behavior by offering the m-services. The framework is comprised by two dimensions: first, the context describes the factors influenced the customer perceptions of using m-services, including time, location, internet condition. Second, the interaction describes the interactions established by the retailers through the m-service at each stage of purchasing, including pre-purchase stage, transport stage, in store stage, comparing stage, purchase stage and post-purchase stage. These two aspects all have discussed through the interviews and found positive for the consumers' behavior.

### **4.1. Context of using m-services**

Through the interviews with participants, the role of context appears to be a critical part of their purchasing experience. They described the time, the location and the internet condition are very important for them to use the m-service instead of other channels.

#### **4.1.1. Time**

For the first factor 'time', it was considered as the key to open the door of m-service, because it allowed consumers to benefit better their fragmented time.

Informant 7, Male, Asian. "I'm so glad to use my smartphone when I have a little time between the work and other activities. For example, I could watch the products and promotion information when I go to the toilet or when I take a little rest between my work times. This really is useful for me to notice and capture the new products because I don't have enough time to go to store every day. I used to be bored when I go to the toilet, but now I feel I could stay there for the whole afternoon."

Informant 12, Female, European. "I just finished my study life of university and I have a part time job in a restaurant, so I have a lot of time now. As I don't have a vehicle to go shopping, so I spend a lot of time on mobile apps. I can spend whole day to compare the price and put it in my purchase list, it's kind of fun."

Informant 5, Male, Asian. "I just like to reserve my tickets or hotels via my iPhone, it's very easy to use and I can do it anytime I want. So, I feel a lot of liberation with it. I even order my pizza with me phone, I don't want to go to the store with too many other customers in the waiting line."

So, we could see there are three kinds of time factors like fragmented time, abundant time and intended time. They all have different rhythm of life, but they all choose to spend their time with m-service to make it more useful.

#### **4.1.2. Location**

The second factor of use context was 'location', as we mentioned before, consumers could use the m-service at anytime and anywhere. It makes these two factors inseparable, for example, consumers could use the LBS to get the quick information when they are in an unfamiliar location.

Informant 9, Male, European. "It was my first time in China for a business conference, I was in the airport and I have to go to the meeting room in three hours. But I lost my laser pen which is very important for my presentation, so I used my phone to find a store not too far from the building where I should go, that is really helpful."

Informant 3, Female, American. "I take the shuttle to go to work every time I have to fly. When I wait the shuttle at the station and wait my plane at the airport, I prefer to search the local information where I will fly to. "

As a result, we considered the location has two aspects: location conversant and location unversant.

#### **4.1.3. Internet condition**

The access of internet of mobile and fixed device is very different. The mobile internet access is slower, the signal is weak at some location, the security problems and the cost of internet is expensive. This factor truly influenced the consumers' purchasing decision.

Informant 7, male, Asian. "Well, it's different to connect to internet at the train from the toilet. I usually take a book when I take the train or a plain because I can't get the Wi-Fi, if I have it everywhere, I will never finish one book in my life."

### **4.2. Interaction at each stage of purchasing**

As we mentioned before, in traditional commerce we follow the follow the laws of consumer behavior to make the market strategy: AIDMA, use the advertisement to attract the Attention and Interest, transform them to the Desire and keep the Memory in their brain, then make the Action of purchase. And when the E-commerce showed up, we changed it to AISAS mode. Consumers are attracted by a good idea or because of a need, they pay Attention to certain products or services, interactive make consumers became Interested in participating, then the consumers go back to the internet to Search for relevant information or information provided by users. They will take the Action after obtaining sufficient information, and sent the experience back to the internet to Share with friends. But in the M-commerce environment, as consumer access to the internet at anytime and anywhere, the factors that influence consumers' behavior are more complex and more diverse which make the purchasing procedure become a 6 steps cycle. Including the pre-purchase stage, the transport stage, the in store stage, the comparing stage, the purchase stage and the post-purchase stage. And we observed the factors of interaction between consumers and retailers at each stage of purchasing.

#### **4.2.1. Pre-purchase stage**

Consumers search and analyze the information they found or promoted from the retailers. Before they go to the store, they usually search the product index and price at their spare time. Retailers must pay very attention at this stage to keep them loyalty by analyze consumers' habit.

Informant 11, Male, Asian. "The promotion they sent me is very interesting because they seem to know what I'm looking for. For example, I need to buy a print machine two weeks ago which I searched it a lot for the best price. And then the Carrefour

sent me a list of printer with promotion, I was so happy and surprised that I found it this way.”

Informant 8, Female, European. “Every time I went to a forum, I see people recommend the baby diaper from Auchan. So I use my iPhone to download the Auchan apps and they even have a forum named ‘Auchan Baby’, I found a lot of articles interesting and I still have some questions in my mind, so I went to the store to ask the sellers there, they were really nice with me. I was so touched and I decided to purchase all I need for my baby in Auchan.”

So, in this stage we can find that promoting, social media and reputation are three factors important for the m-service.

#### **4.2.2. Transport stage**

This stage occurs when consumers go to shopping in store or go to somewhere else. With the technology of LBS, retailers could send the accurate information or highly related information to their customers. Or they can also send the store location to them for the convenience.

Informant 15, Male, European. “...We were in this small town and we don’t know where we could find the store, so Nicolas used his phone to find a Casino which is 10 minutes from us. We were so happy because otherwise we will have nothing to eat for that night.”

Informant 6, Female, Asian. “I think because I wrote barbecue meat in my shopping list, when I was driving to the Carrefour, they sent me the message that they are having the promotion for the barbecue sauce. I mean this is interesting because I just forgot to write the sauce in my list.”

Consequently, we can put the promotion accurate and store location system in the list of factors.

#### **4.2.3. In-store stage**

In this stage, consumers are physically in the store and they will purchase normally. But retailers still need to offer the m-service to make them more satisfied. The in-store function of Walmart is very interesting as an m-service, it switches automatically when consumers enter into the store, and they could locate the consumer’s position and told them where to go for the right product.

Informant 10, Female, Asian. “It’s useful to use the store model because I could find what I want quickly. And I can use my phone to scan the product for more information when I find it. Like a bottle of wine, I can’t find the price and I scan it with my phone, the price came up.”

Informant 2, Male, European. “They have Wi-Fi in Carrefour and the speed is not bad, so I really enjoy the shopping with my wife there.”

#### **4.2.4. Comparing stage**

When consumers touched the products they might buy, this stage will come out. Retailers could interact with them by offering more information.

Informant 14, Female, Asian. "I need to prepare a dinner for my friends and I had no idea in my mind, so I went to Carrefour with no list at all. I planned to buy the first thing I saw in the food region. But, when I picked up one box of chicken and scan it, there is a recipe of curry chicken came out. And they even marked the position of every ingredients I need, so I made my shopping quickly and went back home to prepare the dinner."

So, the personal assistant in store will help consumers to make their decision easier, and they could interact with the retailers for more information.

#### **4.2.5. Purchase stage**

Informant 1, Male, European. "Payment is easier than before, I don't have to bring my wallet every time I go to shopping. I could pay with my smartphone. But I worried about the security problem at the same time, if they steal my phone, I can do nothing then."

Informant 14, Male, European. "It's very useful to keep the member card in my phone. I hate when I have to take three or four member card with me, they take a lot of place. Now I can just scan it in my phone."

We can find that mobile payment and member card management are also two factors important for the interaction aspect.

#### **4.2.6. Post-purchase**

At this stage, consumers could share their shopping experience with friends, families or colleagues by photos, videos and discussions.

Informant 13, Female, Asian. "I'd like to take the pictures of what I bought and share it with my friends. I can put it on Facebook, twitter and Instagram."

Informant 10, Female, Asian. "Every time I see my friends share some nice food, I want to go buy it immediately. Maybe I'm so greedy."

## **5. Conceptual Model and conclusion**

Following the discussions we mentioned above, we can see the use contexts and the interactions of each stage of purchase are two aspects influence the consumers' behavior. In each aspect we defined the factors of m-service. And, we propose the conceptual model of consumers' behavior in m-commerce of retail industry. See at Figure 1 below.

### **5.1. Theoretical implications**

This paper is one of the first studies to focus on the influence of use context and interaction on consumers' behavior. It discovers the three key elements of use context of retail industry, and the factors of these elements were discussed to help us understand the important role of use context. In addition, the interaction of each stage of purchase in m-commerce was discussed to understand the importance of con-

sumers' participation. Especially in retail industry, consumers have more and more interaction with the retailers and their behaviors are changing. The factors we proposed in this paper are rarely mentioned in the previous studies.

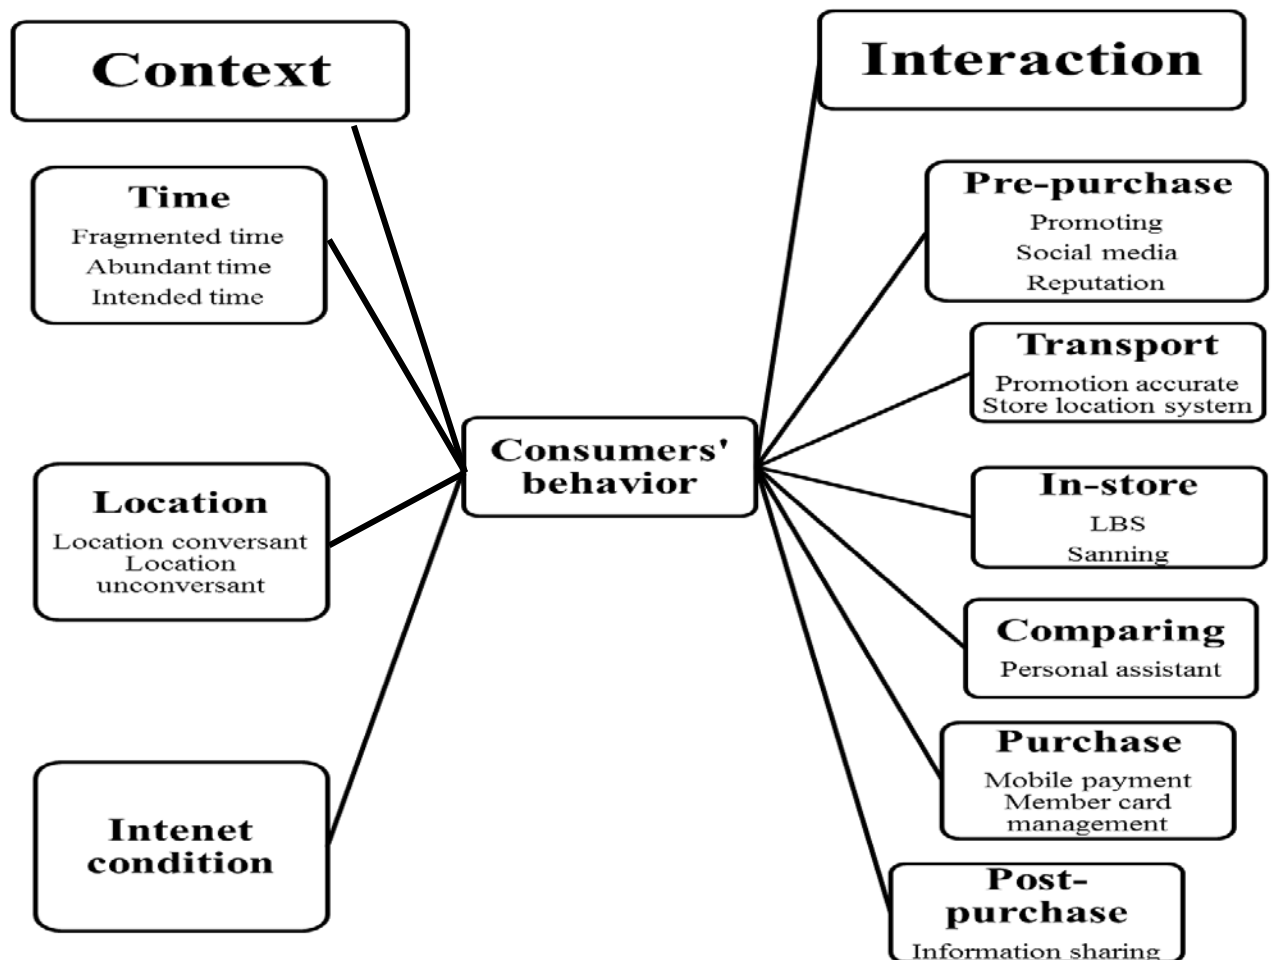

## 5.2. Managerial implications

Retail industry is facing the increasing competition from E-commerce, retailers are looking to M-service as an innovative way to adapt the changing behavior of their customers and make them satisfied. This study proposed the new factors which could influence the consumers' behavior, managers could use them to design the m-service easier to use.

## 5.3. Limitations and future research

The research on the context and interaction are really rare in the past, so we can't find enough back theory to support our model. Most of papers focus on the acceptance of m-commerce, but not the factors influence the consumers' behavior. Especially, this study focuses on the retail industry which is also new for the concept. The number of participants for the interview is also low.

Figure 1. The conceptual model of consumers' behavior in m-commerce of retail industry

<sup>1</sup>University of Brasília

*This paper reviews the literature of coproduction and co-creation of value published over the last 32 years (1983-2015) through the examination of 451 selected research articles. By using a content analysis, it provides a set of seven thematic categories, which are tested on a Multiple Correspondence Analysis – MCA, in order to investigate the relationships between the subfields of coproduction and co-creation of value. We highlight other descriptive analyses such as top publishing authors and most cited papers. A discussion of possible pathways for future studies is also provided.*

## 1. Introduction

The objective of this paper is to systematically review and summarize the scientific production about co-creation of value and coproduction over the last 32 years (1983-2015). Through the analyses performed on this paper, we seek to map the evolution of this field of study, describing its main characteristics and themes researched within it. The present work aims at not only assessing and contributing to the understanding of the structure and trajectory of the content of this literature, but also point out conjectures about future developments on the field and tendencies for upcoming researches.

One of the first papers to discuss the concept of coproduction is the work of Brudney and England (1983), which focus on defining this construct in the lenses of the public services. Since then, many other authors gave contributions to this research field, defining and testing the coproduction construct in many sectors and types of organizations, deepening the understanding of its most efficient practices and the results it may bring to organizations and customers alike. In this time, the concept of co-creation of value, as discussed, for example, in the papers by Prahalad and Ramaswamy (2004) and Vargo and Lusch (2004), began its diffusion through many publications, sometimes proposed as a synonym for coproduction, sometimes as a different construct altogether. Either way, both these concepts represent a great area of interest to marketing, services, and many other areas, and an analysis of their literature structure may help provide future researchers with a direction to further the knowledge on this field.

After 32 years of publications, we ask where this research field of coproduction and co-creation of value stands. To answer this question, we propose the analysis of the structure of the field, describing the main journals, countries and authors who published in the last three decades, while also observing the distribution of publications

through time and the impact of the papers. Complementary, we attempt to organize all selected articles into thematic categories, and analyse the relations between these categories, in order to identify the main streams of research in coproduction and co-creation of value.

To perform the proposed analyses, this paper is structured as follows. After this introductory section, we present a brief overview of the development of coproduction and co-creation of value, followed by a description of the methods employed in this study. We present, in the methods section, a detailed description of the coding procedures, showing the paths taken to create the seven thematic categories for the frequent researched streams on coproduction and co-creation of value. The analysis of the literature, presented after, allow an evaluation of the structure and suggests trends for the research field. Finally, in the last session, we present suggestions for a research agenda from the gaps observed through the analysis.

## **2. Coproduction and co-creation of value: an overview of the research field**

In order to understand and discuss the future of research in coproduction and co-creation of value, it is important to, initially, understand the origins and evolutions in the development of this field. In the beginning, the studies of coproduction focused mainly on the public sector and on citizen participation on the service delivery. Due to the increasing pressure for the government to provide more and better public services, the first studies saw coproduction as a way to raise the quality and efficiency of public services, by looking at the citizens as agents of change and not merely as consumers (Brudney; England, 1983; Schneider, 1987; Neiman, 1989). The realization that some public services can only be delivered in coproduction with citizens also contributed to the development of this field of study (Powers; Thompson, 1994). Brudney and England (1983, 63) defined coproduction as “the degree of overlap between regular producers and consumers”, that is, the degree of overlap determines the type and results of the coproduction. The coproduction concept also proved valuable to increase technology and knowledge transfer between countries and increase the possibilities of growth for developing countries (Quintana, 1984). It was only in the 2000s that coproduction research started to focus more on the private sector.

The growing pressure on firms and marketing diversification promoted a shift from segmented marketing towards a more customer-centric marketing (Sheth *et al.*, 2000; Prahalad; Ramaswamy, 2004). The co-creation concept gained strength as a result of this new marketing approach, which focus on intangible resources, relationships and increasing the value perceived by the customers (Prahalad; Ramaswamy, 2004; Vargo; Lusch, 2004). The integration of resources and complementary competences and the interaction between producers and consumers add value to a service, so both parties benefit from the relationship by co-creating value (Prahalad; Ramaswamy, 2004; Vargo *et al.*, 2008). Co-creation brings the focus mainly to an interaction between consumer and company as the locus of value creation, and this new approach implies that all the points of this interaction are critical to the creation of value (Prahalad; Ramaswamy, 2004). The concept of value co-creation shifts the focus from the output delivered and the value in-exchange toward value-in use, having knowledge as crucial resource (Vargo; Lusch, 2006; Vargo *et al.*, 2008).

Although sometimes the difference between these two concepts seems blurry, some authors assume that coproduction happens within the production process and that co-creation of value happens during the consumption phase (Lusch; Vargo, 2006; Etgar, 2008; Bacile; Goldsmith, 2011). Vargo (2008) and Ertimur and Venkatesh (2010) view coproduction as the activities executed jointly by the firm and the customer to create an output while co-creation of value focus specifically on the value creation to the customer, thus being aligned with value-in-use. To Vargo (2008), the two concepts are not opposites, but hypernymic, that is, coproduction is a part of the co-creation of value. Unlike the engagement of the customer in coproduction of the service, which is optional, the co-creation of value is not (Vargo; Lusch, 2008), and it cannot occur without customer participation (Vargo, 2008). Even with these attempts to differentiate co-creation and coproduction, some authors, such as Needham (2008), Payne *et al.* (2008), Alexander *et al.* (2009) and Lang *et al.* (2009), choose not to distinguish between the two concepts, considering both of them important to increase the quality and quantity of the services provided. Since co-creation, as well as coproduction provide better results for the organizations and the customers and complement each other, this paper does not distinguish between the two approaches and considers both concepts as one field of study.

Over the last couple of years, studies have explored broader aspects of coproduction and co-creation of value, for example co-creation involving the government, private industries and the citizens to increase sustainability (Trencher *et al.*, 2014) and co-creation of value with stakeholders in order to gain competitive advantage (Goulliart, 2014). Jaakkola and Alexander (2014) investigated the role of customer engagement behavior in value co-creation and the influence it might have on the firm through a case study in a public organization. Recent papers also focused on ecosystems of service exchange (Vargo *et al.*, 2015), the different characteristics that drives a citizen to engage in collective or individual coproduction and how the government can increase the collective coproduction (Bovaird *et al.* 2015) and also recognized that innovations is always a co-creational process (Akaka; Vargo, 2013; Vargo *et al.*, 2015).

### **3. Method**

Considering the main goal of this paper – to systematically review and summarize the scientific production about co-creation of value and coproduction over the last 32 years – the first step was assembling a database of articles published on these themes. In order to build such database, we consulted the following multiple research directories: Annual Reviews, Oxford Journals, Cambridge Journals Online, SpringerLink, JSTOR Arts & Sciences III Collection, Academic Search Premier, Directory of Open Access Journals, Sage, ScienceDirect and Emerald Insight. The search option of directories over journals was taken to prevent a journal from being privileged over another in selection procedures, seen that all journals gathered in directories had the same chance of appearing in the research. In addition, since the present paper intends to show the level of diffusion of individual papers according to their citations, we chose not to adopt journals' impact factor as a selection criteria. With the directories list, the next step was the definition of keywords to be used during the search phase. Two terms, and their variations, were chosen: “coproduction” or “co-production”, and “co-creation” or “cocreation”. The search mechanisms were programmed, whenever possible, to search only in titles, abstracts and keywords. In this way, we

limited our results only to articles that had coproduction or co-creation of value as one of their main subjects. A subsequent selection was performed adopting the following discard criteria: a) every paper duplicity was eliminated; b) papers that only mentioned the words coproduction or co-creation were discarded, in order to keep only articles that discussed, tested or mapped these subjects. It is important to notice that we chose not to use year of publication as a search or discard criteria, but in press papers at the moment of the search procedure, which was executed on March 2015, were not considered. With the application of these search and discard criteria, we were able to build a database consisted of 451 papers published between 1983 and 2015.

The following information were extracted from each selected article: journal of publication, year of publication, title, authors, authors' countries, keywords and number of received citations. Statistical analyses were then carried out on these data to achieve the desired results of the present paper. Thus, nine main outputs will be presented in the following sections: categories of keywords after coding, number of articles per category, top publishing journals, top publishing authors, top publishing countries, top cited articles, number of articles published per year, number of published papers per category per year and a Multiple Correspondence Analysis of the categories.

### 3.1. Coding

The coding procedures performed, aligned with the coding method described by Furrer *et al.* (2008), had the objective of building categories representing the main themes discussed in the selected articles. These procedures took into account the original keywords assigned by the authors to their papers. A few of the selected articles had no original keywords assigned and, in those cases, the author of the present paper assigned, individually, keywords base on the title and abstracts of the articles. These new keywords were then triangulated among the authors in order to arrive at a final list of keywords for all articles selected. This set of keywords was converted into one major list composed of 1383 keywords. Three elimination criteria were employed on this list. First, all keywords with only one appearance on the list (1123 of 1383, 81,2%) were eliminated, seen that they were not representative of main themes of research and unhelpful to the creation of categories. Second, we eliminated terms representing pleonasms of the research topic itself, such as “co-creation”, the keyword with highest frequency at 81 appearances, and “value co-creation”, with 78 appearances. Additional terms such as “service” were discarded for the same reason. Third, terms representing countries or research methods were also eliminated, since our purpose was not to identify methodological approaches, but major themes researched on the subjects. Some of the terms discarded in this third criterion were “case study”, “action research” and “methodology”. After all eliminations, the final list of keywords used for categorization was composed of 166 terms.

These 166 unique terms were grouped by iteratively sorting the individual keywords and reorganizing them into coherent categories through content analysis and coding (Bardin, 2006; Flick, 2009). After several rounds of discussion, seven thematic categories were generated, and each unique keyword was assigned to only one category. When it the categorization of a unique keyword was unclear, either because it

could fit on more than one category at the same time or because the authors classified that keyword on different, the papers listing that keyword were analysed with more depth in order to determine the correct category to which assign that keyword. Table 1 shows every original keyword placed in the seven categories created.

| Category            | Original Keywords  |
|---------------------|--|
| Innovation          | innovation; service innovation; creativity; user innovation; new product development; collaborative innovation; idea generation; innovations; open innovation; product innovation  |
| Public Sector       | public services; citizen participation; e-government; local government; citizen coproduction; citizenship; citizenship behavior; customer citizenship behavior; public officials; public policy; public sector; public sector organisations; public sector organizations; state-society relations; community; third sector   |
| Marketing           | marketing; relationship marketing; marketing strategy; services marketing; industrial marketing; social marketing; branding; brands; service marketing; brand management; brand value; brand; brand community; consumer marketing; corporate branding; experiential marketing; marketing theory; identity; market orientation; markets   |
| Customers           | customers; consumer behaviour; customer participation; customer value; customer service management; customer services quality; customer engagement; customer involvement; customer satisfaction; customer co-creation; customer experience; customer integration; customer relationship management; experience; loyalty; customer loyalty; customer orientation; customer relations; consumers; customer; consumer; consumer co-creation; consumer engagement; consumer experience; customer centricity; consumer resistance; consumer work; customer co-production; customer cocreation; customer information; customer roles; customer value co-creation; prosumer; presumption; user involvement; empowerment; satisfaction; well-being; older people; exploitation; football fans; free labor; self-efficacy; attitudes; choice; double exploitation |
| Value               | value; value creation; value-in-use; value analysis; value networks; value proposition; value chain; value propositions; value co-destruction; value-in-context; value-in-exchange; values   |
| ICTs                | social media; technology; web 2.0; online communities; communication technologies; information technology; online community; new media; big data; internet; social networks; simulation  |
| Business & Strategy | strategy; competitive advantage; governance; knowledge management; supply chain management; corporate strategy; business development; business model; business service; capabilities; decision making; decision support systems; distribution management; knowledge; knowledge transfer; leadership development; organizational learning; organizational socialization; performance; sustainability; learning; networking; partnership; crowdsourcing; stakeholders; communication; learning organizations; network; networks; organizational performance; outsourcing; absorptive capacity;   |

|  |   |
|--|---|
|  | crowd-funding; entrepreneurialism; environment; ethical economy; institutional arrangements; institutions; resource efficiency; social capital; stakeholder; stakeholder analysis; working practices; intermediaries; learning methods; participatory cultures; suppliers; structuration theory; systems theory; buyer-supplier relationships |
|--|---|

Table 1. Thematic categories and their original keywords

As pointed out by Furrer *et al.* (2008), previous studies of articles' production have generally classified papers in only one primary category (Helgeson *et al.*, 1984; Yale; Gilly, 1988; Bingham; Bowen, 1994), but, according to Inkpen and Beamish (1994), using a single category fails to acknowledge the cross-functional and interdisciplinary nature of an academic field, in their case, strategic management. Considering that co-creation of value and coproduction are, such as strategic management, cross-functional fields, no limits were set on the number of categories per article, being possible to one paper to fit into one unique category, or be allocated across two or more categories of keywords. This explains why the total percent on the third column in Table 2 is higher than 100%. Among the 451 articles, 129 (28.6%) were allocated into only one category, 171 (37.9%) into two, 107 (23.7%) into three, 28 (6.2%) into four, 13 (2.9%) into five, and 3 (0.7%) into six categories. The overall mean was 2.2 categories per article. Table 2 presents the number of articles per category.

| Category            | No. of articles | %     | Adjusted % |
|---------------------|-----------------|-------|------------|
| Business & Strategy | 252             | 55.9  | 25.5       |
| Customers           | 228             | 50.6  | 23.1       |
| Value               | 180             | 39.9  | 18.2       |
| Marketing           | 97              | 21.5  | 9.8        |
| Innovation          | 90              | 20.0  | 9.1        |
| Public Sector       | 70              | 15.5  | 7.1        |
| ICTs                | 70              | 15.5  | 7.1        |
| Total               | 987             | 218.8 | 100.0      |

Table 2. Number of articles per category

## 4. Analysis

By analysing the frequency distribution of papers among publishing journals on the selected databases, we found that 172 different journals published articles on the themes searched. Of this total, 105 were journals with only one paper published in the period, representing 23,3% of all selected papers; 45 journals had two, three or four publications, summing 25,3% of the total production; 15 journals had between five and eleven paper published, which represents 23,7% of the articles selected; and 7 journals had 12 or more publications on the period, adding up to 27,7% of all papers published on the period. This data underscore that roughly half of the total production of papers on the period researches was concentrated on 22 out of 172

journals. Many of these top publishing journals are focused on the publication of papers in the service or marketing fields, which can be viewed, due to this concentration of publications, as possibly the two main areas of knowledge with an interest on studies about coproduction and co-creation of value. The list of top publishing journals is presented on Table 3.

| Journal   | Freq. | %   | Cumulative % |
|---|-------|-----|--------------|
| Journal of Service Management   | 27    | 6.0 | 6.0          |
| Industrial Marketing Management                                       | 22    | 4.9 | 10.9         |
| Journal of the Academy of Marketing Science                           | 18    | 4.0 | 14.9         |
| Journal of Service Research   | 17    | 3.8 | 18.6         |
| Marketing Theory  | 17    | 3.8 | 22.4         |
| European Journal of Marketing   | 12    | 2.7 | 25.1         |
| International Journal of Quality and Service Sciences                 | 12    | 2.7 | 27.7         |
| Journal of Business Research  | 11    | 2.4 | 30.2         |
| Strategy & Leadership   | 10    | 2.2 | 32.4         |
| Australasian Marketing Journal  | 9     | 2.0 | 34.4         |
| European Management Journal   | 8     | 1.8 | 36.1         |
| International Journal of Physical Distribution & Logistics Management | 8     | 1.8 | 37.9         |
| Managing Service Quality  | 8     | 1.8 | 39.7         |
| Journal of Services Marketing   | 7     | 1.6 | 41.2         |
| Voluntas  | 7     | 1.6 | 42.8         |
| European Business Review  | 6     | 1.3 | 44.1         |
| Journal of Interactive Marketing                                      | 6     | 1.3 | 45.5         |
| Journal of Macromarketing   | 6     | 1.3 | 46.8         |
| Tourism Management  | 6     | 1.3 | 48.1         |
| Business Horizons   | 5     | 1.1 | 49.2         |
| Journal of Business & Industrial Marketing                            | 5     | 1.1 | 50.3         |
| Marketing Intelligence & Planning                                     | 5     | 1.1 | 51.4         |

Table 3. Top publishing journals

We also investigated the frequency in which each author published and calculated the absolute and adjusted frequencies of their appearances on the database. The number of adjusted appearances reflects multiple authored articles, that is, if a paper has two authors, each one received half a point. In the case of three authors, each one received a third of a point and so on. The 451 articles on the database were published by 915 different authors. Of this total, 795 were listed in only one paper, and 89 were listed on two. This means that only 31 authors, representing 3.4% of all authors, had three or more appearances on the database. This data indicates that only small percentage of authors are consistently publishing studies on coproduction and co-creation and, as pointed out by other review authors, these key individuals are one of the most important factors to a field's structure and growth, and through their work it is possible to better understand the past evolution of a field and its likely future directions. 20.18% of the articles were single authored, 35.92% had 2 authors, 28.6% had 3 authors, 10.64% had 4 authors, 2.66% had 5 authors, 1.33% had 6 au-

thors, 0.22% had 7 authors, and 0.44% had 8 authors. The top five publishing authors in terms of adjusted appearances were: Bo Edvardsson, Stephen L. Vargo, Venkat Ramaswamy, Robert F. Lusch and Christian Grönroos. Table 4 provides a list of the 18 most published authors ranked by adjusted appearances.

| Author               | Total Appearances | Adjusted Appearances |
|----------------------|-------------------|----------------------|
| Bo Edvardsson        | 15                | 11.25                |
| Stephen L. Vargo     | 13                | 9.17                 |
| Venkat Ramaswamy     | 7                 | 6.0                  |
| Robert F. Lusch      | 7                 | 5.5                  |
| Christian Grönroos   | 4                 | 4.0                  |
| Bernard Cova         | 4                 | 3.5                  |
| Per Kristensson      | 5                 | 3.0                  |
| Kaj Storbacka        | 5                 | 3.0                  |
| Elina Jaakkola       | 4                 | 3.0                  |
| Paul P. Maglio       | 4                 | 3.0                  |
| Robert C. Ford       | 3                 | 3.0                  |
| Tronvoll, Bard       | 7                 | 2.92                 |
| Adrian F. Payne      | 4                 | 2.7                  |
| Pennie Frow          | 4                 | 2.67                 |
| Jennifer D. Chandler | 3                 | 2.5                  |
| Taru Hakanen         | 3                 | 2.5                  |
| Andrea Ordanini      | 3                 | 2.5                  |
| Thorsten Roser       | 3                 | 2.5                  |

Table 4. Top publishing authors

Although there is some difference in the ranking when considering the appearances of authors before and after adjustment, we found that they are highly correlated. For the top 18 authors listed on Table 4, the Spearman correlation between total and adjusted appearances is 0.783, and the Pearson correlation equals 0.955. When considering all 915 authors, Spearman correlation equals 0.435 and Pearson correlation equals 0.862. These coefficients indicate a strong linear relationship between total and adjusted appearances.

Beyond the top publishing authors, it is important to identify what are the most influential articles published in the period, seeing that publications with seminal roles are accelerating factors to the development of a field (Berry; Parasuraman, 1993). Although the generally accepted method to define and measure the influence or impact of an article is the summed citation counts (Tahai; Meyer, 1999; Ramos-Rodriguez; Ruiz-Navarro, 2004; Bergh *et al.*, 2006), we decided to rank the articles by the number of citations divided by the number of years since the publication. This decision was made because a paper published in early years has a bigger chance to have more citations than a paper published in a later period and, in using an adjusted index, the number of citations is better balanced.

| Article                    | Total Citations | Citations per Year |
|----------------------------|-----------------|--------------------|
| Vargo and Lusch (2004)     | 6573            | 597.5              |
| Payne <i>et al.</i> (2008) | 1122            | 160.3              |

|                               |      |       |
|-------------------------------|------|-------|
| Vargo <i>et al.</i> (2008)    | 1017 | 145.3 |
| Prahalad and Ramaswamy (2004) | 1578 | 143.5 |
| Ostrom <i>et al.</i> (2010)   | 531  | 106.2 |
| Gröonroos and Voima (2013)    | 196  | 98    |
| Brodie <i>et al.</i> (2013)   | 191  | 95.5  |
| Lusch and Vargo (2006)        | 830  | 92.2  |
| Vargo and Lusch (2011)        | 343  | 85.8  |
| Maglio and Spohrer (2008)     | 593  | 84.7  |

Table 5. Top cited articles

Furthermore, this study considered the countries of the institutions each author was associated when their article was published. As with the appearances of authors, both the total and adjusted frequencies of countries' appearances were calculated. The 915 authors published from 43 different countries. The top 5 countries in terms of both total and adjusted appearances were: United States of America, United Kingdom, Sweden, Australia and Finland. Table 6 provides a list of the 18 countries with most published articles.

| Country     | Total Appearances | Adjusted Appearances |
|-------------|-------------------|----------------------|
| USA         | 256               | 169.45               |
| UK          | 177               | 112.32               |
| Sweden      | 97                | 60.43                |
| Australia   | 83                | 52.23                |
| Finland     | 66                | 47.17                |

Table 6. Top publishing countries

As it was the case in the top publishing authors, we found that total and adjusted appearances for countries are highly correlated. For the top 18 countries listed on Table 6, the Spearman correlation between total and adjusted appearances is 0.983, and the Pearson correlation equals 0.999. When considering all 43 countries, Spearman correlation equals 0.992 and Pearson correlation equals 0.999, once again indicating a strong linear relationship between total and adjusted appearances.

An analysis performed to help elucidate how this field of study is developing is the distribution of papers published along the years. The 451 articles selected to the

present study were published from 1983 to 2015. The search for the articles did not consider any initial date, and the first article selected was published in 1983. This shows that this field is being studied for over 30 years. Nonetheless, the distribution of articles is not even over time. The early years of this interval recorded a very low incidence of articles. Until 2003, only 5,1% of the selected papers had been published and only 21,7% until 2009. Also, there were no articles selected during 6 of the first 19 years. These data show that, although this research field is over three decades old, it is still developing, with a steady growth in the number of publications since 2010. Table 7 presents the distribution of articles published by year.

| Year               | Freq. | %    | Cumulative % |
|--------------------|-------|------|--------------|
| 1983               | 1     | 0.2  | 0.2          |
| 1984               | 1     | 0.2  | 0.4          |
| 1985               | 0     | 0.0  | 0.4          |
| 1986               | 0     | 0.0  | 0.4          |
| 1987               | 1     | 0.2  | 0.7          |
| 1988               | 1     | 0.2  | 0.9          |
| 1989               | 2     | 0.4  | 1.3          |
| 1990               | 0     | 0.0  | 1.3          |
| 1991               | 1     | 0.2  | 1.6          |
| 1992               | 1     | 0.2  | 1.8          |
| 1993               | 1     | 0.2  | 2.0          |
| 1994               | 2     | 0.4  | 2.4          |
| 1995               | 0     | 0.0  | 2.4          |

Table 7. Articles published by year

To explore the connections among categories we decided to employ a MCA. A Correspondence Analysis (CA) is a compositional method to a perceptual mapping that is based on variables of a contingency table. The results portray these variables in a common visual representation. A Multiple Correspondence Analysis (MCA) is a form of CA that involves three or more variables related in a common perceptual space (Hair *et al.*, 2009). MCA allows the researcher to explore multi-way tables in order to detect structure in the relationships between variables, showing which rows and columns of a frequency table have similar patterns of counts (Furrer *et al.*, 2008). In this study, the rows and columns of the frequency table are composed by a binary rating, 1 for yes and 0 for no, expressing if each article fits into each of the seven categories or not.

Before proceeding with the MCA, the optimal number of dimensions of the perceptual map have to be selected. To this end, we calculated the eigenvalues, also known as singular values, which are derived for each dimensions and indicate the contribution of each dimension explaining the variance in the categories (Hair *et al.*, 2009). The scores of the eigenvalues calculated were: 0.036, 0.029, 0.022, 0.021, 0.018, 0.014 and 0.009. Since there is no evident break on these values, we chose to perform the MCA with two dimensions for the graphical data representation, as it was done by Furrer *et al.* (2008) and Moreira *et al.* (2014).

The interpretation of the results of an MCA is based on the proximity of the variables on the perceptual map. If two variables have similar patterns of counts in their frequency tables, they will appear next to each other. If the correlation between these variables in the data sample is lower, they will appear further away (Bendixen, 1995). This means that, if two categories are close to each other, that is because a large proportion of articles fit on both of them together, if they are distant from each other, then a small proportional of articles discuss both themes at the same time. Figure 1 presents the general MCA for our data. The categories are represented by the circles, and the size of each circle is proportional to the number of articles associated to that category.

Figure 1. Multiple Correspondence Analysis of the selected articles

A couple main interpretations arise from this MCA. First, there are two isolated categories, Value and Public Sector, meaning that these two themes are often researched on their own. A second is the area with condensed categories. This area, composed by Marketing, ICTs, Customers, Innovation and Business & Strategy, which is slightly further away, suggests that these themes are often researched together. The Customers category seems to be the link between many of these themes, which can be possibly due to the large amount of articles in this category. Business & Strategy, the category with the largest number of articles, on the other hand seems mostly connected to Innovation and Customers studies, but not with Marketing and ICTs which are more closely related to the Customers theme.

Although the distance between categories on the perceptual map may suggest a research gap, a deeper discussion of the value of adding themes together is needed in order to indicate possibilities for future studies. For example, Public Sector and Customers have low correlation, represented by their distance on the MCA. This means that these two themes were rarely combined in previous researches, which, from a pure technical first analysis may indicate a coherent gap for future studies. Nevertheless, it may not necessarily represent a theoretical relevant gap, meaning that a study combining these two themes will present a certain level of novelty, but may not offer a contribution to the advancement of theories concerning co-creation of value and coproduction.

## 5. Conclusions

The present paper is an effort to map the structure and evolution of the co-creation of value and coproduction field of study over the last 32 years (1983-2015). Through a systematic review of the literature produced on this period, we were able to select 451 papers, organize them into seven thematic categories, provide a list of descriptive analyses about the scientific production researched, and discuss the relationship between the many themes and streams of research within the field of co-creation of value and coproduction.

Although this field is over three decades old, we observed that 78.3% of all the scientific production analysed was concentrated in the 2010-2015 period. This suggests that, despite the fact of being a field of study for about 32 years, recent years have seen a considerable growth in academic interest, which means that this field still presents, and maybe more than any other period in time, many opportunities for further studies.

Within the results presented in this paper, a few research gaps can be pointed out. Starting with the incidence of categories in the selected articles, we observed that the most used theme are Business & Strategy and Customers, both appearing in over half the papers considered in this study. This could be explained by the very nature of the co-creation of value and coproduction field. The Business & Strategy theme represents, through many of its keywords, the objectives and results expected and obtained through the adoption of practices for coproduction and co-creation of value. In a similar way, Customers presents part of the equation of what forms a coproduction and co-creation of value. In this sense, it is expected that these categories would

be the most used when analysing the published articles in this field. On the other end of this spectrum, we have Public Sector and ICTs, both represented in 15.5% of the 451 articles selected. In this first level of analysis we can suggest the need for more studies on these two categories, seeing that they are still not as representative as the others.

Considering the results obtained through the MCA, a few other recommendations can be made. As in the other analyses, the Public Sector theme appears as a possible camp for studies, seen that it is the most isolated category. This means that studies in this theme are not usually combined with the other categories. Future researches could explore the relations of Public Sector with other themes such as Innovation and ICTs. Value also appears as an isolated theme, and the same recommendation made for Public Sector can be made in this case. The MCA also points that, besides being one of the most used and highest growing themes, Costumers is the link between many other themes. Once again, the nature of co-creation of value and coproduction could explain the highlight on this category. Nevertheless, future studies may use the Costumers theme in order to explore and better understand isolated or less used categories.

The gaps and indications for a research agenda presented in this study certainly do not cover every research gap in the co-creation of value and coproduction field, but it may give a direction for future discussions concerning the next years of scientific production in this area. This paper's limitations include the directories and criteria chosen for the search procedures, which may have left part of the production in the field out of the study. Another limitation concerns the criteria of categorization of keywords, seen that other procedures could be adopted in order to arrive at a different set of themes. It is recommended, in future reviews, the use of additional databases of articles as an attempt to collect more papers related to this field of study, as well as a revision of the categories proposed.

# Exploring the features of customer value co-creation in health care: literature review

*Liudmila Bagdoniene, Neringa Langviniene*

<sup>1</sup>Kaunas University of Technology

*Nowadays a patient is more often named as consumer of health care services by considering his / her changed role in the process of services rendering. The concept of a patient as value co-creator obligates health care organizations to change principles of their activity and employees' mentality. Referring to scientific literature of marketing, management, health care and medical, the paper analyses the features of customer value co-creation in health care.*

## Introduction

Value co-creation has gained the attention of academicians and practitioners as an overarching concept that describes collaboration among multiple actors (Ranjan; Read, 2014). Nowadays various industries become a context of co-creation's researches: IT sector (Stucky et al., 2011; Vartiainen; Tuunanen, 2013); public services (Alves, 2013); tourism (Rihova et al., 2014); financial services (Chan et al., 2010); universities (Díaz-Méndez; Gummesson, 2012); SMEs sector (Ngugi et al., 2010), etc. Besides, many researchers focus on the different aspects of co-creation: customer motives, involvement and engagement in value co-creation (Füller, 2010; Kristensson et al., 2008; Jaakkola; Aleksander, 2015), recovery strategy (Roggeveen et al., 2012); service innovation (Perks et al., 2012); consumer experience (Kelleher; Peppard, 2011), etc.

But value co-creation in health care is in its infancy and raises a number of questions: whether value co-creation result merely from interactions between the physician and the patient (Osei-Frimpong et al., 2015); what health customers think and feel about collaborating with health care providers in co-creating value (Zainuddin et al., 2011); how to create supportive organizational culture towards patient participation, what its component is and how it manifests (Sharma et al., 2014). Thus these as well as other questions concerning the customer value co-creation in health care should be answered.

Nowadays patients are frequently considered as consumers of health care. More and more they take responsibility for the decisions about their health and want to work with health care providers as collaborators (Chewning et al., 2012). To be co-creators of health, patients ought to be supported for this new role and health care providers must adjust their worldview as they become true health care partners (Lorig, 2002). But the patients cannot be active contributors of health care services if supporting processes, methods and tools that enable the co-creation are missed or not suitably elaborated (Elg et al., 2012; Stiggelbout et al., 2012). Hence, value co-creation success requires the changes in attitudes and behaviour both of customers (patients) and health services providers (Cayton, 2006).

The objective of this paper is based on literature review to reveal the features of customer value co-creation in health care. The paper is structured in the following way. In the first section, the brief reconsideration of customer value co-creation is presented. In the second section, the typical features of customer value co-creation in health care are discussed. Finally, some lines for further studies in customer value co-creation in health care are outlined. For preparing this paper the marketing, management as well as health care and medical literature were examined.

## 1. Conceptualizing the value co-creation

In modern economy the companies have to continuously reinvent themselves in order to adapt to complex and dynamic business environment. The conventional point of view on exchange is being superseded by new forms of interaction. Regarding this point of view, the involvement of the customer in value co-creation is considered and featured as prerequisite for becoming and remaining competitive (Saarijärvi et al., 2013). From co-creation perspective, service providers and customers are no longer on opposite sides, but interacting reciprocity for the development of new business opportunities. It means the mode by which value is created, distributed, paid for, and exploited differs meaningfully from the traditional demand vs supply model (Galvagno; Dalli, 2014). Consequently, the value co-creation is becoming a main concept within different businesses, especially in service business in which market offerings are actually created in the service encounter. How value co-creation phenomenon is defined by different researchers is presented in Table 1.

| Definition of value co-creation   | Author(s)                   |
|---|-----------------------------|
| Value co-creation is a business paradigm describing how customers could be involved as active participants in the design and development of personalized products, services, and experiences  | Prahalad; Ramaswamy, 2004a  |
| Co-creation is more than co-marketing or engaging consumers as co-sales agents. It's about developing methods to attain a visceral understanding of co-creation experiences so that companies can co-shape consumer expectations and experiences along with their customers | Prahalad; Ramaswamy, 2004b  |
| Co-creation is an experience-oriented concept which focuses on the interaction between the firm and the customer  | Ramaswamy; Gouillart, 2010; |
| Co-creation is the process by which mutual value is expanded together, where value to participating individuals is a function of their experiences, both their engagement experiences on the platform, and productive and meaningful human experiences that result          | Ramaswamy, 2011;            |
| Value co-creation is a function of direct interaction between customers and providers   | Grönroos; Voima, 2013       |
| Co-creation is an interactive, creative and social process between stakeholders that is initiated by the firm at different stages of the value creation   | Roser et al, 2013           |
| Value co-creation means that consumers come together with suppliers, service providers or others consumers to generate benefits realized by the user in consumption process   | Loane et al, 2014           |
| Co-creation is the joint, collaborative, concurrent, peer-like process of producing new value, both materially and symbolically   | Galvagno; Dalli, 2014       |

Table1. Definitions of value co-creation

Starting point for value co-creation is motivation of involved actors, primarily, of the company and customer. The motivators can be financial, social, technical, and psychological (Hoyer et al, 2010). According to DeFillipi; Roser (2014), for the company, the customer co-creation can provide increased speed to market; lower risk of market failure; better communication of customer needs and interests; higher rates of positive word-of-mouth recommendation; increased adaptability of company business model; early identification of weak signals in the marketplace; better focus on customer experience and journey; focus on value creation, rather than offering technological solutions. Terblanche (2014) maintains that the value co-creation affects the company's ability to supply personalised services using customer input for development better the value propositions, influence positive customer experiences, higher customer engagement, improved customer loyalty, higher customer satisfaction, competencies of employees, higher employee involvement, improved employee loyalty, feedback and learning loops, enhanced profitability (Chathoth et al., 2014). Engaged in co-creation companies are more successful in creating innovations, increase the business reputation and organizational capabilities (Weber; Van der Laan, 2014). Frow et al. (2015) as company's motives for value co-creation indicate access to resources, enhance customer experience, create customer commitment, enable self-service, create more competitive offerings, decrease cost, faster time to market, and emergent strategy and build brand awareness. Hence, we can conclude that companies may experience many benefits from value co-creation. As customers' motives to enter to value co-creation process, Füller (2010) names the differences of their personalities. He distinguishes the customers who are reward oriented, need driven, intrinsically interested, and curiosity driven. Nonetheless, knowing of the co-creation motives from the perspective of the company as well as customer is still scarce (Payne et al., 2008; Dabholkar; Sheng, 2011; Frow et al., 2015).

The value co-creation involves at least two actors/participants/stakeholders. Frow et al. (2015) denote five groups of actors: customers, suppliers/providers, partners, competitors, and influencers (for example, media, government and regulatory bodies). Despite multiplicity of actors, the customer is stated as main subject of value co-creation (Bharti et al., 2014). The co-creation necessitates to view the relationship between the provider and the customer as a continual, dynamic, interactive set of experiences and activities performed by the provider and the customer, within a context, using tools and practices that are partly overt and deliberate, and partly based on routine and unconscious behaviour (Payne et al., 2008).

As process the value co-creation encompasses three important parts: (1) customer value creating processes, (2) provider value creating processes, and (3) encounter processes (Payne et al., 2008). The customers are more and more seen as an important creative, knowledgeable, and motivated resource for firms that can be involved in value co-creation with the company (Saarijärvi et al., 2013; Aggarwal; Basu, 2014). The customer's value creating process is a series of activities aiming to achieve a particular his/her goal or help to develop the provided service (value co-creation *in use* and value co-creation *for others*). Customer activities should be considered as the starting point for introducing the co-creation concept as well as everyday customer practices (Tregua et al., 2015). During the value co-creation the customers undertake different activities that create value in their own right or are instrumental in achieving value later on by playing designer, manufacturer, chooser, order processor, negotiator, payer, consumer/user, quality controller, maintainer, repairer roles (Hibbert et al., 2012); customers act as the feelers, doers, and thinkers

(Arnoud; Thompson, 2005). The execution of customers' roles in value co-creation directs towards their better quality of life (McColl-Kennedy et al., 2012); however, customers must learn to use, maintain, repair, and adapt the provider's offering to their individual needs, usage situations and behaviours (Vargo; Lusch, 2004).

From the company's perspective, the value co-creation begins at the understanding of the customer's value creating processes. The role of service provider's is to facilitate value creation and take part in the value creating process as value facilitators (Grönroos, 2008). Payne et al. (2008) state that the processes that maintain the value co-creation involve: (1) a review of co-creation opportunities; (2) planning, testing and prototyping value co-creation opportunities with customers; (3) implementing customer solutions and managing customer encounters; and (4) developing metrics to assess whether the company is making appropriate value propositions. The value co-creation's opportunities are strategic options for creating value and vary on the nature of service industry, customer offerings and customer base. The opportunities for value co-creation create technological breakthroughs (e. g., digital TV, fourth generation mobile services), transformations in service industry logics (e.g., new channels for reaching customers) and changes in customer preferences as well as lifestyles (e.g., a trend toward greater individuality that influences the customers' wishes to co-create more individualized services). Planning is the next value co-creation's support process; it starts from an understanding how customers co-create the value and requires changing the dominant logic from "making, selling, and servicing" to "listening, customizing, and co-creating" (Payne et al, 2008). Further process is prototyping. The prototypes help to expand existing alternatives, realize future ones and refuse those that are not marketable. The companies usually make the prototypes of environments, encounters, and content. The elaboration of co-creation metrics is the next step in provider value creating processes. According to Payne; Frow (2005), the metrics that providers use to measure the performance of their customer relationships is not well developed. Moreover, the metrics encompass the processes; function and channel should be elaborated (Payne et al., 2008).

Encounter process is the third part of value co-creation processes. Service encounter indicates the existence of contacts between the customer and the service provider. Encounters can be (1) emotion-supporting, (2) cognition-supporting and (3) action-supporting (Payne et al., 2008). From a company's perspective, service encounter quality can be assessed across a range of factors – employees' competence (listening skills and dedication level (Keng et al., 2007) and personal communication (exchange of information and knowledge (Resnick et al., 2014). Service encounter is the critical moment that leaves customers with an impression about the firm. Given the importance of the service encounter, providers should find the ways to manage their customer-employee's contacts to ensure that their behaviours and attitudes contribute to the delivery of expected outcomes (Lloyd; Luk, 2011).

We briefly present the potential actors of value co-creation and marked the exceptional role of customer in value co-creation, discussed the motives of company and customer to enter in value co-creation and introduce to value co-creation process structure. In summarising it is necessary to highlight that businesses diversity supposes that there is no one-size-fits-all approach to value co-creation and firms have to decide on how they will manage their specific co-creation activities (Roser et al., 2013).

## 2. Features of customer value co-creation in health care

Health care significantly influences world's economies as well as the individuals' quality of life. European health care system is facing serious threat because public health expenditures in the EU's 27 Member States are growing rapidly. On average, they accounted for 5.9% GDP in 1990, and had increased to 7.2% of GDP by 2010. The forecasts show that expenditures may continue to rise 8.5% of GDP in 2060 due to different socio-economic and cultural factors, primarily of aging population (Kantola et al., 2014). Therefore, more attention should be paid to prevention of diseases and healthy behaviour of a population. The traditional view of treating customers as recipients of organisation's activities does not fit well with how customers must engage with health care services providers in order to create the most feasible results. As an alternative, the models of collaborative care, patient-centred (Sweeney et al., 2015), integrated patient care (Singer et al., 2011), person-centred, relationship-centred care (Entwistle; Watt, 2013) are being generated and adopted. This shift can be parallel with the service-dominant (S-D) logic that recognizes the principal role of the customer as co-creator of value and helps to better understand customers' behaviour in health care (Aggarwa; Basu, 2014) (Table 2).

| Author (s)                   | Research scope  | Main findings   |
|------------------------------|---|---|
| Nambisan;<br>Nambisan (2009) | Models of consumer value co-creation in health care   | Four alternate models of consumer co-creation – the partnership, the open-source, the support-group and diffusion models – are identified and discussed;  |
| Gill et al. (2011)           | Concepts influenced the interaction of service participant in the formation of a service            | The four concepts – client orientation, client involvement, provider empowerment and client empowerment – are identified as important to service participant;   |
| Elg et al. (2012)            | Customer value co-creation <i>for others</i> , i.e. health care service development                 | A model for co-creation and learning in health care service development is suggested;   |
| McColl-Kennedy et al. (2012) | Patient value co-creation practice styles   | Five patient value co-creation practice styles, i.e. team management, insular controlling, partnering, pragmatic adapting, and passive compliance, are uncovered;   |
| Gallan et al. (2013)         | Customer positivity as an antecedent to customer participation on value co-creation                 | Customer positivity predicts participation behaviours, which lead to increased perceptions of service quality and satisfaction. The theory of customer value co-creation should explicitly include affective dimensions and antecedents;                                  |
| Aggarwal; Basu (2014)        | Factors of customer effort exertion in value co-creation  | Customer effort exertion is influenced by three factors: personal goal clarity, service relevance and employee interactions. The amount of effort exerted positively impacts customer satisfaction;   |
| Barile et al.(2014)          | Interpretation of information asymmetry and the understanding of co-creation in health care service | Three-step interpretative framework for examining the human side of service interaction is proposed. Critical dimensions of affective interaction and co-creation are information sharing (knowledge and facts), interpretation scheme sharing (reciprocal understanding) |

|                             |   |  |
|-----------------------------|---|--|
|                             |   | and value sharing (relational harmony);  |
| Karlsson et al. (2014)      | Nurturing of service innovation by frontline employees (FE) through value co-creation in health care  | Two ways for nurturing service innovation by FE through value co-creation are suggested. First, service innovation integrated with co-creation (service is innovated during direct interaction and collaboration between FE and the patients), second, service innovation detached from co-creation (FE contribute to service innovation back-office by utilizing their previous experience of co-creating value with their patients); |
| Krisjanous; Maude (2014)    | Customer value co-creation within a partnership model of health care  | Midwifery Partnership Model (MPM) as facilitative of customer value co-creation is submitted; 15 dimensions in which midwifery customers co-create value through partnership are identified;   |
| Loane et al. (2014)         | Consumers' value derived from online health communities   | The results that online communities give consumers the opportunity to create and experience forms of consumer value that would not otherwise be available in a traditional health delivery system are demonstrated;  |
| Sharma et al. (2014)        | Organisational capabilities for customer participation in health care innovation thought the lens of co-creation  | Four categories of organizational capabilities are identified: customer activation, organisational activation, interaction capabilities, and learning agility;   |
| Osei-Frimpong et al. (2015) | Value co-creation processes from dyad of the patient and the physician  | Three critical areas needed to support value co-creation process are identified: social context, beliefs and perceptions, and partnership between the studied dyad;  |
| Sweeney et al. (2015)       | Customer effort in value co-creation (EVCA) in health care; the link between EVCA and quality of life, satisfaction with a health care service and behaviour intentions | A hierarchy of activities representing changeable levels of difficulty for the customer is proposed; 13 activities take place both within the firm (clinic) and beyond it and patient self-generated activities are revealed; the influence of customer EVCA on quality of life perceptions as critical finding is fixed;  |
| Zhao et al. (2015)          | Motivators of activities in value co-creation in online health communities (OHC)  | Social identity as essential determiner of patient value co-creation in OHCs is founded;   |

Table 2. Overview of value co-creation's studies in health care

Today the main question for health care executives is how to build health care system and deliver high quality care in ways that are beneficial for both patients and health care organizations. Cosgrove et al. (2013) suppose that each health care organization must activate patient involvement into the service provision's processes by building the roles for patients because more participatory health care customers lead to better medical outcomes, lower costs, more effective and efficient health care delivery, and increased perception of service quality and satisfaction (Gallan et al., 2013).

What implications for health care managers can be formulated based on the findings of patient (customer) value co-creation studies? Gill et al. (2011) accentuate the reinforcement of open organisational culture, which empowers patients to apply their knowledge and skills and encourages them to make the choices and take the initia-

tives in service co-creation process. Open organisational culture helps to recognize and accommodate patients' individual medical needs and preferences for health care (Singer et al., 2011). For development of open organisational culture it is necessary that health care leaders should implement initiatives including system-wide standards of behaviour; rotation on inpatient units; follow-up calls to all discharged patients to make sure they understand their care instructions; a defined process for employee interactions with patients focused on helping to reduce anxiety and fair, etc. (Hegwer, 2014). The open culture is the condition of more involved and confident patients and doctors tend to maintain the collaborative relationships with patients and encourage their patients to be active and conscious in making decision of health care (Street et al, 2003). The idea of health care organization's openness that helps to envisage customers' value co-creation desires and unlocks the opportunities for them to involve in co-creation advocated by Krisjanous; Maude (2014) too. The findings of Gill's et al. (2011) research also could be used by managers in defining position statement for high contact, high involvement, ongoing services and their succeeding recruitment and selection criteria as well as to staff training that should improve the interactions of managers with their service provision personnel, and service provision staff with their clients.

Value co-creation is not the consequence of merely interactions among the actors; it requires the examination of other attributes to deeper conceive the linkage among the actors. The social context of service encounter, the beliefs and perceptions both of the patient and the doctor and their partnership are imperative for value co-creation process (Osei-Frimpong et al., 2015). Thus health care organizations need to take a holistic view of service delivery and acknowledge all fateful areas of the value co-creation process given for patients the roles of active participants.

As mentioned the customer's participation in health care is critical to achieving the expected outcomes of service. Obviously, the participation of patients' meaningfully diverges due to anxiety-producing situations, uncertainty and risk. Galan's et al., (2013) research aimed to underlying processes responsible for the effects of customer to act on outcomes during a customer's co-created experiences provides few implications for health care service managers and staff. First, health care managers should influence customer affect by designing service interactions via service blue-printing, service mapping or other tool for service delivery design. It allows identifying how and where it is possible to enhance or reinforce patients' positivity and improving managers' abilities to correctly design the physical environment and aligning service delivery capabilities with customer resources and preferences. Second, medical personnel must listen to and translate customer anxieties and preferences into option for specific follow-up behaviours, with at least one of the options available to the patient without unnecessary delay. Third, health care professionals should open their practices helping patients recognize and manage their emotions to facilitate positivity and urge them to be involved in the health care service delivery.

The participation of customers in health care service delivery differs by levels of their efforts. Sweeney et al. (2015) define the customer's effort in value co-creation as the degree of the effort that customers apply to integrate resources, through a scope of activities which describe by different perceived difficulties and propose a hierarchy of these activities. Based on these findings health care organizations can develop strategies for facilitating and encouraging customers to take part in activities, especially those activities that need more customers' efforts. The health care service providers must recognize that their customers diverge in their skills, abilities, and willingness to

co-create value through within-clinic, outside-clinic and self-generated activities. The patient's effort involved in value co-creation should be influenced by personal goal clarity; service relevance, and employee interactions (Aggarwal; Basu, 2014). The comparable idea is maintained by McColl-Kennedy et al. (2012). They suggest that customers co-create value differently, demonstrating variety activities and integrate resources in different manners through interactions with different collaborators such individuals from the focal organization, other market-facing and public sources, private and personal sources. The researchers revealed five health care customer value co-creation's practice styles (team management, insular controlling, partnering, pragmatic adapting, and passive compliance) with different customer roles, activities, and interactions. In these activities which define the style of value co-creation the information plays a principal role, because sharing of information is a key process in actors' interaction and co-creation. Traditionally the health care service, particularly the relationship between the physician and patient, is affected by information asymmetry. According to Barile et al. (2014), this asymmetry might not be merely handled as an asymmetric quantity of information but rather as cognitive abilities with varying interpretations schemes. Therefore, the main mode to reduce such information asymmetry is to recover conditions of consonance by acting on the building of trust-based relationships. Hence, the health care organizations should re-evaluate the suitability of their business models and deeper understand their customers' practice styles as well as the factors that make an influence on these styles. This is important aiming to operate more effectively in increasingly networked and collaborative market (McColl-Kennedy et al., 2012).

Nowadays the customer value co-creation cannot be viewed beyond the unceasing development of new information and communication technologies such as online health communities and social media technologies. The four alternate customer value co-creation models – the partnership model, the open-source model, the support-group model, and the diffusions model proposed by Nambisan; Nambisan (2009) can help health care organizations adopt applicable strategies and practices to incorporate customers as partners in development and delivery of innovative health care service. Loane et al. (2014) declare that online health communities give customers the possibility to create and experience forms of the value that is not accessible in a conventional health care delivery system. Their research highlights the significance of peer-to-peer health networks that eliminate or reduce the barriers of information asymmetry and provide value and maintenance to defenceless people, especially for people with serious illness and limited capacity for involvement in conventional community life. Health care managers should realize that the treatment is only one part of the value aspired by customers. Respect, play, aesthetics, spirituality and ethics compose other “slices” of the value derived from customer encounter with health care system. The administrators of online health community must clearly define their community mission; encourage members' mutual caring through relevant policies; intentionally design the website that could facilitate members to communicate using multiple means, such as recorded voices, icons, animation, and text messages (Zhao et al., 2015).

Service development may be carried out from two perspectives: (1) *inside-out* which explains service development in health care through the lens of organization and (2) *outside-in* which views the service development through the lens of the customer. The health care organization often follows the *inside-out* perspective that frames the patient as passive actors with a limited role. Elg et al. (2012) take notice of customer as value co-creator *for others* (*outside-in*) in development of health care services and

claim that customer co-creation is a powerful mechanism in service development. The crucial issue for practitioners is how the process of co-creation and learning from the patient can be organised and managed. The researchers delineate few issues that need to be considered by providers: (1) each patient should feel protected and be sure that participation in service development will not influence his/her future contact with the doctor and other medical personnel; (2) anonymization should be ensured in respect to the professional and patient relationship as well as the patient privacy; (3) the selection of tools served for maintaining the flexibility of patients should be closely considered; (4) the choice of patients which will be involved in health care service development is a critical activity, consequently, both the health care staff and researchers should be entered in sampling; and (5) the learning from the patient can offer alternatives for different situations.

The value co-creation may be considered as the prerequisite of health care service innovation. In this regard, Karlsson et al. (2014) accentuate the contribution of front-line employees. They nurture the service innovation through value co-creation in two ways. First, service is innovated during direct interaction and collaboration with the patients in certain context (service innovation integrated with co-creation), and, second, frontline staff joints to service innovation back-office by using their preceding experience of co-creation value with patients (service innovation detached from co-creation). To ameliorate the quality of encounter as medium for service innovation integrated with co-creation the health care organization can apply employees education and training, regular assessment and feedback, watchful recruitment and incentive structures (Aggarwal; Basu, 2014). Many health care organizations still lack a comprehension of the capabilities required to adequately react for enhancement of patient's participation. Sharma et al. (2014) suppose that health care organizations considering increased participation of patients should develop organisational capabilities that allow encouraging and supporting patient participation in health care innovation. Furthermore health care service providers require the capabilities to identify and respond to dynamic patients' needs. Given the complexity of many health care organizations managers should stimulate collaborative integration and leadership in organization. The researchers highlight the importance to develop the organisational capabilities that allow to effectively interacting with patients. It means health care organizations would need to recognize patients as personalities in order to build and evolve them, act ethically. Moreover managers must build capabilities to learn from evaluation, and change the processes that hinder to service innovation adoption and diffusion. It is critically important for health care organization to be perceived as knowledgeable, helpful, and customer-focused.

### **3. Future research lines in health care customer value co-creation**

Despite increasing number of studies, the inquiries of customer value co-creation in health care remains scarce. The researchers identify potentially fruitful avenues of studies: the situational and personal factors, the customer value co-creation scale development and validation, the longitudinal changes in customer value co-creation and impact on organizations (McColl-Kennedy et al., 2012); the link between information asymmetry and value co-creation (Barile et al. (2014); the forms of nurturing service innovation through frontline personnel and patients co-creation in different

fields of health care (Karlsson et al., 2014). The health care service includes the different professionals who also cooperate with the patients and enter the value co-creation process. Thus, future studies cannot restrict the doctor-patient; it is necessary to expand the research focus on other professionals and managers participated in health care service delivery (Osei-Frimpong et al., 2015). Barile et al. (2014) suggest that researchers should investigate deeper patients' motives to be involved in health care management in both self-help and collaborative participation. Elg et al. (2012) pose the question that may be answered how health care organisations can develop services from the perspective of patients (co-creation *for others*). Online health communities become a form of service provided by health care organizations to expand face-to-face services for people with particular health problems. In this regard, the future researches should answer which health problems are appropriated for online peer-initiated support and how the structure and functional way of online health community contributes to the perceived value of the experience (Loane et al., 2014). Zhao et al. (2015) take a notice that further studies should examine how different illness attributes and online health community members' demographics characteristics influence customer value co-creation. We provided only a few sketches for further studies. All studies that deepen understanding how patients co-create value to better conduct their health care and how health care organization must manage is important for patients, as well as health care services providers, are welcome.

## Concluding remarks

In contemporary service economy, the value co-creation is a progressively evolved concept within service research and practice. The value creation pivots on the idea that value is generated by interaction among service providers, customers and other co-creators. The customers are no longer passive recipients of value propositions offered by service providers. They are now informed, connected, networked, and empowered as never before. To be competitive service organizations invent new business practices and competencies that need shifting organizations' attention from production to consumption, from service product to process, from transaction to relationship and create the environment that facilitates co-creation and interactions between customer and service organization's staff. A service business is multifaceted; thus there is no universal approach to customer value co-creation and organizations have to decide how to manage their specific co-creation activities and gain positive outcomes but also to avoid possible negative implications of co-creation for an organization.

Customer co-creation in health care is still new practice. The health care is requiring patient's active participation to ensure successful outcomes (Gill et al., 2011). But health care context is rich in complexity and unique challenges for patient participation (Sharma et al., 2014) as well as for service providers. Despite the changes of paternalistic model of health care to more patient-centred pattern and becoming of patient involvement in all health care delivery essence that ensures the responsiveness of services provided to what patients want and need (Pollard et al., 2015), more efforts should be performed to direct attention of both providers and patients towards successful customer co-creation.

We recognize that this research has many limitations. However, as an exploratory article, it provides the stimulus for further research.

# Knowledge-intensive business services: testing a multi-dimensional model in the Basque Country

*Mariangélica Martínez Chávez (PhD), Estibaliz Hernández Eleno (PhD Candidate)<sup>1</sup>, Luis Rubalcaba Bermejo (PhD)<sup>2</sup>...*

<sup>1</sup> MIK & Mondragon Unibertsitatea, <sup>2</sup> Universidad de Alcalá

*The main goal of this paper is to propose and validate a method for the analysis of value creation in the KIS (Knowledge Intensive Services) from a perspective of strategic definition at a micro-economic level (twofold offer-demand approach) that allows:*

- *An understanding of the critical factors that define the relationships between companies that demand and offer KIS (how and why they are produced).*
- *An approximation to a method capable of showing the level of complexity of advanced services as a contribution towards overcoming the characterisation of KIBS through NACE.*

## 1. Introduction

In the field of innovation and the improvement of the competitiveness of enterprises, knowledge-intensive business services, or KIBS, play an essential role in improving the key processes and activities of client companies. This fact becomes more relevant in the current economic context, where the industrial crisis forces us to rethink the way that small and medium enterprises have traditionally done things in our local environment, in order for these to be competitive globally.

In this context, this study aims to analyse the keys to the customer-supplier relationship between companies that demand and provide advanced services. For this we have used the model of analysis proposed by Miles (2012) in which the information flows that take place between the company that supplies the services and the client company are studied. Following this approach, we have studied the case of two companies: EGA Master, a leader in the hand tools sector, which offers a comprehensive solution with ten highly innovative product ranges, whose business model is based on the horizontal integration of suppliers; and Abantail, which offers a specialised and comprehensive design service for the optimisation of Adaptive Design at company level.

The goal of the research carried out is to propose and validate a method for the analysis of value creation in the KIS (Knowledge Intensive Services) from a perspective of strategic definition at a micro-economic level (twofold offer-demand approach) that allows:

- An understanding of the critical factors that define the relationships between companies that demand and offer KIS (how and why they are produced).
- An approximation to a method capable of showing the level of complexity of advanced services as a contribution towards overcoming the characterisation of KIBS through NACE.

In this paper, the methodological design of the research that will drive the validation of the new model proposed is describe. The research will be conducted during the following months.

## **2. Conceptual framework for knowledge-Intensive services**

The service sector is one of the fundamental pillars supporting today's global economy. The growth trend of the sector has been unstoppable in recent years, especially in large metropolitan areas or large urban agglomerations in general. In recent decades, the services sector has become increasingly significant compared to the industrial sector. Even within the industry itself, there is a very marked tendency to combine products with a layer of high added value services as a way of increasing their value in the market.

In the knowledge economy, services such as R&D services computer activities, engineering and consultancy services are all examples of an emergent economy where knowledge takes a relevant place, taking into account that they depend on professional knowledge (related to specific technical fields) and they provide, at the same time, intermediate products and services that are knowledge based (Miles et al.,1995). These are the so called knowledge intensive business services (KIBS), tend to concentrate at metropolitan and well developed regions in contrast to less developed regions, where the presence of these activities is much poorer as they usually depend on the external provision of KIBS (González-López, 2009).

Many authors (Bilderbeek and Hertog, 1998a; Bilderbeek et al 1998; OCDE, 2006) give special importance to KIBS as facilitators, carrying and being a source of innovation. This is why they can easily collaborate with the traditional knowledge system, universities and public research centers, or act as "bridges to innovation" (Czarnitzki and Spielkamp, 2000), facilitating the knowledge exchange between agents due to the high number of interactions amongst them. As an example, KIBS might facilitate their clients' innovations by helping them adopt solutions previously developed in other sectors or companies, for example, any software solution (Gonzalez-Lopez, 2013). Related to this idea, Miles (2008) stands out that KIBS uses different types of highly specialized knowledge, in order to develop specific solutions for their customers.

An advanced service has traditionally been understood to be any activity covered by specific NACE 2 categories, particularly activities belonging to the groups between 69 and 75 - which relate to professional, scientific and technical services - and between 77 and 81, which encompass support activities and administration.

However, this approach seems increasingly reductionist and unsuitable for a rigorous analysis with a view to making important decisions. According to recent studies conducted by MIK during 2014 and 2015, not all activities that are strictly classified within a specific NACE code actually turn out to be advanced services if we look a little more closely at the qualitative aspect of the service. For example, a business that is categorised under “Computer consultancy activities” may be offering basic services (developing a website) or much more advanced services (providing advice on the latest Big Data technologies and techniques, for example). In our opinion, the criterion for the classification of the sector is not sufficient to identify an advanced service, and instead there is a need to establish another series of conditions to understand that we are dealing with a service of this type (Hipp, 1999; Muller & Doloreux, 2009).

Some authors such as Muro et al (2015) are already applying this perspective in their research about advanced services or industries, for these authors, advanced industries should fulfil these conditions:

- An industry’s R&D spending per worker must fall in the 80th percentile of industries or higher, exceeding \$450 per worker.
- The share of workers in an industry whose occupations require a high degree of STEM knowledge must also be above the national average, or 21% of all workers

As a result of applying both characteristics to the USA economy, 50 advanced industries have been identified as can be seen in Figure 1.

Figura 1 Las 50 industrias avanzadas en USA

| The 50 Industries That Constitute the Advanced Industries Sector |   |   |
|--|---|---|
| MANUFACTURING  |   | ENERGY  |
| Aerospace Products and Parts                                     | Motor Vehicles                                      | Electric Power Generation, Trans., and Distribution |
| Agr., Construction, and Mining Machinery                         | Navigation, Measurement, and Control Instruments    | Metal Ore Mining                                    |
| Aluminum Production and Processing                               | Other Chemical Products                             | Oil and Gas Extraction                              |
| Audio and Video Equipment  | Other Electrical Equipment and Components           | SERVICES  |
| Basic Chemicals  | Other General Purpose Machinery                     |   |
| Clay Products  | Other Miscellaneous Manufacturing                   |   |
| Commercial and Service Industry Machinery                        | Other Nonmetallic Mineral Products                  |   |
| Communications Equipment   | Other Transportation Equipment                      |   |
| Computers and Peripheral Equipment                               | Pesticides, Fertilizers, and Other Agr. Chemicals   |   |
| Electric Lighting Equipment                                      | Petroleum and Coal Products                         |   |
| Electrical Equipment   | Pharmaceuticals and Medicine                        |   |
| Engines, Turbines, and Power Trans. Equipment                    | Railroad Rolling Stock                              |   |

Fuente: Muro et al (2015)

We believe that one of the keys to generating high value-added services has to do with the relationships that exist both upstream and downstream in their value chain. To take these key points forward, in the following “Methodological Approach” section

we have selected a theoretical model and a series of propositions that characterise advanced services in a way that goes beyond the NACE 2 classification and that will be the basis of our research.

## 2.1. Methodological approach

In general terms, the methodological design of this study consists of three phases: the first phase involves a literature review and selecting the theoretical model to explain the phenomenon of advanced services; the second phase is focused on designing and carrying out case studies in order to validate the proposed theoretical model; and, finally, the third phase is where the model is adjusted and new ways for validating and implementing it will be defined.

The methodology to be used in each of the phases is detailed below.

- a. **Phase 1 - Literature review and selecting the theoretical model to explain the phenomenon of advanced services:** The literature review has allowed us to determine the critical factors in the problem of advanced services. During this phase, we have identified a theoretical model capable of explaining relations between companies that supply and demand knowledge-intensive services, and a proposal is made regarding conditions that would characterise advanced services.

As far as the theoretical model is concerned, we selected the model developed by Miles (2012: 19) on the basis that it describes the relationships that exist between KIBS and their clients. This model also includes key questions to guide research, which have been useful in the process of analysis.

Figure 2: Model of the KIBS - Client relationship

Source: Miles, I. (2012:19)

Nevertheless, during 2014 and 2015, different exploratory research studies were carried out by MIK where more than 120 KIS enterprises were interviewed and

analysed. One of the main insights of that research showed that not all the companies officially belonging to the particular NACE-KIS groups, were qualitatively considered as “advanced” and viceversa. The second one, is that if we had a deeper look to the type of services they were offering and the relationships with external agents, the model proposed by Miles (2012), shown in Figure 1, doesn’t take into account the provider side, to the same extent that it does take the offerent side. To explain both we are proposing an adaptation of that model that can be seen below in Figure 2.

Figura 3: Proposed theoretical model

Source: Prepared by the authors based on Miles (2012:19)

Regarding the conditions for the categorisation of advanced services (to overcome the traditional NACE classification), the literature review has allowed us to define five conditions to enable us to categorise a service as an advanced service, and which are proposed based on the results of the research carried out by Hipp (1999), Muller and Doloreux (2009), Muro et al (2015) and Miles (2012):

- These are companies that offer services which are required by other companies and not by the end consumer. Business to business demand.
- They carry out complex operations of an intellectual nature where human capital is of fundamental importance.
- They establish a relationship based on close collaboration, co-creation, and cooperation with their customers.
- Their service is an important element of added value in the competitive positioning of their customers.
- They work together with customers, R&D centres, universities etc., to build systems for creation and for the application of knowledge all around them. In other words, they form a bridge between the world of knowledge and the company.

- b. **Phase 2 - Designing and carrying out case studies:** We will use the case study methodology for validating the proposed model, based on the definition put forward by Yin (2009). Designing the case studies therefore involved defining the unit of analysis and the method of collecting and analysing data.

A design involving multiple cases has been chosen in order to address knowledge-intensive services from the perspectives of both supply and demand. A single unit of analysis has also been established (the behaviour of the organisation in relation to the areas mentioned). In conclusion, it is a multiple-case design, which is also holistic (single-unit of analysis).

To implement a first pilot test, we have identified two companies that satisfied the profile required to test if the research was conveniently designed, from two different viewpoints: (i) we selected a company which provides advanced services to the industry and which has experienced significant growth in recent years; this company enabled the model to be applied from a supply-side perspective; (ii) we also selected another company which competes in niche markets with high added value and which requires advanced services (demand-based approach), these being essential to their value proposition.

- Case 1. Supply-side approach: Abantail S.Coop: This company was set up recently (in 2004) and is located in Arrasate (Gipuzkoa, Basque Country-Spain). It is a spin off from a technology centre which has chosen to develop a high value-added strategy to enter a mature market; the company has therefore opted for a competitive strategy based on differentiation, with the aim of becoming part of their customers' production process to help them increase the value that they bring to the market.
- Case 2. Demand-side approach: Egamaster SL: This is a hidden champion located in Vitoria (Álava, Basque Country-Spain). It is a business with high added value; knowledge intensive activities support its value proposition and make it a leader in the sector. It has developed strategic alliances to overcome the competitive challenges and difficulties associated with its size (SME).

Table 1 details the main features of the selected companies that form part of the pilot testing of the research method.

**Table 1: Description of cases used in the pilot testing**

| Company   | Size   | Sector            | Age  | Location                                  | Markets       | Type of legal entity   |
|-----------|--|-------------------|------|---|---------------|------------------------|

Source: Compiled by the authors.

In order to ensure that the further study is valid, reliable and accurate, information will be collected by means of: (i) semi-structured interviews with the en-

trepreneurs and current managers of the company. Lasting between 90-120 minutes and following a protocol with open questions, these interviews derived from a diagnostic model of the resources and capabilities of the companies, based on the guidelines contained in the the European Commission's Smart Specialisation Strategy and investigations on the subject in question (Davidsson, 2004: 127-129; Goodsell, 2007); (ii) other internal sources of information from the companies, such as brochures, financial reports and forecasts; and (iii) external sources such as reports by official organisations associated with the company.

This information will be therefore analysed in two stages: in the first stage, a database will be created with the transcripts of the interviews and the secondary information; and in the second stage, the evidence obtained will be analysed following the logical schema of the defined theoretical model, relating the behaviours identified in the case studies with the propositions and their associated indicators (pattern matching and combination of qualitative and quantitative information). In this process of analysis, it is essential to use the system of propositions defined specifically for this study, which can be seen in Table 2.

**Tabla 2: A set of propositions to overcome the traditional classification of KIS.**

| Propositions to characterise KIS  | Indicators  |
|---|---|
| <b>1 Business demand – B2B relationships between suppliers and customers</b><br><br><i>These are companies that offer services which are required by other companies and not by the end consumer.</i> | <ul style="list-style-type: none"> <li>• % turnover companies/total turnover</li> <li>• Number of explicit processes in which suppliers are involved/Total processes</li> <li>• Number of explicit processes in which customers are involved/Total processes</li> <li>• Relative importance of the process for the organisation – Scale of 1 to 10</li> </ul>   |
| <b>2 Complexity and Human Capital and Degree of Specialisation.</b><br><br><i>They carry out complex operations of an intellectual nature where human capital is of fundamental importance.</i>       | <ul style="list-style-type: none"> <li>• % of graduates/Total staff</li> <li>• % expenditure on R&amp;D/Revenue; training</li> <li>• Index of specialisation in R&amp;D activity in the technological/scientific sphere<sup>1</sup></li> <li>• Number of people in each area of specialisation<sup>2</sup></li> </ul>   |
| <b>3 Co-Creation ratio</b><br><br><i>They establish a relationship based on close collaboration, co-creation, and cooperation with their customers</i>  | <ul style="list-style-type: none"> <li>• % of sales of standardised projects v customised projects v standard core + customisation layer<sup>3</sup></li> <li>• Extent to which the customer is involved in the production of services, on a scale from 1 to 10<sup>4</sup></li> <li>• Extent to which the supplier is involved in the production of products and/or services, on a scale from 1 to 10</li> </ul> |

<sup>1</sup> The Basque Science and Technology Network measures specialisation using the following indicator: “*Index of specialisation in R&D activity in the technological/scientific sphere*”

<sup>2</sup> Miles, 2012:22 identifies three areas of specialisation within KIBS (Miles, 2012: 23, graph 1.2): technical/technological knowledge (T-KIBS), knowledge of professional, legal, consultancy services (P-KIBS) and creative knowledge, involving design, communication (C-KIBS)

<sup>3</sup> Doroshenko et al (2013) use the following question to clarify this point: “*What share of your sales value in 2010 falls into each of these categories? Standard/Standard with a customised Shell/Customised*”

<sup>4</sup> Doroshenko et al (2013:17), analyse the question in this way: “*Estimate the extent to which the customer is involved in the production of services, on a scale from 1 to 10.*”

---

#### 4 Added value and competitiveness

*Their service is an important element of added value in the competitive positioning of their customers.*

- Number of products/services offered jointly with customers/Total products/services offered
- Number of products/services offered jointly with suppliers/Total of products/services offered
- Number of spin-offs created
- Number of joint ventures with other companies

#### 5 Knowledge Systems

*They work together with customers, R&D centres, universities etc., to build systems for creation and for the application of knowledge all around them. In other words, they form a bridge between the world of knowledge and the company.*

- Number of projects/investment in collaboration with the system of innovation
- Transfer, applicability, development etc. of knowledge in the practices, proposals etc. of the organisation
- Importance of universities, technology centres etc., on a scale from 1 to 10.
- Number of key processes in which an agent from the Knowledge System intervenes.

Source: Compiled by the authors.

- c. **Phase 3 - Adjusting the model and identifying future lines of research:** A system has been established to identify and record deficiencies in the theoretical model and this will be applied throughout the data analysis process. The deficiencies identified will be analysed in depth and areas of improvement will be included after another literature review (specifically for the deficiencies identified). These areas of improvement will be validated by experts in the relevant fields. Such as the expert in KIS, Ian Miles, with whom we have contrasted the preliminary design of our research.

Throughout this process, the basic propositions will be taken into account in order to establish whether or not the model is capable of describing how and why the process of value creation in the sector of advanced services occurs, from the perspective of the strategic definition at microeconomic level (twofold supply-demand approach).

It is worth noting that a protocol has been designed due to the importance of replicating the study in order to continue with the process of validating the theoretical model. This protocol details the process of selecting the cases, as well as the process of collecting and analysing the data.

### 3. Exploratory research.

During 2014 and 2015, MIK has conducted several research projects in the field of services, which have shown the importance of generating a model to analyze the qualitative aspects of KIS not only in the offerings side, but also in the provider's one. For that reason, we have selected two companies that appear to have specific characteristics from both sides.

### 3.1. Knowledge-intensive services – a view from the perspective of demand

Table 3: EGA Master

| Company   | Size  | Sector | Age  | Location                         | Markets            | Type of legal entity      |
|-----------|---|--------|------|----------------------------------|--------------------|---------------------------|
| Egamaster | Medium<br><br>Turnover: €5M-<br>€10M<br><br>Empl: 107 | Metal  | 1990 | (Álava, Basque<br>Country-Spain) | 150 coun-<br>tries | Public limited<br>company |

Source: Compiled by the authors.

EGA Master is a company dedicated to the conception, design, manufacture, control, commercialisation and after sales service of high quality equipment and hand tools for industrial-professional use, as well as highly specialised safety equipment, within the metal sector.

EGA Master exports all the items in its catalogue (i.e. 20,000 product references) to more than 150 countries and exports currently account for almost 90% of its production.

EGA Master has opted for a differentiation strategy with respect to its competitors, through innovation and constant development, that allows it to have a continually expanding and increasingly complete range, with the aim of having an increasingly comprehensive offer that is capable of satisfying all the needs of the industry and the professionals working in it, increasing the level of service offered; in other words, to become a single-source supplier capable of meeting 100% of customer requirements.

Addressing the needs of its customers, who do not want to depend on many suppliers to meet their demand for tools – preferring to focus on those who can will fully meet all their needs so that they can streamline their purchases and reduce administrative and transport costs etc. – it has optimised its portfolio of products/services to become this single-source supplier that the customers are looking for.

In this way it has become the only global manufacturer of tools that provides a comprehensive solution with ten highly innovative ranges: piping tools, general mechanical tools, pneumatic and hydraulic tools for underwater applications, non-sparking, titanium non-magnetic, electrostatic discharge (ESD) tools, tools insulated up to 1000 volts, anti-drop tools, tool control systems and explosion-proof and intrinsically safe instruments with ATEX/IECEX certification. There is no manufacturer in the sector anywhere in the world that is able to offer these 10 ranges of tools.

All this comes with a unique and totally innovative service in the sector: the customer's own brand without any charge whatsoever for this service, without additional costs and maintaining the same delivery deadlines as with the EGA Master brand. There is no other manufacturer in the sector providing these conditions: all the advantages of the customer's own brand without any of the drawbacks (minimum amounts, higher prices and longer delivery times).

The same can be said of the innovative and revolutionary services that the company has brought to the sector, being pioneers and still unique in many of these services:

their own brand with all its benefits to the customer without any of the traditional drawbacks such as minimum amounts, lengthening of delivery times and higher prices; catalogues customised for specific customers with their own brand, logo and corporate style without any development costs for these (this good practice and innovative service earned the European Award for Best Practice in Innovation of the EFQM Forum); personal advisory service on safety and risks of explosion for choosing the correct alloy for non-sparking tools; unlimited guarantee for all its tools; catalogue of specific safety tools, unique of its kind in the world and published in 7 languages; comprehensive customer service that covers all their tool needs etc.

In summary, the success of these products and services is based on:

- Incorporating the voice of the customer in all processes to guide the capturing of their needs and expectations, looking at the same time for new opportunities in these. Complete empathy with the customer.
- Innovation based on implementation and creation of value for the customer. In other words, the realisation of ideas into products or services that provide solutions to those needs and expectations gathered from the customer. Value-added proposals aligned with customer needs.
- Proper transmission to the customers of the keys to the new proposals for adding value.

### 3.2. Knowledge-intensive services – a view from the supply-side perspective

Table 4: Abantail

| Company  | Size  | Sector            | Age  | Location  | Markets | Type of legal entity |
|----------|---|-------------------|------|---|---------|----------------------|
| Abantail | Small<br>Turnover €1M-<br>€2.5M<br>Empl.:26 | Advanced services | 2004 | Arrasate<br>(Gipuzkoa,<br>Basque Country-Spain) | Local   | Cooperative          |

Source: Compiled by the authors.

Abantail is a spin-off from two companies that are part of the Mondragon Corporation: LKS, a business services consultancy belonging to the industrial division of the group; and Ikerlan, a research centre specialising in the development of R&D projects under contract for the creation of new products and for the improvement of production processes, located within the Knowledge division of the corporation.

Abantail offers a comprehensive service for the optimisation of adaptive design. This is the design carried out during the order fulfilment cycle and the aim is to customise the product according to the specific needs of each customer for each order.

The service offered by Abantail allows the design of customised products using standard product logic. According to its own testimony, adaptive design “is the ability to design different articles, ‘customised products’, based on the same template or ‘generic product’, which incorporates the anticipated future adaptations. The generic product refers to the set of all articles that can be provided by the company on a

competitive basis and incorporate the anticipated future adaptations, while the customised product is each of the adaptations made to the generic product, i.e. each article that is sold to the customer”.

In many cases, the job of customising a product entails a high cost in terms of time, personnel and materials, which affects the price and the delivery of products, therefore making it less competitive. Abantail succeeds in combining the option to optimise costs while providing a customised service. In this way, it offers its customers the possibility of customising their products manufactured “en masse”, overcoming the typical problems of the mass production paradigm and providing the customisation required by the new producer-consumer trends (mass customisation).

The business operations of Abantail are based on the optimisation of adaptive design as a strategy for industrial competitiveness. It offers a “turnkey” service, including prior diagnosis, product-process consulting, the development of adapted tools and the relevant training.

It has sales configurators for creating quotations, calculating rates and costs and budgeting, as well as technical product-process configurators for the structuring of the generic product and generation of technical documentation, and is able to adapt the most appropriate IT solution for each customer.

As well as offering an advanced service capable of making its customers the most competitive, one of the keys to the success of its value proposition is its commitment to innovation. In addition to the fact that the service itself constitutes an important source of innovation, Abantail focuses its R&D activity on the development of new products, with the aim of: extending the range, entering new markets and adapting products/services to the needs of customers. For this, a budget is allocated to innovation activities, primarily for internal and external R&D.

Also, with respect to the human capital, between 75% and 100% of the workforce has a university education, and between 10% and 25% participate in R&D activities. The company seeks public support for the development of R&D projects at provincial, regional, national and European level. It cooperates in innovation projects with other agents, such as universities, technology centres and the customers themselves.

## **4. Conclusions**

The research carried out will contribute significantly to the literature in terms of the 3 previously identified key principles of investigation, which form the basis of the research carried out: theoretical model, conditions for the categorisation of advanced services and case studies.

- Theoretical model: based on the findings of Miles (2012), a new model is presented to explain the phenomenon of advanced services from the perspective of a twofold approach (supply-demand). This model will be capable of providing a significant contribution, with the identification and management of critical factors in the processes analysed, adding to the existing body of knowledge

and providing an opportunity to transfer this knowledge to companies and other organisations associated with this research topic.

Figure 2 provides an overview of the theoretical model and features the introduction of a new element to the initial model proposed by Miles (2012): a new column for suppliers of both technical elements and knowledge who “push” the activity of the company to provide a product or service with greater added value. Having analysed different exploratory studies in services companies from the perspective of supply and demand, we consider it appropriate, given the importance of the incorporation of external knowledge and the creation of a network of partners-suppliers for the operations of advanced services companies, to provide them with flexibility and make the value proposition of the companies more competitive.

- Conditions for categorisation of advanced services: Through this research it will be possible to check the initial proposal formulated against the 5 conditions in order to categorise a service as advanced. We believe the research will be useful for the incorporation of new indicators to support the proposals made and improving on the classification of advanced services through NACE. Below, the final version of the proposals and indicators is presented for evaluation.
- Case studies: Despite the fact that the main objective of this research has not revolved around the selected cases and their specific conclusions, and that these have instead served as the scope of application for the defined theoretical model, it can be said that these provide important findings and raise new research questions. Both cases provide food for thought concerning the process of strategic definition at microeconomic level and the challenges of SMEs in the new competitive environment, in which the generation of high impact value propositions constitutes an essential requirement for businesses situated in environments in which the management of production costs is no longer enough to develop a long-term business strategy.

## **5. Future lines of research**

This exploratory study has allowed the development of an approach to the study of the field of advanced services in order to improve on the traditional classification based on NACE, attempting to find the keys to characterise this type of service from a qualitative perspective, in terms of the extent to which they display each of the five previously defined characteristics:

- **Business demand**: What is the optimum percentage of services invoiced to other companies to consider a service “advanced”? Would it be useful to clas-

sify the client companies based on parameters such as size, sector of activity, turnover etc. to further refine the characterisation of the service?

- Human Capital and specialisation: Would we be able to find the indicators to measure the degree of specialisation required in each of the areas proposed by Miles (2012): technological KIBS, professional KIBS, and creative KIBS? Would there be any other area of specialisation, beyond these three? Specialisation is measured in expertise. Would a social knowledge aspect be necessary to generate long-term relationships with customers and suppliers and facilitate horizontal integration? On the other hand, might there be a correlation between the salary level and the degree of specialisation of the human capital and could the perceived qualification be analysed in this way?
- Co-creation ratio: Collaboration to address the development of an advanced service requires co-creation “upstream” and “downstream” in the value chain, which seems to be a key to its competitiveness. Would it be useful to analyse the moments of interaction for the horizontal integration of customers and suppliers? Could the degree of complementarity between suppliers and purchasing companies be analysed according to the composition of their internal and external services?
- Added value and competitiveness: For future studies, it may be of interest to include the twofold vision of the client company and the supplier of the advanced service, to analyse the added value offered by the supplier to the client company. Would this improve the competitiveness of its value proposition? How can we measure the degree to which a service contributes to the competitiveness of a customer?
- Knowledge System: At this point, it might be interesting to extend the investigation regarding the roles played by advanced services companies in knowledge systems. To what extent does the advanced services company promote and generate relevant knowledge in the sector? Or is it a mere beneficiary of the results of research of the science and technology system?

From a holistic point of view, another issue to be addressed in the future is the need to find tools and models that help us to modulate the degree to which these five conditions have to be satisfied for a service to be considered as “advanced”.

It is clear that there is still a long way to go to resolve the unknowns that still underlie the fabric of advanced services.

# Competence Screening: Introducing a Concept for Competence Management in Service Divisions

Marc Rusch<sup>1</sup>, Ute David<sup>1</sup>

<sup>1</sup>International Performance Research Institute gGmbH, Stuttgart, Germany

*In this paper, a concept for competence analysis and management in service divisions called “Competence Screening” is introduced. This concept illustrates the competences required for providing specific services. Competence screening enables enterprises to optimize competence planning and development in service divisions, and identify inefficiencies and shortages. Enterprises are able to structure and plan personnel and competences in order to provide efficient, high quality services. This paper presents the concept and application in a specific case.*

## 1. Introduction

Services play an increasingly important role and evolve as the most profitable business division within industrial enterprises. Based on service-dominant logic, services are the major basis for economic exchange and the source of competitive advantage (Lusch and Vargo, 2014, Lusch and Vargo, 2012).

The basis for competitive service provision is operant resources and dynamic capabilities (Lusch 2011). Enterprises that offer services need to handle rising operating costs and increasingly complex services. When assigning personnel, idle time needs to be avoided, while at the same time specific tasks require specialized personnel. Due to demographic trends, the capabilities of the current employees change. A major challenge for service provision is to appropriately and efficiently employ and utilize the resources necessary for service provision (Ballantyne and Varey, 2008).

In order to ensure efficient and high-quality service provision, resources need to be analyzed and optimized according to the specific requirements of service provision (Lusch 2011, Ballantyne and Varey, 2008). Personnel need to be allocated to specific tasks or assigned to teams depending on their individual competences and service requirements. Shortages and oversupply of specific capacities need to be identified in order to decide on training, rotation and employment measures without delay.

Effective and efficient competence management in service divisions requires detailed analyses of demands on personnel and competences. Building on service design, the necessary processes and requirements for fulfilling specific services need to be analyzed (Mager, 2009, Evenson, 2008). Methods for service process analyses are service blueprinting (Shostack, 1982) and process chain network (Sampson, 2012). These methods order tasks according to the degree of interaction with the customer or according to the degree of process control. Existing approaches to visualize service processes do not take into account competence requirements and allocation.

This calls for a concept that introduces competences into process and task analyses. Compared to existing methods, this concept needs to support the allocation of personnel so that individual competences and abilities fit the requirements of the tasks. The concept furthermore needs to reveal competence shortages and oversupply so that necessary personnel rotation, training measures, and employment decisions are made.

This is possible with the “Competence Screening” concept that enables effective and efficient competence management in service divisions. Based on competence screening, individual competences are managed, allocated and developed to ensure timely, high quality and efficient service provision. The concept reveals competence shortages and oversupply and supports planning and managing personnel rotation, training measures and recruitment.

In this paper, the competence screening concept is introduced. The paper is structured as follows. Chapter 2 describes and illustrates the concept. In chapter 3, the concept is applied to a specific case. The paper closes with a conclusion in chapter 4.

## **2. The Competence Screening concept**

The competence screening concept is developed by drawing on existing frameworks such as service blueprinting. Existing approaches are developed further to analyze requirements for competence management in service divisions. Competence screening visualizes processes or tasks and the corresponding competences in a Competence Screen.

A competence screen can be developed within five steps. First, each step of a service process is visualized by using the service blueprinting concept. Within the process, single steps are combined to form activities that cannot be performed separately. This implies that these steps need to be fulfilled by a single employee.

Then, competences and competence clusters necessary for performing the single steps are identified. Fourth, each activity is assigned the relevant competences. In this part, the visualized processes or steps are complemented by competences to set up the competence screen. Finally, the competence screen is completed by integrating demographic requirements for each activity. Each of the five steps is explained in detail below.

In order to develop a competence screen, a basic overview of each step of the service process is needed. A reliable method for visualizing processes is service blueprinting as introduced by Shostack (1982). A service blueprint is a two-dimensional picture of the service process (Fließ and Kleinaltenkamp, 2004). All steps of a specific service process are presented in chronological order on the horizontal axis. The single steps are assigned to different parties involved in the service process on the vertical axis. Five key areas can be identified here. These are usually divided into customer actions, onstage actions, backstage actions, support processes, and physical evidence (Bitner et al., 2008). Process steps are depicted as boxes. The service blueprinting concept is illustrated in figure 1.

Figure 1: Illustration of the service blueprinting concept

The service blueprint shown in figure 1 describes a generalized customer order. Different process steps are allocated to the five layers described above. The process usually starts with a customer action. The customer contacts the company, e.g. via phone or email. The call service team communicates with the customer and takes the order. After that, the order is planned and executed. Finally, a bill is sent to the customer. The bottom line represents the physical evidence involved in the process. Then developing a competence screen, this line is neglected, as it is not relevant for employee competences.

After deriving the service blueprint, the individual process steps are analyzed and aggregated. The aggregation follows the interaction with customers or other departments within the company, and the function within the service process. These aspects imply that the single steps cannot be separated and performed by more than one person. These aggregated bundles of steps are called activities. In the example above, four activities can be identified. These are call service activities, order preparation, order execution, and billing. With this step, the illustration differs from the service blueprint as a new chart is set up. The sequence of activities is drawn on the top horizontal axis.

The third step is to identify required competences within the service process and define different competence layers. Heyse and Erpenbeck (2009) give a solid overview of employee competences. They define four general competence areas. These are personal competences, social-communicative competences, activity and implementation expertise, and technical and methodological expertise. Each competence area consists of different competences, summing up to 64 in total. To apply this model to the competence screening concept, suitable competences of each specific service need to be identified. The level of detail can be chosen for each specific case. Depending on the requirements and use case, competence screening involves general or very detailed competences. Within the competence screen, the relevant competences depict the vertical axis and represent the competence layers as horizontal stripes.

Each activity is assigned to the relevant competence layers. In order to further explicate the relevant competences, details are included in the cells in the intersection of activity columns and competence layers. The resulting competence screen illustrates competences required for providing specific services. Relevant competences are further described in the cells within the competence screen.

Finally, demographic requirements can be analyzed and integrated into the competence screen, e.g. a high amount of travelling or heavy work. Figure 2 illustrates an exemplary competence screen.

|   | Call service   | Order preparation                                  | Order execution  | Billing |
|---|--|--|--|---------|
| <b>Personal competences</b>                   |  |  | _ ability to take responsibility<br>_ ability to work under pressure, time constraints |         |
| <b>Social-communicative competences</b>       | _ communication with customer via telephone or email |  | _ communication with customer during order conduction<br>_ consulting                  |         |
| <b>Activity and implementation expertise</b>  |  |  | _ consulting is required if customer has specific questions                            |         |
| <b>Technical and methodological expertise</b> |  | _ knowledge about specific machine, equipment etc. | _ fault analysis<br>_ knowledge about specific machine, equipment etc.                 |         |
| <b>Demographic requirements</b>               |  |  | _ travelling<br>_ physically challenging work  |         |

*Figure 2: Illustration of the Competence Screening concept*

As figure 2 shows, different activities require different competences and face different demographic requirements. Call service requires mainly social- communicative competences, while order execution requires a broad set of different competences, e.g. working under pressure, communication and consulting skills, as well as technical und methodological expertise. This activity also faces demographic requirements due to a lot of travelling and physically demanding tasks.

### 3. Results

The above introduced competence screening is now presented in two case studies that involve spare part supply and maintenance. Within the case studies, competences for providing entire or parts of services are shown. The competence requirements are compared to the competences available within existing personnel. Deviations of required and available competences are detected. Competence screening supports management and development of competences and processes, and service provision as a whole.

The first example is a spare part supply service. The service blueprint is shown in figure 3. In this example, six parties are identified. These are customer, front-office, back-office, support, preparation, and facility-level.

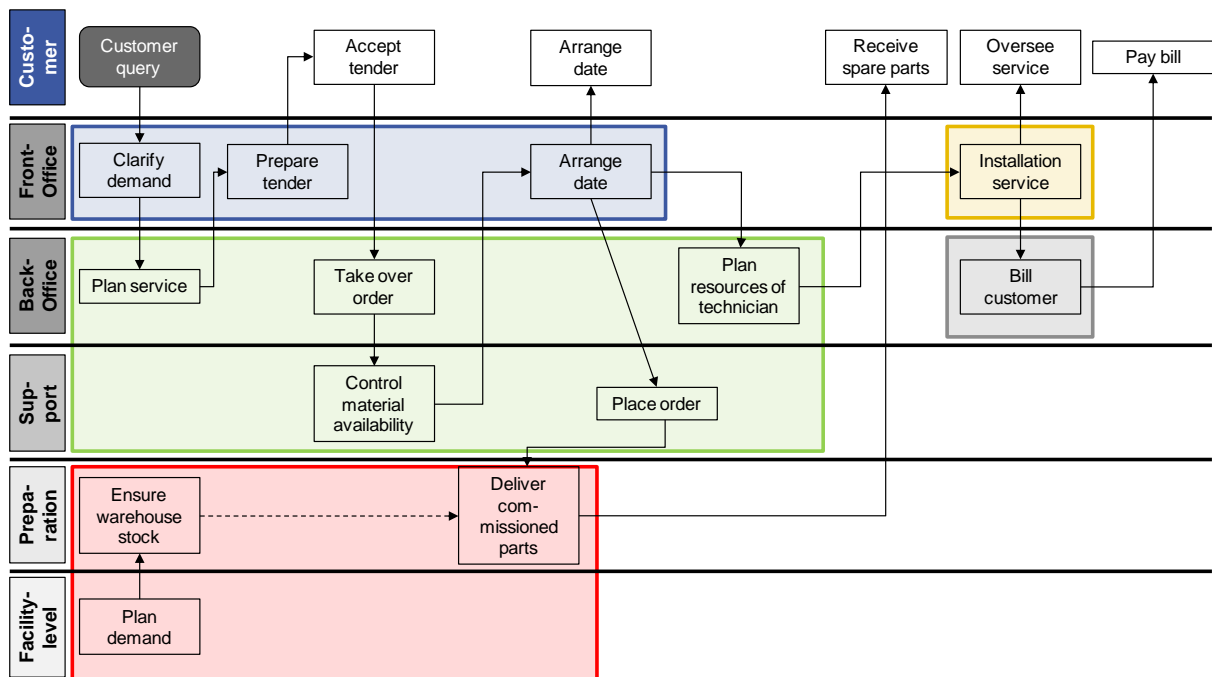

Figure 3: Service Blueprint of a spare part supply

The spare parts supply process starts with a query of the customer, which has to be clarified and planned. Next, the customer is provided with a tender. After the tender is accepted by the customer, the back office continues in processing the order. The next step is material control, which is conducted by the support function. Front office arranges the delivery date, while support places an order for the required spare parts. This is being processed by preparation. This activity ensures warehouse stock and delivers commissioned parts to the customer. After the delivery date is arranged, back office plans resources and assigns technicians to perform installation services. Finally, back office bills the service to the customer.

After blueprinting the process, single steps of the service process are combined to form five activities. Within the spare parts supply process, the activities customer service (blue box), organisation management (green box), warehouse management (red box), field service (yellow box), and billing (grey box) are extracted.

The next step is to identify relevant areas of competences that are necessary to perform the activities. Competences of the customer service are expert knowledge about machines and spare parts. Consulting is required if customers are not sure about their demand, and communication skills are needed to record calls and correspond with the customers. Organisation management is a support function to organize processes. This requires expert knowledge about resource planning software, machines and spare parts.

Warehouse management is a support function to ensure the provision of spare parts. Expert knowledge is required in this area. Field service requires a wider spectrum of competences. This activity requires expert knowledge about machines and spare parts, repairing know-how, consulting expertise, communication skills, and fault analyses knowledge. Perspective transfer is required to perceive the problem and respond flexibly and quickly to new and unforeseen circumstances. The competence screen is shown in figure 4.

Figure 4: Competence Screen of a spare part supply

The developed competence screen of a spare part supply service enables management to plan personnel measures.

The second example is a maintenance service caused by a machine malfunction. The service blueprint is shown in figure 5.

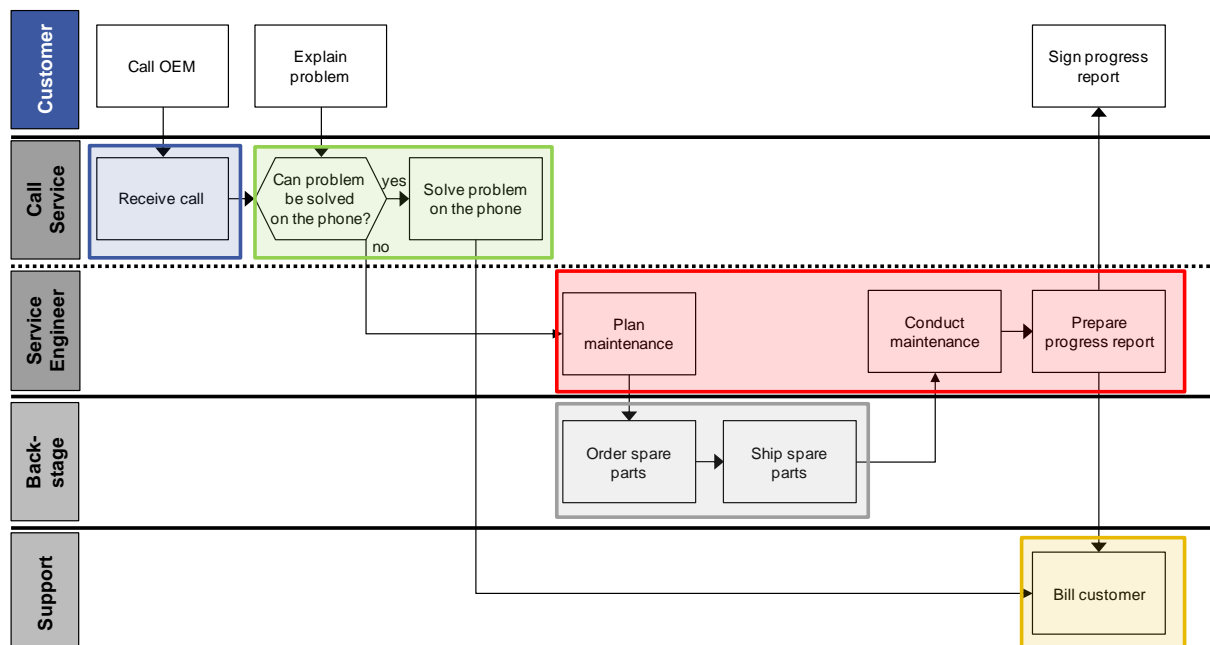

Figure 5: Service blueprint of a maintenance service

The process starts with a customer calling the company due to a machine malfunction. Call service receives the call and connects the customer to indoor service. Indoor service lets the customer explain the problem and then tries to solve the problem via telephone, e.g. with the help of remote maintenance. If the problem cannot be solved via telephone, a service engineer is ordered to plan maintenance. If needed, spare parts are ordered from warehouse and delivered. The service engineer performs the task on site at the customer's. Afterwards, the engineer prepares a report which is signed by the customer. Accounting then bills the customer.

Based on the service blueprint, five activities are identified. In figure 5, the coloured boxes represent the five activities. These are call service (blue), indoor service (green), spare parts provision (grey), field service (red), and finally billing (yellow). Required competences are identified for each activity and the competence screen is developed. The competence screen is shown in figure 6.

|                                 | Call Service   | Indoor Service                                     | Spare Parts | Field Service  |
|---------------------------------|--|--|-------------|--|
| <b>Expert knowledge</b>         |  | _ specific machines<br>_ remote maintenance        |             | _ specific machines  |
| <b>Maintenance</b>              |  |  |             | _ ability to execute maintenance properly                      |
| <b>Consulting</b>               |  | _ address specific questions                       |             | _ achieve long-term improvement                                |
| <b>Communication</b>            | _ with customer via phone or email                   | _ ability to ask relevant and precise question     |             | _ communication with customer on site                          |
| <b>Fault analysis</b>           |  | _ ability to identify faults via phone             |             | _ ability to identify faults                                   |
| <b>Perspective transfer</b>     |  | _ general understanding                            |             | _ solve unforeseen and new problems<br>_ handle new situations |
| <b>Self-responsibility</b>      |  | _ take responsibility for decisions                |             | _ take responsibility for decisions and activities             |
| <b>Flexibility</b>              | _ constant availability<br>_ react to new situations |  |             | _ quick response to customer requirements                      |
| <b>Demographic requirements</b> |  | _ ability to work with remote maintenance software |             | _ travelling<br>_ physically demanding                         |

*Figure 6: Competence Screen of a maintenance service*

As figure 6 illustrates, each activity requires different competences. Call service requires solid communication with customers and constant availability. Indoor service, especially when providing remote maintenance services, requires detailed knowledge about machines and the ability to understand the problem and solve it. Employees also need good communication and consulting skills and need to be able to take responsibility for decisions they make.

The provision of spare parts is a support activity that is not considered in this screen - the same with billing. Field service has a broad list of competences which service engineers need to fulfil. This activity requires detailed knowledge about machines and maintenance processes. Soft skills are necessary as these employees are in direct contact with the customer. There are also different demographic requirements that come along with travelling and physically demanding tasks.

## 4. Conclusion

This paper presents the competence screening concept which illustrates the competences required for providing specific services. This is necessary to optimize competence planning and development in service divisions, and identify inefficiencies and shortages. The approach may e.g. be applied when new services are introduced or existing competences, capacities and processes are evaluated.

The competence screening concept has theoretical and practical implications. The concept draws on service-dominant logic as resources and competences are the major driver of service success. The approach enables the appropriate allocation of resources to ensure efficient and high-quality service provision. Competence screening extends existing literature on service and competence management.

Competence screening is a contribution to management methods, in particular process analysis. It fills a gap that is so far not covered by other approaches like service blueprinting or process chain network. The developed concept contributes to service design literature. By using this concept, services may be designed and optimized taking into account competence requirements and available resources.

For praxis, the presented concept offers the possibility to plan personnel measures effectively and efficiently, and ensure efficient and high-quality service provision. The concept enables solving the current challenges imposed by rising costs, complex services, specialized work force, and demographic changes.

Based on the concept, enterprises are able to structure and plan personnel and competences. Personnel are allocated to specific tasks and processes according to their competences and abilities. Shortages and oversupply, and needs for training, rotation and other employment measures are identified. Competence screening ensures effective and efficient competence management in service divisions.

In order to further develop and prove the concept, competence screening needs to be applied to a wide variety of cases. As individual cases require different competences, competence layers are adjusted accordingly. Applying competence screening in different cases within one single enterprise enables the enterprise to identify their main competences and define a company-specific competence set.

# **Berghäll\_The concept of commitment in explaining micro-level vitality and innovation of an sdl-network dyad**

## **Abstract**

Service dominant logic (Vargo & Lusch, 2004, 2008, 2011 among others) has been a clear line of service science research since its introduction in Journal of Marketing in 2004. A core of the service dominant logic (SDL) is the notion that, in exchange, the service value of the “commodity” defines the value of the exchange relationship to the “customer”. While this exchange can have a monetary value definition, in the actual exchange setting, the actual valuation is done by the individual entering this exchange relationship. While value can be co-created (Gronroos et. al.) as a process, in essence, it is the valuation done by each of the exchange partners separately. Thus, valuation of the “commodity” is a perceptual matter. Further, as value can be derived from very different features of the exchange, the criteria defining the valuation can be very different from what the original producer intended. Thus, for us, the core ingredient and motivation leading the partners to an exchange relationship, i.e. the service relationship, is what we try to understand. We approach the issue from an dyadic perspective in an institutional setting. Vargo (2014) builds an institutional theory framework around the core ideas of SDL. He argues that radical innovations only happen with institutional change. In practice this means that the social system values, roles, role definitions and structures need to change in order to provide a path into new ideas, solutions and innovation. He uses the concept of network vitality to describe the generic capability of the network to enter into in-depth exchange relationships derivative of radical exchanges. Our paper makes an inquiry into this concept of vitality through the concept of commitment (and trust). We argue that the nature of the exchanges is defined by the level of commitment existing in the exchange relationship. Thus, on a very basic level of the dyad, the depth and quality of the exchange is defined by the will and ability of the partners to challenge the “existing” wisdom. While the level of commitment (and trust) can vary between network members, and is even likely to be asymmetric, the vitality of a network is defined, on a micro-level (of the institutional theory) through the level of commitment existing. Thus, we build a basis of micro-level vitality through the concept of commitment and broaden this towards explaining innovation potential of the engagement. This is a work-in-progress paper and was inspired as a response to Vargo’s Key Note presentation in RESER 2014 (Vargo 2014).

## **1 Service Dominant Logic as an Axiom of Economic Exchange**

Service Dominant Logic (SDL), developed by Vargo & Lusch (2004, 2008, 2011, 2014) argues that all exchanges are based on the service value perceived by the partners of the relationship. The value, being a derivative of the perceptual processes of each individual, can thus be very different for each of the parties. While SDL has theoretical outcomes, it is more axiom-like a concept in that it is a basic assumption of economic exchanges (service value) dominates the exchange. Thus, the proposition of service being at the core is not necessarily tested (e.g. Hunt, 1991).

Thus, while the perceived service value dominates the exchange relationship the perceptual processes themselves become interesting, and further, the exchanges between the parties. The exchanges create mutual value that has caused some scholars to use the term value co-creation (e.g. Vargo & Lusch, 2008; Gronroos, 2009). Our interest here is to build a theoretical model on how the dyad-level exchanges could be described as resulting in higher level outcomes of network vitality and network innovativeness. We do this by combining the SDL ideas with the concepts of Trust & Commitment and the notion of expert knowledge.

## 2 Three Institutional Layers

Institutional theory (e.g. Scott, 2004) divides the spheres of institutions into three layers. These are the macro-level, the meso-level and the micro-level layers. Vargo used the institutional structure to broaden the SDL into networks, and aggregate-level models of societal actions (Vargo, 2014). At the same time he discussed network vitality as an important concept in describing service exchanges. Our response here is to describe the micro-level (Vargo, 2014) exchanges with the classical KMV-model (Morgan & Hunt, 1994) ideas, and further supplement these ideas with some social psychological views of relationship engagements (Rusbult, 1980, Bui et al. 1999, Berghäll, 2002 & 2003). In our case micro-level could be described as the simplest level of a network – a dyad. The meso-level would then consist of the network of dyads, while the macro-level would be described as the network of networks.

## 3 Micro Level Exchanges – Commitment and Trust

What ties people into relationships? How strong are such relationships? What constitutes the basis of long-term orientation in a relationship, and what are the outcomes of close interpersonal engagement? The concept of commitment in business exchanges generally refers to a phenomenon in which one side of a social interaction voluntarily restricts one's behavioural alternatives due to the presence of a *long-term orientation*. Committed partners are willing to *invest* in valuable assets specific to an exchange (Anderson and Weitz, 1992; Gundlach, Achrol and Mentzer, 1995). Commitment is essential for successful long-term relationships (Gundlach, Achrol and Mentzer, 1995), and is also of critical importance regarding network operations (Anderson, Håkansson, Johanson, 1994, p.7). Furthermore, similar to the concept of trust, commitment has also been found to exist on significantly different “levels” in individuals with a relational orientation, compared to those with a transactional orientation (e.g. Gabarino, Johnson, 1999, p. 81). Therefore, as commitment implies a willingness to make short-term sacrifices to realise long-term benefits (Dwyer, Shurr, and Oh 1987), commitment is also viewed as being central to successful relational exchanges (Morgan and Hunt, 1994).

Alongside these disciplinary discussions, which are also present in Social Psychology, commitment has been a similar focus of inquiry. Based on the Kelley and Thibaut (1978) ideas of interdependence, and the Rusbult (1979, 1980, 1983) views of relationship commitment, later work has come to argue that *“commitment reliably promotes pro-relationship motivation and behaviour”* (Wieselquist, Rusbult, Foster and Agnew, 1999). Commitment is thereby associated with *“a) disparagement of alternatives... b) willingness to sacrifice... c) accommodative behaviour”* (Agnew, Rusbult, van Lange and Langston, 1998). This work also states that a partner in a *“committed couple can be described as a person a) who has a strong personal intention to continue the relationship b) feels attached... c) feels...obligated... d) imagines... long-term future... e) places primacy in... relationship... f) has overcome challenges... g) has poor alternatives... h) has many tangible and intangible resources that would be lost if the relationship were to*

*end...and... i) confronts difficulties in ending (or strong social pressure to continue) a relationship"* (Arriaga and Agnew, 2001). Commitment is also seen as determinant of the higher-order concept of relationship quality (Fletcher, Simpson and Thomas, 2000). Thus, it seems fair to argue that commitment is often seen as a key explanatory feature of interpersonal relational experiences. These experiences occur on the level of subjective experiences (i.e. perceptions; Lewin, 1935), and are by structural nature implied from Rusbult's (1983, p. 102) observations concerning *"the tendency to maintain a relationship and to feel psychologically attached to it"*. Lydon, Pierce and O'Regan (1997, p. 105) tend to model commitment as two-dimensional, and label *"the positive attitude or satisfaction dimension of commitment"* as Enthusiastic Commitment, and the *"feeling one ought to continue a relationship"* as Moral Commitment. Thus, it seems that relationships might be explainable using the concept of commitment.

### **The Antecedents of the Model**

Drawing from the KMV-model (Morgan and Hunt, 1994), the Investment Model (Rusbult, 1980, 1983), the two-dimensional views of Relationship Commitment (Lydon, Pierce, O'Regan, 1996) and the classic views of the structure of perceptions (Lewin, 1935), symbolic interactionism (Mead, 1934), and the ideas of Marketing as Exchange (Bagozzi, 1975a) it is summarily proposed that relationship perceptions are two-dimensional and consist of the holistic evaluations of the relationship, which happen on the perceptual levels of emotion and conscious calculation. As both of the mediating dimensions of Relationship perceptions seem to be based on some type of holistic impressions, the emotional layering of relationship evaluation in particular should be based on very general feelings or impressions of the relationships. It is thereby proposed that the Rusbult (1980) Investment model of the concepts of Psychological Rewards and Costs could adequately represent such evaluations. According to this model, *"Cost"* is defined as the psychological burden, anxiety and distress-causing elements of relational engagement, while the psychological rewards consist of the positive feedback and gratifying subjective experiences felt by a person.

On the calculative level, Relationship Benefits (from the Morgan and Hunt, 1994), Relationship Costs, Relationship Alternatives (from Rusbult, 1980), Relationship Investments (again from Rusbult, 1980), and Relationship Termination Costs all represent the cognitive evaluations of relational engagement. As in a business setting, where the *"monetary"* calculations hold centre stage in motivating the involvement, it is also argued that the core of the calculative antecedent consists of the computation of relationship *"monetary"* benefits against the liabilities of relationship (monetary) costs. Here, the Morgan and Hunt (1994) concept of relationship benefits must overlap onto positive monetary evaluations. Simultaneously, the concept of Relationship Investments (from Rusbult, 1980) must overlap with the relationship exit inhibitors mentioned in the Morgan and Hunt (1994) concept of Relationship Termination Costs. This would leave the exogenous constructs of the relationship conscious sphere as those of Perceived Economic Benefits, Investments and Alternatives.

### **The Outcomes of the Two-layer Mediating Structure**

In considering the one concept of Rusbult's model (1983), Relationship Stability, this seems to coincide semantically with the Propensity to Leave concept of the Morgan & Hunt (1994) model. However, here we

are faced however with some striking differences considering the relationships. First, the Rusbult model deals primarily with romantic involvement. In romantic involvement's, it is natural to assume that the decision to leave is indeed a very grave one. Contrary to this, business relationships are seldom exclusive, and even when they are exclusive they nonetheless deal with issues that are less- involving for the relational parties. Second, the level at which the relational partners consider the matters must be very different. One can assume that while the business relationships are analysed on a cognitive level, the romantic involvement, by definition, happens on a emotional level. Third, with the emotional complexity of romantic involvement, the "stay/leave decision" must reflect a vast multitude of psychological material that is involved in the decision-making process. So while Relationship Marketing theorists can distinguish between certain outcomes of relational interaction, these are likely to be less complex by their psychological nature, and shallower in terms of involvement than are the romantic involvement situations. As such, all of Morgan & Hunt's (1994) concepts might be assumed to be captured in the Rusbult (1980) concept of Relationship Stability. Thus it is proposed that the core outcome, or behavioural intent, of the model is the "length" of the long-term orientation. As this evaluation happens on the conscious level it also is a cognitive outcome. However, as Morgan and Hunt (1994) argue the emotional outcome could consist of functional conflict and uncertainty. Thus, this outcome could be a measure of emotional security, or trust, felt by the dyad member.

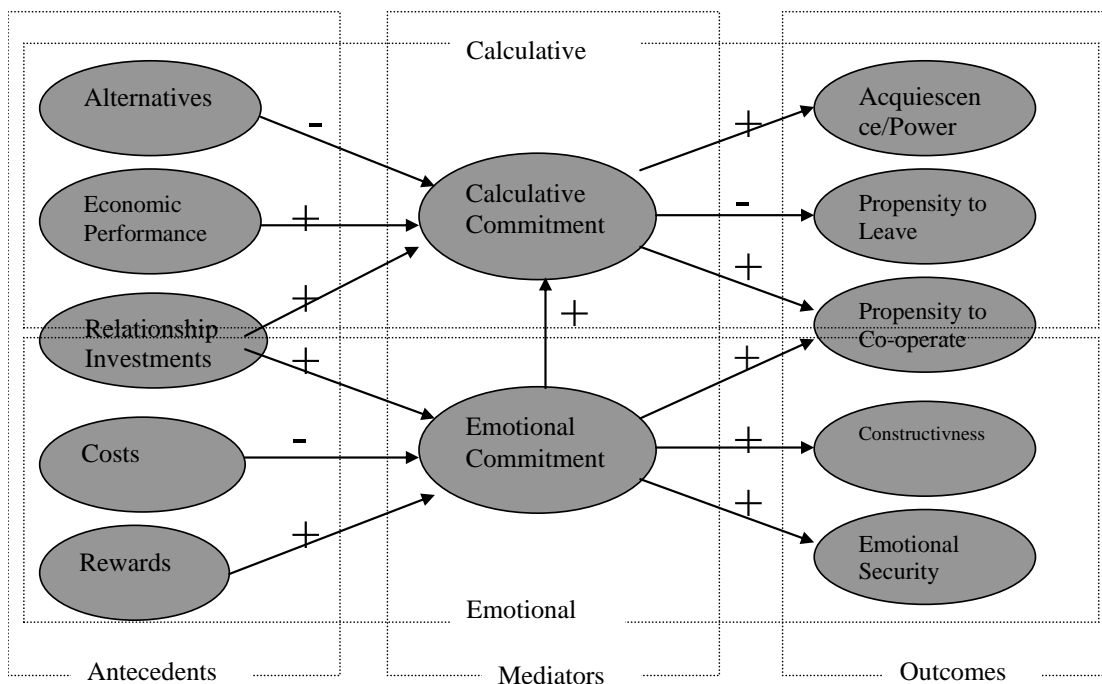

Figure 1: Relational model of Socio-Economic Exchanges (Berghäll, 2002, 2003)

While these issues describe the functioning of the relationship the "service" itself can be more complex. To tackle this complexity the concept of expert knowledge is tackled next.

## 4 The Concept of Expertise

Pedagogical studies have always been interested in how expertise is formed. A social psychological study on mushroom collectors (Fine and Holyfield, 1996) argues that those people whose understanding on the subject (here mushrooms) had more layers and was deeper by each layer, where seen by other members of

the group as experts. While the previous seems intuitively plausible, the definition doesn't escape the social boundaries by which it is tied to.

To understand expertise, it is vital to understand what expert knowledge is and how it comes about. According to Bereiter and Scardamalia (1993, 43) expert knowledge is the only an essential factor of expertise, but it does not make anyone an expert as such. Expert knowledge should not be seen too narrowly, because it, first of all, contains a number of concepts grouped under the terms of formal knowledge and skills. These two forms of knowledge can fairly easily be verified. But the third form of expert knowledge, hidden or tacit knowledge, is not that easy to be seen or pointed out. Nevertheless, Bereiter and Scardamalia (1993, 46) state that this kind of knowledge most profoundly distinguishes experts from non-experts. So, while Shipp et. al (1993) define a skill as "*...a developed ability that can be refined through practise and typically is constituted of potential, aptitude, motivation, style, knowledge, experience, and reflective evaluation*" the expert knowledge seems to have an operational or pragmatic dimension to it.

Bereiter and Scardamalia (1993, 47) list three forms of hidden knowledge that have a major role in expertise: *informal knowledge, impressionistic knowledge and self-regulatory knowledge*. *Informal knowledge* is quite close to some kind of common sense that an expert has over his or her area of expertise. It has been affected by informal knowledge. *Impressionistic knowledge* takes also feelings into account, because in some situations, feelings are an essential and inseparable part of expert knowledge. *Impressionistic knowledge* forms basis for an expert's practical and theoretical judgements. *Self-regulative knowledge* is self-knowledge relevant to performance in some certain domain. It is knowledge that works well for a certain expert, but it does not necessarily work for any other experts.

Referring to several analysis (Bereiter & Scardamalia, 1993; Eraut, 1994; Eteläpelto & Light, 1999), Tynjälä (1999, 359) states that expert knowledge can be seen as a combination of three different components: 1) formal knowledge (declarative knowledge), 2) practical knowledge (procedural knowledge) and 3) self-regulative knowledge.

Formal knowledge can be loosely described as the knowledge that is found in textbooks (Bereiter & Scardamalia 1993, 62). Formal knowledge forms the basis of expertise. The knowledge can be both very concrete and abstract or theoretical knowledge of some area. (Tynjälä 2002, 171) Practical knowledge is acquired and developed in practise i.e. in practical situations where a certain expertise is needed. Practical knowledge is contextual and social in its nature and it can be mentally conscious or subconscious. Tacit knowledge or expert's hidden knowledge are examples of this kind of knowledge. Also an expert's skills can be considered as a form of an expert's practical knowledge. (Katajavuori 2005, 17-18; Bereiter & Scardamalia 1993, 47). According to Tynjälä (2002, 171-172), an expert's self-regulative knowledge is related to the conscious and critical evaluation of one's own performance. If Ackerman et al. (2003) define critical thinking as a person's ability to "*...use information to identify, analyse, and draw conclusions...*", the self-reflective critical skills are by definition meta-cognitive skills. Thus, we arrive at the concept of meta-cognitive skills.

Meta-cognitive skills can be described as conscious evaluation of one's cognitive functions, such as thinking and learning. These skills make us aware of our know-how and its limitations, and thus they enable us to improve our performance (Katajavuori, 2005, 18). The key to professional development is to make the hidden knowledge visible, which paves the way for critical reflection and transformation (Tynjälä 1999, 361). Therefore one can say that expert knowledge is dynamic. It is not something that one could simply achieve

and possess, but it also includes action – doing and learning. According to Bereiter and Scardamalia (1993, 66), “*formal knowledge is converted into skill by being used to solve problems of procedure*”. And respectively, “*formal knowledge is converted into informal knowledge by being used to solve problems of understanding*”. This, thus explains while a lot of scholarly research is interested in the issues of experiential learning (see for instance: Smith and Doren, 2004).

Bereiter and Scardamalia emphasise problem solving as a key factor in becoming an expert. Thus, these arguments highlight the importance of experiential learning so vividly propagated by scholars of business pedagogy (see. for instance: Smith & Doren (2004); Gremler et al. 2000). We argue that this situated learning describes micro-level exchanges where the relational dimensions of the engagement support this learning (or not).

So as already argued, expertise can also be seen as a communal or societal level phenomenon (Bereiter & Scardamalia 1993, 246). When the societal and communal dimensions of expertise are emphasised, then the know-how will be emphasised as consisting of the social and networking skills of an individual (Tynjälä al. 2004, 92). So while the social context of the learning is important, as in the case of the mushroom collectors (Fine and Holyfield (1996), the structure and the operational readiness of the knowledge are also critical definers of expert knowledge. Thus, one could argue that while context-specificity in learning produces context specific knowledge, the experiential (or emotional) nature of the context of learning produces something that escapes the context-specificity.

Figure 2: Two imaginary experts with their own definition of their surroundings and the problem at hand.

## 5 Micro-Level Drivers of Network Vitality

In line with relational concepts and the social psychological views of commitment, we see, that the micro-level drivers of network vitality (or close relational exchanges) are an outcome of the relationship motivational factors (the antecedents) and the related outcome (the outcomes). Thus, what we call the propensity to engage in relational exchanges is what we have labeled as *Vitality Potential* (Vit.Pot.) of each partner. The following describes the concepts in more detail.

In a dyadic setting each of the parties can have (and are likely to have... in line with the logic of SDL), their own perceptions of the value received and created. In line with Morgan & Hunt (1994) one would expect the relationship for each of the engagement to be reflected in the levels of Acquiescence, Propensity to leave (low), Co-operation, functionality of conflicts, and felt security (low un-security). Higher level of each would present the partner in the dyad with a higher propensity to engage in close and deep relational exchanges. Thus, one could call the outcomes of KMV-model (Morgan & Hunt, 1994) as being descriptors of dyad-level potential of network vitality. Similarly, in line with the Social Psychological views of commitment, Security, propensity to leave, and propensity to co-operate, will be the outcomes that need to be high in order for the dyad to function.

Further, as the previous vitality potential is different for each of the partners the total vitality potential should be some sort of a sum of the two vitality potentials (potential of A + potential of B = total vitality potential). However, as these potentials are a direct outcome of the antecedents of the relational models the outcomes are likely to also derived by the model antecedents. We therefore call, the antecedents as motivational factors of the engagement. Thus, the concepts of perceived benefits, perceived alternatives, perceived costs and rewards, opportunism are likely to condition the level that the vitality potential can reach. Vitality is likely to be high if motivational factors are high resulting in high levels of the outcome variables, and vice versa. (morgan & Hunt, 1994; Berghäll, 2002).

While the present concepts described the relationship functioning we combined these ideas with the concepts of expert knowledge.

## **6 Vitality and Expert Exchanges as Predictors of Innovative Activities**

In line with the previous section of expert knowledge, in a dyadic setting, the exchange setting is described by two different perceptual maps of the challenges at hand. The elements of the challenge and the depth of processing of the "issue at hand" is likely to be different between the dyad partners. However, the more similar the perceptual maps are, the easier it is for each of the partners to negotiate a mutually satisfying solution. Also, the more vitality potential there is the more likely it is that the partners are willing to challenge each other and let the other one challenge oneself (e.g. high levels of cooperation, functional conflict, and security). Thus, while similar perceptual maps present an easier prospect for the social negotiation setting, it also easily leads to non-radical outcomes. This is because the sphere of possible outcomes will be reduced. Similarly, different perceptual conceptualizations lead to more challenging outcomes. Further, the more advanced or "state-of-the-art" the perceptual definitions of the exchange setting is in the minds of each of the actors the more likely one is to advance towards new radical innovations. However, the last is subject to the previously mentioned motivational factors but also to the cultural and organizational norms being free enough to let the innovation activity take place (or limiting the outcomes to already accepted operational modes of activity). By the last we mean that if the mandate of the partner entering the exchange setting is strictly tied to predefined outcomes (for instance when business exchanges are directed by a rigid strategy execution), the radical innovations are un-likely to occur. On the level of radical innovations, especially the concepts of Co-operation, Functional conflict and Security of the relationship seem to describe setting were the existing knowledge can be challenged.

On the base of the previous the following diagram presents the logic of the model of micro-level network vitality and innovation potential.

Figure X: The model of Relationship Innovation Propensity (RIP)

As already mentioned the sum of Innovation Potentials result in the total Innovation potential of the dyad ( $\text{Inno.Pot A} + \text{Inno.PotB} = \text{Total.Vitality.Pot.}$ ). Further, the complexity of processing for actor A + complexity of actor B result in Innovation potential ( $\text{Comp.A} + \text{Comp.B} = \text{Innov.Pot.}$ ). Last, the organizational cultural and managerial limitation provide each actor with a freedom of movement in the relational dyad, thus resulting in a threshold of the possible innovation outcome ( $\text{Mandate A} + \text{Madate B} = \text{Mandate Potential}$ ). The figure above present s the ideas developed so far. The Pluses represent the hypothesis of the effect directions. As cab ne seen there are seven direct effects. Thus the hypotheses are as follows:

1. The higher the vitality potential of actor A the more likely the total vitality potential of the dyad is likely to be.
2. The higher the vitality potential of actor B the more likely the total vitality potential of the dyad is likely to be.

3. A higher complexity of processing for actor A leads to a higher potential for innovative outcomes for the dyad.
4. A higher complexity of processing for actor B leads to a higher potential for innovative outcomes for the dyad.
5. The higher is the total vitality potential of the dyad the more likely it is to result in innovations.
6. The higher is the total innovation potential of the dyad the more likely it is to result in innovations.
7. The higher is the mandate given to actor A, the more likely the dyadic exchange is lead to innovation.
8. The higher is the mandate given to actor B, the more likely it the dyadic exchange is lead to innovation.

## **7 Discussion and Conclusions**

This paper discussed the concept of network vitality (Vargo 2014) through the concepts of relationship commitment (trust) and complexity of the relational exchanges (expert exchanges) in a dyadic setting. It built a model of vitality through the concept of vitality potential of each dyad partner separately. Through the concepts of Acquiescence, Propensity to Leave, Co-operation, Functional Conflict, and Security on got a view into the possibility of disproportionate propensities to engage into close exchanges, but also a view into why (motivational factors lacking) few engagements result in highly challenging mutual exchanges. Further, the similarity of the expert knowledge is likely to ease or complicate the exchange setting but also is a predictor of how radical the outcomes from the engagement might be. This last observation describes why organizations striving for tight strategy related managerial steering could also be limiting innovation activities to incremental outcomes. Further, the organizational culture might act as a similar hindrance of innovation through the mandate it provides with different layers of employees. Concluding, one can say, that even though the work is still in its early phases the model can have some interesting and broad outcomes. The key critic here of course being the measurement of such complex issues especially if striving for a confirmatory setting.

# Enhancing the service value proposition in tradition to transformative service research

Neringa Langviniene<sup>1</sup>, Liudmila Bagdoniene<sup>2</sup>

<sup>1, 2</sup> Kaunas University of Technology

*Service value proposition is in the topics of many researches recently. In the context of transformative service research, the framework for evaluation of service value proposition impact on the customer's wellbeing is prepared. Since transformative service research demands covering long-term period and multidimensional evaluation of wellbeing – major points of aspects of wellbeing are discussed here, in the paper. The customer's perspective, as main value co-creator and determiner, is analysed in wider meaning, as of any entity could be engaged: individual, community or a part of a society.*

## Introduction

Transformative service research (TSR) is related to the platform of service researches empathizing the well-being of individuals (they could be customers and providers) and communities (family, society). Services are perceived no longer as a final product, but as engine for societal transformations (Sangiorgi, 2011). The service production and consumption continues to grow (Gallouj et al., 2015), together with larger employment in this part of the economy and stimulated attention from policy makers, businesspersons, as well as scientists. The traditional service research discovers the impact of service, service quality on consuming, satisfaction of a customer, his/her loyalty (Rosenbaum et al., 2011; Rosenbaum, 2015).

TSR examines positive and negative affect (Davis, Pechmann, 2013) of service consuming on the well-being of different entities: individuals, collectives, and ecosystem (Mick et al., 2012; Anderson et al., 2013), giving the focus on long-term impact, as mentioned already. TSR uses the wider approach to consuming of any service, emphasizing the need to supply more (in value for any concerned part) for less (attempt, costs, resources used, etc.); emphasizing the benefit both for consumers and service entities (Davis, Pechmann, 2013).

Among strategic services research priorities – TSR has already been distinguished for several years (Ostrom et al., 2010; Anderson et al., 2013; Ostrom et al., 2015; Sweeney et al., 2015). Many other strategic research priorities are developed, too: measuring and optimizing service outcomes, understanding the service value in the global context, enhancing the positive outcomes in services, giving ideas how to improve customers' wellbeing by consuming the services (Mende, Doorn, 2014), etc. Research questions for discovering the transformative impact on well-being arise – such as how to improve the wellbeing, how to reduce negative impact of the consuming, and what service value proposition is significant, etc. Ostrom et al. (2015) present the framework for services research priorities in 2015, where many dependence relations among strategic priorities, design priorities, value creation priorities and out-

come priorities are developed. Our literature review showed scarce attempts in developing impact on wellbeing of the service customers of service value propositions construct. Service providers change their service value propositions in order to gain competitive advantage (Kowalkowski, 2011) but seldom take care on what influence on final customers is really made before, during and after purchasing these services.

The aim of the paper is to develop a framework for discovering the impact of service value proposition on wellbeing of service customers, all within the conceptual context of transformative service research.

Methodology of the research. Scientific literature analysis on service value proposition, its constructs and logics are revealed. The paper presents a conceptual analysis of service value propositions from transformative services research perspective. A six-step process of service value proposition builder is interlinked to the service customer and his/her perception of wellbeing from different wellbeing perspectives.

Theoretical results: the conceptual framework, what can be used as tool for identifying, measuring and optimizing (or/and improving) the service value proposition for customers' wellbeing, is expected.

The managerial implications cover guidelines for the service researches, which perform researches in the tradition to transformative service research, highlighting the necessity to improve the wellbeing of different entities through the service, as framework will serve as a tool for further transformative and customer researches, too. The insights for service providers in the transformative services industry, with conceptual path in identifying, measuring the service value proposition, identifying the gaps between service value proposition and customers' value perception, taking the strategic decisions on enhancing the value in order to improve the well-being of service customers, are expected likewise.

## **1. Service value proposition**

The attempts to find the way to deliver the exceptional services value recently are growing. Understanding the customer value, its main dimensions, developing value proposition – all that enable to gain the supplier competitive advantage (Rintamäki et al., 2007). The value is a concept analysed already for longer than two decades; and recently value proposition concept is a key research priority settled by the Marketing Science Institute (Payne, Frow, 2014a); one of among fifteen research priorities in a rapidly changing economy, according to Ostrom et al. (2015). The service value proposition is essential strategy in any commercial service enterprise (Payne, Frow, 2014b) as value creation is the fundamental mission of any business. Measuring and optimizing the value, creating clear path for the customer satisfaction could be one of strategic decisions of any service provider in the high competition market (Ostrom et al, 2010).

In common terms, *service value* is understood as service customer benefits (product, service, and image) for his/her incurred costs: price, costs of acquisition, maintenance and service disposal. Skålen et al. (2015) quote Lanning and Michaels, who described the service value proposition as clear, simple statement of the benefits, tangible and intangible, that supplier will provide, along with the approximate price it

will charge each customer. From customer's perspective, the service value is more personal and holistic expression of the service quality. The mission of service value proposition is to answer the customer why he or she should buy the service from a particular provider, not from another one in service market. Usually this assessment is subjective one, considering positive and negative consequences of the service. From provider's perspective, the service value is expressed through service value proposition, where segmentation, service improvement and communication (Rintamäki et al., 2007) are strategic priorities of the provider. The buying motives of the customer, his/her appreciation of valuables are captured in the service value proposition, too.

Comparing the service value proposition and core service offering, the former precedes the latter (Kowalkowski, 2011). The superior service value, probably, enables the provider to sustain competitive advantage and better financial performance (Payne, Frow, 2014b). Nevertheless, the process of the building the service value proposition is never ending, as rivals can absorb the experience of leaders very quickly. They (rivals) can even overtake them.

The service value generates various valuables for a customer, not only savings and benefits to him or her. Literature analysis findings (Rintamäki et al., 2007; Skålén et al., 2015) reveal such values as: enhancing customer experience, increasing customer retention, improving quality, demonstrating thought leadership, reducing costs or (and) complexity, improving understanding or (and) stability, reducing risk, increasing agility, enlarging competitive differentiation, generating revenue (i.e., for business customers), promoting growth, etc. Customer-oriented focus of the service value proposition underlines long-term orientation, established and effective collaboration between the provider and the customer, experienced staff and value-creation opportunities, internal knowledge and competence as advantage, long-term focus in selection of providers (Kowalkowski, 2011), and so on.

Service value providers do not deliver the value itself, but they create the service value proposition in co-creation with a customer (Kowalkowski, 2011; Frow, Payne, 2011). The service value proposition may be explicit or implicit, including tangible or (and) intangible elements. It should appeal to the strongest drivers for customer's decision-making drivers as the customer can take or refuse the decision about the purchasing the service in any / many stages of purchasing decision-making process.

To understand more clearly the process of service value proposition, dividing to separate stages of service value proposition could be beneficial. Thus, close co-operation with a customer in all stages of value builder is necessary (see Fig. 1):

1. *In the first stage*, specifying the group or customers of the service provider is targeting, which market proposition being created.
2. *In the second one*, shaping the value experience, how customer perceives the relation between benefit and costs for the service, answering what does the market value most.
3. *In the third stage*, choosing the offerings, it is the product and service mix (bundle, package), what service provider actually is selling.

4. *In the fourth one*, defining, which customer needs is provider satisfying, how offering delivers the customer value, what benefits the market will derive from the product or service.
5. *In the fifth stage*, qualifying the alternatives in the market for the customer and in differentiation from and better than alternatives here.
6. *In the last one*, proofing substantiated creditability and believability of service offering, value proposition.

Fig. 1: The builder of service value proposition

The service value proposition is a promise of the value to be delivered and a belief from the customer that value will be expected. The service value proposition is an offering to customers representing a promise of benefits (Payne, Frow, 2014). In addition, the key success of services providers lies not only in offering the value proposition, which, after being approved by customers, enables the mutual co-creation, but in clear anatomy of service value proposition (which parts they consists of) (Skålen et al., 2015). Although recently scientists, services businesspersons recognize the urgency of the value proposition, urgency to co-create with a customer, surprisingly few researches are made on that topic, according to Skålen et al. (2015).

The service value propositions could be one of three kinds, according to Anderson et al. (2014):

- *All benefits*, when suppliers list all benefits they believe they might offer. This orientation to the consumer requires least knowledge about him/her and minimum attempts in working on the service value proposition. There are several drawbacks on that approach. One of them is that a customer might not notice the benefit of a service value proposition at all. Large companies with small level of customization lose control on individualized needs of their potential and current consumers. The second fear is that a consumer might not find difference in the service among many market alternatives.

- *Favourable points of difference*, it is the approach, which recognizes that the customer has alternatives. The service providers can use two-three points for differentiation of their service value from other alternatives. The service might have several points of differences targeting to the specific group of their customers.
- *Resonating focus*, the approach, called by Anderson et al. (2014) as “gold standard”. The suppliers, keeping their strategy on that position, can provide such customer value proposition by choosing their offering on the few of elements to target customers. This type differs from the second (favourable points of difference), as on-two points of difference are delivered, extended to improve and growing the value to target customers. The unnecessary elements (services, products, values) are not provided. This approach lets the supplier to deliver costs savings to the customer.

Service value proposition, acting under the *all benefits* value, should answer the customer why he/she should purchase service from a particular provider. The value proposition of *favourable points of difference* recognizes the outfall that a customer should find the answer, why he/she should buy here instead of a competitor, other alternative. The resonating focus answers the question how market offering delivers the superior value to the customer compared to other best alternatives. Authors (Payne, Frow, 2014a) recently agree that the third approach of the service value proposition is preferable and the most promising. Mass-consuming, oversaturation of the market by products is not glorified anymore.

Other approaches to deliver the service value also exist. To be competitive one and to deliver the superior value – service supplier should engage the customer into the service process (Frow, Payne, 2011). The help of a customer as a co-creator is unappreciated, as he or she both participates in choice, in preparing, in producing, as well as in consuming the service. The customers, doing business with the providers, influence the service performance, as well as service perception, and value. Besides that, the performance benefits and pricing-based benefits, relationship-building value and co-creation value are especially important to the service customer (Payne, Frow, 2014a), as opposite to the value of production items.

Otherwise, one more solution to enhance the service value proposition – is to choose the strategy for development of the business: 1) reduce cost and performance; 2) increase performance and price; or 3) enhance the value without increasing price. The first is traditional one, but competitors also can easily overtake this practice. To increase performance and price is rather risky practise, as the service provider might not be always sure, if he or she wins from that. The customers usually avoid paying more even if they perceived they get larger value from a service. The third strategy for development of the service value seems might bring the largest value for a customer as a price is not going to be larger.

The service value could be by the value it reflects, according to Rintamäki et al. (2007): *economic*, based on price of a service; *functional*, based on specific functional needs; *emotional*, where experiential needs are dominating; *symbolic*, based on self-expression needs. It highly relates to what a customer expects from consumed service: to satisfy their needs cheaply, to solve problems, actualize himself (herself), etc.

The value concept for different stakeholders might be different. Each entity as customer market, referral market, supplier and alliance market, influence market, recruitment market, and internal market (Frow, Payne, 2011) has own point of view to the service value proposition benefit. The S-D logic states that service providers offer value proposition, that value is being co-created during the interaction; however, the customer in the context, not the provider, or other entities, determines it (Skálén et al., 2015). Thus the service value proposition is a promise that a customer and other interested parties will benefit from the service offering, how it is offered, how customers will be involved in the value co-creation/co-production. The paper focuses on service value proposition, upon the customer markets: buyers, intermediates and final consumers. Even if the value for other markets should be estimated, the value for the customer could not be the point of parity – underestimating the value for a customer will destroy the value for other stakeholders, undoubtedly, too. For example, reducing costs for the customer should not increase the damage for environment.

## **2. Transformative service research**

Transformative service research with increasing interest from scientists, businesspersons, society differs from the traditional one in many cases. According to Crockett et al. (2013), problem identification in the transformative service research is associated with significant social problems and multi perspective (in comparison to simplified problem and specialization in the traditional research). Wider data techniques applied, comparing to the traditional; as well as sampling, are flexible and creative, instead of representative, large. The transformative service research emphasizes consequential benefits instead of short-term one. There are many other differences in the transformative service research comparing to the traditional one. Scientists (Anderson et al., 2013; Crockett et al., 2013) emphasize them in order to engage/attract more scientists from different science fields, transdisciplinary teams with broad range of knowledge, expertise and resources, in order to cover multidimensional aspects of our life, in order to increase the individuals, the community's wellbeing.

The urgency of research translation in the traditional research is underestimated, too. After publishing results of any survey, many researchers hope that they have done their best in order to improve individuals' life. However, to be published – results usually are presented for individuals from the same community: scientists, several businesspersons, students, etc. The translation of results to "normal" language, understandable for any representative of our entity is emphasized in the transformative service research only, too. This is possible engaging consumers, policy makers, managers, scientists in sharing information, processing surveys, shaping instrument for the research, etc. Not only academic journals or conferences as communication means should be included, but also social media, networking, the Internet, increasing the wish of any actor to share well practice in enhancing his/her or whatever wellbeing.

The aim of the transformative service research has many qualities, such as highlight sociocultural and situational contexts, disseminating findings to different shareholders (Davis, Pechmann, 2013). The transformative service research seeks better quality of life for present and future generations, according to Zayer et al. (2015). Primary qualities – the improvement of wellbeing and collaborating with the customers – are emphasized. To give the ideas – how to improve consumer's life with one or another

service (Mende, Doorn, 2014) – the second motive might be mentioned. Rosenbaum (2015) emphasizes that the research should focus on creating positive changes and improvement in the wellbeing of individuals. He criticizes that 25 years of traditional service research had no or little benefit on the customers' welfare. Services organizations using segmentation on the ground of the traditional research (Rosenbaum et al, 2011) ignore or even harm the consumer wellbeing as target segments usually include the most profitable customers, forgetting the deprived one. While the traditional service research traditionally focuses on the managerial and marketing issues and profits, the transformative emphasizes the consumer wellbeing, what depends a lot on delivering and designing services, implementing policies, and shaping the service value proposition so that the providers and the customers, as well as any other related shareholders – could benefit.

Unfortunately, the transformative service research successfully ploughs ones way in many disciplines as sociology, psychology, etc., but business researches in the transformative service perspective are still sparse.

Growing attention to the transformative service research opened many untouched fields in the services marketing. One of such is what role of services is played affecting the consumer wellbeing, according to Anderson et al. (2014). The interrelationships among *value creation priorities*, including 1) understanding value creation, and 2) enhancing the service experience – and other priorities in the transformative service research, such as *strategic priorities*, *design and delivery priorities*, and *outcomes priorities* are underlined in 2015 (Ostrom et al, 2015).

Recently scientists try to explore that role, trying to look deeper into the services, which could influence directly or indirectly the wellbeing of many entities, access to services, decrease of disparity, health care, etc. Of course, the service economy, what makes the largest part of any advanced economy, has a large impact on the wellbeing, too. It could be positive, as well as negative one. Blocker et al. (2013) entitled the negative wellbeing as *ill-being*. The traditional service research does not study how to sell services more, but what effect in buying the services could be, and how to improve the wellbeing sense of customer, his/her family, collective before/during or after purchasing, for example, expensive service. The transformative service research challenges researches to undertake studies in fundamental problems and opportunity searching (Crockett et al., 2013). They do not focus on single problem or opportunity for any single entity, such as a particular service provider or a customer. That is why the transformative services researches, which main task is to explore ways in improving the wellbeing, should be applied to services *per se*.

Conceptualizing the transformative service research, the authors (Anderson et al., 2013) stress that a relation between services' entities and consumer wellbeing occurs. Giving the framework for the TRS entities and wellbeing outcomes, the above-mentioned authors displayed that both *services entities*, such as sector, organization, offering, process, employee; and *consumer entities*, such as ecosystem, collectives, and individuals, affect the wellbeing outcomes. The impact could be direct, as employee's impact on the customer wellbeing, or indirect, as offering's impact on ecosystem. Looking deeper, the transformative service research analyses deeper connections, such as between service offerings and individual's wellbeing (Hall et al., 2015). The services touch many fields in our daily life and their effect could be positive and negative. Currently rising attention to sustainable development forces the researchers to investigate what exactly in the service providing systems, separate

processes, value elements have positive or negative outcomes, enhancing the former, minimising the latter.

The service provider cannot manage several effects, such as consumer interaction with service sector (the impact is minimal by a single provider), macro environment influence, etc. However, the service offerings, the processes, the employees could be under control of the service provider. The service providers' offering may have different benefits for the services customer: technical, economic, service, social (Anderson et al., 2014). The question whether *wellbeing* is performed as outcomes of service value proposition – is essential. Traditionally the focus on service outcomes that compose the thought on wellbeing outcomes, such as equity, social justice, human capabilities and development, freedom, happiness is needed, as service consumption influences customer wellbeing, life satisfaction, and perceived quality of life. Sweeney et al. (2015) state that satisfaction with concrete events and experiences spills over life domains, work, leisure, health, family, and entire life satisfaction; thus enhancing the service value proposition for customer may help to improve the wellbeing of most of them.

The transformative services research offers the platform for investigating long-term impact on customer's wellbeing; often not separating from wellbeing of the family, collective. The challenge of TRS is to improve life in current conditions, demands, and potentialities (Crockett et al., 2013) as increasing the production can negatively affect the ecological, social environment, and hereby overall wellbeing.

### **3. Setting the framework**

Although customer-oriented value proposition factors are crucial in defining what aspects should be evaluated, the providers' perspective is usually dominated in building the value proposition. One aspect that is more urgent should be taken into the domain: stakeholders' needs should be as possible as balanced (Frow, Payne, 2011) in order to improve the wellbeing of the customer (directly or indirectly). The wellbeing commonly is understood as positive evaluation of the quality of life experience. Any wish of an individual is to improve his/her wellbeing, state of being comfortable, healthy, happy with all (many) sides of his/her daily life. The transformative service research focuses on peculiarities of the role of the services and services customers themselves play in affecting the customer's wellbeing (Rosenbaum et al., 2011).

As all interested parties determine the service value proposition, the wellbeing is also related to all parties concerned (Skálén et al., 2015), such as enterprises, customers, other actors in the market, community. Even if the paper reveals the wellbeing of customer; identifying stakeholders; determining values; shaping the offerings; clearing the value provided; withstanding the alternatives and differentiating; and proofing the evident benefit to other related stakeholders are required.

The subject of wellbeing might be assessed objectively and subjectively, but the essential matter to look at it more deeply from the customer's perspective – to evaluate subjectively how the customer perceives the service value proposition, defining social, emotional, functional welfare as outcomes of service value. According to Rintamäki et al. (2007), the service value proposition, which is defined from customer's perspective, plays the strategic role in suppliers' pursuing the competitive advantage

before others. Even if the service value proposition and customer's wellbeing are two interrelated but independent streams of literature, the literature analysis showed that the link between service value proposition and wellbeing of a customer really exists. Moreover, it might be used in identifying the successful service value proposition in the tradition to the customer wellbeing.

In response to the transformative service research the focus on the value should be resonating, without any unnecessary elements, tangible or (and) intangible. Resonating focus is considered as advance because of basement on points of parity with and clear difference points from supplied by competitors. These two categories are different, but they play the complementarity role: a) points of parity give the same value, functionality, performance to the customer as those of the next best alternative; b) difference points – explicit values, what are extremely different from competitors. Resonating focus in service value proposition is the way, where unnecessary elements in consuming are avoided, the most valuable elements are provided.

Rath, Harter (2010) in their research proved five groups of the wellbeing affecting individuals' life, and exploring elements of the countries wellbeing. The first group relates to the element how an individual occupies his/her time and does every day – *career wellbeing*. The second – *social wellbeing* – tidily relates to relationships and love in the individual's life. *Financial wellbeing* is about efficiency to manage individuals' economic life. *Physical wellbeing* is the fourth element of the wellbeing, guaranteeing good health and energy to get things done. In addition, *community wellbeing* gives the sense of community, of engagement with area of individual life. Measurement of Happiness indexes of individuals, communities refer to objective estimation of wellbeing. This index uses criteria for evaluation education level, literacy, access to health care, mortality, etc.

The research is related to estimation of individual hedonistic wellbeing. Long-term individual wellbeing is tidily related to collective wellbeing and cannot exist separately (Anderson et al., 2013); thus these concepts are used in parallel. Subjective evaluation of the wellbeing is more individual instrument, what depends a lot on individual's estimation of his/her quality of life.

Usually an individual chooses himself/herself the bundle of elements, which satisfies his/her, wishes, what could be improved, etc. The individual decides – what elements of *physical*, *mental*, *spiritual* or *social* wellbeing – are the most important for him/her in long period as the transformative service research grounded on long-term impact on the individual's quality of life (see Fig. 2).

These four types of the wellbeing are highly interrelated. As an individual decides himself / herself what it is more important, what elements of wellbeing are crucial, the elements shaping the bundle are provided in the dotted package.

- *Physical wellbeing*, measured on health status: body and mind. On the one hand, improving the physical state enables to improve emotions of the individual, his/her mental and spiritual wellbeing. Disharmony of health status, on the other hand, reduces the satisfaction with life; it is mental, spiritual wellbeing as well.

Fig. 2: A framework for identifying service value proposition link to customer's wellbeing

- *Mental wellbeing*, measured on how individual is feeling how he/she can manage with daily stress. Mental wellbeing is evaluated through feeling of satisfaction, pleasure, confidence, engagement with daily family and working life. Individuals' ability to get balance in his/her life.
- *Spiritual wellbeing*, measured on individual's feeling of belonging and relations with the world; his/ her perception of meaning of life. Increasing the spiritual wellbeing let individual to live giving priority to his/her life, refusing from stress,

daily routine, etc. That part of wellbeing is tidily relates to spirit, freedom of relationship and joy with life.

- *Social wellbeing*, measured on what role of community an individual plays, getting satisfaction from relationship with other people. That part of wellbeing is measured on many elements related: food, cloths, and accommodation, education and health services. Economic stability, satisfaction with job, moral standards, and freedom to change the life, income equality, social trust, social networking, and child development – these factors influence the wellbeing of individuals.

Political freedom, peace, stability, equity are external elements creating the positive outcomes for social wellbeing (Hall et al., 2015). Resources, social position, life chances, prestige, psychological profile, integration, personality traits, previous experience, employment, education, integration – all these aspects usually overlap in their parts of the individual's wellbeing.

In detail, shaping the *market element* in the service value proposition, all four parts of wellbeing should be estimated. Physically customers should have access to daily or casual services, local or foreign services providers, commercial and non-commercial services, depending on situation, of course. Mentally service providers should seek the balance for the service consuming, as taking about services or final that is more important looking to the transformative services perspective, many services should help individual to solve daily problems, routine tasks at home, find holiday solutions, etc. Spiritual or emotional wellbeing it is about relationship with environment, other people, himself/herself. Individuals need to feel connected with and significant to others with whom they collaborate (Mende, Doorn, 2014). Building positive relationship is important. In addition, social wellbeing market shaping cover wider aspects of our life, satisfying him/her in security, accommodation, catering, rest organization, etc.

Service researches (Ostrom et al., 2010) use the term *experience* for all aspects of production, delivery and creation of value from customer's perspective. Physical *value experience* covers costs, producing and consuming the service, decrease of value because of age, market conditions, and reduction in purchasing power. Growing economy brings not only increased consuming but also increased costs for services, too. Mental value, sometimes called as mental health, is experience to enjoy the life, to create a balance in all fields of one's life. It is rather subjective well-being, perceived autonomy, competence and self-actualization. Spiritual value experience covers practice to be other-oriented before self-oriented that is important too, but not as high as earlier. It is not related to religious but to humans' belief that he or she is growing spiritually. Social value experience –is experienced changes of environment of an individual, what shapes needs, wishes for their life, as well as consuming services.

Talking about *offerings*, we should remember the resent trend in sustainable world (even a need) of minimising the services package as resonating their value. Delivering service in a sustainable manner, for example, improving health of individuals, (Ostrom et al., 2010) is a priority task for many service business executors recently. The challenge providers meet – how to prepare an offering, covering majority or even all aspects of the customer's wellbeing. Physically it could be realised through service product in a wider meaning, price, and package. However, the service offering usually contains more intangible values than physical ones. The service provider

should think about what exact services help to reach the balance in the individuals' mental wellbeing, balance in routine, busy life. Spiritual wellbeing formulates a task to provide services, which can help to join the community, refuse from unnecessary care about troubles. Social offering covers services provided in wider meaning: package, tangible, intangible value, tangible, intangible offers.

*Benefit* also has four strains in the service value proposition. Physical benefit and wellbeing of customer depend a lot on his or her co-creation in services. While production item benefit could usually be accessed in advance, the physical benefit depends a lot on how a customer is involved physically, does whether? an outcome is suspected quickly or not (for example, after health care services); as well as on his or her participation in the service production process. It is a large challenge for a provider as many kinds of services have less touchpoints, where services could be displayed physically. Mental benefit for the consumer covers less stress in daily life, new energy for life, business, job, responsibilities, enjoyment in his/her life and environment. Spiritual benefit for individuals manifests in self-actualization, flourishes people, who take time for themselves, to get in peace with themselves. Social benefit of individual has broader meaning, as welfare of a society, in producing and consuming services. Social benefit has a priority in the transformative service research before private benefit.

In relation to resonating focus to *alternatives* in services market, physical wellbeing should be communicated very well. As, in some cases, providers physically can demonstrate their differentiation, it is easier explained for improving physical wellbeing. Preparing the value proposition no provider supposes that he/she is the single one, but creating the exceptional value proposition, with one-two qualitative, clear differentiation with closest competitors (not only geographically) is required. Mental alternatives depend a lot on an individual: one wants passive rest, others – active, one wants engagement into decision-making, service co-production, others not. The service *per se* also affects the shaping of mental alternatives for the consumer. Alternatives for spirituality wellbeing, personal growth depends on an individual, his or her family, peers, and community. The provider should evaluate – wants or not a consumer, consuming the service, to grow, to get or to share knowledge, to participate, to be beneficial for others, and the way to organize that. The consumers usually find positive effect in their wellbeing when they are engaged into the co-production of services (Mende, Doorn, 2014). For example, getting more information about personal investment into financial funds, giving more ideas about health treatment help to a customer to be responsible for his or her decisions, as well as evaluate services as higher quality. Sometimes participating in the service production reduces the fear of a customer depending on a service provider, directly improves the objective wellbeing (i.e. reduces illness, increase literacy, financial stability). Not all services have direct impact on social wellbeing of a society, but educating customers, giving more information about necessity to save the world in minimising damage for environment could be beneficial. Social alternatives mean buying services by not refusing ourselves, being ourselves. There are many alternatives in services market but individuals usually try to purchase and consume services, which they like: music, education, travel, etc.

*Proofing* the improvement of the wellbeing of an individual is the last step in the service value builder. As improvement of wellbeing is long-term phenomenon, the proof of service value proposition is difficult task for the service provider. Proofing the physical wellbeing of service value proposition providers use calculation and measure-

ment of costs and benefits, experiments, demonstrating visible value for customers. Engagement of customers into the process, after-selling communication could be helpful. Mental, spiritual and social wellbeing are difficult to demonstrate, that is why here customer's participation, co-creation, discussion and constant improvement corresponding to customers wishes are necessary. Demonstrating social wellbeing society's help could be involved, too.

Improvement of the service value proposition consequences the improvement of individuals' wellbeing. Physical wellbeing is to be easier demonstrated, created and communicated. While spiritual and mental depends a lot on an individual and subjective estimation of his or her life. Social wellbeing covers many aspects of individuals' life and depends on tangible, intangible elements of services, individuals' attitude, and relation with family members and other service entities. Covering majority aspects of customer's wellbeing in preparing service value proposition will guarantee the improvement of wellbeing, individual satisfaction with life, with provider, with his suggested service value proposition.

## **Discussion**

The interest for the transformative service research has been growing recently. The drivers in service economy (Gallouj et al., 2015), such as transformative power of new technologies, human capital, transformation and globalisation of markets, changing role of state and other authorities, environmental challenges, will affect well the interest on the transformative service research, too. It is believable that interest and necessity to cover wider field of interests in order to guarantee, to improve the wellbeing of individual – will replace the interest to short-term outcomes of service business and marketing. Improved working conditions, life standard, better access to literacy and education, aging population, increased consuming in many advanced and growing economies shapes more opportunities to engage in community, with sense of membership of wellbeing shaping. The complementarities among entities enhance them own wellbeing as well as other shareholders. According Gadrey (Gallouj et al., 2015), winning services, such as repair, maintenance, local government, services for elderly people, as well as children, have more perspectives in future service economy. That's mean, that new and increased consuming are not exalted, estimating that the service producing and consuming outcomes could be positive, as well as negative: for a customer, family, even a provider and entire community.

Service regression and service extension in the context of the transformative service research should be also emphasized. The resonating focus on the service value proposition formulate a task for a provider to be competitive one with two-three valuable qualities, what it is impossible (almost or hardly) to be copied by competitors, but valuable for customers, minimising negative outcomes (such as damage for environment, for example, for family), and maximising the positive one. To optimize the value of the service is one of the most important tasks (Ostrom et al., 2010). It is a strategic execution priority of any business – to improve wellbeing through the transformative service. As service dominant logic asked scientists about theories and frameworks helpful for the service to move forward, deep absorption of these phenomena might open more opportunities for providers to be competitive.

To keep in step with drivers of the future service economy (Gallouj et al., 2015) and directions of development, sustainable development of the service value proposition, developing several key qualities, covering physical, mental, spiritual and social wellbeing, is required. Changes in technologies are leading to changing how customers serve themselves before, during and after buying services (Ostrom et al., 2015). Higher level of their participation could be both positive and negative for service quality, but shape a sense of co-producer that is in itself good. The customer engagement helps to differentiate the service value proposition, to be unique.

The transformative service research during the last decade covered issues for improvement of many services, such as health, financial, education. As not all services, seem, have direct positive impact on wellbeing, such as retail, hospitality, entertainment (Rosenbaum et al., 2011), etc., splitting kinds of wellbeing of a customer and how he or she perceives service value for him or her – that could help both to understand and to improve outcomes of consumed services. The services have potential to uplifting changes and improvement in customers and communities wellbeing (Sangiorgi, 2011), to create new behavioural and interaction models, as well as new value for all shareholders involved in services processes.

The implications for the transformative service providers are related with regard to special attention to aspects, forming the service value builder on four wellbeing perspectives: physical, spiritual, mental and social. To increase customers' wellbeing, the transformative services providers can make insights how to prepare, to test and to improve their service for long-term success satisfying the customer and guaranteeing their complete wellbeing.

## **Concluding remarks**

This paper provides a theoretical contribution to the service marketing researches by exploring the application of the concept of service value proposition to the customer wellbeing.

Practical implications of the paper reveal the guidelines for practitioners how to formulate new service value proposition or improve it in the harmony to the wellbeing of service customers. We can recommend that service providers might emphasize on their service value proposition builder examining their current value propositions, preferable and considering how it could influence the wellbeing of their customers' wellbeing. Service providers need to be more aware of the value proposition as the enterprise key strategies, but it should correspond to the wellbeing of customers, getting balance in social, physical, mental and spiritual welfare. The link between constantly improved service value proposition and wellbeing of its users has become acknowledged in scientific research recently.

We stress that the service providers should analyse, control and constantly improve their service value proposition through all stages of its builder in order not only to gain competitive advantage (it becomes not the most urgent task) but also to help to improve customer wellbeing. The resonating focus on the service value proposition refusing unnecessary tangible and intangible elements of the value, improving one-two elements and communicating it to the market properly – will guarantee such service value proposition, what satisfies both interested entities (and even more): pro-

vider, as well as customer. Even if narrow specialization in the market seems to be risky, continual maintenance of the value proposition builder in respond to the customers' wellbeing, doubtless, will be proper support in the competitive market in long-term success.

We believe that conceptual framework for link of the service value proposition to customers' wellbeing helps managers of service firms to identify, shape, improve service value proposition in all six steps of value builder, quickly reacting to customer's wishes, needs and appreciation. It helps to distribute service process in the most proper way to balance the wellbeing elements of the customer: his/her social, mental, physical and spiritual wellbeing.

Since the paper has presented a conceptual attempt to frame the impact of service value proposition on customers' wellbeing, empirical research should test the measurement proposed. Future research directions could also explore ways to develop, add, delete, if necessary, other capabilities to evaluate.

# Exploring Customer Value in the Experience Economy Service Encounter: An Exploratory Study

Claire Forder

Roskilde University

*Customer value has long been researched in both product and service regimes and is considered by both perspectives as a key source of competitive advantage. Despite the considered strategic advantage of the construct of customer value, there remain disparate definitions of this concept. Research on expected customer value in the service encounter within the discipline of hospitality still seems to be in its infancy. The purpose of article, based on an exploratory qualitative study is to attempt to conceptualise how hospitality frontline managers define and/or describe expected customer value in service encounters. The aim being twofold; a) to understand how practitioners, working within the experience economy understand expected customer value and b) how these descriptions relate to and/or fit with or differ from current thinking about value in the experience economy, which may contribute to a better theoretical understanding of value in the experience economy service encounter. Thematic coding of frontline managers' descriptions/definitions of expected customer value in the service encounter revealed an (untested) conceptual framework consisting of six central constructs of expected customer value; Service Value, Behaviour Value, Economic Value, Psychological Value, Social Value and Co-creation Value .*

## Introduction

For any organisation, but in particular for companies working within the experience economy, understanding what creates customer value can give a competitive edge. The concept of the experience economy is not a new phenomenon. It can be traced back in time to Roman/Greco understanding of selling experiences (Boswijk, Thijssen, & Peelen, 2005). Since the rise of commoditised mass tourism in the 1970s with the advent of jumbo-jets and cost-effective transportation, tourism experiences became subordinate to money generating products with relatively little focus given to the experience (Poon, 1994). Growing affluence in western societies and changing trends in consumer consumption away from mass consumption of tourism products towards self-actualization through experiences, is changing tourism (Cordente-Rodríguez, Mondéjar-Jiménez, & Esteban-Talaya, 2012). According to a report compiled by Earnest and Young, a key emerging tourism trend consisting of increased demand for experience-based tourism is challenging the hospitality industry (EY, 2015). Changes in consumer behaviour towards experience as a key value driver, suggests a need for the tourism industry to shift from modernity driven commoditised mass-tourism thinking towards a post-modern understanding of tourism as a co-created experience rather than a product. Understanding and reacting to this shift can be a source of competitive advantage (Prahalad & Ramaswamy, 2004).

One of the core concepts of the experience economy is adding to customer value by creating memorable experiences ((Otto & Brent Ritchie, 1996; Sørensen & Friis Jensen, 2001). Customer value is a much researched phenomenon, extant literature reveals disparate understandings and definitions of the construct from both organisational and customer perspectives (Bille, 2010; Bitner et al, 1990; Gronroos, 2006; Parasuraman et al, 1985; Sheth et al, 1991; Sheth & Uslay, 2007; Vargo et al, 2008; Verhoef et al., 2009). However, there seems to be limited empirical evidence or research focused on how *front-line practitioners* understand customer value.

The purpose of this paper is to unveil how front line managers working in the Danish experience economy understand customer value. Given the strategic advantages implied with a shift from product/service based to value adding experience based management, how do practitioners who are expected to facilitate customer value, understand the concept of customer value? What value do they expect a customer to take away from a service encounter? In order to answer these questions, the paper has been structured as follows: firstly, a

discussion of the central concepts used is conducted; a) as “expected customer value” is examined in the context of the service encounter, the phenomenon of the service encounter is briefly discussed; b) because the study is set in the context of the experience economy, and the two constructs of experience and value are central and intertwined in the experience economy, an abbreviated discussion of these concepts follows; c) given the focus of the study, the concept of customer value is also debated. Secondly, the methodology used to explore frontline managers’ understanding of customer value in the tourism service encounter is explained. Thirdly, an analysis of the available data will be presented followed fourthly, by a conclusion including limitations and implications.

## The Service Encounter

Extant service literature reveals varying definitions of service encounters ranging from undefined periods of time where a customer as any interaction with a with a firm to clearly defined touch points (Bitner et al., 1990; Mattila & Enz, 2002; Mattsson, 2009; Surprenant & Solomon, 1987). Service encounters have further been defined by Surprenant and Solomon (1987) as having a human element. Bitner et al (1990) present four typologies of service encounters based on the perceived level of customer participation (Bitner et al., 1990). These typologies range from low levels of customer participation to high level customer participation, where low participation is classified as merely the presence of the customer and little else, and high participation where the customer is engaged in co-creating the service product (Bitner et al., 1990). Shostack (1985), on the other hand, defines three concrete types of service encounters from remote encounters to telephone contact to face-to-face interaction (Shostack, 1985).

In tourism literature Otto and Brent Ritchie have noted the “intimate, hands-on nature of the service encounter” (Otto & Brent Ritchie, 1996). Sørensen and Jensen distinguish three types of tourism encounters one being the customer/employee interaction, the second being customers’ usage of companies services and communication encounter, described as sales and marketing activities (Sørensen & Jensen, 2014). Moreover, Sørensen & Jensen highlight the special nature of the tourism encounter as these encounters can also embody “the end; the actual tourism experience” (Sørensen & Jensen, 2014). In the context of this study, service encounters are taken to be the face-to-face interactions between staff and customers mostly occurring on the front-line. Recognition is, in this study, given to the fact that there are varied kinds of service encounters of both typology and temporality.

## Experiences and Value

It could be argued from the customer point of view, that the main purpose of the tourism industry is to expedite experiences. From the organisational perspective, the better the customer experience, the more value perceived the greater the chance of positive word of mouth (free marketing) (Taghizadeh, Taghipourian, & Khazaei, 2013). Positive word of mouth has the dynamic effect of attracting new customers with comparatively less effort than strategically designed marketing strategies. Also, the better the experience the greater the chance of customers returning the higher the probability of retaining the customer and increasing potential for augmented revenue (Mittal et al., 2005; Swanson & Hsu, 2009). Furthermore, Pine and Gilmore argue that customers are willing to pay higher prices for “an experience” describing this phenomenon as the fourth source of value (Pine & Gilmore, 2013). In the experience economy, experiences and value are inextricably linked. Boswijk et al make a distinction between experiences and meaningful experiences (Boswijk, Thijssen, & Peelen, 2007). They define experiences as; *“An immediate, relatively isolated event with a complex of emotions that leave an impression and represent a certain value for the individual within the context of a specific experience”* (Boswijk, Peelen, & Olthof, 2011, p. 60). On the other hand, they apply Snel’s definition of meaningful experiences which is *“Experience is a continuous, interactive process of doing and undergoing, of action and reflection – of cause and effect – that is meaningful to the individual in (more than one) different contexts of his*

*life, An experience causes an individual to change his perspective on the world and/or himself (Snel, For the love of experience, 2001)".*

From these two definitions, a compelling argument can be made that the more profound the experience, the more memorable and longer lasting it will be and the greater the value will be attributed to it. In the experience economy, organisations should be aiming to create profound, long lasting (positive) experiences that are remembered and talked about with others. Due to the inherent nature of the tourism product, customer involvement in the production and consumption of the experience is essential (Sørensen & Jensen, 2015). Service Dominant Logic (SDL) emphasises the role of the customer in co-creating value which is also a prerequisite for the creation of memorable experiences (Gronroos, 2006; Vargo & Lusch, 2004; Vargo et al., 2008). Chandler and Vargo argue that experiences related with the purchase of a product are essential for the realisation of its actual value (Chandler & Vargo, 2011).

## **Customer Value**

As with service encounters, the concepts of value and customer value have varying definitions ranging from the purely economic definition of transactional value and cost, benefit, sacrifice evaluative value (Zeithaml, 1988) to service marketing definitions of value-in-use, value-in-context and co-created value (Grönroos & Voima, 2011; Prahalad & Ramaswamy, 2004; Vargo et al., 2008). Untangling these varying definitions is a challenging enterprise, as Day (2002) notes "a thorough understanding of the concept remains elusive" (Day, 2002), and it is beyond the scope of this paper to nail down a paradigmatic definition of customer value. That being mentioned, some central concepts of value will be discussed. Woodruff defines two perspectives of customer value "organisational value that quantifies the monetary worth of individual customers" (Woodruff, 1997) and value from the customer perspective he labels as customer value (Woodruff, 1997).

Smith and Colgate later refine these two perspectives where customer value is that value perceived by the customer (value gained) and value for the firm defined as customer lifetime value (Smith & Colgate, 2007b). The focus of this paper is the former, however seen from the firm perspective; in other words, a "company interpretation" of customer value through the voices of frontline managers. Growing recognition in service marketing literature of the central role of the customer in creating value, has given rise to concepts such as value co-creation and value in use. In tourism the customer plays a central role in value creation as it is often the experience that can create or destroy value, and the tourist is an active player in creating the experience. As noted by Grönroos & Voima, companies can only ensure value propositions, it is the customer who decides whether to partake in the proposition and thus "co-create value" and "value is socially constructed through experiences" (Grönroos & Voima, 2012). Thus, value-in-use is a longitudinal evaluative process individual to the customer and his/her experiences.

Value in context, on the other hand is defined as value determined by specific environmental contexts within specifically a network setting (Chandler & Vargo, 2011; Helkkula, 2009). Various conceptual frameworks of value have also been presented, most notably by Sheth et al (Sheth et al., 1991), Holbrook (Holbrook, 1998), Smith and Colgate (Smith & Colgate, 2007b) and Woodruff (Woodruff, 1997). Given the context of this study, it is interesting to contemplate which, if any, of the above definitions of value will be applicable to how practitioners working within the experience economy, more specifically the hospitality sector, understand customer value. In other words, how do front line managers understand customer value in relation to the theories already mentioned?

As service encounters have long been recognised as the mechanism by which customers evaluate value (Palmer, 2004; Surprenant & Solomon, 1987). It therefore stands to reason, with the action of the service encounter and interaction with customers, frontline managers can develop an evaluation of expected customer value. Therefore, in this study, the face-to-face service encounter was used as the unit of analysis. Front-line managers were chosen to be the initial source of information, as they are responsible for operationalizing the strategies and values of organisation (Lockwood & Jones, 1989). Additionally, they

typically over-see, if not have the direct responsibility for, training front-line employees, which was confirmed by many of the interview respondents. Finally, many front-line managers have held front-line employee positions and often experience customer contact on a daily basis. Thus it was considered that they would be reliable, experienced and credible evaluators of customer value. The responsibilities

## Methodology

Taking a constructivist grounded theory approach (Charmaz, 2014, pp. 14–15), no one particular theory was operationalised in the development of the data collection instrument. However, although one of the guiding principles of grounded theory is to begin without any specific theoretical framework (Glaser & Strauss, 1967), inspiration from already existing theories on value and customer value were used as pointers to develop the open questions for the semi-structured interview guideline. As is the principle of grounded theory, the results of this study are data driven rather than hypothesis driven (Charmaz, 2014; Glaser & Strauss, 1967). As mentioned above, the motive was to understand how frontline managers understand customer value. As exploratory research is particularly useful when there is a need to develop new understandings of existing phenomena (Mouton & Marais, 1998) this approach was taken. The explorative semi-structured interview data collection instrument was a 15 item interview guideline with open questions centred on two central themes: 1) frontline managers' understanding of the service encounter, and: 2) their understanding of value in the service encounter. In the latter case, respondents were asked (amongst others) to describe both; what they thought gave customers value in the service encounter; and were also encouraged to tell stories/incidences which exemplified customer value. In this paper, the focus is on the responses to the latter two questions.

The choice of using open-ended, semi-structured interviews was based on Brinkmann and Kvale's category of conceptual interviews whose purpose is conceptual clarification (Brinkmann & Kvale, 2015, p. 176). Conceptual interviews "explore the meaning and conceptual dimensions of central terms" (Brinkmann & Kvale, 2015, p. 177). According to Brinkman and Kvale (2015), conceptual interviews can "serve to uncover respondent's discourse models, that is, their taken-for-granted assumptions about what is typical, normal or appropriate" (2015, p. 177). Therefore, the purpose of the semi-structured interviews was to attempt to reveal frontline managers' taken for granted assumptions of customer value.

The interview guideline was debated in a focus group session consisting of a group of selected interviewers to ensure common understanding of the questions and agreement on recording techniques. This group tested the guideline to judge informant understanding of the questions and the guideline was readjusted according to feedback. The guideline was pilot tested by teachers in a Danish educational institution, who undertook thirty interviews across a broad range of service sector companies. From this pool, fifteen interviews were selected using two pre-determined criteria: 1) chosen companies had to fit within the Danish Association of Hotels, Restaurants and Tourism's (HORESTA) classification of the experience economy "tourism, hotels and restaurants only" (Road, 2012); 2) Informants' sector experience had to exceed one year. It was considered that the longer the sector tenure the higher informant credibility through more experienced accounts. Interviews not meeting these two criteria were excluded from the analysis. The selection of interviews resulted in a cross-sector group of interviewees who had an average working tenure of approximately 10 years. The majority were women and the highest educational level was at Bachelor's, although the majority of the informants had taken a two year tertiary level education with focus on the service sector. Most of the participants worked in the hotel sector although 3 represented the restaurant sector and one represented the cruise sector. The interviews were recorded and transcribed verbatim in preparation for a thematic coded analysis.

## Analysis

According to Mills et al, thematic analysis is not so much a research approach, but is more an analytical method (Mills, Durepos, & Wiebe, 2010). Thematic analysis is useful for analysing and making sense of large amounts of data (Mills et al., 2010). Thematic analysis relies on the creation of codes to identify patterns, relationships and repeating themes and topics. Data driven coding is one of the key analytical tools of grounded theory (Charmaz, 2014, p. 109; Glaser & Strauss, 1967, p. 36). As customer value was only one of various themes in the semi-structured interview, the initial coding focused on sections of the transcript where respondents specifically explained customer value or specific stories reflecting customer value were given. These descriptions and narratives were consequently positioned into a coding framework. Admittedly, this process ran the risk of taking the descriptions out of context, but care was taken to include the entire discussion from the start of the invitation to describe customer value until the context was changed with an entirely new topic such as company value derived from the service encounter. Additionally, each interview was thoroughly combed for direct or indirect references to customer value as a result of interviewer probing, which were also included in the coding framework. After close reading of the selected sections, the process of identifying initial coding categories started. Initial codes created were simple classifications of, for example, demographic aspects of the respondents, requiring no definition. After which, more advanced codes in the form of abbreviations such as CHCA were attached to common descriptions of leisure tourist's preferences for, for example, conducting casual information exchanging conversations with staff which was one typical example given of customer value. Each code assigned a particular word used to describe customer value was then defined as in the example given above. The coding process continued until all coding categories were all inclusive, in that all response possibilities were included (Gorden, 1998). After all the codes had been defined, they were refined so that they became mutually exclusive so that no one code could fall into two categories simultaneously (Gorden, 1998). The coding process proceeded hermeneutically in a back and forth process between the text and the codes until a pattern of six theoretical categories emerged.

The six categories have been labelled 1) Service Value, 2) Behaviour Value, 3) Economic Value, 4) Psychological Value, 5) Social Value and 6) Co-creation Value. Table 1 below, shows the six categories and a selected example of some of the words used by frontline managers to describe customer value in the service encounter.

**Table 1: Six Categories of Customer Value from Front Line Managers' Perspectives**

| Service Value  | Behaviour Value  | Economic Value  | Psychological Value  | Social Value  | Co-creation Value   |

*Source: 15 interviews from eight hotels ranging from three to five stars, one upper-range hostel<sup>1</sup>, two mid-range to fine-dining restaurants<sup>2</sup> and one cruise agency.*

Service value, as explained by the respondents, is the value the customer gets from the service itself. That is, a smooth, fast and efficient well-functioning service is considered to add value to the customer. This category can be equated to Sheth et al's (1991) and Smith & Colgate's Functional Value (2007a). There is dissension in the service literature of the relationship between quality and value; as to whether quality is a function of value, whether they are two separate constructs or if value is derived from quality (Graf & Maas, 2008; Sanchez-Fernandez & Iniesta-Bonillo, 2007; Sweeney & Soutar, 2001). It seemed apparent, in the various interviews, that most of the respondents agreed high service quality would create value for the customer. It could be argued, due to the intense focus on service quality during the 80's and 90's (Brady & Cronin, 2010; Grönroos, 1984; Parasuraman et al., 1985) and with the popularity of quality instruments such as Servqual (Parasuraman et al., 1985), that service quality (from the customer perspective) is these days taken as a given requirement.

The category termed "behaviour value" was derived from the many repetitious explanations and descriptions related to appropriate staff behaviour creating value for customers. In fact, the interviews revealed that appropriate staff behaviour seemed almost more important than service value. From the interviews, appropriate staff behaviour included smiling, having eye-contact, positive greetings, recognising the customer, listening to the customer etc. Smith & Colgate's (2007a) study include appropriate staff behaviour as part of functional value, whereas Sheth et al's (1991) functional value is merely limited to how well the product/service serves its function or purpose. Woodruff's (1997) discussion of customer value does not include staff behaviour evaluation as a source of value but, like Sheth et al, (1991) is limited to "product attribute" evaluation (Woodruff, 1997). There is extensive research on the relationship between employee behaviour and customer satisfaction (Kattara, Weheba, & El-Said, 2008; Mittal et al., 2005; Seidman & Johnson, 2002) (to name but a few) indicating a positive relationship between appropriate employee behaviour and customer satisfaction. As well, evidence has shown a positive relationship between perceived value and customer satisfaction (Gordon & McDougall, 2014; Heinonen, 2006). Moreover, as the scope is the hospitality sector and much of hospitality literature emphasises the importance of positive employee behaviour (Kattara, Weheba, & El-Said, 2008; Mittal et al., 2005; Seidman & Johnson, 2002), behaviour value could only perhaps be considered unremarkable if this were *not* mentioned. It could be relevant here to raise the question, given changing customer/tourist behaviours towards value giving experiences rather than "products", as to whether perceived service quality and behavioural value are now, in the minds of customers, actually hygienic factors rather than serving as value adding factors? In other words, value is created merely because these are present in the service encounter? Perhaps a well-functioning service is only really noticed if it does not function and/or staff behavioural aspects are non-positive.

The category of economic value arose from respondent comments related to perceived customer evaluations of price versus expectation, (such as "is this what I paid for") and remarks related to customer appreciation of "free gifts" or perceived extra services. Economic value can be equated to Smith & Colgate's cost/sacrifice source of value (Smith & Colgate, 2007b), but which is included in Sheth et al's functional value (Sheth et al., 1991). Holbrook's (1998) typology of consumer value does not include the economic aspect of customer value which is, however, extensively discussed in other literature relating to this con-

<sup>1</sup> An upper-range hostel is classified as having a higher price than typical hostel prices

<sup>2</sup> Mid-range to fine dining classification of restaurants was done on a price base evaluation.

struct (Graf & Maas, 2008; Grewal, Monroe, & Krishnan, 2014; Sanchez-Fernandez & Iniesta-Bonillo, 2007; Zeithaml, 1988) (to name but a few).

The psychological value category was derived to distinguish descriptions of customer value from “external” factors, that is, those factors that externally facilitate value, from descriptions of the “internal” value evaluating process of the customer. In other words, the value creating elements of the service encounter which reside in the mind/desires/expectations of the customer. This category could be equated with Sheth et al’s (1991) emotional value, Holbrook’s (1998) intrinsic and other-oriented typology or Smith and Colgate’s experiential/hedonic value category (2007b). It can also be found in Otto and Brent Ritchie’s “psychological environment, which they describe as the “subjective, personal reactions and feelings experienced by consumers as they consume a service (Otto & Brent Ritchie, 1996). As can be seen in table 1 above, words, expressions and phrases related to this category indicate a subjective, customer oriented perceived value. In the words of the respondents, value for the customer in the service encounter went beyond staff behaviour and service quality towards an element of specialness and unexpectedness for customer. In tourism literature, this uniqueness often refers to experiential value (Graf & Maas, 2008; Grewal et al., 2014; Sanchez-Fernandez & Iniesta-Bonillo, 2007; Zeithaml, 1988). According to Helkkula et al, (2012), experiential value is “value in the experience [considered to be } the value that is directly or indirectly experienced by service customers within their phenomenological lifeworld contexts” (2012, p. 61). It has been argued in literature that experiential or psychological value is an aspect of customer value previously understated in earlier research, but which emphasises a holistic concept of value (Turnbull, 2009).

Social value was driven from the data by often-repeated comments that customers experienced value in the service encounter if they were given opportunities, or made opportunities, to engage in informal, knowledge exchanging activities with either members of staff or with other customers. The social element of this category also included indications that customers wanted to engage with the local community and not be “just tourists” removed from or superficially engaged in the local environment. Social value is discussed in Sheth et al’s five value framework as perceived value of symbolism and image in reference to other groups (Sheth et al., 1991). Smith and Colgate categorise social value within the symbolic/expressive source of value in their value framework (2007a). That is, their category of symbolic/expressive value has an element of creating social meaning through, amongst others, interactions (Smith & Colgate, 2007a). It was evident from the interviews that this category was considered an important part of value creation for customers, even if the effort to facilitate these interactions was not necessarily value creating for the respondents.

The final category called co-creation value was not created from the data as a representative category, but simply because of its comparative insignificance in the descriptions given by the respondents of customer value. That is to say, co-creation of value and recognition of the customer’s role in creating value was only mentioned by two respondents. Given the theoretical recognition of the inextricable nature of tourism, experiences and value (Boswijk et al., 2007; Forder, Sørensen, & Jensen, 2014; Sørensen & Jensen, 2015) and considering the respondents all worked in what is considered to be an element of the experience economy (hospitality and tourism) (Oh, Fiore, & Jeoung, 2007) the absence of descriptions regarding the customers’ role in creating value could be regarded rather unusual.

## **Conclusion, Limitations and Future Research**

As customer value has been defined as an holistic, a-priori, active, post-priori evaluative activity influenced by past experiences with a temporal element created in part by the customer (Grönroos & Voima, 2012; Oh et al., 2007; Sørensen & Jensen, 2015; Vargo et al., 2008), it can be considered problematic to categorise the concept in a flat non-dynamic fashion as has been done in this article. However, it is important to remember here that these categories were data driven without prior reference to a specific theory. It is therefore very interesting to note that the data driven categories are very similar to Sheth et al’s five value framework (Sheth et al., 1991) and Smith and Colgate’s four value framework (Smith & Colgate, 2007b), thus confirming the rigorousness of these conceptual frameworks of cus-

customer value. An arguably significant difference to both of these theories is the category of co-creation value, which is not an explicit category found in either Sheth et al or Smith and Colgate. Additionally, theoretical reference to value-in-use and value in context is equally applicable to the empirical categories mentioned giving credence to these definitions of value. Two interesting variances between, for example, Sheth et al (1991) and Smith and Colgate's (2007a) studies and this study are; firstly, aforementioned studies are not empirically based in Denmark, which could prove that customer value, as perceived by frontline managers, is well supported by customer value theory across national boundaries. Secondly, this study, unlike the study conducted by Sheth et al (Sheth et al., 1991) was undertaken in the hospitality industry, indicating that perceived customer value may not vary significantly between service vs product based industries. Additionally, although the empirical evidence for Smith and Colgate's (2007b) research is unclear, their study, similar to this investigation, also seems to be based on a multiple case analysis. In this study, representatives of a mixture of hospitality industries were interviewed resulting in very similar results. Finally, it needs to be highlighted, that the results of this research is founded on the interpretations of experienced frontline managers, they are just that, interpretations which could fit with any definition of value one propounds. Two conclusions can be tentatively drawn from this study. The first conclusion could be that frontline managers have a thorough understanding of what creates customer value supported by available theory and as evidenced by their descriptions of customer value. On the other hand, given changing consumer trends, and the resulting interest in experiences as value-creating mechanisms, an alternative argument could be proposed; that frontline managers in the hospitality sector have a "standardised" conception of consumer value and are perhaps lagging behind the consumer quest for experiences.

The analysis shows that frontline managers do make reference to good experiences, so there appears to be general awareness of the importance of experiences. Yet only sporadic use of the central terms and concepts of the experience economy is in evidence. It could be argued that frontline employees are not actively focussed on creating memorable, unforgettable experiences for customers but are perhaps more focused on other elements of the service provision, such as the service function and employee behaviour.

This study has implications for the Danish tourism industry at sector, organisational and hospitality educational levels. At a sector level, it raises questions as to whether the Danish tourism industry is managing to compete successfully for the experience seeking tourist and encourages further research as to whether this is the case or not. From an organisational perspective, further research needs to be done in order to understand if and how organisations are working to create the conditions desired by today's tourists. Finally, research into current hospitality programmes needs to be carried out to understand how new trends in the tourism sector are being incorporated into educational platforms and whether they are successfully educating experience economy employees.

Some limitations should be considered regarding this study. Although interviewees represented a broad cross-section of the tourism industry, organisations working exclusively with experiences, such as museums, amusement parks and the like were not represented, thus the potential views of these sources are not represented and may present a very different picture than that of these informants. The purpose of this study was to investigate how frontline managers describe customer; as a result the perspective of the customer has not been included in the research. This could be seen as a limitation, given the central role of the customer in the experience economy and co-creating theories. However, with the discovery of a sixth category denoting co-creation as a value creating factor for the customer in the service encounter, a strong case can be made for the need for further research in understanding customer value.

# Clarifying Service Classification Concepts: An In-Depth Literature Review

*Erik Kolek, Dennis Behrens, Univ.-Prof. Dr. Ralf Knackstedt*

University of Hildesheim

*Very different views, meanings, concepts, and definitions of services are illustrating the importance of service classifications and the need for service classifications. To conduct a comparison and to detect current research gaps seems to be impossible, because of the extreme variety of service classifications. An in-depth literature review is an effective method of choice to clarify service classifications. New three- and multi-dimensional service classifications must be developed. The focus is on representing hybrid service bundles. Service classification researchers must reflect the service technology use, service encounter, and service time consumption. Service modelling languages can be developed or enhanced on this basis.*

## 1. Introduction

There are numerous different types of service classifications with highly diverse dimensions, scopes, and representations developed in the service science literature. This high variety leads to the objective to clarify the existing service classification concepts. The stimulus for this research paper has its origin in the many different views, meanings and definitions of services stated by various scientific authors. Therefore, an overview about the term service is stated to illustrate why it is important to know the diverse possibilities for service classification. The heterogeneous definitions of services are reflecting the various service classifications with highly different dimensions and amounts of dimensions. This multifaceted overview of meanings of services and classifications emphasizes the importance of the three associated **research questions**:

- **RQ1: Which service classifications concepts exist in the literature?**
- **RQ2: Which concepts are demonstrating research gaps?**
- **RQ3: Which service classifications must be developed in further research?**

It is known, that there can be found many various forms of service classifications in the literature, but they are extreme different in their views, dimensions and representations that as a result none of these will exactly fit into the needs e. g. for digitalization or hybridization of services. Each service classification will only describe some attributes to structure such a classification framework. The missing concepts represent the research gaps for the development of a new service classification framework e. g. for digital services or hybrid service bundles distinguished by the different allocation degree of both material products and immaterial services. Services clarified by their attributes like their skills for digitalisation or hybridization have an impact on significant conceptual insights for further service science research.

Hence, the service definitions and service classifications are described first (see section 2). After that step the conducted in-depth literature review is explained based on guidelines (see section 3). In the fourth step the developed three-dimensional literature conceptualization framework is established (see section 4). Fifth, the literature review results are presented (see section 5). Then, the concepts of service classifications are discussed (see section 6). Finally, an outlook is stated (see section 7).

## **2. Literature Review Background**

### **2.1. Service Definitions**

The term service encounter refers to any kind of interaction between customers and service providers according to Surprenant and Solomon (1987). Every customer is unique and therefore a personalized service must be offered. Interaction is a critical determinant for the degree of customer satisfaction. In a person-to-person situation, the service provider can strategically react on the customer's needs.

Also Bitner et. al. (2000) recommends the definition that every single service encounter is an opportunity for a company to sell itself in terms of customer satisfaction, customer loyalty, word of mouth, sales and profitability. These service encounters exist in actual service settings, over the phone, through e-mail or the internet. The central objective is to increase the customer loyalty by satisfying its personal desire and needs. They point out that traditional service industries are hotels or banks.

For instance, digital services are independent, tradable performances which are provided by the digital service skills of the vendor (potential dimension) and by the integration of the external factor with the aid of digital data exchange (process dimension) targeting an effective impact on the external factors (result dimension) (Bruhn, 2002).

Hence, customer integration means customer participation with a central meaning for the service production and it focuses on the cooperation process between vendors and customers. In this view the customer has the position of a co-producer of the service. He works together with the vendor during the service production process, which emphasizes this central meaning of the customer participation. The customer moves himself for the service delivery in the observable service area, so called service encounter, which is characterized by the rooms of the vendor (Fließ, 2006).

Customer integration can be seen as an active participation of the customer on a contractual specified service preparation with contribution of external factors or take-over of subservices with the result that the service activities of the vendor are influenced or partial replaced (Büttgen, 2007).

Inside the product development process the customers have different functions and are an important part of the service. A customer as a service recipient can be seen as a resource when generating and creating new ideas. Additionally, a customer can become a co-producer in relation to the concept and design of the service. By testing a specific product or service the customer takes over the role as a regular producer. As a buyer the service recipient takes part when creating ideas in the market introduction of a product or service (Lattemann et. al., 2008).

The development of web 2.0 leads to customers who are taking over the role or function as a producer of products, services, and information. Forms of information produced are web blogs, wiki systems, online communities, or virtual realities. User created content in any arrangement dominates the internet, where users are able to publish content (Büttgen, 2009). That is why services are seen as performances for their preparation or delivery and why the participation or integration of the customer in the service production process is absolute necessary. The integration of the customer takes place in three different and simultaneously possible approaches. First, the customer as a person produces active services. Second, the customer provides one or more objects, animals, plants or his body with the result that changes can be realised on these external factors. Third, the customer provides information to specify the service. The service process result is then intangible (Fließ, 2009).

The meaning of service integration focuses on the integration of the external factors and immateriality. Recognising that fact, sales objects of service vendors are service skills of humans or object systems, especially of machines, which are produced on the basis of internal factors direct on the humans or objects of humans, both are seen as external factors, with the objective to cause changes or keep conditions. Concentrating on the service process in which the integration of the external factors occurs during the service preparation has an effective impact. Services are independent and tradable performances with three dissimilar orientations. First, in the potential orientation performances are linked with the provision or use of service skills. Second, in the process orientation internal and external factors are combined during the service preparation process. Internal factors are for example business rooms, employees and trainings. External factors are not in the range of influence of the service provider. Third, in the result orientation this factor combination of the service provider has the objective to achieve an effective impact on the external factors like on humans or objects of humans (Haller, 2010).

The quantity of these interacting resources, which are delivered by the customer and the service provider, are building a service system. Services are offered functionalities, which are produced by the interaction of resources. This functionality leads to a change of the condition of minimal one resource of the service system. At a minimum one of the changed resources must belong to a customer for whom the change represents a value (Böttcher, 2011). Since web 2.0 customer integration has developed from its basics to a digital form of customer integration. This process has been taken from customer integration 1.0 to customer integration 2.0 (Fließ et. al., 2011).

Customer integration means that consumers are integrated into business processes by using provided resources and receiving a more active role by completing tasks on their own. In the passive role a customer who does not take part of the actual process can be called inert, whereas a customer without motivation or time receives the status idle. Active roles of customers can be split into two groups with direct and indirect relationships between customer and service providers (Heidemann et. al., 2012).

Georgi and Mink (2013) state that since the development of the web 2.0 the service encounter have changed in terms of a stronger connection between the service customers and service providers. The services of a provider for a customer have been enhanced due to new service technology as a key element of service digitalization. Customers become co-producers in the service production process and influence the service output quality directly.

## **2.2. Service Classifications**

One established service classification consisting of active and passive roles for customers is described by Mersha (1990). These customer roles are defined in a contact model. The active role of a customer is defined as a direct contact between the customer and the service provider. The passive role is defined as the contact between the customer and service system. A hybrid role as a form of passive and active role is possible as a service output as well.

Meier and Piller (2001) categorize the digitalization of services into four groups: differentiation services, service modularization, add-on-e-services, and core e-service customization. The differentiation services with low support or even no possibility for digitalization count toward secondary services. Examples are repair services or delivery services. Service modularization counts toward primary services. For instance, a hospital that offers additional services such as further treatment or better rooms can be described as a type of modularization. The add-on-e-service as another secondary service can be digitalized. That means complete service transactions and service provisions are possible digitally. Even providing personalized services for customers will provide a higher chance for customer loyalty. The core e-service customization is positioned within the group of primary services like consulting services and information services.

Chase (2010) classifies service systems by a range of required customer contacts during the production of service products. He differences services into three groups: the pure services, mixed services and quasi-manufacturing.

Salegna and Fazel (2013) developed a service classification to illustrate the degree of service customization. This degree is described by a fragmentation into a high and low level of customization. The high level of customization represents an emphasis on service customization, meaning individualization, personalization and customization of services. In contrast, the low degree of customization characterizes a lack of customization of provided services or offered products. In the dimensions of services and products another fragmentation into attributes represents the labelled degree in terms of tangibility and intangibility.

## **3. Literature Review Guidelines**

### **3.1. Literature Data Collection**

The resulting benefit of the literature data collection is characterized as a state of the art in the field of service classifications. Hence, a research path for revision and as a basis for arrangement of the various findings is drawn. Innovative findings, influences, senses, and literature review carefulness are addressed (Webster; Watson, 2002). The challenge was to decide to include relevant articles. To avoid gaining only keyword literature, the life circle of the searched keywords and discovered changes over time in these key terms are also studied. Constantly, the literature is observed with a topic based lens represented by the research questions, which addresses the phenomenon of diversity in the service sciences specified by the various service definitions and service classifications (Levy; Ellis, 2006).

First, the literature review scope is defined. The focus is to learn from the service research outcomes and the goal is to detect the central issues. Therefore, the literature review organisation is conceptual. The perspective is to grasp a neutral representation without personal opinions. The scholar is called service science. The coverage of the in-depth literature review is stated as representative (vom Brocke et. al., 2009).

Second, the research topic is also conceptualized. Mind mapping is used to link the discovered central search terms and handbooks for teaching students to outline our working or topic definition. The search strategy is in-depth, because of the sample of journals and conferences which are relevant (vom Brocke et. al., 2009).

Third, the start of the literature search characterizes the top ranked journals and conferences in the field of service science (Based on VHB). It is searched in the databases of these journals and conferences, both with the developed set of keywords like service typology or service classification. A backward and forward literature search is realised. In the backward search older literature is detected, which are cited in the research articles. Further references are discovered during the forward search of articles, which cited the articles. The sum of literature is limited by analysing the article contents in the following order: titles, abstracts and text with regard to the visualized service classifications (vom Brocke et. al., 2009).

Fourth, a literature analysis and synthesis is accomplished. Therefore, the concept matrix of Webster and Watson (2002) is used to foster the discussion. It segments the on-topic concepts in different units of analysis and arranged and synthesised the ex-ante research results completed by other service scientists.

Fifth, as a result of the in-depth literature review a research agenda is obtained. The basis of this agenda is the concept matrix and itself can be seen as a basis for further literature reviews. The empty fields in the concept matrix mark or highlight the concepts or research fields, which are significant important for further research. These empty fields are demonstrating the research gaps. In this research paper, the major findings of the in-depth literature review are presented (vom Brocke et. al., 2009).

### **3.2. Literature Data Analysis**

The literature data analysis is based on the concept matrix of Webster and Watson (2002) and demonstrates how the relevant literature is analysed (vom Brocke et. al., 2009). It is critical to know that one or more relevant concepts can structure one or more relevant articles. This is familiar to Webster and Watson (2002) to handle the application of the literature. The target is to identify, why the offered information in the literature is important. To find patterns, relations and findings to underline associations is essential. Therefore, different forms of conceptualization based on the literature data sets to gain new knowledge are applied. The result of this literature data analysis process is a contribution to the body of knowledge (BoK). A concept-centric approach is conducted following the question: how are the research results linked with the research questions? The research results demonstrate a better comprehensible BoK (Levy; Ellis, 2006).

There is no intention to argue critical, but to review the literature from a neutral position by the research results. The completed researches of service scientists are respected and decisions to include the literature into the existing research stream are

made very carefully. Compromises are realised to focus on the knowledge, which is accumulated during the in-depth literature review. The target is to define the agenda for the further research and to state recommendations how to close existing research gaps. In the concept matrix is highlighted what is known and what is essential to know. Therefore, this completed research paper focuses on different service classifications. It is argued from a concept, empirical and practical point of view. These points of views are discussed and evaluated frequently to ensure the quality of the conducted in-depth literature review (Webster; Watson, 2002).

## 4. Literature Conceptualization Framework

### 4.1. Conceptualization of Service Classifications

The developed three-dimensional literature conceptualization framework for the literature organization covering heterogeneous service classifications with highly diverse dimensions has a pre-filter function for the literature review conducted. To explain that function, it must be stated that all collected literature is tested, organized, and accepted through this framework, before it is decided to place it as selected relevant literature into the concept matrix to demonstrate current research gaps. Hence, the literature review is grounded on different concepts of service classifications: representations, dimensionality, and scopes. The development of this literature conceptualization framework (see figure 1) is orientated on Klör et al. (2014).

Figure 1. Literature Conceptualization Framework (Based on Klör et. al., 2014).

### 4.2. Scopes of Service Classifications

First of all, there are a number of heterogeneous service classifications with highly diverse dimensions. Every dimension has its own name and description. That is the reason, why it is so difficult to put all these dimensions together in one concept matrix. Therefore, scopes of service classifications are defined on the basis of the various dimensions of service classifications:

- **Service Immaterially** can be described by the service classification dimensions like: tangibility (Shostack, 1977), intangibility (Bell, 1986), and result dimension: degree of immateriality: material/immaterial (Engelhardt, 1995).
- **Customer Integration** is defined by the service classification dimensions like: customization of the service and necessity of customization (Lovelock, 1983), degree of service customization (Bell, 1986; Haywood-Farmer, 1988), customer disposition to participate (Larsson; Bowen, 1989), and process dimension: degree of integration: integrative/autonomous (Engelhardt, 1995).
- **Service Interaction** is shaped by the service classification dimensions like: degree of fluctuation and interaction between customer and service provider (Lovelock, 1983), degree of interaction: interactive/independent (Engelhardt, 1995), low/high performance ambiguity and goal incongruence/goal congruence (Bowen; Jones, 1986), degree of labour intensity and degree of contact and interaction (Haywood-Farmer, 1988), contact intensity: low/high (Barth et. al., 2000), passive and active contact (Mersha, 1990), and personal (Mills; Margulies, 1980).
- **Service Technology Use** can be formed by the service classification dimensions like: type of connection (Lovelock, 1983), simple/complex technology and mechanistic/organic interface (Haynes, 1990), technology as enabler for employees and customers (Bitner et al., 2000), interface (online/internet) and purpose (customer service) (Meuter et al., 2000), and digitalization of service provision (Meier; Piller, 2001). Service technology use is not only based on the use of information systems, but also on the use of machines during the service production process.
- **Service Complexity** can be constructed by the service classification dimensions like: maintenance, task (Mills; Margulies, 1980), service task (Davis, 1999), service recipient (Lovelock, 1983), service recipients people/things (Hsieh; Chu, 1992), nature of service provision (Lovelock, 1983), high/low complexity (Shostack, 1987), service delivery (Davis, 1999), degree of variation (Schmenner, 2004), and level of input uncertainty (Larsson; Bowen, 1989).
- **Service Individualization** can be assembled by the service classification dimensions like: diversity of variants (Barth et. al., 2000), diversity of demand (Larsson; Bowen, 1989), degree to which the offer is limited and nature of service (Lovelock, 1983), degree of individualization: standardized/customized (Engelhardt, 1995), importance of the individual service from a customer perspective (Meier; Piller, 2001), and low/high divergence (Shostack, 1987).
- **Service Production Process** is described by dimensions of service classifications like: production factors mobile and stationary (Sampson; Snape, 1985), rigid and flexible processes of goods, information, and humans (Wemmerlöv, 1990), and service process structure and service package structure (Kellogg; Nie, 1995).
- **Service Encounter** can be labelled by service classification dimensions like: number of delivery places (Lovelock, 1983), the drivers of service encounter satisfaction meaning customization/flexibility, effective service recovery, and spontaneous delight (Bitner et al., 2000), and use of persons and IT (Leimeister, 2012).
- **Service Time Consumption** is termed by service classification dimensions like: types of utility creation: time utility/space utility (Hsieh; Chu, 1992), time, which is spend at the service encounter differentiated in short (minutes), middle (hours),

and long (days) (Wakefield; Blodgett, 1999), and relative throughput time for a service transaction (Schmenner, 2004).

### 4.3. Representations of Service Classifications

The third dimension of the developed literature conceptualization framework is specified by the different representations of service classifications:

- **Material Products** are represented in service classifications. Especially early forms of service definitions and classifications tried to separate material products from immaterial services. That is the reason for including material products as an important unit for service classification conceptualization. Bell (1986) represents goods with high materiality and a low degree of adaption. Real physical goods are contained in the service classification of Choi et al. (1997).
- **Immaterial Services** are illustrated in service classifications. As expected nearly all service classifications are demonstrating examples of immaterial services. Bell (1986) represents services with low materiality and a high degree of adaption. Also Schulze (2000) is illustrating immaterial services like supportive-interactive services (software development), problem-orientated-interactive services (insurance), and personal-interactive services (training).
- **Service-Product-Bundles** or hybrid service bundles can be also part of the representation of a service classification. Here, an individual mixture of material products and immaterial services is visualized. To give an example, Leimeister and Glauner (2008) placed hybrid products between material products and immaterial services on the dimensions interaction and immateriality.
- **Service Business Models** are placed in service classifications. One example from Silvestro et al. (1992) is the dimension number of customers processed by a typical unit per day. They are clarifying professional services, the service shop, and mass services. Another example is stated by Mersha (1990) with passive and active customer contact clarifying different kinds of services like data processing services. Besides Schmenner (1986) is differentiating the service factory, service shop, mass service, and professional service by the customer contact. Davis (1999) is also representing service factories, service stores, service shops, and service complexes on two task-orientated dimensions.

### 4.4. Dimensionality of Service Classifications

Inside the service classifications it is discovered that different service scientists are focusing on different quantities of dimensions. These developed classifications are illustrated by one, two, three, or more dimensions, but mostly by two dimensions:

- **One-Dimensional** means that the service classification consists of one dimension. For instance, Shostack (1977) illustrates different kinds of services on one dimension from tangible dominant (salt) until intangible dominant (teaching). A second example is represented by Chase (1978) with high contact of pure services and low contact of manufacturing.

- **Two-Dimensional** describes a service classification matrix existing of two dimensions. One example is the service classification of Larsson and Bowen (1989) for differentiating the service design by the dimensions of demand diversity and customer participation. The service classification matrix of Doster und Roegner (2000) contains the two dimensions integration and individualization and separates service business models into four quadrants.
- **Three-Dimensional** refers to a service classification that is more detailed because of the three dimensions. Often a service classification matrix is the foundation and extended with a third dimension. For instance, Weiber and Adler (1995) are establishing the three dimensions search attributes, experience attributes, and trust attributes for classification of immaterial services and material products.
- **Multi-Dimensional** explains a complex service classification with more than three dimensions. This complexity occurs during the service classification because of the high amount of service dimensions, which are represented by several different degrees. For instance, Benkenstein and Güthoff (1996) are illustrating the five dimensions individuality, multi personality, length of production episode, and number of partial performances, and heterogeneous of partial performances.

## 5. Literature Review Results

The literature review results are stated as a service classification research agenda based on the concept matrix from Webster and Watson (2002), which indicates the research gaps in the fields where no cross is made. This concept matrix is grounded on the developed literature conceptualization framework based on Klör et al. (2014) for the organization of the literature detected and presented in table 1.

*Table 1. Service Classification Research Agenda.*

| Used for<br>Classifi-<br>cation | Concepts of Service Classifications |                      |                     |                        |                    |                           |                                 |                   |                          |                   |                     |                         |                         |                 |                 |                   |                   |

## **6. Discussion of the Literature Review Results**

### **6.1. Limitations of the Literature Review Results**

The boundaries of the in-depth literature review conducted and its application is outlined by other or further dimensions of the literature conceptualization framework, use of a keyword string, and missing double-blind review process.

First, there can be other or further dimensions of the literature conceptualization framework. For instance, there might be more representations or scopes of service classifications like service use behaviour of customers. On the other hand, the concepts are well-grounded based on the dimensions and illustrations of the service classifications. Hence, the developed framework is a methodical background for realising and structuring an in-depth literature review of service classifications by other researchers.

Second, the use of a keyword string in the literature review is neglected like Klör et. al. (2014) did. However, a set of keywords with different keywords and synonyms of keywords in a keyword search is applied. The search result is not only keyword literature, because the life circle of the keywords specified in keyword changes is also observed. Over the decades published articles from different authors established diverse keywords with the same and changed meanings. The forward and backward search aided not to miss relevant service classification literature.

Finally, no double-blind review process during the literature integration in the concept matrix is conducted. First, it is not explicit recommended (vom Brocke et. al., 2009). Otherwise, it is not explicit necessary, because the dimensions and illustrations of service classifications are observed. These are transferred into the concepts of service classifications with the aid of the literature conceptualization framework.

### **6.2. Implications of the Literature Review Results**

Starting in the 1960s service classifications are one- and three-dimensional, material products and immaterial services are represented by concentrating on the scope service immateriality.

Later, in the 1970s one and two dimensions, immaterial services and service business models, and the scopes service interaction, service individualization, and service production process are in the discussion of service science researchers.

From 1980 the research of service classifications became famous in service science. Here, the researchers focused on two-dimensional service classifications for the positioning of immaterial services while applying the scopes customer integration, service interaction, service complexity, and service production process.

This growth of conducted service classification research increased to its top in the 1990s. Service scientists are concentrating on two dimensional service classifications, highlighting immaterial services and service business models, using the scopes service immateriality, customer integration, service interaction, service individualization, service production process, and the service encounter.

Since the year 2000 service classification research seems to be decreasing. Nonetheless, two dimensional service classifications are established to demonstrate material products, immaterial services, and service business models covering the scopes customer integration, service interaction, service technology use, service individualization, and service production process.

Service classification research since 2010 focused on one and two dimensions, the representation of immaterial services and service business models, the scopes service immateriality, customer integration, service interaction, service technology use, and service complexity.

Based on this conceptual foundation in the realized in-depth literature review the analysis of the concept matrix visualizes the needed further research as a meaningful service classification research agenda (see table 1) of open research gaps. The in-depth literature review conducted validates understandable the time based development of the open and closed research gaps. Further research must close the current research gaps. Service classification development is realized on a conceptual level first and then with the aid of an empirical foundation. Service classification researchers must reflect the scopes service technology use, service encounter, and service time consumption and represent service-product-bundles or hybrid service bundles with a three- or better multi-dimensional visualization.

## **7. Outlook**

New service scripts (Schank;Abelson, 1977) or service business models especially for service implementation in the market can be planned on the foundation of the literature conceptualization framework. Chances, risks, strengths and weaknesses are visible, if the scopes of service classifications are reflected in the business plan or service script. Just think on a new restaurant service script, where exclusive food is served (service individualisation), where you can order your meal with a tablet computer installed at the table (service technology use), where the customer sees the open kitchen (service immateriality), where he can interact over the tablet computer for example to ask other guests how their food tastes (service interaction), where they can pay online with the tablet computer (customer integration), and where they get food suggestions on the tablet computer (service complexity).

Service modelling languages can be developed or enhanced concerning the contributions of this in-depth literature review. The established literature conceptualization framework aids to develop a modelling language for service engineering. This service modelling language can exist of three levels: service classification level, service conception level, and service blueprinting level. The first service classification level is grounded on a service classification framework, which orders the representations by dimensionality and scopes. The second service conception level is then described by e. g. service scripts or service business models based on the concepts applied during the service classification development: scopes, dimensionality, and representations. The third service blueprinting level details information about the service process by using service modelling languages like blueprinting for service process modelling. This service modelling language with its three levels can be applied for the digitalization of services, modelling the service episodes, customer contact points and service process activities of both the customer and service provider. The per-

ceived service quality as a result of the customer comparison between expected and perceived service can also be enhanced, because the determinants of service quality like access, communication, competence, courtesy, credibility, reliability, responsiveness, security, tangibles, and customer understanding and knowing can be positive influenced (Parasuraman et al., 1985) by the service modelling language specified.

## Acknowledgements

The German Federal Ministry of Education and Research funded this complete research paper in the scope of the research project "Cooperation Experience" with the promotion sign 01XZ13012. Furthermore, we acknowledge thankfully the support of the project management agency German Aerospace Center (PT-DLR).

# Know Your Customers: Developing Innovative Services to Enhance Acceptance of Electric Vehicles

*Sabrina Cocca, Michaela Friedrich*

Fraunhofer Institute for Industrial Engineering IAO

*The field of electric mobility is characterised by numerous business opportunities for companies from different industries. At the same time, there is still a lack of acceptance of electric vehicles on the part of (potential) users. Smart business models and user-friendly services hold the potential to balance the real and perceived drawbacks of electric mobility to make it suitable for everyday use. This paper presents the results of empirical research into the importance of services for achieving market acceptance of electric mobility. Furthermore, it presents a first version of a user-centric, agile Service Engineering reference model that is based on the empirical findings and directly aimed at developing user-friendly services for electric mobility.*

## 1. Motivation

Electrically powered vehicles—including but not limited to electric cars, e-bikes, e-scooters, buses and lorries—are still undergoing a process of rapid technological development. Other related issues, such as the standardisation of charging technology and autonomous vehicles that navigate automatically to charging points, are in the focus of numerous research and development activities worldwide. At the same time, however, suppliers are facing a considerable marketing issue, since electric vehicles do not yet meet with sufficient acceptance in the market. Nevertheless this consideration is only one side of the coin reflecting a typical dilemma between supply and demand: potential users are supposed to adopt the new mobility concept—but do not find the wide-area infrastructure necessary to make the use or even purchase of electric vehicles useful and attractive in the first place. The activities of the presented findings are based on a German research project: DELFIN (German acronym for “services for e-mobility—fostering innovation and user-friendliness”). Germany is an interesting case for researching the acceptance of electric vehicles: until now, the focus here has been on technological development, which means that the technical conditions are overall quite positive. But at the same time, acceptance of electric mobility (also: e-mobility) in the population seems to be comparably low—at least according to the sales figures: there are 23,611 pure-electric cars and 123,767 hybrids (incl. plug-in hybrids) on German roads (as of 1 July 2015; calculated by KBA, 2015). This is equal to around 0.29% (pure-electric) and 0.99% (hybrid) respectively of total new car registrations in 2015. Diesel- and petrol-fuelled cars together represent around 98.33% of new car registrations in 2015 so far (1 January to 30 June).

## 2. Objectives and methodology

To address the lack of acceptance, to explore the potential of services for achieving acceptance of electric mobility, and to define an approach that delivers innovative e-mobility services systematically, the research work underlying this article is based on the following main objectives:

- To investigate the role of services in supporting the diffusion process of electric mobility in the market
- To analyse and explore how services help to improve the user-friendliness of electric mobility, in order to achieve better acceptance in the market
- To find a practical solution for implementing user orientation in the process of developing new services in the field of electric mobility

To achieve the abovementioned objectives, the following steps are being completed (cf. Fig. 1): comprehensive analysis (A1 to A3); development of an innovation model for creating e-mobility services systematically (Service Engineering reference model), including easy-to-use guidelines (D1 to D3); and transfer of the results to practitioners (T), including an optional loop to revise the innovation model according to practitioners' feedback.

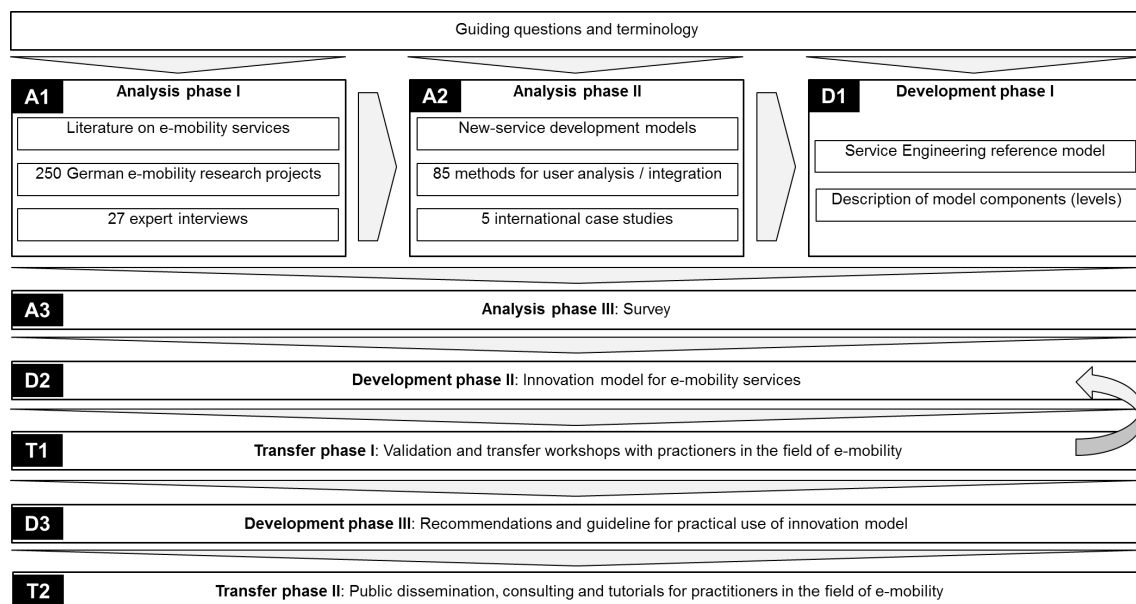

Fig. 1: Methodology

### Analysis phases

(A1) First, a comprehensive research on **250 publicly funded projects** in the field of electric mobility in Germany was conducted in order to get an overview of those services that are implicitly as well as explicitly required to support the dissemination of electric mobility over and above technical progress. Based on these first findings,

**27 expert interviews** with professionals from scientific research and companies of different sizes were conducted in order to discuss the findings from the previous projects analysis and to get an idea of the importance of services for the diffusion of e-mobility offerings in different application fields (e.g. public transport, individual mobility, corporate fleets).

(A2) Second, research on existing **models for developing new services** was conducted in order to detect recent trends and white spots. Then a comprehensive analysis of **85 methods** for user analysis and user integration was carried out, covering different disciplines such as new product development, software development, and new service development (NSD). The methods were classified either as methods for user analysis or as methods for user integration (“co-creation”). Each of the methods was evaluated to determine the phase of NSD in which it is applicable. In addition, **international case studies** are being conducted (ongoing) to find examples of good practice as to how services are used to support the implementation of e-mobility offerings in the market. There is a specific focus on how users are integrated along the whole process of NSD, and what methods of user analysis and user integration are particularly effective. The results will be used to state which methods are the most suitable, as well as to identify white spots with regard to new methods or combinations of methods.

(A3) Third, a **survey** among e-mobility users and providers will be conducted in order to validate the findings so far and to generate additional information for the Service Engineering reference model to be developed. The results of the survey are not available yet but are expected to be published in the first half of 2016.

### **Development phases**

(D1) Based on analysis phases (A1) and (A2), a **Service Engineering reference model** for creating e-mobility services will be developed.

(D2) Based on the feedback of the survey (A2), this model will be further developed into a more comprehensive **innovation model**. For instance, upstream processes such as strategy development and idea generation will be added and connected with the core development process of a service.

(D3) As a third step, the practically validated innovation model will be enriched by a **guideline** and specific **recommendations for practitioners** so that it will be applicable and useful for companies in e-mobility business.

### **Transfer phases**

(T1) To ensure dissemination of the innovation model and to collect feedback from practitioners, it will be presented and discussed with experts from science and business. This step also allows for a loop to phase D2 to make sure that the final innovation model will be in line with practitioners’ needs.

(T2) The innovation model for e-mobility services including recommendations and a guideline for its practical use will be published as a final version and distributed in print format as well as digitally. Furthermore, there will be tutorials and workshops as well as individual consulting offerings for e-mobility practitioners.

### 3. Developing user-friendly e-mobility services: A systematic approach

First in this section, findings from the analysis phases are presented and summarised (section 3.1.). After that, conceptual considerations about how to address the findings using a reference model for developing e-mobility services will be described (section 3.2.).

#### 3.1. Developing services for electric mobility—analysis results

##### Analysis phase 1 (A1):

##### Characteristics and requirements concerning electric mobility

###### *Characteristics of the e-mobility market*

The main perceived **drawbacks of electric mobility** include long charging times, high prices (in comparison to cars with an internal-combustion engine), limited range and a still inadequate charging system, to name just the most common ones from recent studies and the daily press (cf. Kolz; Schwarz, 2015). But owners or regular users of electric vehicles perceive **advantages** as well. The most important benefits seen in electric mobility in general, and in buying an electric vehicle, are ecological advantages and driving pleasure. In a recently published study, the owners of electric vehicles surveyed say they are satisfied after purchase and would recommend buying an electric vehicle to others (Frenzel et al., 2015). Still, the owners of electric vehicles, in particular electric cars, are considered “early adopters” in Germany.

The analysis of 250 publicly funded German research projects led to the conclusion that research and development (R&D) activities are mostly focused on the **technical aspects of electric mobility**, with the exception of the “Service Innovations for Electric Mobility” funding priority established by the German Federal Ministry of Education and Research (BMBF) at the end of 2013 in order to close this gap and the “Showcase Regions” (Schaufenster Elektromobilität, 2015), which include service issues within a living lab approach. In sum, the main target in R&D so far has been to develop and produce electric vehicles, batteries and charging solutions that are technically competitive with petrol- and diesel-fuelled vehicles and the well-established, dense network of service stations that has evolved steadily over several decades. At the same time, in the context of electric mobility, research into services and business models is relatively uncharted territory in comparison to the leverage effect they offer in terms of acceptance and commercialisation.

###### *Role of services in the e-mobility market*

A different approach is to ask how to integrate electric vehicles into people’s mobility behaviour in their private and professional life, and what services and business models could help to make it easier and more appealing for users to adopt electric vehicles. Assuming a **service-dominant view** implies that services are the frame of an offering within which a technical product (here: electric vehicles, charging systems, etc.) is used or embedded (e.g. car sharing, public transport) or that refers to a technical product (e.g. repair, maintenance).

The results of the 27 expert interviews show that the field of mobility in general and electric mobility in particular is characterised by numerous factors and developments that lead to new business opportunities on the one hand and uncertainty on the other hand:

- **New services and business models are emerging due to new market constellations** (cf. Cocca; Klemisch; Meiren, 2015):  
Roles are changing, because new (start-ups) and existing market players (e.g. large energy suppliers, car manufacturers) are mingling; structures (e.g. value chains and value networks) are in flux; and companies thus may rethink their strategy and portfolio fundamentally. Furthermore, the role of customers in business models is changing (e.g. prosumers, sharing), which leads to a shift in the relationship between service provider and consumer in contrast to traditional service models.
- **Service networks** (cooperation) and **IT support** (digitalisation) are gaining in importance (cf. Hottum; Kühl; Stryja, 2015):  
Industries previously alien to each other may be even forced to cooperate to offer integrated services (e.g. energy and automotive), and there is a need for supporting IT platforms to facilitate cooperation and to deliver the services to customers.

In this context, the **relevance of services is seen as “high to very high”** for the acceptance and hence dissemination of electric mobility in the market (cf. Kolz; Schwarz, 2015). Services can tackle two issues in order to foster electric mobility most effectively. First, they can support the functioning of the system, for example comprehensive charging services that make it possible for users to use electric cars according to their needs, or a comprehensive repair and maintenance network that is comparable to the service network for petrol- and diesel-fuelled cars. Second, the potential for user delight should be thought of in the context of electric mobility and systematically engineered into e-mobility-related services (Cocca; Klemisch; Meiren, 2015).

Main findings from A1:

- Services hold considerable potential for achieving acceptance of electric mobility in the market, but they are still underestimated and not developed systematically in business practice, and they are still given insufficient consideration compared to technical R&D.
- New services in a highly dynamic market such as (electric) mobility may be linked with fundamental strategic decisions. Innovation in the field of e-mobility services should therefore include the development of a clear strategy beforehand.
- Services for electric mobility are often based on new business models, in particular concerning new cooperation constellations (cooperative service networks) and IT support (digitalised services, digitalised business models). For this reason, it is important first to explicitly describe the business model before starting to design the associated service(s).

- Systematically designing a user experience that supports the acceptance of electric mobility is crucial, and services offer the opportunity to bridge the gap between technological solutions to (potential) users.

## Analysis phase 2 (A2):

### User analysis and user integration in new service development

#### *User-centric design, co-creation and agility*

To create user-friendly e-mobility services efficiently and effectively, suitable innovation approaches and new-service development processes are required. Integrating stakeholders into service development, and in particular **user or customer co-creation**, is a key trend in service research (cf. e.g., Toivonen, 2014; Fischbacher, 2005). Here, the principle of *customisation* is brought one step further: “*The difference between ‘co-creation’ and ‘customisation’ lies in the degree of involvement of the customer; in general terms, the customer plays a less active role in customisation than in co-creation. [...] In contrast, co-creation refers to the involvement of the customer as an active collaborator right from the beginning of the innovation process.*” (Kristensson; Matthing; Johansson, 2008, p. 475). In software development, the shift towards stronger user and customer integration occurred with the beginning of **agile approaches** and the emergence of **user-centric design**, which are now being combined with each other. The motivation behind agile development is to focus on the people involved and their interactions rather than clinging to processes and tools (Blomkvist, 2005; Chamberlain; Sharp; Maiden, 2006). In 2001 the *Agile Manifesto* was established, promoting “*better ways of developing software*” (Beck et al., 2001) based on the following fundamental principles: to value *Individuals and interactions* (over processes and tools), *Working software* (over comprehensive documentation), *Customer collaboration* (over contract negotiation), and *Responding to change* (over following a plan). Since then, numerous agile methods for software development have started to emerge (cf. Moniruzzaman; Hossain, 2013).

Generally, an agile approach and user-centric design seem to be suitable in the field of e-mobility services, assuming the abovementioned characteristics of the market context (see A1), because it puts the focus on involving the targeted users directly in the design process of a service, allowing even fast-changing requirements to be considered. As to the lack of acceptance of electric mobility in the market, it is important to facilitate the integration of (service) users from the very beginning of the development process and to head towards a more experimental approach—as is the idea in prototyping. Currently available NSD approaches seem to contrast strongly with the idea of agility and user-centric design—despite the fact that there are quite a lot of substantiated and widely accepted models. *Meiren et al.* (2015) have compared selected process models for NSD, as shown in figure 2. The researchers’ main finding is that NSD models follow linear processes, with the implicit claim that the approaches fit all types of services and—in contrast to iterative approaches—that the requirements do not change or that no new requirements will pop up during the development process, whether on the part of customers, through frame conditions

(e.g. political, legal, economic), in relation to internal demands (e.g. change in strategy, reorganisation), or simply from feedback during testing.

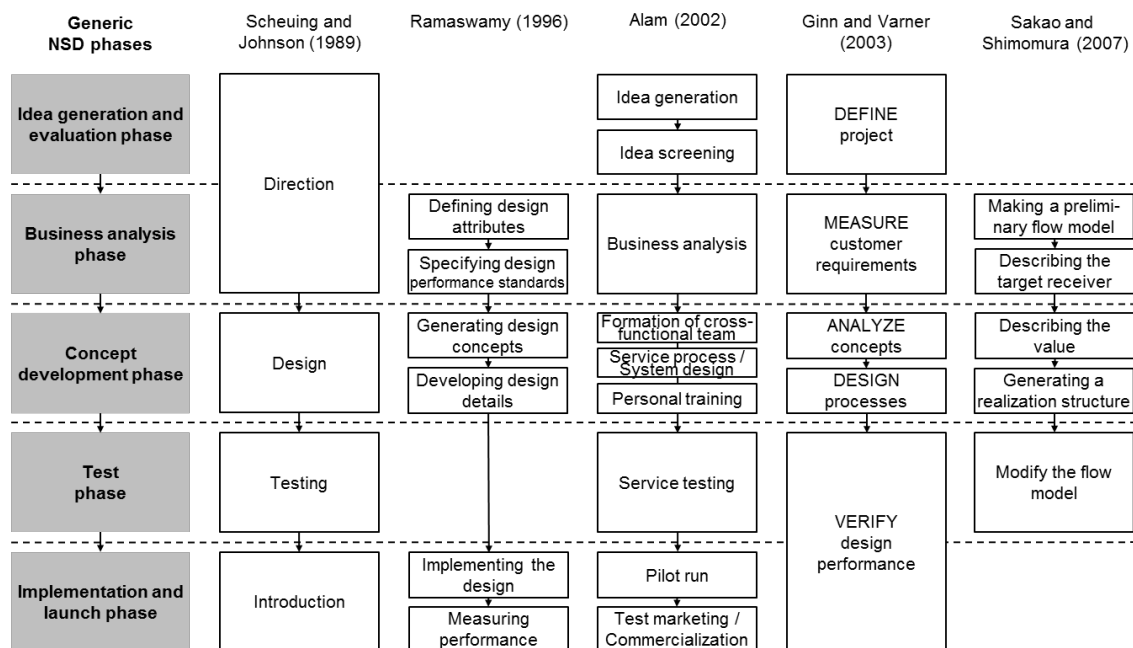

Fig. 2: Comparison of selected process models for new service development (Meiren et al., 2015)

But why would it make sense to use agile approaches for NSD as well? *Ojasalo and Ojasalo* (2015) have proposed a model of *Lean Service Development* that takes into account the need for stronger user orientation and focuses on learning cycles and rapid prototyping. This could be seen as a starting trend in the service research community. But from the practical side as well, a need for agile NSD approaches can be derived: applying sequential approaches in business practice indeed leads to intuitive modifications to process-activity models during development. As shown in (Cocca; Franke; Schell, 2015), a service developer facing uncertain market situations, high interdisciplinarity, and a highly specialised field of services (e.g. consulting) will tend to develop service “prototypes”, discuss and test them with customers, and generally make several iterations between the development phases. This means that there might be pre-defined processes and activities, but in practice the approach would be applied and modified by individuals, all happening in interactive processes.

For the field of electric mobility—with many different types of services, the need to integrate users, and high market dynamics—linear approaches seem to be outdated. Furthermore, as many service types in the field of electric mobility are based on IT platforms and related software, a convergence of NSD with software development approaches seems to be sensible.

### Methods for user-centric design

Besides the question of *how* users can be integrated into new-service development processes (methods and tools), the question of *where* or *when* in the development

process to integrate them should be addressed. The initial target is to include the user perspective as comprehensively as possible within the innovation process. Thus, different types of methods for user analysis or user integration should be used, covering the development phases as thoroughly as possible (cf. Cocca; Klemisch; Meiren, 2015). To this end, research on **methods** that focus on users or customers within development processes was carried out. The methods were collected and categorised according to a 3-level maturity model of customer integration, as shown in figure 3, and according to their applicability in different stages of the NSD process. The maturity model used is based on previous research work about how companies view their customers when developing new services (Nägele; Vossen, 2006). The five levels foreseen in the original approach have been reduced to three: the user as the *point of perspective* in the development process, the user as an *information provider*, and the user as *co-designer*. The original model additionally included the lowest level “customer as consumer” and the highest level “customer as partner”. For the current research, the lowest level has been omitted because no user-centric methods are used there, so it does not contribute to the target. The highest level considers customers as partners, pointing to a sustainable co-creation relationship. For the development process of services, there is no difference between this level and the level of “customer as co-designer” in terms of the methods applied. To avoid redundancy, this level has been excluded as well. The first and lowest level understands **users as the point of perspective** assumed for developing a service. It describes the situation in which a company does not directly ask or gather any information from service users about their needs and requirements concerning the service to be developed. To achieve user-oriented offerings though, the service developers assume the perspective of users in an analytical approach and by deductive reasoning. Methods such as cognitive walkthrough, internal expert workshops or actors maps are suitable methods to be used for this purpose, e.g. to pre-structure the context of the service and its users. The second level represents **users as information providers**. It includes traditional methods of market research used by companies, such as surveys, customer workshops or eye tracking, but also findings from complaint analyses or data collected via customer relationship management (CRM) tools. The third and highest level of customer integration in the development process sees **users as co-designers**. It considers customers or users as partners within development projects. Well-known methods in this category are user stories, idea competitions or living labs. In contrast to the other two categories in which the focus is solely on user *analysis*, the main purpose here is user *integration*. The higher the chosen level, the higher the degree of customer orientation.

Fig. 3: Structuring approach for methods analysis

So far it has been possible to compile a raw list of 85 common key words representing methods in the wider sense (incl. approaches, concepts and tool-like methods) and classify them along this structuring approach. Some of the key words represent methods that refer to or use other methods in combination or that subsume methods on another level of abstraction. As the main aim is to finally come up with a selected list of applicable methods for practitioners, the methods research should not lead to an exhaustive, disjunctive database, but rather to a collection of methods to choose from in the transition from the developing phase of the research project to the validation and transfer phase with practitioners. The following table gives an overview of the number of methods in each category:

| <b>Role of users in the development process</b> | <b>Number of methods (common key words) found</b> |
|---|---|
| Co-designer                                     | 33  |
| Information provider                            | 31  |
| Point of perspective                            | 21  |
| <i>Total:</i>                                   | <i>85</i>   |

Table 1: Numbers of methods collected and categorised for user analysis and integration

#### Main findings from A2:

- Traditional NSD models follow a sequential routine. In comparison to the needs of a more dynamic and user-centric design context in the field of e-mobility services, this appears to be outdated. This means an agile and user-centric approach is required.
- To achieve market acceptance for new technologies and the (service) business models in which they are embedded, users need to be integrated stringently into the development processes. To this end, methods and tools for thorough user analysis and user integration should be provided in a standardised way and along the whole development process—clearly assigned to development phases and subordinate steps. The degree of user orientation of the methods may vary. They might treat users and/or customers as the point of perspective, as information providers, or as co-designers.
- There needs to be a review of whether there is a requirement for new methods or new combinations of existing methods for user orientation (white spot analysis concerning methods for user analysis and user integration, as well as for agile project management methods).

### 3.2. Service Engineering reference model for electric mobility

The core element of the innovation model for e-mobility services is a *Service Engineering reference model* including a process-activity model for developing services systematically, emphasising thorough user analysis and integration, and providing a flexible, configurable approach.

#### *Requirements regarding the Service Engineering reference model*

From the main findings of the analysis phases, more specific requirements regarding the reference model were derived:

- The Service Engineering reference model should support service innovation in the field of electric mobility and guide practitioners systematically through the development process. This means that it should focus on the actual development process, but it should also be linked with upstream steps such as strategy finding and idea management. As an innovation is achieved only when a service has been successfully realised in the market (cf. Schumpeter, 1912), the reference model should also include market launch as a major step. Furthermore, to offer commercialisation opportunities for technical e-mobility solutions, the reference model should include business model generation as a major step at the outset.
- As the market for electric mobility is not yet established, with new business opportunities still emerging and e-mobility providers still facing a lack of acceptance in the market, the Service Engineering reference model should support the integration of relevant stakeholders, of which the most important are the (potential) users and/or customers.
- In view of the required focus on interaction within the innovation process and in particular within the core development process of a specific service, the Service Engineering reference model should follow an agile approach.
- Despite the fact that the Service Engineering reference model must be generic enough to cover all e-mobility services, at the same time it should be specific enough to guide practitioners through the development process. As a solution for this dilemma, the reference model should be built up in a modular way and it should be easily configurable.
- To support practical applicability, the Service Engineering reference model should provide not only a clear process-activity model, roles and recommendations, but also a set of methods and tools—in particular regarding user analysis and user integration.
- The model should refrain from too high a degree of formalisation, in order to stay aligned with the idea of agility; and it should feature recommendations for agile project management to support people involved and interactions.

#### *Conceptual considerations for the Service Engineering reference model*

The Service Engineering reference model includes six components, with each superordinate level passing on its characteristics and influencing the subordinate level(s) (see figure 4). This framework will be filled to achieve a comprehensive

innovation model for e-mobility services. To deliver support for practitioners, the reference model will be provided together with a guideline for companies that intend to develop and offer services in the field of e-mobility, and it will be complemented by workshops and consulting.

Fig. 4: Components of the Service Engineering reference model

The current stage of the reference model is conceptual and the interim results so far will be described in the following paragraphs.

### Level 1: User analysis and user integration

In the level of user analysis and user integration, the model gives recommendations of where and how users are analysed and integrated. Thus, it “passes” its characteristics and findings to the levels below. Three types of addressees of a service are distinguished in the model, encompassing private (“business-to-consumer” perspective) as well as corporate customers (“business-to-business” perspective): the (end-) **user** of an e-mobility service, the **purchaser**, and the (internal or external) **contractor** of the developing project. In reality, they can be identical persons or groups. In the innovation model, the customer types are defined as follows: the user is the person who actually *gets in touch* with the e-mobility services, no matter if this happens intentionally or incidentally, and thus the term encompasses potential users as well. The purchaser is a person who *pays* for an e-mobility service. The contractor here is defined as the project initiator; this could be an internal stakeholder (e.g. corporate management, business development), or an external stakeholder (e.g. customer of a service consulting project), bringing their own requirements and expectations into the development process. In fact, the latter type is no “customer” of the service to be delivered, but is to be integrated into the innovation process. The distinction between user analysis and integration helps to define the degree of co-creation to choose, according to figure 3. It is important to note that a higher level (full integration) is not necessarily better than a lower level (e.g., analytical approaches with low or no activity on the side of the users). The idea is to combine analytical-empirical approaches with approaches of co-creation with users, customers (and, if necessary contractors) in an effective way; e.g., starting with user analysis and refining the findings by choosing and integrating users accordingly.

## Level 2: Configuration mechanism

In developing the innovation model, one of the most striking challenges is to find a balance between generality (so the model can apply to all types of e-mobility services), and detail (so practitioners can be guided through the innovation process). To adapt the model to the context and complexity of the development project, a configuration mechanism is defined. The aim is to reflect the heterogeneity and the different degree of complexity of e-mobility services. In particular, the configuration mechanism is intended to support the modular modification of the process activity model (level 3). For this, a system of characteristics and a modular concept is developed. The result will be an easy process chart that will help the user of the innovation model to decide which variant, i.e. which modules to follow (“self-test”). The decision points will be based on **guiding questions** that help to categorise the service that is to be developed (service type), and to understand the effects on the process-activity model, the methods and tools to be used, and so on. Based on the result of the self-test, the developer is able to configure the innovation model according to the service type in an easy way. So far, relevant guiding questions have been collected and categorised and the effects of their parameter values investigated. The idea is illustrated in figure 5. The guiding questions are currently being developed in an experimental group process, and will also be part of the validation process (T1, figure 1).

Fig. 5: Configuration principle for the innovation model based on guiding questions

## Level 3: Process-activity model

The process-activity model describes how a service is developed practically, which main phases are to be walked through, which single steps and tasks are part of the phases, and how single steps are linked (e.g. loops, interfaces, decision points). It represents the core of the reference model when it comes to practical application in an NSD context.

The following requirements for the process-activity model were defined, based on the previous analysis phase:

- Building upon and further developing the systematic approaches of Service Engineering
- Linking service description, process modelling and resource planning—as well as the marketing concept developed in parallel—to the previous step of business model development
- Mapping the user perspective as accurately as possible throughout the development process, and translating user, customer (and, if required, contractor) needs as exactly as possible into service functionalities
- Agile development approach, with a focus on testing and feedback, prototyping, and using short, iterative development cycles; refraining from too high a degree of formalisation (cf. agile manifesto; shift to support from level 4: agile project management and interactions).
- Applicability to all different kinds of services in the field of electric mobility, thus configurable
- Intuitive comprehensibility and practicability, i.e. easy to use for small and medium-sized companies that often do not have professionalised service innovation departments and/or service R&D departments

The process-activity model will be divided into two main parts. The core is represented by the main development phases and areas of activity, including single and multiple **iterations** (loops), and decision points: *requirements analysis*, *design*, *testing*, *implementation*, and market launch. Recommendations and decision support concerning *strategy finding* and *idea generation* for e-mobility services will be inserted as a preceding block, accompanying the innovation process. The final process-activity model will be cyclic, which means that after the market launch the process begins again by rethinking strategy and continuously generating ideas (e.g. collecting ideas from customer feedback, competitors, employees), or by reacting to changing requirements.

Service testing is emphasised within the design phase. Currently, three testing iterations are considered, depending on the complexity of the e-mobility service: concept test (iterations, drafting and versioning), lab test (e.g. simulations using virtual reality and business theatre), and market test (piloting, user and customer feedback).

#### **Level 4: Organisational arrangements**

The systematic development of services remains uncharted territory for most technology-based companies. Often there are no specialised units within the company to take on this task, or no clearly defined responsibilities (Schäfer, 2014; Meiren, 2006). For this reason, the Service Engineering reference model includes a fourth level dedicated to organisational arrangements, mainly organisational structures, and roles and responsibilities. Furthermore, rethinking service development approaches to move them from formalisation and linearity towards

interaction and agility necessarily leads to modifications in organisational structures, as well as in roles and responsibilities. Thus, a model that includes explicit roles such as user, customer, (contractor), service development team, management, and agile roles taken from the *Scrum* method is being developed in the DELFIN project.

#### **Level 5: Methods and tools**

The main objective of this level is to provide practitioners with concrete methods and tools to be used along the process-activity model (level 3) and to support agile project management (level 4). The focus is set on methods and tools for user analysis and user integration, to avoid the risk of user acceptance lacking before market launch by ensuring an early alignment with users' and customers' needs. The catalogue to choose from will be compiled from the methods research and complemented by suitable tools (templates, checklists, software etc.).

#### **Level 6: Case examples**

To illustrate levels 1 to 5 and support applicability of the reference model to business practice, it will be accompanied by case examples, with step-by-step explanations.

### **4. Summary and conclusion**

The markets emerging around electric mobility hold considerable potential for new business models and new players as well as for new cooperation constellations between companies from different industries. Vastly uncharted, dynamic market territories confront companies with risks, but at the same time are attractive for pioneers. User-friendly services offer lucrative opportunities for pioneers because they can support the market success of electric mobility effectively, but they are as yet underestimated and not developed systematically in business practice, and they are still given insufficient consideration compared to technical R&D. As to applied NSD, user integration is crucial, because potential customers are still reluctant about electric mobility due to fragmentary infrastructure and a lack of experience. This means that the market success of e-mobility services is subject to the condition that users are considered and integrated during the whole innovation process. No suitable development approach has yet been found that systematically addresses and makes use of user-friendly services in the field of electric mobility.

This article and the underlying research work are intended to address this gap in the field of service research and to make use of the potential of services to foster electric mobility. The first steps towards a user-centric, agile Service Engineering reference model have been finished, and will be followed up towards a comprehensive innovation model including recommendations and guidelines for its use.

## 5. Acknowledgements

The work and results described in this article are part of the DELFIN project. The DELFIN project (German acronym for “Services for e-mobility: Promoting innovation and user-friendliness”) is funded by the German Federal Ministry of Education and Research (BMBF) under the subsidy ID 01FE13001.

## **XXV. International RESER Conference :**

1. Introduction
2. Innovation dans les services chemin faisant
  - 2.1. Le déroulement de l'innovation dans les activités de services
  - 2.2. Spécificité des services hospitaliers
3. De la veille à l'animation des projets
  - 3.1. Animation et veille
  - 3.2. Animation et innovation
4. Deux cas d'animation de processus d'innovation
  - 4.1. Le cas « Assiette durable ».
  - 4.2. Le cas « DAV / B2K ».
5. Conclusion

# **Le rôle de l'animation dans la construction de projets innovants, le cas des structures hospitalières.**

*Sid Ahmed GOZIM<sup>1</sup>, Marie-Christine MONNOYER<sup>2</sup>.*

<sup>1</sup>Université d'Aix Marseille, <sup>2</sup>Université Toulouse 1 Capitole/IAE

## **1.0 Introduction**

Le développement de la réflexion sur l'innovation dans les services a permis de mettre en évidence la complexité d'un processus qui suppose une multiplicité d'opérations matérielles, informationnelles, méthodologiques et relationnelles, s'appuyant sur des compétences très diverses tant chez l'innovateur que ses partenaires (Djellal & *al.*, 2004). Parallèlement, le rôle de l'activité d'attention à l'environnement sur le déclenchement et le développement d'une innovation a été mis en évidence par (Gozim, 2015). Alors que cette fonction d'animation est totalement occultée par la majorité des auteurs, Lesca (2003) n'hésite pas à la considérer comme un facteur critique au succès et à mise en place et à la pérennité d'un dispositif de veille stratégique, sans pour autant développer son rôle sur le processus d'innovation.

L'absence de rapprochement dans la littérature des services entre veille et innovation et plus spécifiquement entre les deux processus et leurs différentes étapes a conduit Gozim (2015) à investiguer les liens entre la pratique de la veille et la dynamique de l'innovation dans ce secteur d'activités. Quoiqu'étudié par quelques auteurs (Jain, 1984 ; Engledow & Lenz, 1985 ; Fuld, 1991 ; Lesca & Chokron, 2002), le rôle de l'animation sur la richesse de la veille nous a semblé sous estimé et par là même son impact sur le processus d'innovation de services. Le rôle du chef de projet, considéré, dans la majorité des cas, comme l'animateur (Quang & Gonin, 1992), le meneur d'hommes (Rojot & Bergmann, 1989) dans la conduite du processus d'innovation semble être compris de façon différente selon les structures. Gozim (2015) ayant pu faire état d'une intégration de la veille tant en phase amont qu'en phase opérationnelle du processus d'innovation, il nous a paru intéressant de se pencher sur les modalités d'introduction de la fonction d'animation. Nous souhaitons montrer dans cette communication comment elle intervient en amont du projet et lors de sa phase opérationnelle. Nous nous efforcerons de faire apparaître qu'elle relève du contexte managérial et non pas seulement des caractéristiques personnelles de l'animateur. Elle favorise ainsi tant la conduite du processus d'innovation, que l'émergence d'innovations complémentaires.

Après une présentation de l'état de l'art sur nos deux angles d'analyse, nous en confronterons les conclusions à 2 études de cas réalisées dans les secteurs privé et public hospitalier, sur des innovations non médicales.

## **2. Innovation de service, chemin faisant**

Un certain nombre d'auteurs spécialisés dans le champ du management des services (Jougoux, 1993 ; Everaere, 1997 ; Durieux, 2000 ; Flipo, 2001 et Abramovici & Bancel-Charensol, 2002, etc.), et plus particulièrement celui du marketing des services (Shostack, 1984 ; Eiglier & Langeard, 1987 ; Scheuing & Johnson, 1989 ; Jallat, 1992 & 1994 et Lovelock & Lapert, 1999, etc.) ont consacré

des investigations aux aspects spécifiques de l'innovation. La plupart ont insisté sur le fait que les processus connus pour les biens matériels nouveaux devaient être revus pour tenir compte des caractéristiques des services et de l'organisation des entreprises du tertiaire.

## 2.1 Le déroulement de l'innovation dans les activités de service

L'ancrage de cette révision peut être situé dans la « *co-production* » du service entre prestataire et client, spécificité majeure de la relation entre ces deux (2) parties prenantes (Eiglier et Langeard, 1987 ; Gadrey, 1994). « *Les acteurs de l'offre et de la demande coopèrent à des degrés divers pour l'obtention de services et d'effets utiles. Il s'agit de processus de coopération portant sur la conception, sur la réalisation, sur le contrôle et sur l'évaluation d'une réalité "non déjà là", faisant l'objet d'une demande (souvent imprécise) à laquelle répondent des offreurs* » (De Bandt & Gadrey 1994, p. 20). De cette implication réciproque et unique peut naître l'innovation. Chaque nouveau service étant « *co-produit* » par le prestataire et le client selon des rôles et enjeux variables, par rapport à la nature du service et au contexte politique de la gestion de celui-ci. Il n'est donc pas étonnant de définir comme facteur essentiel de l'instauration d'une dynamique d'innovation cette relation, qui ne saurait être réduite au quotidien de l'exploitation courante (Flipo, 2001).

Les travaux de Djellal & Gallouj F. (1999) permettent de classer de multiples cas de figures d'innovation en fonction des circonstances du déclenchement du processus. Cependant, afin de demeurer pragmatique, uniquement trois cas seront distingués : celui où le client est clairement à l'origine de l'innovation (market pull), puis celui où il s'agit des prestataires (*technology push*), et enfin un troisième cas, où l'innovation s'avère être le fruit direct de l'interaction, à la suite d'initiatives et de circonstances qui peuvent être dues au hasard.

- Dans le premier cas de figure, l'aspect de « *co-production* » est particulièrement évident, car le client demande généralement à un prestataire de lui résoudre son problème, en raison de son incapacité à le faire lui-même, d'une absence de volonté, ou étant occupé par d'autres préoccupations jugées plus importantes (Sundbo & Gallouj F., 1998). Aussi, la solution ne saurait être trouvée par le prestataire unilatéralement, cela signifie que le client est nécessairement impliqué dans la recherche de solution (Goffman<sup>1</sup>, 1968).

- Dans le second cas, le terme « *technology* » fait référence au savoir-faire du prestataire qui est à l'origine de l'innovation, et non pas seulement aux équipements technologiques auxquels il a recourt. Si la proposition peut émaner directement du prestataire de services extérieurs, les salariés peuvent aussi chercher, à travers de nouvelles technologies ou une veille spécifique, des opportunités de développement pour l'entreprise dans laquelle ils travaillent.

<sup>1</sup> Dans son étude des interactions entre les patients et le personnel soignant d'un hôpital psychiatrique, Goffman (1968) a eu pour objectif d'identifier un système d'interactions spécifiques, de comprendre le comportement de chacun en l'expliquant par rapport à celui des autres.

- Enfin, une idée remarquable peut naître puis murir à la suite d'une rencontre fortuite à l'occasion d'interactions inédites entre les intelligences (prestataires / clients / autres parties prenantes). L'exploitation de circonstances, d'opportunité de mouvements spontanés peut ainsi faire l'objet d'une rationalisation d'ensemble : l'action des clients et simultanément la prise de conscience chez le prestataire, puis, l'intervention de multiples parties prenantes nécessaires à la cristallisation du projet, enfin, la mise en œuvre d'un réel processus d'innovation géré par les parties prenantes, nourri d'une grande énergie de part et d'autre.

## 2.2 Spécificités des services hospitaliers

En l'absence d'une concurrence aussi pressante que dans la majorité des autres secteurs d'activité, le processus d'innovation dans les services non médicaux du secteur hospitalier trouve essentiellement sa dynamique créative dans celle des salariés, en fonction de la liberté d'expression accordée (Gozim, 2015). L'analyse du processus de la prestation de services hospitaliers et des innovations correspondantes réalisée par l'équipe de l'université de Lille (France) permet d'enrichir notre réflexion, dans ce contexte particulier et d'affiner l'analyse des relations entre les acteurs de l'innovation dans ce secteur.

S'appuyant sur la représentation lancastérienne élargie du produit ou du service F.Gallouj (2002) et Gallouj *et al*, (2004) rendent ainsi compte des nombreuses caractéristiques du service obtenues, par la mobilisation de compétences, de matériel, de méthodologies, de relations. Par ailleurs, ils rappellent l'impact de la prégnance des tutelles sur les organisations prestataires et ses effets sur la dynamique d'innovation née des interactions entre agents prestataires et client usager.

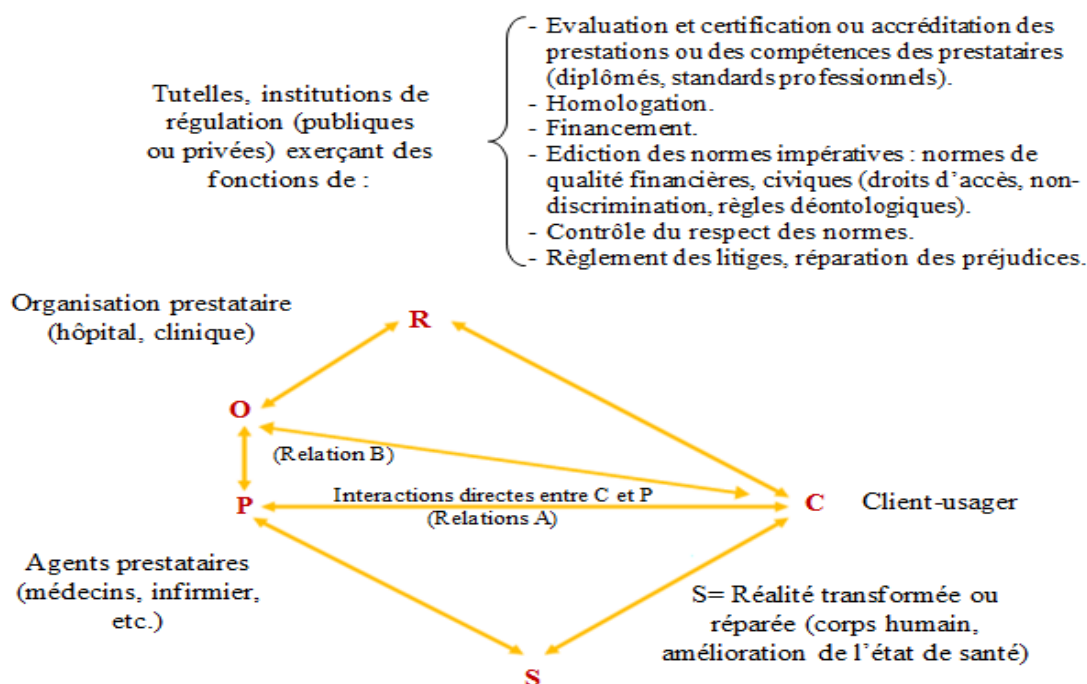

Fig. 1: Pentagone des services hospitaliers

Source : Djellal F., Gallouj C. & Gallouj F, (2002),

Mais parallèlement, comme dans de nombreuses organisations productives aujourd'hui, les interactions internes entre services prennent régulièrement la forme de relations de clientèle (Sasser & Arbeit, 1976 ; Grönroos, 1978, Berry, 1981). Ainsi le service informatique devient-il le prestataire du service restauration de la clinique lorsque ce dernier veut transformer l'offre de repas (mode de fabrication, variété des plats, ..) proposée tant aux patients qu'aux salariés de la clinique (Gozim et Monnoyer, 2014). De même, tous les départements dédiés aux soins sont-ils clients de la filière blanchisserie de l'hôpital (Gozim, 2015).

Capron, (2006) évoque dans le processus de développement de l'offre de services, un mixage de « market pull » et de « technology push » Il nous semble tout à fait envisageable d'y intégrer dans les services non médicaux en milieu hospitalier, le troisième cas envisagé par Djellal & Gallouj F. (1999), à savoir l'exploitation d'une idée ou d'une rencontre fortuite, selon les circonstances des relations prestataires / clients, ou prestataires / marchés, au sens plus large.

Néanmoins, ce constat n'est pas suffisant pour prétendre que l'innovation sera féconde. Le rôle d'une surveillance de l'environnement de l'entreprise sur la qualité de la prise de décision mise en évidence par Lesca (1986) est souligné sur la dynamique de l'innovation par des chercheurs comme Simon (1960) et Aguilar (1967). Cette dynamique s'enrichit dans un environnement managérial porteur, qui, dans le cadre de la gestion de projets innovants, organise et favorise les interactions entre les individus, la circulation de l'information, l'adaptation rapide à des événements inattendus (Jougleux, 1993), sur une base de co-développement avec les clients, et non pas seulement de satisfaction immédiate.

### **3. De la veille à l'animation de projets**

Qu'elle soit passive ou active, la veille permet de porter une attention à l'environnement et de décoder les signaux dont il est porteur (Martinet & Ribault, 1989). Elle soutient alors l'activité, le métier et les processus clés de l'organisation, la prise de décision des managers et la réalisation d'une stratégie délibérée ou émergente. Les travaux de Lesca et son équipe (2006) ont fait apparaître les effets positifs de la veille anticipative sur l'identification des phénomènes potentiellement intéressants pour le développement de nouveaux produits ou services. La veille consiste alors à identifier des discontinuités ou des ruptures (exploration de l'environnement) qui pourraient alimenter très en amont des démarches d'anticipation, d'innovation et de créativité. De même, les travaux de Simon (1960) mettent en exergue, les effets de la veille sur le processus de décision stratégique via la phase d'intelligence de l'environnement. Notre investigation sur le terrain permet de constater que l'exploration et l'intelligence de l'environnement peuvent se situer en amont ou en parallèle du processus d'innovation non médicale. La veille s'intègre donc dans la construction du projet innovant (Gozim, 2015). Ce rapprochement nous conduit à analyser la fonction d'animation tant dans le processus de veille que dans celui de la conduite de projets dans les services non médicaux du secteur hospitalier caractérisé comme nous l'avons dit précédemment par la multiplicité des inter relations internes et externes. En effet, certains éléments de littérature insistent sur le rôle de l'animateur dans ces deux processus.

### 3.1 Animation et veille

Dans le contexte de l'animation d'un processus de veille, Romani & Bournois (2000) rapprochent l'animation de l'organisation de la communication, interne et externe, de l'intelligence stratégique. Le réseau externe lie l'entreprise à l'extérieur par un flux d'informations, à caractère stratégique, dont le contenu est technologique, concurrentiel et commercial. Le veilleur se doit donc d'être un animateur, avec ce que le terme porte en lui de capacité d'écoute. Quant aux réseaux internes, Romani & Bournois (2000) considèrent qu'ils doivent être animés pour rester vifs, vivaces et vigilants. Réunions régulières<sup>2</sup> (47,5 %) et rencontres individuelles (38,4%) sont les modalités les plus courantes pour entretenir les réseaux. La diffusion régulière de supports est présente mais beaucoup moins utilisée (9,9%). Rappelant le rôle du responsable de l'intelligence stratégique dans l'animation des réunions, Romani & Bournois (2000) insistent sur les modalités qui permettent d'entretenir les réseaux de personnes. Il s'agit bien d'une « façon de faire » pour motiver les personnes ou les participants au réseau d'intelligence stratégique. Ils concluent que : « le système d'animation consiste essentiellement en la mise en œuvre par les participants, de l'action collective finalisée ».

Doucet & Gingali (2004), prenant en compte la dimension sociologique de la veille stratégique, vont dans le même sens, pour montrer comment cette activité peut acquérir une légitimité. Lors de la mise en place du dispositif de veille, les auteurs évoquent l'animation d'un « groupe de travail » composé de personnes de compétences diverses. Celui-ci permet de positionner les membres du groupe dans une dynamique et par conséquent, de favoriser leur niveau d'implication.

S'agissant de la position de l'animateur au sein de l'organisation, les auteurs tels que Engledow & Lenz (1985), désignent l'animateur par le vocable de « champion », précisant que celui-ci devrait être haut placé dans la hiérarchie de l'entreprise et ainsi disposer d'une forte influence sur les participants du dispositif, mais aussi sur la direction générale. Mais, le champion doit être épaulé par les participants du groupe de travail de la veille qu'ils appellent « sponsors » (Simon & Kern, 2001). Ces auteurs identifient aussi plusieurs autres rôles clés, à savoir : « the CI leadership, the CI practitioner, the CI champion, the CI sponsor ». La qualité de leurs interrelations affecte leur influence sur les utilisateurs potentiels des informations de veille, mais aussi sur les veilleurs sollicités pour rechercher ces informations et la prise en compte de l'utilité de celles-ci.

### 3.2 Animation et innovation

L'innovation est avant tout un processus collectif (Van de Ven, 1986 ; Djellal & Gallouj F., 1999 et Le Masson, Weil & Hatchuel, 2006). Elle ne peut être « vendue » en interne que si les initiateurs et leurs politiques sont crédibles ; en effet, satisfaire au jour le jour des clients de plus en plus exigeants, rend le personnel en contact lui-même de plus en plus exigeant vis-à-vis de ses managers (Flipo, 1984). Dès lors, la valorisation de l'esprit d'équipe, de l'œuvre collective, du bien de l'entreprise tout entière pour chaque projet d'innovation est une pratique incontournable. « *L'agir*

<sup>2</sup> Les objectifs de ces modalités (les réunions) peuvent être envisagés à des fins plus larges telles que la création collective de sens, la détermination des besoins des « clients » du dispositif, la connaissance de « *qui détient quoi ?* », la suscitation continue de l'intérêt des membres de l'entreprise à l'égard de la veille, etc.

*ensemble* » est devenu une exigence : il ne s'agit pas seulement de tenir un discours, mais d'instaurer un véritable système de management qui favorise le comportement synergique des groupes de projet (Borzeix, 1998).

Le cycle de développement d'une innovation s'étend généralement sur plusieurs mois, voire même sur des années (Maidique & Zirger, 1985). De ce fait, l'énergie déployée par les acteurs de l'innovation doit être à la fois parcimonieusement répartie selon les étapes afin de durer, mais aussi judicieusement employée, de telle sorte que ces étapes soient franchies de manière décisive, empêchant ainsi le processus de s'enliser. Par ailleurs, le processus d'adoption de l'innovation ne s'entame pas au moment de la commercialisation du service nouveau, mais bien avant, puisque celui-ci doit d'abord trouver sa légitimité à l'interne (Flipo, 2001). Le management de ce processus doit donc se situer dans une continuité durant tout son déroulement, du début « *interne* » à la fin « *externe* ». La rupture de cette continuité peut s'avérer une cause majeure d'échec, ou du moins de difficultés, à laquelle peut s'ajouter l'ignorance réciproque des acteurs des processus interne et externe.

Qu'il s'agisse de la phase de veille ou de celle du développement de l'innovation, la littérature, et en particulier Martinet & Ribault (1989) jugent que : « l'animation garantit la cohérence de l'ensemble de tout le travail ». Tabatoni & Jarniou (1975) précisent que l'animation permet de gérer un processus d'intégration d'efficacité individuelle, pour améliorer l'efficacité organisationnelle. Ils estiment que l'animation a pour but : « *d'harmoniser les significations des tâches et des relations au sein de l'organisation qui sont susceptibles d'interprétations diverses de la part des personnes et des groupes* » (Tabatoni & Jarniou, 1975, p. 138). Pour sa part, Hermel (1989) a porté l'éclairage sur une autre dimension de l'animation : « donner de la vie et insuffler régulièrement de l'énergie à l'unité, (...) combattre la routine et l'entropie, (...) permettre l'innovation et l'anticipation ».

Cette double analyse de la littérature laisse apparaître un consensus quant à l'intérêt d'une animation tant dans les phases de veille que dans les phases de conduite de projets. Le titre de champion donné à l'animateur, chef du processus veille ou du projet, son intégration dans les équipes dirigeantes montre que cette fonction requiert des qualités personnelles originales, mais aussi un savoir faire reconnu et accepté par la structure, au delà des curriculum vitae traditionnels.

La confrontation de ces résultats à deux cas observés sur le terrain, permet de réifier les effets de l'animation et d'effectuer des propositions managériales.

#### **4. Deux cas d'animation de processus d'innovation**

Comme nous le rappelions en introduction, la conduite du processus d'innovation semble être comprise de façon différente selon les structures. En ayant choisi d'introduire formellement la veille dans le processus d'innovation, c'est toute la démarche d'animation, de l'idée à sa concrétisation, que nous avons observée dans deux structures de soins, l'une privée l'autre publique. Les deux études de cas présentées rapidement ici sont issues d'un travail doctoral dans lequel plus de détails peuvent être trouvés (Gozim, 2015).

Nous avons fait le choix de présenter les cas sous forme narrative en faisant apparaître *en italique* dans le texte, les éléments relatifs à la pratique de l'animation de la veille ou de la construction du projet.

#### 4.1 Le cas « Assiette Durable »

La clinique P, établissement de soins privé à but lucratif, a été confrontée à une triple évolution qui a affecté son activité : baisse de l'activité des médecins, concurrence accrue d'autres établissements de santé, baisse du niveau de prise en charge des soins par la sécurité sociale française. Ces évolutions ayant eu une forte incidence sur le chiffre d'affaires, la clinique P a décidé de mettre en place une nouvelle stratégie. Cette dernière a consisté, bien sûr, à être vigilant en matière de coûts, mais surtout à attirer plus de patients.

La nouvelle direction de la clinique a décidé d'aller à la rencontre de ses différents services, pour demander ce qui pourrait, à leurs yeux, améliorer les prestations offertes à la clientèle. Toutes les suggestions convergeaient étonnamment vers la refonte des menus. *Ce projet était en quelque sorte ancré dans les esprits. Lors des entretiens menés dans le cadre de cette recherche, les employés du service restauration ont stipulé que cette idée leur trottait déjà dans la tête depuis environ dix (10) ans, mais ils n'avaient jamais franchi le pas, puisque l'ancienne direction ne souhaitait pas s'aventurer sur cet axe-là.*

Parallèlement, une diabétologue, membre du conseil d'administration de la clinique P, découvre un ouvrage qui avait pour titre : « Tous gros demain ? : 40 ans de mensonges, 10 kilos de surpoids » du chercheur et agronome Pierre Weill<sup>3</sup>. La lecture de ce livre a eu un tel impact sur la conception de l'alimentation auprès de cette diabétologue, que celle-ci a tenu absolument à faire partager la vision de l'auteur à ses plus proches collaborateurs<sup>4</sup>. L'auteur a été invité pour animer une conférence. Celle-ci était basée sur son nouvel ouvrage intitulé : « Mon assiette, ma santé, ma planète », qui à l'époque n'était pas encore commercialisé. Les idées de l'auteur furent qualifiées de « révolutionnaires ». Il s'en est suivi une réflexion approfondie et prise de conscience de chacun des membres de l'établissement, ayant pour conséquence l'entame du projet « Assiette Durable ». Le contenu de l'innovation consistait en la refonte des menus patients en fonction désormais de nouveaux critères tels que la démarche de développement durable, l'évolution de la société, une meilleure connaissance de certaines pathologies, des régimes spéciaux, des allergies, des problèmes de surpoids, etc.

*La veille personnelle menée par la diabétologue se traduit par une animation de la réflexion tant au sein du conseil d'administration que dans l'équipe diététique et soins. L'idée que dans l'établissement, les clients seraient soignés mais qu'ils bénéficieraient aussi d'une nourriture saine et mise en œuvre dans le cadre d'une « éthique » est apparue comme une évolution de la stratégie lisible, tant en interne qu'en externe. Selon l'un des chefs cuisiniers « la restauration n'était pas valorisée à sa juste valeur, contrairement à aujourd'hui ». La nouvelle direction estime avoir trouvé un moyen d'apporter une valeur ajoutée aux patients, tout en améliorant l'organisation du service restauration, via une nouvelle motivation des employés.*

<sup>3</sup> Weill P. travaille depuis quinze ans sur le lien entre modes de production agricole et santé. Il a signé de nombreux articles scientifiques sur le sujet.

<sup>4</sup> Par la suite, la diabétologue a voulu connaître leurs impressions vis-à-vis de l'ouvrage. Autrement dit, celle-ci a voulu constater la bonne réception des informations et des idées qu'elles véhiculent auprès des personnes concernées.

Dès lors, une « commission menu » pluridisciplinaire s'est constituée et réunie, à plusieurs reprises, dans le but de recueillir des informations sur les besoins de l'ensemble des catégories professionnelles œuvrant au sein de la clinique P. Cette commission fut constituée de médecins de différentes spécialités, de chefs cuisiniers et d'une spécialiste de la construction des menus, de diététiciennes, de soignants (aide-soignante et cadres de soins), d'une hôtelière, d'une gouvernante, d'un membre du service qualité et d'un informaticien. *Dans le cadre du processus d'innovation, le travail de la commission alimente une interaction entre de multiples acteurs, issus de champs ou secteurs différents et des positionnements hiérarchiques différents.* Ce groupe de travail pluridisciplinaire réfléchit à la meilleure prestation à apporter au patient, formule des suggestions en se basant sur leurs connaissances et compétences et élabore un cahier des charges, définissant les règles pour reconstituer une nouvelle carte. Toutefois, l'aspect développement durable n'a pas été abordé lors de cette commission.

Outre la cellule pluridisciplinaire, c'est-à-dire la « commission menu », la construction du projet « Assiette Durable » s'est également appuyée sur *des cellules mono-disciplinaires, qui ont été mobilisées* au cas par cas, pour chaque axe d'amélioration du projet : communication vers les patients, les salariés commensaux et vers l'extérieur, développement durable, optimisation des dépenses sans impact sur la qualité, développement de partenariats pérennes avec les fournisseurs, etc.) gravitant autour de l'axe principal, à savoir la refonte des menus. Il est à préciser que pour chacun de ces axes, *un « pilote » a été désigné*<sup>5</sup>. Carte blanche lui a été accordée afin de recruter les personnes ayant les compétences requises pour œuvrer sous son autorité à la bonne exécution de la tâche qui lui été confiée. Il était tout à fait envisageable pour un individu appartenant à la cellule d'avoir un besoin d'informations et de collaborer avec des personnes évoluant au sein d'autres services ou cellules, sans pour autant en demander l'aval à son supérieur, à savoir le pilote. Par ailleurs, Il n'était pas à exclure que celui-ci, aille requérir de l'aide auprès d'autres individus ou pilotes.

La collaboration des chefs cuisiniers avec les diététiciennes s'est révélée cruciale pour le projet. Il fallait en effet élaborer les menus, les agrémenter, les écrire, sachant que cette fois l'aspect développement durable était constamment présent dans les esprits. Les cloisonnements latéraux habituels entre la restauration et la diététique, liés aux différences de sensibilité (processus de fabrication versus équilibre alimentaire) ont été rompus. *L'affirmation des nouveaux impératifs stratégiques de l'administration de la clinique a permis, en effet, de résoudre le manque habituel de communication entre les deux (2) services, en favorisant un esprit de connivence, de complicité et d'interaction nécessaire au développement d'un travail collectif .*

La construction du projet n'a pas impliqué les seuls cuisiniers et diététiciennes puisqu'il a fallu élaborer une application informatique pour constituer les recettes, un logiciel pour mettre en place les menus. Le service informatique a été très sollicité par les diététiciennes et les chefs cuisiniers, pour faciliter leur travail et permettre un gain de temps et accélérer la communication entre l'hôtelière en contact avec les patients et les cuisines. Si un plat n'était pas apprécié, si un menu était trop lourd,

<sup>5</sup> Autrement dit, un responsable de l'animation.

l'hôtesse acheminait l'information vers ses supérieurs - c'est-à-dire, les diététiciennes et le chef de projet - qui prenaient par voie de conséquence les mesures nécessaires. *A ce stade, les hôtesse ont eu la liberté de transmettre directement et en temps réel les renseignements qu'elles jugeaient pertinents aux utilisateurs potentiels désignés.* Le service restauration pouvait, dès lors, avoir un retour, une critique constructive, lui permettant de se réajuster et de s'améliorer. C'est ainsi qu'un certain nombre d'aller-retour fut effectué, renforçant en cela l'idée d'un processus d'innovation non linéaire.

Enfin, le service communication a eu pour mission de faire connaître en interne le projet et les nouveaux menus.

*Les employés<sup>6</sup> ont été informés des étapes de développement du projet via un article publié dans le journal interne de l'établissement<sup>7</sup>, par courriels, ou via des écrans télé<sup>8</sup>, etc.*

*Concernant les patients, un support explicatif, décrivant la nutrition durable au sein de la clinique, a été fourni aux patients. Une chaîne de télévision destinée à l'aspect : « restauration durable » a été créée.* Enfin, l'hôtesse chargée d'amener le plateau repas au chevet du patient devait expliquer les choix effectués dans la confection du menu. Toutefois, il s'est avéré que celle-ci avait du mal à mettre en exergue tout ce qui se faisait en rapport avec le projet, ce qui réduisait les effets attractifs recherchés. La direction aurait donc pu porter une réflexion sur une politique de « marketing interne<sup>9</sup> » destinée aux hôtesse, dans le but de mieux leur expliquer l'intérêt de l'innovation (Flipo, 2001), sachant qu'elles représentaient un véritable cordon ombilical reliant l'établissement à ses patients (Jallat, 1992).

*D'autre part, plusieurs soirées furent organisées avec le corps médical, en rapport avec la refonte de menus et les axes d'amélioration adoptés. Il était question d'inciter les soignants à être attentifs au thème de l'alimentation, de les motiver pour collecter et transmettre les informations pertinentes<sup>10</sup>.* Il était tout autant nécessaire que les professionnels de santé puissent évoquer le projet, si l'occasion venait à se présenter.

*Pour ce qui est de la communication destinée à l'externe, une rubrique a été créée sur le site internet de la clinique, des articles ont été proposés dans des revues spécialisées et généralistes.* Néanmoins, cela demeure insuffisant au regard du chef de projet.

<sup>6</sup> L'ensemble des employés tout autant que les patients ont été impactés par ces nouveaux menus, puisque tout ce qui est servi aux patients l'est au restaurant de l'établissement.

<sup>7</sup> Consultable par le biais de l'intranet.

<sup>8</sup> La cafétéria dispose d'un écran télé géant diffusant les informations et les reportages en boucle. Toutefois, le son est coupé pour ne pas déranger le personnel en train de déjeuner.

<sup>9</sup> La meilleure méthode pour réussir le marketing externe dans une entreprise de services consiste à considérer le personnel en contact comme les premiers clients de l'entreprise d'où cette expression « marketing interne » (FLIPO, 2001).

<sup>10</sup> La diabétologue que nous avons interrogée estime être à l'écoute du patient concernant les aspects se situant hors du contexte médical, précisant en cela l'importance que celui-ci accorde aux services annexes. Elle stipule qu'il faut toujours avoir des retours qu'ils soient positifs ou négatifs, et faire remonter les informations, évidemment après les avoir préalablement filtrés. Autrement dit, il ne faut pas tenir compte des remarques injustifiées, mais sélectionner les informations qui vont réellement renseigner sur la situation actuelle et aider à apporter le changement.

D'après le directeur technique, informatique et logistique : *« il était très important qu'une personne puisse chapeauter et coordonner les opérations. Quelqu'un qui puisse cadencer le processus d'innovation, poser la question : où on en est ?... S'assurer qu'il n'y a eu l'économie d'aucune phase, observer un certain cap, déterminer un planning sans pour autant l'imposer »*. Celui-ci précise, en outre, que le projet « Assiette Durable » fut parfois confronté à des écueils à tel ou tel stade de son développement, ce qui impliquait un besoin d'informations spécifiques pour pouvoir franchir ces obstacles. *En l'occurrence, des réunions furent organisées lorsqu'un problème était identifié, qu'il fallait comprendre et résoudre. Dans cette situation, le chef de projet éprouvait un vif intérêt à motiver le personnel pour rechercher des informations afin de parvenir à formuler des solutions.*

Pour conclure le directeur technique, informatique et logistique affirme que : *« l'intérêt de travailler à la clinique P, c'est d'être écouté, c'est le dogme de la direction, à savoir qu'il est à la portée de tout le monde de proposer un projet, sachant que la direction est ouverte à quelque suggestion que ce soit, si toutefois celle-ci est bénéfique aux patients, aux équipes et qu'il n'y a pas de problèmes économiques derrière »*. La direction de la clinique encourage donc les équipes et les services à proposer des projets, plutôt que de leur en imposer.

La présentation de ce cas nous semble mettre en valeur l'efficacité des pratiques de l'animation de la veille et de la gestion de projets sur le déroulement du processus d'innovation, mais aussi la perception des manques à certaines étapes et leur mémorisation par les personnes interrogées. Il nous semble aussi qu'il met en exergue les effets positifs de l'animation sur l'« empowerment » des acteurs impactés par la construction du projet et sa réalisation. En effet, la dynamique inter-fonctions suscitée par l'animation du champion de la veille, comme celle du champion du projet permet aux équipes de se découvrir réciproquement, de connaître la réalité du travail des autres et d'en mieux comprendre les difficultés et la valeur. Le caractère personnel de ces découvertes permet une appropriation des informations par les salariés qui semble beaucoup plus forte que celle qui est le fruit de la lecture de documents, de tableaux d'affichage et même d'écrans vidéo, même si cette dernière reste nécessaire du fait de sa durabilité dans le temps.

#### **4.2. Le cas « DAV<sup>11</sup> / B2K<sup>12</sup> »**

Le projet « DAV / B2K » est né des conclusions du groupe de travail relatif au contrat linge<sup>13</sup> entre la blanchisserie et la direction des soins du centre HP. Ce groupe qui

<sup>11</sup> Distributeur Automatique de Vêtements.

<sup>12</sup> Le modèle a été baptisé B2K.

<sup>13</sup> La forte augmentation du volume de linge à traiter (+ 36 % en 20 ans) a rendu indispensable une standardisation des flux de linge. La logique client / fournisseur instaurée à travers le contrat linge au sein de l'établissement a permis :

- Un lien direct entre la blanchisserie et les services : le chargé de clientèle et son équipe de référents linge sont à l'écoute des besoins des soignants sur les sites.
- Un plus haut degré de rationalisation et d'hygiène : le linge mis sous housse et transporté sur des étagères mobiles est livré directement dans les services.
- Une meilleure gestion des stocks : chaque service de soins se voit attribuer une dotation en linge adaptée à ses besoins.

Ce contrat linge concerne les services de soins du centre HP mais aussi des clients extérieurs comme l'ICR (traitement du cancer) et quelques associations humanitaires (Restaurants du Cœur,...).

faisait collaborer des cadres, des aides soignants, des infirmières et des médecins, a décidé de mettre en place une démarche d'amélioration continue de la qualité, pour répondre aux critiques dont le traitement du linge faisait l'objet, et tout particulièrement celui du nettoyage des tenues professionnelles. *Le responsable de la filière blanchisserie, qui avait travaillé précédemment chez le leader européen des blanchisseurs privés*, a proposé à la direction des soins de mettre en place un système automatisé de distribution des tenues pour en améliorer l'accès aux soignants

Le personnel soignant a besoin de disposer de tenues décontaminées 7j / 7 et 24h / 24, quel que soit son lieu de travail au sein de l'hôpital. L'analyse des besoins en linge des services de soins<sup>14</sup> a été effectuée par deux responsables (magasin et adjoint fonction linge) à l'issue de réunions de *travail avec les cadres de santé, qui, faut-il préciser, exercent une influence sur le personnel soignant*.

Le but du DAV est de centraliser la distribution des tenues en un seul point pour réduire la manutention et les flux, éviter les pertes et les vols, avoir un outil de suivi pour déterminer ce qui a été fourni et connaître les rotations. Désormais, il n'est plus nécessaire de délivrer les tenues directement auprès des services concernés. Pour disposer de sa tenue, le soignant se sert directement au niveau du distributeur, qui a d'ailleurs été positionné à un endroit stratégique, c'est-à-dire à proximité des vestiaires.

Le distributeur automatique présentait un défaut au niveau du récupérateur de cintres portant les vêtements. En l'occurrence, la barre de déchargement s'est révélée inadaptée au nombre de cintres entassés. Le référent linge / DAV nous a confié avoir soumis une solution à ce problème, mais celle-ci avait été rejetée : « à l'hôpital ce n'est jamais possible à cause de l'argent et c'est dommage ». Le référent avait imaginé une installation pour éviter que les cintres ne tombent sur le distributeur et ne provoquent un blocage. Le responsable de la filière et chef du projet « *DAV / B2K* », qui a rejeté l'idée du dispositif, nous a expliqué que sa décision avait été prise en prenant en considération l'investissement nécessaire, mais surtout que cela n'avait pas été prévu dans le budget initial. Il a nous a précisé que : « *si la proposition avait été formulée par quelqu'un occupant un poste hiérarchique plus élevé, cela n'aurait eu aucune influence sur ma décision, parce que les idées sont préétablies* ».

Une fois l'installation achevée, un test<sup>15</sup> a été effectué avec un premier service, s'en est suivi un second, trois mois plus tard. D'après le chef de projet : « *la blanchisserie s'est occupée à tour de rôle des services de soins qu'elle avait ciblés, avec un travail de communication dès plus remarquable* ». C'est la responsable antenne linge<sup>16</sup> qui

<sup>14</sup> La responsable magasin a été en contact avec les services de soins pour déterminer le nombre d'agents qui allait être concernés par le nouveau système et combien de tenues seraient requises. C'est ainsi que l'on peut considérer la relation avec les services de soins comme une source d'information de nature pratique et relationnelle, ayant permis de disposer de renseignements nécessaires pour aider à la progression du projet.

<sup>15</sup> Le chef de projet nous a confié qu'un DAV avait déjà été mis sur pied dans la région, chez un établissement hospitalier privé, qui n'est autre que l'ICR : « ... ils se sont un peu cassés les dents, mais ça nous aura au moins permis d'éviter de faire les mêmes erreurs ».

<sup>16</sup> La responsable antenne linge RAN fait partie intégrante de la sous-filière clientèle. De ce fait, elle est chargée de chiffrer le nombre de tenues nécessaires, afin de satisfaire les besoins de l'ensemble des services concernés par le B2K. Celle-ci est en contact permanent avec les soignants, ce qui lui permet de disposer des informations

a fait la promotion du nouveau système automatisé. Celle-ci s'est efforcée de convaincre les soignants de l'utilité du système : envoi de lettre d'informations DAV, mise au point et collage d'affiches, création et distribution de flyers, « quick forum » maison du personnel<sup>17</sup>, mailing spécifique pour les médecins, mise en place panneaux indication DAV, visites de l'engin par les cadres utilisateurs, réunions d'information, recours à un film explicatif, etc. Bien que les avantages de l'innovation soient perceptibles par les soignants, puisqu'ils peuvent disposer de linge à toute heure, la tâche de conviction s'est révélée difficile : « il a fallu au préalable que le personnel soignant concerné s'approprie la machine, alors que jusqu'à présent il était en quelque sorte materné, puisqu'on lui ramenait son linge directement à son service ». Enfin, l'innovation a permis une économie de la main d'œuvre.

*Le directeur communication culture, relations usagers, médiation et association du centre HP explique qu'il lui paraît nécessaire de porter l'attention sur ce qui était technologiquement désavantageux, en soulignant toutefois la possibilité d'agir en conséquence. Par exemple, si l'outil venait à tomber en panne, un dispositif devrait être mis en place, s'appuyant sur des individus effectuant des astreintes.*

Le chef de projet « DAV / B2K » nous a précisé qu'une formation avait été spécifiquement prodiguée aux référents linge pour les inciter à adopter un comportement plus courtois et aimable, à faire preuve de davantage de tact et de diplomatie, en particulier en cas de désaccord.

Le responsable client, adjoint fonction linge et la responsable antenne linge contredisent le responsable de la filière blanchisserie, en déclarant qu'aucune formation en rapport avec les services de soins n'avait été destinée aux référents. D'ailleurs, le référent linge / DAV confirme qu'aucune formation ne lui a été proposée. Seule celle destinée à l'hygiène lui a été imposée, comme pour tous les autres membres du personnel de la blanchisserie. *Pour sa part, la responsable magasin déclare avoir suivi une formation pour gérer les conflits entre collègues, mais sans rapport avec les services de soins.*

Par ailleurs, contrairement aux affirmations de son supérieur hiérarchique<sup>18</sup>, le responsable client, adjoint fonction linge ne peut considérer les réunions de sensibilisation comme des moyens de facilitation du développement des projets innovants. Selon ses propos : « *des réunions ont lieu, mais seuls les dysfonctionnements et les erreurs y sont exposés* ». Pour la responsable antenne linge, il fut un temps où les réunions de sensibilisation existaient, mais ce n'est plus le cas<sup>19</sup>. Elle précise que : « celles-ci ne sont plus organisées sous prétexte que le personnel et les dirigeants de la blanchisserie sont constamment débordés ».

---

qui lui sont requises. Elle nous a confié que nombreux sont les conflits avec le magasin de la blanchisserie qui, la plupart des temps, ne tient pas compte de ses calculs, essayant toujours de négocier, étayé par leurs propres chiffres.

<sup>17</sup> « En fait, une permanence de deux (2) heures a été organisée à l'heure du repas où les agents ont pu être informés qu'il y a une nouvelle machine qui arrive et un nouveau système, c'est de la communication ni plus ni moins », selon le chef de projet.

<sup>18</sup> En l'occurrence, le responsable de la filière blanchisserie.

<sup>19</sup> Elle peut l'affirmer au vu de son ancienneté, car c'est depuis presque trente (30) ans qu'elle travail pour la filière blanchisserie.

Malgré les divergences d'opinions, il y a tout de même une bonne entente au sein de la filière. *D'après le responsable de la blanchisserie, c'est la communication facilitant la coordination qui en est à l'origine. Quant à la responsable magasin, celle-ci affirme sa satisfaction au travail en mettant en avant l'ambiance qui y règne, valorisant l'esprit d'équipe et l'œuvre collective.*

Le chef de projet du « DAV / B2K » estime que, malgré les difficultés rencontrées, la filière blanchisserie dispose bel et bien d'une culture organisationnelle d'innovation. Il s'en attribue le mérite et considère que c'est grâce à son cursus, n'ayant pas évolué au sein de structures hospitalières, mais plutôt dans le secteur des entreprises privées. Etant responsable de la blanchisserie, il nous a confié qu'il gère la filière comme s'il s'agissait de sa propre entreprise. Il a ajouté que : « si les rênes du pouvoir avaient été confiés à une tierce personne du secteur hospitalier public, cela aurait été forcément différent ».

La présentation de ce cas nous semble mettre en exergue les conséquences d'une animation chaotique tant pendant la phase de veille que dans la construction du projet. On peut aussi s'interroger sur les effets négatifs d'une hiérarchie trop rigide qui bloque la pratique d'une veille continue tout au long de la préparation du projet, et d'une remise en cause de certains choix. La centralisation de la communication sur des outils désormais traditionnels, documents papier et vidéo, ne semble pas efficace dans des structures qui supportent une charge d'activité intense. La faiblesse de l'animation semble alourdir la demande de formation des salariés. Cette exigence nous semble pouvoir être considérée comme l'expression d'un besoin de communication orale et interpersonnelle. Les échanges internes au sein de l'équipe en charge du projet auraient sans doute permis la diffusion de connaissances tacites et leur explicitation auprès des personnes impactées par le projet, en réduisant ainsi les coûts, et favorisant l'empowerment des salariés.

## **5.0 Conclusion**

Comme nous l'avons indiqué au début de cette communication, la problématique de l'animation dans le cadre de la veille stratégique et du management des projets innovants a été très peu étudiée. Notre ambition, à travers cette communication, était de s'appuyer sur les conclusions de la littérature relatives à l'animation pour décrypter les pratiques d'animation observées sur les activités de veille stratégique et celle de construction d'un projet d'innovation non médicale dans des terrains hospitaliers privé et public.

Nous avons constaté, à partir de l'étude du cas « DAV / B2K », les effets d'une présence moindre d'éléments d'animation dans la pratique du management de projet, et l'absence presque complète d'une fonction de veille stratégique. Si certains de ces effets peuvent être attribués à l'attitude du chef de projet et responsable de la filière blanchisserie, la structure du processus d'innovation n'apparaît pas seulement liée à cette personnalité. L'organisation hiérarchique, les contraintes de temps, rigidifient les processus et les relations interpersonnelles, brident la créativité et sans doute encouragent la culture du silence et la rétention d'informations.

Dans le cas « assiette durable », au contraire, les deux responsables de la veille adoptent la position de « champion », définie par la littérature. Ils s'appuient sur des formes de management participatif via des réunions de proximité thématiques qui

permettent la construction du projet innovant « chemin faisant » en impliquant une grande variété de personnes aux fonctions et statuts différents. Les échanges interpersonnels qui en résultent, favorisent le décroisement des services et la circulation des connaissances tacites, voire explicites, des personnels et diminuent le sentiment d'un manque de formation. On peut même penser que ce décroisement joue un rôle important dans l'acceptation de l'innovation par tous ceux qui en sont impactés, car l'efficacité des documents écrits ou vidéos semble se réduire avec leur généralisation dans des structures productives en situation de sous effectif. Il semble que l'orientation proactive des structures de soins privées, dynamisées par le besoin de résultats financiers positifs, les rend plus sensibles aux effets bénéfiques sur la dynamique d'innovation, de la pratique de l'animation de la veille et de la gestion de projets.

Le travail doctoral sur lequel repose cette communication a permis de valider ces conclusions sur d'autres cas, mais il serait nécessaire de les confirmer par des recherches complémentaires s'appuyant sur des enquêtes plus systématiques.

## **Innovation management in healthcare services. Two countries in comparison**

*Extended Abstract*

*Laura Castrén<sup>1</sup>, Markus Scheuer<sup>2</sup>*

*<sup>1</sup>Aalto University, <sup>2</sup>Rheinisch-Westfälisches Institut für Wirtschaftsforschung*

*In Finland and Germany, like in most developed countries, healthcare services are comprised of intertwined endeavours of cross-functional teams. Their innovative behaviour is carried out mostly in invisible and intangible processes instead of R&D departments. The intangible nature of innovations challenges management processes. The healthcare service innovations require context-specific means to benchmark and measure the management. This paper provides a framework for enabling a revision of the invisible innovation management process into a more tangible and measurable form.*

### **1. Introduction**

In most OECD-countries healthcare has been over thirty years both "*stirred and shaken*", quoting James Bond, the famous secret agent. Instead of slowing down, the pace of change is accelerating, and challenging management processes. The administration, clinical procedures and service provision culture have to be updated. Simultaneously, the changes promote a management style that is more aware of the factors that contribute to service innovations in the healthcare context. In order to continuously improve the multiple and complex factors of service innovations in the context, their critical drivers should be discovered, and evaluated and benchmarked. This paper provides a theoretical framework for such service innovation management measurement.

Healthcare faces major pressures that drive the practitioners to aspire service improvements in terms of efficiency, effectiveness and quality. Aging population, budget cuts, quality deficiencies, demanding patients, a shortage of personnel, and ubiquitous healthcare digitalisation, all challenge the healthcare service providers. What is more, the Internet has changed health-related behaviour and altered the information asymmetry between providers and customers; the Internet provides healthcare service users with an easy access to e.g. diseases-specific information.

Since Schumpeter's pioneering work in 1911, academic interest on innovation has grown, inspiring a growing number of fields of research, ex-

tending from sociology to management, psychology and business administration. Innovation research also covers multiple layers of analysis: individuals, groups, organizations, economies, and societies. Research on innovation prerequisites, processes, characteristics and outcomes is both vast and complex. However, the literature indicates that in order to achieve sustainable and continual performance improvement, the organisation needs to aspire and enable uninterrupted, strategy-driven development and innovation. Without a systematic measurement which enables the combination of economical and other metrics, financial and human resources will be wasted (Kaplan; Norton, 1996; Melnyk et al. 2010). The difficulty to identify and define a service innovation has biased academics and practitioners to understate the importance of innovative behaviour in services. A definition of Gallouj; Savona (2009) suggests a fruitful premise for research on innovations in services; according to the authors, service innovations are “*changes affecting one or more vectors of characteristics (both technical and service) or of competence*”. The definition clarifies Schumpeter’s original definition of innovation accordingly, innovations is a ‘*new good... or a new quality of good, new method of production or an introduction of a new production method*’. In innovation management, according to Ortt and Duin (2008), it is possible to identify four generations wherein an era and contexts differ. The first generation was R&D laboratory-related, the second implemented project management methods to R&D, the third tried to reinforce co-operation in cross-functional teams, and the fourth tried to incorporate stakeholders to innovation process. They disagree with some authors, such as Miller (2001), and Niosi (1991), who promote an idea of a fifth generation, and promote an idea of *contextual innovation management* that capitalises the context specific traits and their adaption to new surroundings.

This paper attains to fill a knowledge gap in the service innovation management literature so as to service innovation management evaluation, and to a need of practitioners to benchmark a service innovation management process. To meet the need, we provide a service management measurement (SIM) model. This builds on previous research in technology- and product-related innovation management and service innovation management research. The theoretical framework draws from several sources of management science: service innovation literature, strategy-related literature, the resource-based view (RBV) that brings forward the essential success factors, e.g. organisation-related particular skills, knowledge and other assets (e.g. Penrose, 1959 and Rumelt, 1984 ), and efficiency-based approach that emphasises capitalisation ability of internal and external prospects (e.g. Teece et al. 1997).

## 2. Literature review

The innovation management measuring focuses mainly on manufacturing, or more precisely on a product and technology-based innovation management, which differs from service innovations management (Cooper, 1993; Kleysen; Street, 2001). In the recent literature review on innovation management measurement, Adams et al. (2008) indicate how a mul-

tifaceted product management process includes seven main categories: 1) *inputs* that means tangible resources, human resources and tools, 2) *knowledge management* aspect emphasis idea generation, knowledge repository, and informal and formal information flows, 3) *innovation strategy* that highlights orientation and leadership in terms of innovation, 4) *organization culture* includes 'atmosphere' and structure, 5) portfolio management tries to balance risks and returns, 6) *project management* includes efficiency, tools, communication and co-operation and 7) *commercialization* is based on market research, testing and marketing.

An organisation's strategy can be seen as a manifestation of its goals and the way it carries out value in context (Eisenhardt, 1997). In his influential work on strategy Rumelt (1980) suggests four aspects to be looked at: *consistency, consonance, advantage, and feasibility*. Here *consistency* refers to the organisation's ability to incorporate its objectives, policies and plan of actions, *consonance* to legitimacy of the whole field of operation, *advantage* to competitive position and *feasibility* to resources at hand, both financial and other. The definition of the core competencies of the organisation is critical. However, certain flexibility and openness to changes have to be preserved (Mintzberg, 1994).

Organisational culture reflects a decision making criterion that is seen desirable or punishable in a certain context. Therefore, culture serves as a mediator between change management and innovative performance (Amabile, 1998). The leadership style is an essential element that can either induce or inhibit the generation of ideas and resulting potential innovations. As an example of the former we could mention the transformational leadership, which refers to a leadership style wherein innovative behaviour is reinforced and rewarded (Bass; Avolio, 1994. Gardner; Avolio, 1998)

Tuominen and Toivonen (2007) as well as Sundbo contribute to service innovation management research. According to them, '*organization atmosphere*' in services has a prominent role in detecting latent needs and innovative solutions In their view, *innovativeness* refers to an organizations' capability to generate innovations, embed innovations in organization or adopt an innovation that has been created in other organisations, whereas research on *creativity* focuses on individual and group-related traits such as personality and cognitive characteristics and organisation size, working models and process. Although 'atmosphere' affects work motivation in every industry, the management's role as an enabler or a barrier of innovative behaviour can be more crucial in services than in the manufacturing industry since the user interface is an essential source of innovations in services.

Sundbo (1996) draws from the contradiction of management's role which on one hand boost employees' idea generation, but on the other hand directs ideas according to strategy to improve the realisation of ideas. His concept of a '*balanced empowerment*' reviews the dual system in every organisation: there is an informal interaction structure among personnel on one hand, and on the other hand a formal management structure with

expressed official goals, norms and values. Sundbo suggests that the management should find a balance wherein the personnel's experiences with customers are harnessed for the sake of innovation generation, but in the framework of organization's goals. Sundbo builds on dynamic capabilities framework (Teece, 2007) that reviews how organisations adapt to changing surroundings, and how actively and proactively the organisation tries to shape an environment towards a desired direction.

Cormican and O'Sullivan (2004) suggest that cross-functional teams create preconditions for product innovation and make it possible to improve the utilisation of multiple but differing skills and competencies. Mixed backgrounds in terms of education, sex and age support innovative behaviour (Bantel; Jackson, 1989) and role diversity is a prerequisite to promote innovative projects. The management structure, the ability to perform and the capability to generate innovations are inter-related; organic and egalitarian management structures enhance an inclination to idea generation without an anxiety of failure.

Allen proposed a somewhat confusing term, a *technological gatekeeper*, for persons who are able to construct bridges with members of external professional knowledge. A technological gatekeeper is a community member who has connection to external sources of information and who is able to benefit their community with the newest information (Tushman, 1988). In the service innovation literature the role of a customer or a user is often emphasized (e.g. Vargo; Lusch, 2008) but knowledge intensive businesses have also an essential role as source of innovation (Hertog, 2000).

This conference paper discusses healthcare service innovations management measurement on the bases of literature. We review the challenges applying existing indicators in the healthcare context. In the following section we will briefly highlight the methods, and discuss the research process.

### **3. Method: Converting the insights in the literature into an empirical survey**

The measurement builds on existent literature on both technological and service innovation management, management measurement and current challenges in the healthcare development.

After having discussed the theoretical aspects of the management of innovation in a complex organisation like a hospital, we aim at using them for an empirical survey in Finland and Germany. With the assistance of an advisory board we have pre-tested the measurement instrument.

We started by using the PIM-scorecard published in Cormican/O'Sullivan (2004) developed for "auditing best practice for effective product innovation management". As some of the questions therein appeared to us to be difficult to use in a questionnaire, we made a pre-test. The pre-test consisted in face-to-face conversations about the draft of the questionnaire with hospital managers, our target group.

The main problems in the PIM-scorecard seemed to be based in the design of it which was more a tool of soul-searching by managers alone for themselves than a classical questionnaire. They mainly appeared in questions which were formulated in a fashion that managers in-charge cannot answer in another way than by: "I fully agree!" Examples of such questions which might make sense in self-auditing but not in asking another person are:

"All processes are lead by customer-needs."

"The managers utilize and develop specialized knowledge" and

"The communication skills are an essential part of professional knowledge."

The consequence of these difficulties which were not expected beforehand is that the survey has not yet been submitted to the field.

#### **4. Conversation**

The authors would like to hear in the session from our colleagues what could be done otherwise to overcome the problems.

The awareness of the need of service innovations is awakening but the practitioners as well as the academics still need the discussion on how to improve the innovative process in order to gain results that can improve efficiency and quality of the contemporary service economy in many OECD countries.

As we have said above we will empirically test this measurement and report about results in the next Reser-Conference. We welcome new partners and hope that the comparative research on the topic will provide valuable knowledge in terms of service innovation management in healthcare in each and every partner country.
