The first lesson was taught by Peter in his class of 40 students. Prior to this lesson, students had been taught the expansion of quadratic factors of the form  $(p + q)(p + r)$ . Peter introduced the lesson by asking the students to identify the coefficients of  $x^2$  and  $x$  in the expression  $x^2 + 4x + 3$ . Whereas all the students could correctly identify the coefficient of  $x$  as 4, most of them were unable to correctly identify the coefficient of  $x^2$ . Students gave responses that included:  $x \times x$ ,  $x$  and 2 - presumably from the exponent 2. The teacher asked them to discuss in pairs and seek a correct solution. After a while, a student correctly identified the coefficient as 1, but could not explain her answer. The teacher explained why it is 1.

Peter then asked the students to factorize the expression  $x^2 + 5x + 6$ . After about five minutes, he asked the students to form eight groups of five members each and he distributed the pieces of paper in Figure 1 to each group. He explained the first task of the activity and allowed 15 minutes for the task. After 15 minutes, only two groups had formed the rectangle. Peter allowed a further 10 minutes for discussion before calling upon groups to present their work. The teacher grouped the students' work in categories as shown in Table 1.

Category	No. of Group(s)	Rectangle	Area
One	4	Correct rectangle	Correct working
Two	1	Correct rectangle	Wrong working
Three	2	Correct rectangle	No area worked out
Four	1	No rectangle formed	No area worked out

**Table 1: The categories of groups and how they carried out the task**

One group from category one and the category two group were asked to present their work shown in Figure 2 and Figure 3 respectively.

**Figure 2: Correct working**

**Figure 3: Incorrect working**

The Figure 2 representative explained thus,

Student 1: Length,  $L = 1+1+1+x = (3+x)$  and width,  $W = 1+1+x = (2+x)$ . Area,  $A = L \times W = (3+x)(2+x)$

The Figure 3 representative explained,

Student 2: The width has two pieces of  $x$  each giving an area of  $x \times x = x^2$ . The length has a piece of  $x$  at the bottom and the upper part has two pieces of  $x$  plus the big piece whose length is  $x$  giving a total of  $4x^2$ . Total area,  $A = x^2 + 4x^2$ .

Due to pressure of time, Peter summarized the lesson by explaining task two procedurally, thus, to factorize a quadratic expression such as  $x^2 + 5x + 6$ , identify the factors of the constant term, 6, that sum to 5, the coefficient of  $x$ . Thereafter he told the students to factorize  $x^2 + 3x + 2$  as homework, before administering the post-test. The results of the pre-test and the post-test are shown in Table 2.

Items	Percentages of correct responses	
	Diagnostic pre-test	Post-test
Question 1	3	30
Question 2	3	10
Question 3	70	43

**Table 2: The percentage correct responses of the pre-test and post-test from the first lesson**

### First lesson's reflection session

Peter felt that his introduction took more time than he had expected: as he remarked,

Peter: I would have taught how to get the coefficient first before I look at this lesson.

Other highlights during the reflection include:

Dominic: The students had some fear I do not know what they were fearing [...]

John: I think we should have done some peer teaching. We forgot how the students would present their work and this became unexpected challenge.

Researcher: Peter gave students a long time for discussion because he wanted everybody to obtain the correct answer not knowing that the strength of learning at times is in the few mistakes made by students.

Based on the reflections, the post-test results and the fact that the lesson was not implemented as planned, the teachers modified the lesson, which was retaught in John's class (second lesson).

### Second lesson

John introduced his lesson by asking students to expand the expression,  $(x + 2)(x + 1)$ , which they did to obtain  $x^2 + 3x + 2$ . He then asked them to identify the coefficients of  $x^2$  and  $x$  from  $x^2 + 3x + 2$ . The majority answered the question correctly. John then asked the students to factorize the expression  $x^2 + 5x + 6$ . After about five minutes, he asked the students to form seven groups of four members each. The class had 28 students present. He distributed the pieces of paper shown in Figure 1 to each group and stated the tasks for the activity as: (1) Form a rectangle with all the pieces of paper given and work out the area of the rectangle formed. (2) Find the relationships between the constant terms of the factors of your worked-out area and i) the coefficient of  $x$  in the expression  $x^2 + 5x + 6$ , ii) the constant term in the same expression  $x^2 + 5x + 6$ . This was part of modification made on the lesson. After 15 minutes, he stopped the group work and asked some groups to discuss their work with the whole class. Table 3 shows how groups carried out the tasks, with same categories as in Table 1.

Category	No. of Group(s)	Rectangle	Area
One	3	Correct rectangle	Correct working
Two	1	Correct rectangle	Wrong working
Three	3	Correct rectangle	No area worked out

**Table 3: The categories of groups from the second lesson and how they carried out the task**

One group from category one and the category two group were asked to present their work. The representative of the category one group explained the working thus,

Student 1: Width =  $1 + 1 + 1 + x = 3 + x$ , Length =  $1 + 1 + x = 2 + x$

$$\text{Area, } A = L \times W = (2 + x)(3 + x) = x^2 + 5x + 6$$

The representative of category two explained her work referring to a figure similar to Figure 3.

Student 2: The two strips above are multiplied to obtain  $x^2$  and the four pieces on one side (pointing at the width with 1 unit by  $x$  units strip and the three 1 unit by 1 unit) are counted and multiplied by  $x$  to obtain  $4x$ . Area,  $A = x^2 + 4x$ .

After the presentation, John discussed task two with the whole class. With the help of the students and referring to student 1's expression, John simultaneously presented the factors of 6,  $\{(1 \times 6), (2 \times 3), (-1 \times -6), (-2 \times -3)\}$  and the addends of 5,  $\{(0 + 5), (1 + 4), (2 + 3) \text{ and so on}\}$ . He introduced the second activity that asked the students to factorize,  $x^2 + 3x + 2$ . The students correctly factorized the expression. The teacher summarized the lesson and administered post-test questionnaire. Both pre-post results are shown in Table 4.

Items	Percentages of correct responses	
	Diagnostic pre-test	Post-test
Question 1	26	86
Question 2	0	71
Question 3	48	86

**Table 4: The percentage correct responses of the pre-test and post-test from the second lesson**

The teachers prepared the lesson to apply the generalization of patterns of variation and invariance. This was realized fully in the second lesson.

Varied	Invariant	Discernment
$x^2 + 5x + 6$	Working out the area of rectangles formed.	Factorization of a quadratic expression with a unit coefficient of $x^2$ depends on the factors of the constant term that sum to the coefficient of $x$
$x^2 + 3x + 2$		

**Table 5: Generalization pattern of variation and invariance applied in the enacted object of learning**

The two different expressions were varied to help the students to generalize the process of factorizing a quadratic expression with a unit coefficient of  $x^2$  such as  $x^2 + bx + c$ . The students applied the cuttings to form the rectangles whose areas represented the factorizations of the given quadratic expressions, that is,  $x^2 + 5x + 6$  and  $x^2 + 3x + 2$ .

## Discussion and conclusion

The activities proved challenging as students took time to discuss and explore ways of factorizing the expression  $x^2 + 5x + 6$  (Lester et al., 1994). At the end of the discussion, eight groups out of 15 did not factorize the expression, and one group even failed to form the rectangle, as shown in Table 1 and Table 3. Peter even allowed more discussion time but still some groups could not form the rectangles. Peter therefore, did not apply fully the patterns of variation and invariance. Marton's (2015) cautioned teachers to take control of students' own work during learning to implement the planned patterns of variation. The effect was reflected in post-test results of Table 2. A comparison of pre-post results (*lived objects of learning 1 and 2*) of the two lessons, Tables 2 and 4, show that at the pre-test, Peter's class had higher scores in questions 2 and 3 but at the post-test, John's class, where the pattern of variation was fully applied, had a notable improvement in all the questions than Peter's class. Question 2 that addressed the *critical feature* had a slight improvement of 7% in Peter's class compared with 71% in John's class.

The content of the lessons addressed the “what” aspect of *the object of learning*. Eight groups had difficulty expressing the sides of their rectangles in algebraic form, thus failing to factorize the expression  $x^2 + 5x + 6$  as shown in Tables 1 and 3. The expected algebraic expressions for the sides of the rectangle fall within the topic of formation of algebraic expressions taught in the first year of high school according to the Kenyan mathematics syllabus for high schools. Also, in the introduction of the first lesson, the students could not identify the invisible 1 as the coefficient of  $x^2$  from the expression  $x^2 + 4x + 3$ , which suggested that students either did not understand multiplicative identity property of real numbers or they did not know the term coefficient. These cases show that students could not recall what they had been taught earlier. These were learning moments for teachers to realize that the problems that students experience in quadratic expressions and equations originate from the introductory contents of the algebra.

The planning gaps identified during the lessons contributed to the time management issues especially, the first lesson where students did not work on the second activity as was planned; and they also had a short time to discuss the second task of the first activity. The effect was reflected in the post-test outcome from the first lesson's class as shown in Table 2. From these observations teachers learned that LS design is helpful in focusing the teachers in every aspect of the lesson that improves students learning. They also learned that a good implementation of a lesson by applying patterns of variation can improve students' learning as suggested in the second lesson's post-test result Table 4. The teachers appreciated the implementation of the second lesson where students were able to generalize the conditions for factorization of a quadratic expression with a unit coefficient of  $x^2$ .

Peter: Yeah the lesson was good. I am sure now they are aware that they can use that formula without the cuttings and factorize any quadratic expression.

Dominic: The fact that the two activities were discussed helped the students to see the relationship and I am sure they can now factorize the quadratic expression without any problem.

The teachers also learned the need for explicit preparation of all activities and for good time management, as they stated during the reflection session after the first lesson and confirmed the

same after the second lesson through the post-test result. This supports Hiebert, Morris and Glass's (2003) suggestion that lessons should be treated as experiments with explicit preparation of all activities. The teachers learned that the LS design through its post-test aspect helps monitor students' learning progress, which enables a teacher to address students' errors/misconceptions in the immediate subsequent lessons.

### Acknowledgment

This study is supported by a University of East Anglia doctoral studentship. I thank the teachers and students who participated in data collection, the Principal of the school and the entire school community that cooperated with the research team. I sincerely thank my supervisors, Elena Nardi and Tim Rowland, for their support in the writing of this paper.

*This article focuses on the relations between the activity of the teachers and the contents of textbooks and the teacher's manuals. Through the observation of lessons, we analyse and discuss how the teachers follow the recommendations written by the authors of teacher's manuals. We describe the adjustments made by these teachers, comparing them to the recommendations written by the authors of teacher's manuals. The observations lead us to point out some didactic obstacles and to mention the major role of an epistemological and didactic teacher training.*

**Keywords:** *Mathematics textbooks, primary school, didactic, resources.*

## Introduction

The present study constitutes a part of a larger research project investigating the place of mathematical textbooks in the French publishing market and the role teachers assign them in the daily practice (Mounier & Priolet, 2015). In France, teachers may decide for themselves and in each of their classes whether they want to resort to textbooks or not, and which resources they wish to use, on the condition of respecting the national curricula. The resources and their uses have been already the object of plentiful scientific literature (Pepin, Gueudet, & Trouche, 2013; Fan, Zhu, & Miao, 2013; Matić & Gracin, 2015; Lenoir et al., 2001). This paper examines how two teachers interact with mathematics textbooks in teaching the same topic; it focuses on the use of number lines. The choice of this theme seems to us relevant, with regard to the works of Hamdan and Gunderson (2017, p. 587) that show how “the number line plays a causal role in children’s fraction magnitude understanding, and is more beneficial than the widely used area model”.

## Theoretical framework and research question

### The teaching activity

The teacher has “to prepare the course”, “to handle the class” and “to teach the class” (Amigues, 2003, p. 11). His activity results from a compromise between his objectives, his own purposes, his constraints, and the resources of his work environment (Goigoux, 2007, p. 47). So, it exceeds the context of the classroom. Then, the teaching activity has to be considered outside and inside the classroom, but, in this article, we mainly reserve the expression “teaching activity” for the activity of teaching in the presence of pupils.

### Resources, textbook and teacher’s manual

Within the framework of his teaching activity, the teacher interacts with a set of resources. To define the concept of resource, Adler (2010, p. 25) refers to two meanings of a word: a “reserve” from which the teacher can draw, and the action “to be nourishing again”. We define the resource as “product of the human activity, developed to join a finalized activity” (Rabardel, 1995, quoted in Gueudet & Trouche, 2010, p. 58). As produced by an author, the textbook and the teacher’s manual are resources for the teacher. The resource “Textbook” is intended for the pupils in the class and it is in connection with the curricula. The “teacher’s manual” is the documentation annexed to the textbook, intended

for the teacher and who allows “to understand better the transactions of the teachers with the curricular resources in mathematics” (Remillard, 2010, p. 201).

### **Teacher-resources relation**

The teachers are differently positioned with regard to the use of the resources according to “modes of commitment” (Remillard, 2010, p. 214) being able to be shaped by particular expectations, convictions, habits or past experiences. This positioning may have an important effect when the use of the resource leads to the adoption of a didactic device structuring the session. The didactic devices in a primary class come down to three devices (Rey, 2001, pp. 31–35). In the first one named “explanation-application”, some part of knowledge, for example the definition of a mathematical object, is presented to the pupil. Practical exercises follow the presentation of this knowledge. In the second named “observation-explanation-application”, in the first instance the pupil is asked to observe an object, for example a geometrical figure then to generalise from this observation. Practical exercises are then proposed. In the third named “problem-explanation-application”, in the first instance the pupil starts with the active manipulation of material or conceptual resources is brought in to the apply to problem-solving. This phase is followed by the shaping of the knowledge and then by the series of exercises. Some teachers sometimes make some adjustments. If the teacher’s degree of expertise and the level of training are not sufficient, these adjustments can lead to “problems of coherence between objects of teachings, processes and activities” (Arditi, 2011, p. 361). Besides, from a generative document, expert teachers can proceed to relevant adjustments whereas, for lack of self-important training, the novice teachers are sometimes going to bring modifications going against the intentions of the authors of textbooks, the specialists of didactics (Margolinas & Wozniak, 2009; Priolet, 2014).

### **Research questions**

Considering the above research, we question the relations between the activity of the teachers and the contents of mathematics textbooks and of teacher’s manual. Do teacher-users of a medium operate different types of adjustments during the activity of teaching in the presence of their pupils, and do they follow the model led by the teacher’s manual?

### **Methodology**

In order to answer our research questions, we provide a qualitative approach based on observation of practices used by teachers or semi-structured interviews with them.

### **Participants**

This case-study involves two female teachers, Teacher B and Teacher A. Both of them teach at the 4<sup>th</sup> level of elementary school (9–10 year-old pupils), in two schools located in two small towns in the centre of France. Teacher B has been teaching for 15 years and Teacher A for 10 years. None of them has studied higher education in mathematics. They both teach all school subjects.

Both teachers belong to a sample of 10 teachers of the 4<sup>th</sup> level of elementary school who declared using mathematics textbooks and being volunteers to participate in our research. We had chosen this level regarding the introduction of fractions and decimal numbers. The ten teachers had agreed to be observed, by one of the two researchers, in their class, during a lesson of mathematics concerning the numbers, then to be interviewed during a semi-directive interview. For this case-study, we chose

Teacher B and Teacher A among these 10 teachers for two reasons. Firstly, Teacher B and Teacher A have the same textbook<sup>1</sup> in their class. Secondly, when we observed them teaching in their classroom, both presented a lesson on the theme of fractions and decimal numbers.

## Method

In the classroom of Teacher B, the observation lasted 57 minutes and the interview 36 minutes. In the classroom of Teacher A, the observation lasted 33 minutes and the interview 44 minutes. We did not film the learning sessions, but some photographs have been taken, related to the use of the textbook or other artefacts. An observation table has been assigned in two parts :

- The observation of the classroom with identification of the different moments of the learning session (total duration, duration of each phase), duration of the phases of use of the textbook by the pupils, identify the moments while the teacher uses her teacher's textbook.
- The database about pupil and teacher documentation.

Following this observation of sessions, a second data collection was made through semi-structured interviews. An interview guide was set up on these subjects: preparation of the observed session, place taken by the manual during the session, manual's choice, general use of the teaching and pupil's guide and during the session, and finally, teacher training. The interviews often relied on the photographs that we had taken during the session concerning the use of the manual by the teacher or by the pupils. They can be linked in a methodological way with the self-confrontation method (Theureau, 2010).

For the “fractions and decimal numbers” topic, the classroom manual has eight sessions numbered from five to twelve in its summary. The selected lessons for the analysis are lessons 8 (Teacher B) and 9 (Teacher A), because both of these lessons refer to the use of number line.

Both interviews were transcribed. All the data collected through observation and interviews have been analysed (Bardin, 2007) in order to extract those concerning the presence and frequency of use of the textbook and the resources used by the teacher for the conception of his teaching. The times of effective use of the textbook by the pupil have been converted in percentages of the total duration of the lesson.

## Results

For each teaching activity, we present below a lesson in which we can spot the relation that each teacher has with the textbook and with the teacher's manual in her teaching activity.

### Teacher B

Teacher B herself chose the textbook given to each of the pupils of her classroom. She reports using it frequently in class, mainly for the exercises. The Teacher's manual is present in the classroom. Teacher B reports that she doesn't use it because she has been disappointed by its general contents. She organizes the distribution of the lessons of the year herself.

---

<sup>1</sup> Whereas in our study (Mounier & Priolet, 2015), there are at least 23 different textbooks in France for this level of teaching.

Today, she proposes the following situation: she shows on the board a big number line she has prepared herself (Figure 1).

**Figure 1: number line showed on the board (Teacher B)**

In the first part of the lesson, she explains to the pupils how she made this number line: “the unit is here (u), so here between 0 and 1 there are 10 parts”. She tells them that point A is equivalent to four-tenths of one. Then she asks pupils to write on their board the fractional numbers to which the points placed on the number line are associated. In the second part of the lesson, pupils open their textbook to do the 4<sup>th</sup> exercise (Figure 2).

**Figure 2: Exercise number 4, page 43 of the pupil's textbook**

For this lesson related to session 8 of the manual (*À portée de maths CM1*) page 42–43 and named “decimal fractions”, the teacher's manual first planned a research path with an individual preparatory report (Figure 3) to the activity “Let's look together” in the pupil's manual (Figure 3).

**Figure 3: teacher's manual page 37**

### Teacher A

In Teacher A's classroom, each pupil has got a textbook. This textbook has been chosen by one of the colleagues predecessors of Teacher A in that school. She declares to have adopted this textbook which was already present in the class before she came. Teacher's manual is present in the classroom. Teacher A reports: “Mathematics is absolutely not my field. I refer a lot to the teacher's manual but

after this I try to appropriate it". She says that she follows the annual distribution of the lessons in the manual. She also uses the manual's exercises.

For this lesson related to session 9 of the manual (*À portée de maths CMI*) page 44–45 named "Decimal fractions", the teacher's manual first planned a research path with the number line drawn at the board (Figure 4) to prepare the activity "Let's look together" in the pupil's manual (Figure 4).

**Figure 4: Teacher's manual p. 39 (Beginning of the research path)**

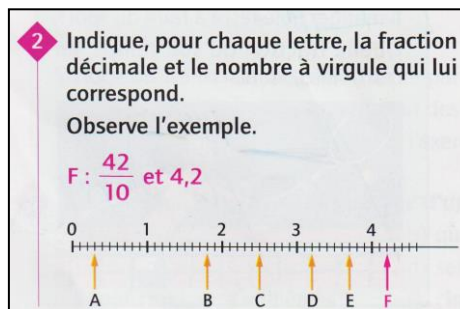

Teacher A reports referring to the teacher's manual to build the "Let's look together". While the teacher's manual suggests as support for each exercise a number line increased without digital marks, this teacher writes a number line increased in tenth marks-units from 0 to 3, on the blackboard.

**Figure 5: Photography of the board during the lesson (Teacher A)**

Then she asks the pupils to indicate which fraction corresponds to such a graduation (yellow arrow).

On the board, she writes two answers  $\frac{20}{10}$  and  $\frac{2}{10}$  (Figure 5) proposed by two pupils. She asks them to explain their process. Then Teacher A asks all the pupils to open their textbook to individual work on exercise number 2. In this second part of the lesson, and especially with this exercise number 2, the pupils have to use a number line (Figure 6).

**Figure 6: Exercise n°2 page 44 of the pupil's textbook**

During the interviews, Teacher A and Teacher B report that they want to do the best to help their pupils to understand the fractions and the decimal numbers. So, Teacher A decided to write a number line increased in tenth marks-units on the blackboard instead of the number line increased without

digital marks which was suggested by the teacher's manual. Teacher B decided to explain to her children what each graduation means on the number line.

## Analysis and discussion

We use Rey's model (2001) to analyse the didactic set up plan in each of these two classes. We compare it with the model underpinned by the instructions provided by the teacher's manual's research path.

Although the authors declare in the preface (page 3, pupil's textbook) that the "teacher is a professional that chooses and assumes his pedagogy" and in the preamble (page 3, teacher's guide) that "the guide is conceived in order to give the teacher the freedom of his own ways", the instructions which are supplied in the scenario of the teacher's manual about the research path of both consider lessons, seem to lead an approach of the "observation, explanation, application" type.

Our observations show that Teacher B operates the didactic device "explanation-application", whereas Teacher A tends to use the "observation-explanation-application" device. Teacher A modifies the starting situation support by converting the teacher's manual (number line increased without digital marks on a number line increased in tenth marks-units from 0 to 3).

This modification of the support does not favour the devolution (Brousseau, 1998) of this problem to the pupils. It has transformed, by reducing it, the difficulty of the task planned by the authors' textbook: to question on the density of decimal numbers which constitutes an epistemological obstacle to the pupils' understanding.

Although the authors of the textbook declared that teachers keep their pedagogic freedom, in both of the observed situations, both teachers do not commit the pupils in an approach of type "problem-explanation-application".

## Conclusion

In order to analyse the relations between the teaching activity and the contents of mathematics textbooks and of teacher's manual, we have referred to the didactic model of Rey (2001). Our purpose was to detect the adjustments operated by two 4<sup>th</sup> level of elementary school teachers who use the same mathematics textbook. We observe that both do not follow all the recommendations of the authors of the teacher's manual. For example, the teachers redefine the task planned by the authors of the textbook, then changing the planned didactic device, from a model of "observation-explanation-application" led by the teacher's manual, into a model of "explanation-application" (Rey, 2001). This change may reduce, in a way, the pupils of the understanding of the density of the order of decimal numbers. Thus, our analysis reveals a problem of coherence, already pointed by Ardit (2011) between the adjustments operated by the teacher-user and the authors-designers of the textbook. This echoes the question of the validation of the collected knowledge (Bruillard, 2010), in particular in the context of the development of the recourse to the digital resources.

In conclusion, we notice that the logic of the teacher and the logic of the textbook cannot be the same. We observe that this gap can interfere with the aimed knowledge, from which we conclude in the necessity for the teacher to exercise an epistemological and didactic vigilance on pupils' understanding. It seems to us essential, following the example of Charles-Pézar (2010), to include this issue in the training of the teachers.

# Critical incidents as a structure promoting prospective secondary mathematics teachers' noticing

Giorgos Psycharis and Despina Potari

National & Kapodistrian University of Athens, Greece; [gpsych@math.uoa.gr](mailto:gpsych@math.uoa.gr), [dpotari@math.uoa.gr](mailto:dpotari@math.uoa.gr)

*This study builds on the idea of using “critical incidents” as a tool for inquiry and reflection in the context of mathematics teacher education. The analysis was based on 22 prospective teachers’ portfolios reporting and interpreting selected critical incidents on the basis of their observations of mathematics teaching conducted by other teachers and by themselves in the context of their field experiences. The critical incidents addressed a multiplicity of issues related to mathematics teaching and learning. Prospective teachers’ noticing developed in terms of what and how they notice indicating a more relational way of conceptualizing mathematics teaching and learning.*

*Keywords: Noticing, critical incidents, prospective mathematics teachers, teacher education.*

## Introduction

In this paper, we study prospective teachers’ (PTs’) noticing of mathematics teaching in their initial field experiences through their engagement in identifying and interpreting critical incidents taken from everyday classroom situations in the context of a teacher education course. Critical incidents are everyday classroom events which have significance for the teachers, make them question their practice and seem to provide an entry for their better understanding of teaching-learning situations (Hole & McEntee, 1999). To observe and question mathematics teaching is a rather demanding task for both practicing and prospective teachers. A number of research studies have indicated that PTs face difficulties in identifying salient aspects of classroom instruction. For instance, they tend to describe the lesson as a chronological order of disconnected events (Sherin & van Es, 2005), they keep their attention primarily on the teachers rather than on the learning students (e.g., Van Es & Sherin, 2002) and they have difficulties in developing interpretative analysis of classroom instruction (Jacobs, Lamb, & Philipp, 2010).

Research suggests the need for the development of structures that foster teachers’ systematic reflection on teaching practice and help to make the act of noticing critical aspects of classroom interactions more concrete (Mason, 2002). Examples of such supportive structures are: the use of theoretical tools to code teaching (Mitchell & Marin, 2015); the decomposition of video lessons in small parts (McDuffie et al., 2014); the identification of critical incidents from classroom teaching (Goodell, 2006). These structures have been exploited in situations where prospective mathematics teachers analyze teaching of others mainly through video noticing (e.g., Sherin & van Es, 2005) while few studies refer to PTs’ reflection on their own teaching (e.g., Goodell, 2006). However, there is an open discussion on if and how reflecting on other teachers’ practice transfers for reflecting on PTs’ own practice (Stockero, 2008). Many research studies prioritize helping PTs to focus on students’ mathematical thinking (e.g., Jacobs et al., 2010) while few studies aim to facilitate PTs’ attention to other important features of mathematics teaching and their interrelation to students’ learning (McDuffie et al., 2014). Linking students’ learning opportunities to teacher’s

discourse moves is a rather demanding task and it poses a research challenge in the area of prospective mathematics teachers' noticing.

In our study, we attempt to explore how critical incidents can be used as a structure to support PTs in reflecting on mathematics teaching recognizing interrelationships between teaching and learning. Our research questions are: (a) What is the nature of critical incidents that PTs identify while reflecting on mathematics teaching conducted by other teachers and by themselves? (b) How does PTs' noticing develop when identifying and interpreting critical incidents related to students' mathematical activity?

## **Theoretical framework**

Under a community of inquiry perspective, Jaworski (2006) introduced the concept of critical alignment, in which participants align with the practice of mathematics teaching while critically questioning aspects of it. Critical alignment is promoted through the tool of inquiry. Inquiry is a process of encouraging critical reflection and promoting critical alignment (Jaworski, 2006). In this perspective, reflection is considered as a tool that allows participants to be engaged in a continual reconstitution of the practice of teaching. The reflective process involves "firstly, a recognition of questions to address, identifying some perplexity, making some aspects of teaching problematic; and, secondly, through some processes of enquiry, to seek solutions, or resolutions to, or new ways of understanding, the problems identified" (Jaworski, 1998, p. 7). This perspective is close to our view of a critical incident as a continuum involving identification, interpretation and potential action where critical questioning is a constituent element of it.

Researchers have been concerned about the introduction of sufficient structures for making the act of inquiry into teaching practice more concrete. An example of a structured framework for reflection on classroom episodes, are critical incidents. In mathematics education, the idea of critical events/moments in mathematics teaching has been used as an analytical tool in studying mathematics teaching and learning. Skott (2001) used the term "critical incidents of practice" to describe moments of a teacher's decision-making in which multiple and possibly conflicting motives of his activity evolved that challenged the teacher's own school mathematics images and provided learning opportunities for students. As a developmental tool, critical incidents have been used by Goodell (2006) in pre-service mathematics teacher education. She analyzed PTs' reports of critical incidents and she found that the issues raised concerned: teaching and classroom management; student factors; issues concerning relationships with colleagues, parents and students; and school organizational issues. She also identified that PTs fruitfully addressed important aspects of teaching for understanding such as the necessary conditions, factors facilitating teaching for understanding and barriers to teaching for understanding.

Noticing has been introduced to mathematics teacher education to study shifts in the structure of teachers' attention and, through this, to address different levels of awareness both in mathematics and in mathematics teaching (Mason, 2002). According to van Es and Sherin (2002), noticing is a more complicated action than just observing teaching. Rather, it requires teachers to notice what is significant in a classroom interaction, to interpret this noteworthy incident on the basis of their knowledge and experiences, and to link these with broader principles of teaching and learning. Van es (2011) proposed a framework for learning to notice students' thinking constituted of four levels

of noticing according to “what teachers notice” and “how teachers notice.” As regards to what the teachers attend to, the four levels include: making general observations about the whole class environment (Level 1 – Baseline Noticing); focusing on teacher pedagogy and begin to attend to students’ thinking (Level 2 – Mixed Noticing); attending to particular students’ mathematical thinking (Level 3 – Focused Noticing); and interrelating particular students’ mathematical thinking and teachers’ teaching strategies (Level 4 – Extended Noticing). When it comes to how the teachers notice and provide interpretations, the four levels include: providing general impressions and descriptive comments (Level 1 – Baseline Noticing); providing primarily evaluative with some interpretative comments and beginning to refer to specific events and interactions as evidence (Level 2– Mixed Noticing); providing interpretative comments, referring to specific events and interactions as evidence and elaborating on events and interactions (Level 3 – Focused Noticing); and making connections between events and principles of teaching and learning and suggesting alternative pedagogical actions (Level 4 – Extended Noticing). This framework provides a base for teacher reflection as well as a tool to describe the development of teachers’ noticing. The above studies indicate that noticing critical aspects of mathematics teaching of others and prospective mathematics teachers’ own teaching seems to constitute a basis for professional learning.

## Methodology

The research took place in the context of a 14-week mathematics education undergraduate course (taught in one semester by the second author) included in a university program of a mathematics department leading to a first degree in mathematics. Enrolling in the course in which the study took place, PTs had already successfully passed at least four courses on pedagogy and mathematics education. The aim of the course was to engage PTs in critical consideration of aspects of mathematics teaching as they emerge from the complexity of teaching practice in schools. Every second week for the entire semester PTs were asked to participate in a number of field activities (over six field activities-weeks) while each week following the activities in schools included a three-hour meeting at the university. PTs’ field activities consisted of observing other teachers’ mathematics teaching for six hours in total (first three field activities-weeks), designing and teaching a lesson in one group of students outside the classroom for one teaching hour (fourth field activities-week), and designing and teaching lessons in the whole classroom for two teaching hours (fifth and sixth field activities-weeks). The 22 PTs (9 males, 13 females), who served as participants in this study, were divided into pairs and carried out collaboratively the field activities under the supervision of eight postgraduate students of mathematics education who acted as mentors.

Inquiry into mathematics teaching was a rather new practice for PTs and was supported through the discussions in the university meetings and the field activities. Critical alignment with the practice of the mathematics teaching in which they were engaged through observing and teaching, was expected to be developed through the process of inquiry and questioning aspects of practice. Critical incidents were expected to facilitate this process. PTs’ field activities were based on the cycle observing-reflecting-designing-implementing-reflecting. For instance, PTs were asked to: identify the specific content of a lesson in the curriculum and to trace it throughout the different grades; look for possible research evidence related to potential students’ difficulties; keep systematic notes from and/or record the lessons; reflecting on their classroom experiences; and analyzing lessons. In this context, PTs were asked to select critical incidents and provide a reflective account on the basis of

justifying their selection, interpreting them and proposing potential teaching actions. Instructional practice in the university sessions aimed to support PTs' reflection on their recent field experiences and to link emergent issues with existing mathematics education research in order to develop deeper levels of awareness. PTs were introduced to the idea of critical incidents through (a) a brief presentation of Goodell's (2006) study (including the meaning of critical incidents, the classification of them and examples from PTs' written reports), and (b) analysis of transcripts of lessons to identify critical incidents and discuss/justify in the class their criticality. The teacher educator facilitated the discussion, but also challenged the PTs to justify their selection of the critical events, to provide evidence of their claims, to make interpretations, and describe their potential teaching decisions. The PTs themselves presented the analysis of the critical incidents and their reflections in the university meetings. Overall, PTs' field activities and the discussions in the university meetings revolved around the idea of critical incidents and thus they were compatible with our research focus.

The data for this study consisted of: (a) PTs' personal portfolios including their written accounts of critical incidents, and material related to the design, implementation, and presentation of the field activities in the classroom (e.g., worksheets, lesson plans, presentation files); (b) video recordings of all meetings at the university (8 in total) and (c) researchers' field notes. In this paper we analyse the data from the PTs' portfolios. The analysis was carried out in three levels. In the first level, we adopted a grounded theory perspective (Charmaz, 2006) and identified thematic areas indicating what the PTs noticed (first research question). In the second level, we analysed the critical incidents, their interpretation and the potential actions that PTs reported in their portfolios for each week's assignment in terms of the levels of van Es' (2011) framework. Finally, we traced PTs noticing over time looking for shifts in what they noticed in students' activity and how they interpreted it.

## Results

### The nature of critical incidents from PTs' portfolios

In Table 1, we present a categorization of the critical incidents that the PTs identified in their reports in two cases; one is while reflecting on the observations of other teachers' teaching and the second while reflecting on their own teaching. The total number of critical incidents in the first case was 72, while in the second 54. In both cases, the incidents reported most often were related to students' activity (35 out of 72 - 49% in the first case, and 21 out of 54 - 39% in the second) and in particular, to their conceptual difficulties. Another category of incidents focused on teaching - especially on the interaction between teacher and students (e.g., how the teacher responded to students' questions and answers). Thirty-three out of seventy-two (46%) incidents in the first case fell in this category and eighteen out of 54 (33%) in the second case. A third category appeared mainly when PTs reflected on their own teaching, concerned students' learning in relation to teaching (5% in the observations and 22% in the personal teaching). A fourth category that emerged only in the second case included three incidents focusing on epistemological issues.

Below, we present some illustrative examples of the above categories and we elaborate on the issues emerging from the analysis of the critical incidents in relation to our research goals. Focusing on students' activity, the PTs recognized misconceptions and difficulties in using mathematical language, performing procedures, connecting representations, and developing problem solving strategies. For example, the confusion between perimeter and area was noticed by one prospective

teacher, Marina, while observing a lesson in an eighth grade class: “The teacher asked the students to draw a triangle and then to name the sum of the sides. One student answered ‘area’ and another one ‘perimeter.’ The first one seemed to confuse area and perimeter”. As regards to the unexpected students’ responses, one prospective teacher, Leonidas, reported students’ innovative approaches in finding triangular numbers in the Pascal triangle: “One student discovered a personal algorithm to calculate triangular numbers only by observing the arrangement of numbers in the Pascal triangle”.

<b>Incidents from classroom observation (72)</b>		<b>Incidents from personal teaching (54)</b>	
<b>Students’ activity</b>	<b>35 (49%)</b>	<b>Students’ activity</b>	<b>21 (39%)</b>

<b>Epistemological issues</b>	<b>0 (0%)</b>	<b>Epistemological issues</b>	<b>3 (6%)</b>

**Table 1: Categorization of the PTs’ critical incidents**

Concerning teaching and in particular teacher-student interaction, the PTs commented on positive and negative ways that the teacher or PT reacted to students’ contributions. A positive example was when Vassilis noticed that the classroom teacher acknowledged different solution strategies and discussed those in the classroom. Stella referred to a negative example from her own teaching: “One student proposed to find the requested area through transformations, which is a good approach. However, I directed her to follow the approach described in the textbook”. Stella also noticed the classroom norms and their effect on the mathematical communication: “Although the students provided repeatedly wrong answers, the teacher did not evaluate them and encourage further discussion”. The quality of the tasks in relation to the mathematical content was related to the teacher’s choices of the content, its integration in the designed tasks, and its transformation in the classroom teaching. Anthi reported: “I was impressed by the way that the teacher introduced students to the idea of limit in the context of geometry. ... This experience can help students to get an intuitive sense of the idea of limit”. By being involved in designing and teaching, PTs started to consider the complexity of teaching. In particular, they started to recognize the gap between planning and teaching and the dynamic character of teaching as it is indicated in the following example from Sofia’s reflection: “Although I had designed a realistic problem with the aim of engaging students in making sense by themselves of the notion of circle, during the implementation, I ignored the design. Actually, I took a directive stance to secure that the task would lead the students to the expected conclusions”.

Moreover, the PTs started to relate different aspects of teaching such as classroom norms, classroom interaction, and nature of tasks to students' learning. For example, Alexandros, recognized the mediation of digital tools in supporting students' understanding while reporting on his classroom observations: "I noticed a student who had difficulty realizing that the ratios in Thales' theorem remain constant independently of the position of the non parallel lines. She understood this property through dragging these lines in Sketchpad". Another example is about the relation between the presentation of a task and students' engagement. In an application of the Thales theorem, Leonidas noticed that the complexity of a geometrical figure in the task he designed posed barriers to students' participation: "Students' participation dropped vertically when they were asked to discern ratios of segments in the shape. So, the weak students could not consider at all even simple questions such as 'Show me a line that intersects the parallels'".

Finally, in the category "epistemological issues" we include critical incidents that refer to the nature of mathematical content from an epistemological point of view. For example, Anna noticed in her teaching that some students did not verify the validity of their findings, a process that she considers important in mathematics: "I chose to discuss this incident because verification constitutes an important process in mathematics. However, students often are not engaged in this".

### **The growth of prospective teachers' noticing**

Here, we use the van Es' (2011) framework to trace PTs' development of what and how they notice when observing teaching and reflecting on their own teaching. The analysis of the portfolios indicated that most PTs progressed to higher levels of the van Es' developmental trajectory where relations between teaching and learning were noticed and connections between events and principles of teaching and learning were made. Below, we illustrate this shift through a representative case of a PT (Katia).

Katia provided a written account of the critical incidents she selected as part of the course assignments involving observations and designing and teaching. During the observations, Katia offered general descriptions of the whole class environment and incidents related to students' difficulties. She shifted from a baseline noticing in her first two observations (level 1) to mixed noticing (level 2) in the third one both in what and how she notices. For example, in her written account based on the second observation she gave as a critical incident the students' lack of motivation to participate in the lesson due to the fact that some of them would not have been examined in mathematics in the university entry examinations. As regards how she notices the above critical incident, she provided descriptive and evaluative comments considering teaching independent of students' behavior. In reflecting on her potential teaching actions, she mentioned that she would insist on inviting students to pay attention. In her account based on the third observation, Katia focused on students' difficulty to transform the formula of the area of a trapezium  $E = (B+b) \times h/2$  to an equivalent expression in terms of another variable (e.g., the height  $h$ ). This time she provided evidence of this difficulty by specifying students' errors in algebraic manipulations. She also noticed that the teacher used numerical examples with the same structure to address these difficulties. Commenting on this critical incident, she wrote: "Although students do well with numbers and equations with one variable, they get confused when more variables are involved and they panic". It appears that Katia begins to notice students' thinking and refer to teacher-students interactions in the teacher's attempt to address students' difficulty. While she was

challenged by the teacher educator to look for further evidence to support and interpret her observation (by discussing with the classroom teacher and one student who demonstrated this difficulty after the lesson, and by reading a relevant research paper), she still confirms students' difficulty without offering an explanation.

Katia's noticing was further developed while reflecting on incidents selected from her own teaching. She started to attend to subtle aspects of tasks and the way they influence students' activity, to develop interpretations based on her classroom experiences and research readings and to deviate from her planning at contingency moments. Our analysis provides evidence that while reflecting on her own teaching she was able to consider teaching and learning in a relational way and to provide justified arguments and alternative pedagogical solutions reaching focused noticing (level 3) and extended noticing (level 4). The following example illustrates this finding. Katia designed a lesson for the teaching of area measurement in grade 7 by taking into account research findings on students' strategies on area measurement. Her main goal was to engage students in calculating the area of irregular figures by developing as a main strategy the dissection of the shape in other shapes whose area could be calculated by the known formulas. The students were really engaged in the process and developed different strategies. Katia reported as a critical event the fact the use of the word "irregular" in the given worksheet raised a lot of questions in the classroom: "I did not expect that the word "irregular" would create questions and negotiations. However, I exploited to see how students think about these figures". In her analysis of the phenomenon, Katia refers to specific student's ideas about the meaning of the word "irregular" and how this influenced students' work.

## Discussion

The critical incidents that PTs identified in their portfolios addressed a multiplicity of issues related to mathematics teaching and learning focusing mainly on students' activity and on student-teacher interaction. A similar picture was also formed in the study of Goodell (2006) where students' conceptual understanding and classroom interaction were the most dominant categories of the selected critical incidents. As regards the context in which the selected incidents emerged, there were not distinct differences in the nature of critical incidents that the PTs selected through their observations of other teachers' teaching and of their own. At the level of classroom management, the PTs found it more difficult to focus on the teacher-student interaction in their own teaching than in other teachers' teaching. Nevertheless, when PTs reflected on their own teaching, they started to see more clearly the impact of teaching on students' learning. One possible explanation could be that PTs' engagement in analyzing other teachers' teaching provided them a reflective stance towards their own teaching. A similar finding has been reported by Stockero (2008) who identified that PTs' experiences in analyzing video lessons of other teachers can enhance deeper levels of reflection on their own teaching. Tracing PTs' critical incidents, their interpretations and suggested teaching actions indicated shifts in their ways of noticing. Most PTs reached levels 3 and/or 4 of the Van Es' framework (2011) in terms of what and how they notice realizing interrelationships between teaching and learning. This finding adds to existing research on developing structures in teacher education facilitating PTs' noticing and enriches discussions that have taken place in previous CERME conferences (e.g., Potari et al., 2011). Integrating selection and reflection on critical incidents in teacher education provides a structured way that helps PTs to become aware of significant classroom interactions and to develop a critical way of addressing them.

# Exploring how ‘instructional products’ from a theory-informed Lesson Study can be shared and enhance student learning

Ulla Runesson Kempe, Anna Lövström and Björn Hellqvist

School of Education and Communication, Jönköping University, Sweden; [ulla.runesson@ju.se](mailto:ulla.runesson@ju.se).

*In this paper, we present how experiences gained from a theory informed Lesson study in regard to a specific learning goal can be shared and used by other teachers in new contexts. A group of teachers worked together in a cyclic, iterative process of planning, evaluating and revising teaching. The aim was to provide possibilities for grade 2 and 3 students to become familiar with negative numbers. The teacher group draw the conclusion that the pupils needed to be able to differentiate some aspects of negative numbers. The conjecture was put to the test in a follow-up study with five new teachers and eight classes. One lesson was taught based on the empirical finding in the Lesson study. When learning gains from pre- to post-test in these classes were compared to those in the Lesson study, similarities were found.*

*Keywords: Lesson study, sharing instructional products, negative numbers, variation theory.*

## Introduction

Morris and Hiebert (2011) have presented Lesson study as a model for transforming teachers’ craft knowledge into professional knowledge i.e. making it public, sharable, storable and verified as well as improved and should be organized around public changeable knowledge products. Their arguments are based on the necessity to reduce differences in classroom instruction (Morris & Hiebert, 2011, p. 5). The aim of this paper is to illustrate and discuss what an instructional product, generated on the basis of a pedagogical theory and empirically grounded, could look like and whether making use of such a product can be productive to enhance student learning. We report on how a theory-framed version of lesson study – Learning study – can produce ‘instructional products’ useful outside the specific context. Insights gained from one Learning study (LrS) about how to enhance the learning of negative numbers were communicated and used by new teachers in new contexts.

## Lesson Study not just professional development

Stigler and Hiebert (1999) pointed out the effectiveness of Japanese Lesson study (LS) model for improving teaching and learning of mathematics. There are extensive reports on the effectiveness of Lesson study for teachers’ improvement of teaching skills, how they learn to reflect, on changes in motivation and capacity to improve instruction and the development of content and pedagogical content knowledge (e.g. Lewis, Perry & Hurd, 2009). Furthermore, it is often pointed out that Lesson Study can promote the establishment of learning communities and teacher collaboration, a culture of mutual accountability, shared goals for instruction and a common language for analyzing instruction (e.g. Chichibu & Kihara 2013; Hunter & Back, 2011; Toshiya & Toshiyuki, 2013). To us, with these purposes, Lesson study will be restricted to a model for professional development only, not as a system that can generate new and relevant knowledge recognized as a legitimate knowledge source for professionals.

Hiebert and Morris (2011) take Lesson study further when they promote it as a system for “the creation of shared instructional products that guide classroom teaching” (p. 5). ‘Instructional

products' should be designed with a specific learning goal in focus and detailed enough to guide classroom instruction. An instructional product is the current answer to common and shared problems on teaching and learning. It is tentative, changeable and thereby open to improvement. Therefore, such 'local theories' embedded in the instructional product must be communicated, shared and improved by other teachers in other contexts. In this way, they could be tested and verified under new and local conditions.

## Learning Study

Learning study is a theory-informed version of Lesson study (Marton & Pang, 2003). It shares features with Lesson study, such as the collaboration among teachers and the iterative design of planning, implementing, observing and revising of the lesson, but it is framed by a theory of learning—variation theory (Marton, 2015). Just as with Lesson study, there are reports on the positive effects of Learning study on teachers' professional development (e.g. Lo, Chik & Pang, 2006). Learning study is also a model for constructing knowledge concerning the objects of learning as well as the teaching-learning relationship. It takes the professional task as the point of departure and generates public and sharable knowledge for the improvement of teaching and learning, exactly in line with what Hiebert and Morris (2011) advocate.

The knowledge produced in Learning study is an instructional product, not in terms of a lesson plan or specific teaching methods, but in terms of what is found to be necessary to learn in order to develop a specific understanding, skill or attitude. It is not about learning in a general sense, but in relation to specific learning goals (cf. Hiebert & Morris, 2011). In Learning study, variation theory serves as a tool for teachers to identify the necessary conditions of learning the object of learning. Learning, from this theoretical perspective, is seen as a change in one's way of experiencing something. How we experience something has to do with what aspects we notice and become aware of. For every object of learning there are certain critical aspects necessary to discern.

'Critical aspects' are dimensions of variation in the object of learning that the learner has not yet learned to discern and attend to. It has been suggested, however, that the critical aspects must be identified for every group of learners (Pang & Ki, 2016). Variation theory takes a relational perspective on learning, meaning that the critical aspects are not merely a feature of the content (a concept for instance), but a feature of the experienced object of learning. They cannot be derived at "from disciplinary knowledge alone or as taken-for-granted truths" (p. 333). Learners bring various experiences to the classroom and experience phenomena in different ways. Therefore, to identify the critical aspects, learners' ways of experiencing must be taken into account. In Learning study, this is done by carefully diagnosing—via interviews and/or written tests—before and after the lesson. So, 'critical aspects' should be defined in relation to the phenomenon in question as experienced by learners rather than in relation to what is deemed critical in the curriculum or subject discipline (Pang & Ki, 2016, p. 328).

Marton (2015) asserts that one cannot become aware of new concepts or aspects without becoming aware of differences (i.e. variation). Variation theory is used when the teachers explore students' prior understanding and to what extent the object of learning has been achieved by the learners after instruction. The exploration of teaching and learning in the Learning study entails identifying what aspects of the object of learning that are critical for learning and how to make it possible for the

learners to experience them. When planning the lesson, variation is used for creating problems, example spaces and choosing representations for example.

### **Teaching and learning negative numbers—some recommendations**

Gaining understanding of the nature of negative numbers has been problematic for early mathematicians to comprehend (Bishop et al., 2014), as well as for teachers to teach and learners to learn (e.g. Ball, 1993). The difficulties have to do with the meaning of the numerical system and the magnitude and direction of the number, the meaning of arithmetic operations, and the meaning of the minus sign (Altıparmak, & Özdoğan, 2010). For Swedish students the meaning of the minus sign is probably particularly difficult, since in Swedish a number like  $-2$  (in English: negative two) is pronounced as ‘minus två’ (minus two) and written  $-2$ . Thus, there is no linguistic and symbolic difference between the minus as a sign for the operation and as a sign for the number.

It has been recommended that teaching of negative numbers should take the point of departure in real life problems or situations known from the children’s experience and transformed into mathematical models. For instance, using ‘a house’ with floors above and below the ground floor, or a bird flying/diving above/below sea level, has been suggested (Ball, 1993). Usually in the Swedish mathematics curriculum negative numbers are contextualized within discussions about temperature below and above zero and with the help of the thermometer. However, there might be a risk with this. The number system and the ordering of integers might not be visible when negative numbers are talked about as ‘minus-degrees’ (in Swedish: ‘minus-grader’). Every child probably knows that it is colder when the temperature is  $-10$  degrees C compared to a temperature of 3 degrees C. This may be confusing when they have to learn that  $-10$  is a smaller number than 3. This was also found initially in the Learning study reported here. So, the teachers decided to use the number line only and talk about the numbers within a mathematical context instead of referring to temperature or depths.

### **A Learning Study on expanding students’ number range from N->Z**

In the Learning study (LrS) one of the authors of this paper worked in collaboration with two primary school teachers and 64 students in four different classes in grade 2 and 3 (8–9 years old) in Sweden. The teachers wanted to extend the students’ experience of numbers to include the negative numbers also. In doing so, they explored what the students must learn—thus finding the critical aspects—in order to be familiar with integers and how to teach this in a way that would enhance the students’ learning.

The LrS encompassed four cycles, that is, four lessons were taught with four different classes. A diagnostic pre- and post-test was given to the students. Results from this, together with a close analysis of the recordings of the lesson, gave insights into what is critical for learning and how the content must be handled to promote learning. Thus, when the learners failed to learn that which was targeted, they had to go deeply into the lesson and inquire how the content was handled and whether it was made possible to learn that which was intended. This analysis became the basis for the planning of the following lesson in the cycle, which was taught by a new teacher, and to *new students*, and again the recorded lesson and the diagnostic post-test are analyzed. The iteration proceeded until all classes were taught. Hypotheses about the critical aspects were tested in class. So, the critical aspects emerged as a result of trying them out in class and carefully analyzing students’ learning outcomes and what was made possible to learn in the lesson. When it was found that the learning outcomes

were not as expected, the teachers had to consider the possibilities for learning during the lesson and, by being guided by variation theory, discuss learning in terms of discernment. As the process continued the critical aspects became more specified; from something to be discerned, to something that should be differentiated, namely:

- To differentiate the value of two negative numbers
- To differentiate the function of the minuend versus the function of the subtrahend in a subtraction
- To differentiate the minus sign for negative numbers versus the minus sign for subtraction

To get the students to discern the critical aspects, carefully constructed examples, based on the idea of variation/in-variance were used. So, for instance, the examples  $3 - 2 =$  and  $2 - 3 =$  ('3' varies; minuend/subtrahend) were contrasted as operations on the number line. The choice and character of the example space (Watson & Mason, 2006) was changed and developed during the process. It was not until lesson 4 that examples like  $2 - 4 =$  and  $-2 - 4 =$  were implemented in the lesson, for example. Since the results on the post-test after lesson/class 4 were significantly better compared to the previous lessons, it was concluded that the examples chosen and how they were sequenced seemed to be important for the possibility to discern the critical aspects.

### **Putting the conjecture to the test: The follow up study**

Lövström (2015) concludes that when the critical aspect was phrased in terms of differentiation, that is what things could be compared, it indicated not just what dimension that must be opened up, but also what values in that dimension that were critical and needed to be contrasted (two or more negative numbers). Thus, critical aspects in terms of differentiation highlight a specific subject matter and students' experience of the content, and furthermore, provide directions for handling the content.

To put the conjectures of the critical aspects identified in the LrS to the test, a follow-up study (FS) with eight classes of new learners (N=116) and five (partly) new teachers were conducted. All the teachers had more than 15 years of teaching experience. All but one were primary school teachers that were not specialized in mathematics. Three of the teachers taught two classes each. One of them had participated in the LrS and is one of the authors of this paper. All except one were, to a varying extent, familiar with variation theory. The teachers were selected on the basis of previous interest in Learning study and variation theory and asked to teach one lesson (three of the teachers in two different classes) about negative numbers. One of the classes was grade 7, a group of learners with difficulties in mathematics; all the other were grade 2 and 3. Swedish was the first language for the majority of the students, but several other languages were represented in all classes. The guardians had given their written consents to student participation. The students were given a test (with a few exceptions identical to the test in LrS) before and after the lesson.

The FS was planned in a 3-hour meeting with the teachers and two of the authors of this paper. Results from the pre-tests in the eight classes were presented and discussed and it was found that the 'new' group of students had similar problems to the students in LrS. So, the critical aspects identified in LrS were assumed to be valid for the new group of students also. The results from LrS were presented to the teachers and the identified critical aspects were described and discussed. A video-recording of lesson 4 was observed by the group. Some sections were repeatedly paid attention to. It was specially observed and discussed in detail how the number line was used in the lesson. The aim was to conduct

the eight lessons as similarly as possible in terms of how the critical aspects were handled. Similar, it was important that all the examples presented and discussed in lesson 4, were present in all the ‘following up-lessons’ just as the usage of the number line. Except for these requirements, the teachers were free to arrange the lesson in their own fashion—to choose group- or individual work, for example.

The FS did not have the same iterative design as the LrS. It was conducted in parallel during the same week. The lesson was conducted mainly in whole class, intersected with individual and/or group-work. The interaction was more of a discussion between the teachers and the students with probing questions around the examples presented on the board. The examples used opened up dimensions of variation and were designed to make the critical aspects possible to discern. The teacher drew the learners’ attention to differences in the midst of similarities and the students were required to justify their answers, sometimes after discussion in peers/groups. The lessons lasted about 60 minutes. In our experience, in Swedish schools it is uncommon that such a long period of time is allocated to whole class teaching of mathematics among younger students. Still, the students seemed to remain concentrated and focused.

The data consists of video-recordings of eight lessons, and results on four tasks (1, 3, 4 and 9) in the pre- and post-tests. Here, only results from pre- and post-test are drawn on. In task 1 (a–e), students should identify the biggest of five numbers. In a) all were positive numbers, b)-c) negative and positive numbers and zero, and e) negative numbers only. The object of learning was not preliminary to operate with negative numbers, but in order to test if the students were able to experience that there are numbers, operations with negative difference were chosen. So, task 3 (8 items) involved subtractions with positive or negative difference. The subtrahend and the minuend were positive numbers except in g) where the subtrahend was negative. Similarly, task 4 was a subtraction with negative difference. Here the students should also give a justification of their answer. Task 9 was about the difference of the meaning of the minus sign. The test comprised another four tasks not accounted for here.

Some preliminary results based on a measurement of correct answers on the pre- and post-test are presented here. Results on the pre-test were compared to the post-test on each task and on a group level. A comparison between the LrS-group and the FS-group was also made. Preliminary results are presented in this paper.

## Results

Preliminary results from the analysis of two tasks for all the groups are presented in Table 1 and 2.

Item	a	b	c	d	e
<b>Pre-test</b>	113(97)	84(72)	104(90)	65(56)	34(29)
<b>Post-test</b>	112(96)	102(87)	112(97)	97(84)	85(73)

N=116

**Table 1: Numbers (percentage) of students who answered correctly on task 1, ordering of numbers**

In task 1 there were learning gains in terms of numbers and percentage of students who displayed the targeted experience of integers on all except one item. As can be seen from Table 1, the frequency of

correct answers was higher on all items on the post-test, except for a) (which had a high rate from the beginning). The highest increase is on d): from 56% to 84% and e): from 29% to 73% who answered correctly. Item d) (negative numbers and zero) and particularly e) (negative numbers only) were initially more difficult than the others (lower scores on the pre-test compared to the others). Although significant progress was made, item d) and e) have lower scores on post-test compared to a-c. There were still students (15–26 %) who did not manage to find the biggest number among negative numbers or negative numbers and zero after the lesson.

The analysis of task 3 and 4 (Subtraction pos./neg. difference) suggests improvement on all items except a) c) e) and f). These subtractions (positive difference) are well known to the students, but their encounter with subtractions with negative numbers might have confused some students.

Item	a	b*	c	d*	e	f	g*	h*	4
Pre-test	113(97)	15(13)	105(90)	19(16)	115(99)	113(97)	11(9)	17(15)	17(15)
Post-test	96(83)	57(49)	90(78)	62(53)	112(96)	110(95)	51(44)	52(45)	61(52)

N=116 \*negative difference

**Table 2: Numbers (percentage) of students who answered correctly in task 3 and 4**

The frequency of correct answers on the subtractions with negative difference is particularly interesting. Item b), d), g) and h) show a similar result. About half of the students could solve these correctly after being taught just one lesson. Before they were taught, the average frequency of correct answers on these items on the pre-test was slightly more than 10 % (13.6). So, there was a significant improvement on the post-test.

Item g)  $-2 - 2 = ?$  is perhaps the most interesting. This item had the lowest frequency of correct answers before the lesson. Only 9% managed this on the pre-test. 44% answered correctly on the post-test. To be able to solve  $-2 - 2 = ?$ , one must differentiate the minus sign as an operation sign and the sign for negative numbers. Task 9 was designed to test whether the learners could understand the two meanings of the minus sign. On the pre-test, 8 students (7%) could tell the difference between the minus sign in the operations  $4 - 7 = -3$  and  $4 - 3 = 1$  respectively. After the lesson, 42% answered correctly.

## Conclusions and discussion

What has been reported here is not a description of the ‘best’ lesson design or an answer about how to teach negative numbers. It is a theoretically and empirically grounded description of some necessary conditions for learning about negative numbers among young students, generated by a group of professionals. Our interpretation of the analysis so far is that, *the simultaneous differentiation of the value of two negative numbers, the differentiation of the function of the minuend and subtrahend, together with differentiating the meaning of the minus sign*, seem to be necessary conditions for learning about the nature of negative numbers. Although learning was improved, still there was a fairly large group of students who seemed not to have learned that which was targeted. So, the ‘instructional product’ is open for development and improvement.

As was described above, finding the critical aspects is a transactional process comprising the learners, their learning (what they learn), what is targeted, or, using Dewey and Bentley's (1949) description: a transaction of the known, the knowing and the known. This was demonstrated in the reported LrS; what was found to be critical emerged as the teachers got deeper understanding of how the learners responded to instruction, what was made possible (and not possible) to learn in the lesson in relation to the targeted 'known'. The object of learning, in terms of what is critical for learning, is constituted in a transactional and continuing process in LrS. The instructional products produced in LrS are hypotheses of what is needed to learn, that can and must be tested and developed to deepen the understanding of teaching and learning. The object of learning and its critical aspects are dynamic and emergent, and this study supports this proposal. In this study, there are most likely things that have been taken for granted or even neglected that might be critical.

Hiebert and Morris (2011) call for a need to accumulate evidence about what works and what does not across different classroom settings (p. 5). Our analysis suggests that the results for the FS-group on the post-tests reflect the results for the LrS-group after the lesson. Our study supports finding from Kullberg's study (2012); when critical aspects generated in LrS become visible as dimensions of variation in new settings, similar learning outcomes are gained. This further suggests and points to possibilities that the development of effective ways of teaching could be shared among professionals.

# A case study of a first-grade teacher's quality of implementation of mathematical tasks

Vuslat Şeker<sup>1</sup> and Engin Ader<sup>2</sup>

<sup>1</sup>Middle East Technical University, Faculty of Education, Ankara, Turkey; [vuslatseker@gmail.com](mailto:vuslatseker@gmail.com)

<sup>2</sup>Boğaziçi University, Faculty of Education, İstanbul, Turkey; [ader@boun.edu.tr](mailto:ader@boun.edu.tr)

*The aim of this study is to investigate changes regarding a first-grade teacher's quality of implementation of mathematical tasks within the scope of a professional development (PD) program. The quality of implementation of mathematical tasks was analyzed through the instructional quality framework developed by Stein and Kaufman (2010) including maintaining cognitive demand, attending to students' thinking and the intellectual authority in mathematical reasoning. This is a qualitative case study focusing on the teaching of a first-grade teacher with 40-year experience. 13 lessons were video-recorded and weekly meetings were audio-recorded. All data were transcribed for content analysis. The results indicated that there was a slightly positive change in quality of implementation of tasks throughout the PD program.*

*Keywords: Mathematical tasks, cognitive demand (CD) of a task, intellectual authority, student thinking, quality of implementation.*

## Introduction

Mathematical tasks are the units of instruction that create an environment for students to work mathematically. To explore mathematics instruction and potential changes in it, an investigation of teachers' selection and implementation of mathematical tasks is necessary (Hsu, 2013). Stein et. al. (2000) characterized use of a mathematical task through four successive phases in Mathematical Task Framework (MTF); (1) task as appears in curricular materials, (2) task as set up in the classroom, (3) task as enacted in the classroom and (4) student learning. Teachers select or develop, present and implement mathematical tasks in their instructional processes.

Stein and Kaufman (2010) defined the high-quality mathematics lessons through the maintenance of high level cognitive demands (CDs), attending to student thinking and vesting intellectual authority in mathematical reasoning. The first is to maintain a high level CD through the steps of MTF. Doyle (1988) described cognitive demand of a task as the cognitive processes necessary for successful completion of the task. If mathematical tasks require high CD level, these tasks need to foster students' high level cognitive processes such as reasoning about the mathematics concepts involved, problem solving, making justifications, making sense of representations etc. Maintaining high CD of a task would require sustaining a focus on such processes through the steps of MTF.

Based on Doyle's (1988) work, Stein et al. (2000) divided mathematical tasks into two categories as high level CD and low level CD. Each category consists of two subcategories. Memorization tasks and procedures without connection to mathematical concepts tasks (P without C) belong to low level CD. The procedures with connection to mathematical concepts tasks (P with C) and doing mathematics tasks are high level CD (see Stein et. al., 2000 for a detailed explanation of these categories in Task Analysis Guide). Literature indicates that students show their best performance on reasoning and problem solving when tasks are maintained in high level CD (Stein et. al., 2000).

However, in most practices high level CD cannot be maintained and there is a decline in CD during set up and implementation of tasks (Tekkumru-Kisa & Stein, 2015).

Attending to students' thinking is about paying attention to what students tell regarding mathematics (Stein & Kaufman, 2010). The goal is to gather students' strategies, representations, understandings or thinking, and to use them in classroom discussion in order to support conceptual understanding. Vesting intellectual authority in mathematical reasoning emphasizes that the authority in the classroom needs to be in mathematics itself, especially in mathematical reasoning. Therefore, teachers are not acting as the judge to tell whether student responses are right or wrong (Stein & Kaufman, 2010).

Approaches to mathematics teaching have been going through changes in many countries in the last two decades. The emphases on problem-solving and reasoning for conceptual understanding, i.e. reflections of high levels of CD, are prominent in many countries' recently revised mathematics curricula and curricular materials. At times of change, teachers are the agents who enact curricular and pedagogical changes by arranging the learning environments according to the needs of students. However, teachers have difficulties while adapting new approaches in implementing new curriculum (Davis, 2003). Even though teachers are expected to implement tasks focusing on conceptual understanding, studies demonstrate that they continue to teach mathematics in a traditional way; focusing on practicing procedural skills (Hsu, 2013; Stein et. al., 2000). In Turkey, where there are similar changes in the curriculum, mathematical tasks in textbooks are aiming to reflect this focus (Ubuz et. al., 2010). Thus, teachers' implementation of mathematical tasks requires a close attention in this context.

In various international studies, the whole process in MTF has been investigated considering the change in curricular approach (e.g. Charalambous, 2010; Stein & Kaufman, 2010). The studies mostly focus on how CD of a task is maintained through the phases of MTF (e.g. Charalambous, 2010). In the context of Turkey, studies related to investigating teachers' implementation of mathematical tasks are scarce (e.g. Ubuz & Sarpkaya, 2014). More specifically, according to our knowledge there has not been any study conducted considering all three components of instructional quality.

Due to demands of a new curriculum from teachers, we conducted a professional development (PD) program in a private primary school in Turkey. We aimed to investigate how the quality of teachers' implementation of mathematical tasks progressed through the PD program. The current paper reports a part of this project. The aim of this article is to examine the case of a first-grade classroom teacher's quality of implementation of mathematical tasks throughout a year. The research question is:

How does a first-grade teacher's quality of implementation of mathematical tasks change during a professional development program?

## Method

A qualitative case study approach was adopted, aiming for in-depth analysis of a particular complex situation in a realistic context. Neşe (pseudonym) was a first-grade teacher at a small private primary school in İstanbul and was one of the participants who joined the PD program. We chose the case of Neşe to further analyze in this study because of her experience in teaching and her initial resistance to changes regarding the quality of implementation of mathematical tasks.

## The participant

Neşe had approximately 40 years of experience in teaching as a classroom teacher and had deeply rooted classroom practices. In her classroom, there were 16 students whose SES backgrounds varied from middle to high. At the beginning of the study, Neşe reported that she already taught in a way to foster high level cognitive processing. When she acknowledged that she could not follow the kind of teaching suggested by the quality of implementation of tasks framework, she highlighted that her first graders required detailed teacher directions of what needed to be done, tasks focusing on singular skills or knowledge at a time. She wanted to spoon-feed them since she believed the students needed experiencing success in tasks. She explicitly referred to her experience as a reason for her resistance to making changes in her practice. Neşe was a typical case of experienced teachers with deep-rooted beliefs and skeptical to new approaches (Ghaith & Yaghi, 1997).

## Data collection

In the PD program, we adopted Borko's (2004) phase 1 teacher professional development research approach through the collaboration of teacher and researchers in one school. We, as two mathematics education researchers, aimed to create a community of learners where researchers and teachers discussed their ideas together. Classroom observations were done approximately twice in every month. While observing the classrooms, we were nonparticipant observers who took field-notes and video-recorded the lesson. The video recordings were used for two purposes; (1) collecting research data and (2) supporting teacher reflection. We had weekly meetings with teachers to discuss their implementation of mathematical tasks based on the videos. The teachers watched their videos before the meetings and reflected on them. There were 23 meetings lasted for 40 minutes and were audio-recorded. Furthermore, mathematics lesson plans for the coming week were also discussed. We gave suggestions for lesson planning and teaching but made sure teachers made the final decisions. Besides, in order to explore MTF's first step, before observation, we wanted teachers to send us their plans for the lessons to be observed. 13 lesson observations were conducted in Neşe's classroom. 44 mathematical tasks were implemented in these lessons. However, not all tasks were present in the lesson plans Neşe provided.

## Data analysis

For the quality of implementation of mathematical tasks, all videos were transcribed and coded using the Classroom Observation Coding Instrument (Stein & Kaufman, 2010). Based on the instrument, we coded intellectual authority in mathematical reasoning ranging from 0 to 2 and attending to students thinking ranging from 0 to 3. While coding, the enactment episodes of instructional tasks were used as the unit of analysis. For the maintenance of CD, we used the paths provided by Charalambous (2010) (see Figure 1). For interrater reliability, two mathematics education researchers coded 4 of the 13 lessons including 11 of the 44 tasks independently. Cohen's kappa was calculated to check agreement between raters for coding CD of tasks, CD of task set-up, CD of task enactment, student thinking and intellectual authority. Cohen's kappa values were  $\kappa = .784$ ,  $\kappa = .694$ ,  $\kappa = .792$ ,  $\kappa = 1.00$ , and  $\kappa = .792$  respectively, which shows a high level of agreement between raters. Beyond the provision of descriptive statistics, we will present key episodes from her teaching practice and comments in the meetings to document teacher resistance to change and teacher change in terms of her quality of implementation of tasks.

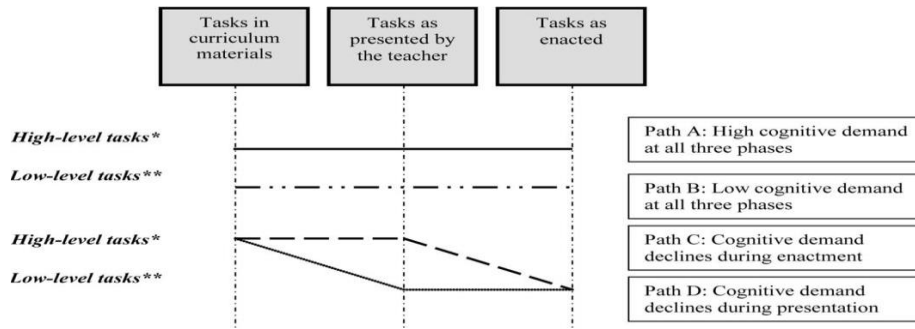

Figure 1: Paths for the maintenance of CD (Charalambous, 2010, p.258)

## Results

Neşe used 44 tasks in total throughout 13 lessons. Sixteen of 44 tasks were not laid out explicitly in the lesson plans Neşe provided. Table 1 summarizes CDs of the tasks with respect to semesters. The table shows that about 61% of the tasks in the second semester were set up as cognitively demanding compared with only about 43% of the tasks in the first semester. In the first semester, about 57% of the tasks Neşe presented required low cognitive processes (i.e. recalling information, applying algorithms). Table 1 also indicates similar trends in enactment phase; Neşe implemented about 61% of the tasks at a high level in the semester 2 while she enacted about 33% of the tasks at this level in the semester 1. When the maintenance of CD was analyzed, it was observed that Neşe mainly maintained CD at its intended level for all phases for both semesters. While Neşe maintained about 59% of first semester's tasks at a low-level (Path B), she maintained 73% of second semester's tasks at a high level (Path A). For only two tasks throughout the whole year, she did not maintain cognitively challenging tasks; the decline occurred during enactment phase (Path C). Analyses showed that Neşe's choice of tasks determined the level of CD to be maintained.

CD levels of tasks	Semester 1						Semester 2					
	Planning		Set-up		Enactment		Planning		Set-up		Enactment	
	f	%	f	%	f	%	f	%	f	%	f	%
Memorization	3	14.3	3	14.3	3	14.3	0	0	0	0	0	0

Table 1: Descriptive analysis of CD levels of tasks

Table 2 shows the limited work Neşe did to uncover student thinking in the first semester (i.e. she mostly asked for short or one-word answers). She did not connect students' responses in the discussion. However, there were slight differences in her use of tasks where she used students' answers to direct and connect the discussion on 8.7% of the tasks in semester 2. She demanded explanations from the students, called on certain students for directing the discussion to specific outcomes and connected the discussion for a fruitful experience for students as a classroom community.

	Semester 1		Semester 2	
Categories for attending to student thinking	f	%	f	%
(0) no attention to student thinking	6	28.6	6	26.1
(1) limited attention - some student explanation	11	52.4	10	43.5
(2) purposeful selection of responses, attention, but no connected discussion	4	19.0	5	21.7
(3) purposeful selection, attention and connected discussion	0	0	2	8.7

**Table 2: Descriptive analysis of attending to student thinking**

Table 3 shows that the nature of Neşe's practices on judging the correctness of students' work was slightly different in the second semester. She was in charge of deciding what was correct or not for most of the tasks in semester 1. Although she wanted students to prove or check the correctness via mathematical tools, she was the one confirming students' answers at the end. In semester 2, she continued with similar teaching practices; but she also experienced teaching episodes where mathematics was the tool students used to decide on the correctness.

	Semester 1		Semester 2	
Categories for intellectual authority	f	%	f	%
(0) judgments of correctness derived from teacher or text	11	52.4	7	30.4
(1) judgments of correctness sometimes derived from teacher or text, but also some appeals to mathematical reasoning	10	47.6	14	60.9
(2) judgments of correctness derived from mathematical reasoning	0	0	2	8.7

**Table 3: Descriptive analysis of intellectual authority in mathematical reasoning**

### Illustrative episodes from Neşe's lessons

In this part, we will present two episodes from Neşe's quality of implementation of tasks. The first episode illustrates Neşe's common use of non-challenging, low level CD tasks throughout all phases of MTF. There were elements representing her resistance to changing her practice. The second episode presents how Neşe maintained a cognitively demanding task through letting her students struggle and encouraging their ideas to come out, practice emerging more prominently in the second semester. Neşe's comments from meetings about the tasks in the episodes gave insights about the nature of change in her practice.

*Making 10.* This episode is from a lesson on pairs of numbers that make 10, covered at the beginning of the PD program. In the plan of the lesson, Neşe stated the lesson goal as discovering the pairs of numbers that make 10. The task in the episode included nine possible pairs that would make 10. The students needed to find one of the pairs to make 10. The task and the coding decisions for this episode are presented in Table 4. While implementing the tasks, Neşe directed students to count the flowers as seen in the sample item. In doing so, she made available the unknown to the students. Neşe eliminated opportunities for students to explore the pairs that make 10 by focusing on the counting procedure and finding the answer. This led students not to use high cognitive processes, or think about the operation they were engaged in; counting the flowers was enough for the completion of the task. Neşe had similar trends in her implementations of the first semester's tasks.

The Task	Coding Decisions
<p>How many more needed to make 10?</p> <p>Sample item: <math>2 + \square = 10</math> </p> <p>Sample episode:</p> <p>Neşe: Elif, there are 2 flowers. Which number should I add to make 10? I can count these flowers to find out. Let's count.</p> <p>Student: One, two, three, four, five, six, seven, eight. Eight.</p> <p>Neşe: Well done, this is it!</p>	<p>The task was coded as procedures without connections for task selection, set-up, and enactment. Neşe expected students to count the flowers to decide what would be the unknown of the pair that makes 10. Since the focus was on counting the flowers, students enacted the task by not relating with pairs of 10, but counting the flowers and writing the unknown number. During instruction, she did not attend student thinking; she asked for completion of the task. The judgments regarding correctness were derived from the teacher; she checked students' work constantly.</p>

**Table 4: Making 10 task and coding decisions of the making 10 task**

In the follow-up meeting of the lesson, Neşe did not prefer to comment on the episode before we made any comments. We pointed out the discrepancies between the CD of Neşe's expectations from the students as reflected in her activity and the goal she noted down for this task. We discussed the importance of giving opportunities for higher-level thinking and mechanisms for shifting teaching towards this aim. After such comments from the researchers, Neşe wanted us to lower our expectations from her and emphasized her teaching habits by saying:

Neşe: If I bring open-ended tasks to the classroom, the students could not complete the task. I need to use such repetitive activities for students to learn. I have been using teacher-centered approach for years. Do not expect me to improve my teaching. At most, two years later I will be retired from teaching. Do not try hard for me. Contribute to younger teachers (personal communication, November 26, 2014)

Yet we emphasized that we believed that there would be changes if she wished to work together. This extract shows that Neşe held on to her experiences in teaching and her expectations about student learning. Neşe was reluctant to change because she wanted to retire from teaching in two years. This reaction is an evidence of her resistance to change her implementation of tasks.

*Subtraction Problem.* This episode is from a lesson on problem solving using subtraction, covered towards the end of the PD program. The task and coding decisions are presented in Table 5. During the episode, Neşe expected students to analyze the problem and to explain their thinking by modeling the problem and writing mathematical sentences. Therefore, she maintained the complexity of the task by pressing for meaningful explanations so that the students realized the unnecessary information by asking, "Why do you think it is unnecessary information?", "Can you explain in more detail?", "Why don't I use money?" "Why is the result 11, not 14 or not 27?" In the post-lesson meeting, Neşe examined her lesson in detail before the researchers made any comments. She referred to the maintenance of CD in her comments. She had certain concerns about the set-up phase of the task after watching her practice.

The Task	Coding Decisions
Examine the following problem situation by modeling it. Write mathematical	Contextualized task was coded as procedures with connections for all phases of MTF. Applying general subtraction procedures were necessary with the need of

<p>sentences and solve it. Explain your reasoning.</p> <p><b>**</b>There are 6 roses in our vase. Dad brought 8 tulips too. Mom told that dad spent 10 ₺ for the tulips. Next day, mom realized 3 flowers faded. How many flowers are left in the vase?</p>	<p>conceptual connections to complete the task. Neşe expected students to connect multiple representations by asking for a model and mathematical sentences. She attended to student thinking by demanding justifications from students. She mostly directed students to the models for checking the correctness of their answers.</p>
---	--

**Table 5: Subtraction problem task and its coding decisions**

In the meeting following classroom observation, Neşe stated that the task was too abstract and hard for the students. Then she pointed to getting students to struggle in order to construct meaning through abstraction as a necessary practice for learning:

Neşe: It would not be easy for students, but it is good to present the task abstractly. It is challenging for them and for me too. I think I maintained the high level CD. I did not just expect them to apply the subtraction procedure. I wanted them to question the problem situation, and the unnecessary information within the problem. I wanted them to explain their thinking by using manipulatives. It took a long time, but it was necessary for students to experience high level cognitive processes. (personal communication, May 6, 2015).

This episode and Neşe's interpretations showed the importance she gave to supporting students' reasoning in her teaching practice. The focus on explanations and justifications helped the teacher implement the task with high quality. The post-lesson interview provided evidence for teacher's change in her emerging practice and comments during the PD program.

## Discussion and conclusion

This study aimed to investigate the changes in a first-grade teacher's quality of implementation of mathematical tasks during a PD program. Neşe, our case, was one of the experienced teachers having difficulties with adapting educational innovations into their practices as illustrated in the literature (Ghaith & Yaghi, 1997). The PD program aimed to meet the needs of new approaches to mathematics education. The results indicated a slight positive difference in Neşe's practices between first semester and second semester based on maintenance of high levels of CD, attending to student thinking and intellectual authority. The teaching episodes showed that the PD program contributed to the teacher's approach towards implementing high quality of tasks that focus on problem-solving, reasoning and conceptual understanding (Stein & Kaufman, 2010). Neşe was resistant to change at the beginning of the PD program; her selection and implementation of tasks were low level CD in general (e.g. the making 10 task). However, high expectations from the researchers and the post-lesson interviews persistently focusing on the quality of implementation of tasks contributed to emerging changes in Neşe's teaching practice as well as the nature of her comments (e.g. the subtraction problem task). This study contributes to the existing body of literature on change of teachers' practices about the implementation of mathematical tasks within the context of a PD program. This study might inform future studies to explore facilitators' actions that lead to change in teacher practice. Further research might explore how change occurs in an experienced teacher practice to work with other experienced teachers. Especially in Turkey, there are a limited number of studies related to the classroom practices

of primary school teachers in a climate of change in curricular approaches (e.g. Ubuz & Sarpkaya, 2014). Results of this study provide information about mechanisms of change in context and contribute to the development of larger scale PD programs.

### Additional information

Work in this paper was supported by a grant from Boğaziçi University Scientific Research Projects (BAP) Fund, with project code 15D01P1 and project number 9420.

# Long-term learning in mathematics teaching and problematizing daily practice

Helén Sterner

Linnaeus University, Växjö and Dalarna University, Falun, Sweden

[hse@du.se](mailto:hse@du.se)

*This paper stems from research on mathematics teachers' participation in a particular collaborative learning process that addresses the issue of mathematical communication and mathematical reasoning in relation to the teaching of algebra. Although results from the developmental research revealed changes in the working group's meaning making about mathematical communication and reasoning, whether these changes are long-term and influence the teachers' mathematics teaching over time remains unclear. The aim of this paper is to discuss possible theoretical frameworks and ways of understanding mathematics teachers' long-term learning about mathematical communication and reasoning by describing what they can learn in an organized community of practice (Wenger 1998) when working with key mathematical issues. I will use the data and results from the developmental research to design another study on long-term learning.*

*Keywords: Collaborative learning, long-term learning, mathematical communication, mathematical reasoning, mathematics teaching.*

## Introduction

Changing mathematics teaching is a complex process that requires the improved alignment of theory and practice (Sowder 2007). To that end research has failed to focus on answering questions about how mathematics teaching can change as a result of collaborative teacher learning projects (Sowder 2007). In this paper, I present an earlier study (Sterner 2015) as a background for a discussion of potential ways of conducting further research on understanding what a developmental research project can achieve in three years after its completion. The previous study addressed a school developmental project in mathematics in a middle sized community in Sweden. Figure 1 illustrates the background of the study and a possible direction for further research.

**Figure 1: The study's chronological development.**

The first section of this paper focusses on the learning process and results of a working group (i.e. the reflection group) that formed part of the developmental research study (Fig. 1). The second section comprises questions about possible ways to conduct further research three years after the study's completion. The bulk of research in the field of teacher learning and development has indicated the

failure of teachers to learn how to promote and support teaching and student learning (e.g. Borko 2004; Opfer & Pedder 2011; Sowder 2007). New issues emerged during and after the previous study, including ones addressing what happened in mathematics teaching after the completion of collaboration in the reflection group and how research on mathematics teaching can integrate the significance of context. Among other questions, whether we can listen to teachers' voices (Potari, Figueiras, Mosvold, Sakonidis & Skott 2015, p. 2972 - 2973), and what comes to mind when teachers listen to their own narratives three years after the completion of work in a reflection group are of particular importance (Fig. 1).

## Background

As Figure 1 illustrates, results from a pilot study (November 2012 – February 2013) revealed teachers' difficulties with describing the concepts of mathematical communication and reasoning, as well as with applying those concepts in their teaching. Based on the results, the main study (Sterner 2015) was designed as a collaborative development initiative in a working group called *reflection group*. The author and five mathematics teachers in grades 1-6 collaborated on the key issue of mathematical communication and reasoning in relation to their teaching of algebra. Since the reflection group met monthly for a year the study can be characterised as *developmental research*, which Jaworski and Goodchild (2006) have defined as:

Research which both studies the developmental process and, simultaneously, promotes development through engagement and questioning (p. 353).

The developmental work in this study addressed change achieved in an ongoing investigative process which occurred in parallel with the active creation of the participants' meaning making related to the key issue. However, as Goodchild (2008) pointed out, transformations through such dialectic cyclical processes of research and development are complex. In a literature review, Sowder (2007, p. 158) outlined 10 important issues facing mathematics teachers' development. Three of those issues were of specific importance to the study at hand and constituted the underlying questions addressed in the developmental research study:

1. How do teachers learn from their professional communities about teaching mathematics?
2. What can teachers learn from investigating their own teaching of mathematics?
3. What can be learned from research on teacher change?

In this paper, I discuss theoretical frameworks for understanding mathematics teachers' sustainable and long-term learning by describing what teachers can learn in an organised community of practice (Wenger 1998) addressing a key mathematical issue. The teachers in the reflection group wanted to develop their understanding of communication in mathematics teaching in order to stimulate mathematical reasoning in their own teaching of algebra.

## Methodology

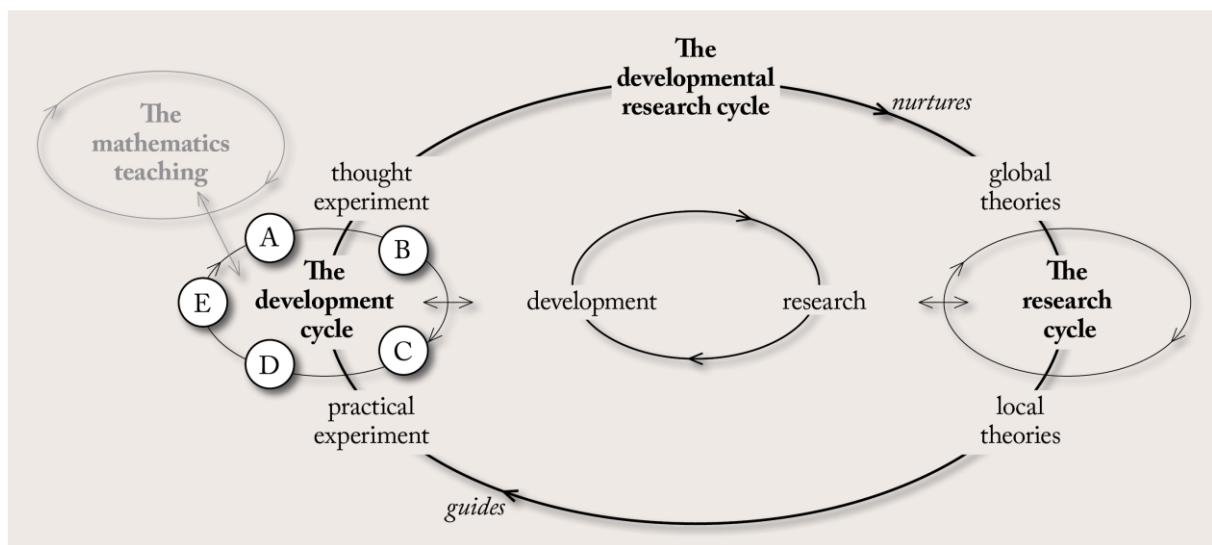

The study derived from a developmental project that adopted the perspective of collaborative learning among mathematics teachers and a researcher when designing tasks and environments to investigate

students' learning of mathematical reasoning related to algebra. A socio-cultural approach was adopted and the focus of the study was the learning process of the reflection group.

The theoretical perspective employed was that of communities of practice (Wenger 1998), in which learning is an aspect of participation in a social practice, whose participants engage in the negotiation of meaning (Wenger 1998). The theory of communities of practice (Wenger 1998) focusses on meaning making, participants' learning, and their reification of the key issue in a social context. Negotiating meaning is a central and dynamic process when teachers participate and reify. In that sense the reflection group's joint enterprise (Wenger 1998) was its members to understand more about communication and reasoning in their own mathematics teaching.

The process in the reflection group concentrated on two interacting parts: participation and reification (Wenger 1998). Framing the case as a community of practice shed light on the teachers' negotiation of meaning. At the same time the negotiation of their experience with teaching and learning related the key issue of mathematical communication and reasoning to their teaching of algebra.

The developmental research cycle method (Goodchild 2008) and the theory of communities of practice (Wenger 1998) together shaped the methodology of the study (Fig. 2). Developmental research and choice of methodology were intended to provide duality between a developmental and a research process over time and to enable a participant's perspective. Figure 2 illustrates my interpretation of Goodchild's (2008, p. 8) schematic figure of the developmental research cycle.

**Figure 2: Interpretation of the developmental research cycle (Goodchild 2008, p. 208)**

This study draws upon the idea that mathematics teachers' professional development should be based on their own classroom practice and students' learning (e.g., Broodie 2014; Goodchild 2014; Goodchild, Fuglestad & Jaworski 2013; Kazemi & Franke 2004; Matos, Powell & Sztajn 2009). The reflection group constituted a learning community that reflected on their teaching practices as well as on their students' mathematical communication and reasoning related to algebra. Working collaboratively, the mathematics teachers developed a shared repertoire (Wenger 1998) of the key issue, mathematical communication and reasoning in relation to their teaching of algebra. Developmental research represents a methodology based on interacting cycles of research and development (Goodchild 2008). As illustrated in Figure 2, the developmental research cycle constitutes the largest ellipse that spans the entire study since a cyclical process clearly exists between development and research. The ellipse on the left, representing the developmental cycle (A-E),

illustrates the work performed in and organisation of the reflection group (Sternier 2015). The developmental process appears as a cycle between a practical experiment and a thought experiment (Fig. 2). Every meeting of the reflection group were started at phase C (i.e. common reflections, challenges and questions and activities completed by the students when working on mathematical reasoning in algebra). This meetings were recorded. The ellipse on the furthest left, representing mathematics teaching (Fig. 2), illustrates the teachers' own practice in which they attempt to align and adjust common mathematical tasks and make individual reflections. Figure 3 illustrates systematic reflections in the process and the three levels of reflection in the reflection group.

**Figure 3: Systematic reflections among participants in the reflection group**

The discussions in the reflection group provided empirical data that nurtured the research cycle. In Figure 2 the research process appears as a cyclical process between global and local theories. My interpretation of global theories (Goodchild 2008) is comparable to a theory-guided design research approach (Gravemeijer 1994; Gravemeijer & Cobb 2013) that in turn produces new theories (Gravemeijer 1994; Goodchild 2008). The research process guides the developmental cycle by means of local theories, which nurture the research cycle in the form of thought experiments and new questions. Reflecting together in the reflection group (phase C, Fig. 2) and the challenges of group members' own teaching resulted in problematizing questions.

## Analysis and results

The analysis of the reflection group's discussions involved three steps. The first two continued throughout the developmental research process and constituted tools used for reflection in the reflection group (Fig. 3). The third step of analysis occurred following the completion of work in the reflection group. All three analyses were based on Wenger's (1998) concepts of participants' meaning making, reification and shared repertoire related to the key issue. The first two analyses and the preliminary results motivated the reflection group to negotiate their meanings of the key issue and wielded questions about what the group needs to discuss in terms of mathematical communication and reasoning. The reflection group returned to the preliminary results of analyses in order to identify further opportunities for development (Goodchild et al. 2013). As a participant researcher, I provided reflection to the group members with "findings of the research" and problematizing questions based on their own thoughts and questions.

During the ongoing data analysis from the reflection group discussions, new questions emerged when participants problematized daily mathematics teaching practices and became aware of new questions and challenges in their practice. The key principle in that process was reflection on three levels, as illustrated in Figure 3, since an essential component of developmental research is participants' interpretation (Kvale & Brinkman 2009). Wenger's (1998) modes of belonging (i.e engagement,

alignment and imagination) served as the participants' means for aligning and changing the discussions and activities of the reflection group. Those alignments and changes derived from participants' negotiation of meaning and reification of the key issue. The following dialogue from the initial analysis reveals that participants' shared repertoire concerns their frustration with failing to understand the meaning of reasoning in mathematics teaching.

*Majken:* There is, generally speaking, no resistance among the students to conducting mathematical reasoning, but when we tell them to do so, they have no idea what it means.

*Irma:* We need to provide them with tools that enable them to practise mathematical reasoning.

*Majken:* But how can we do it, when we don't know the meaning of mathematical reasoning ourselves?

The dialogue led to consider textual content of mathematics as a science and in teaching from Lampert' (1990; 2001) and the National Council of Teachers of Mathematics (2008). Lampert (1990; 2001) described the science of mathematics as the formulation of assumptions followed by investigations to verify or refute them. When it comes to learning from a participant perspective, Lampert (2001) has outlined how she stimulated students' mathematical reasoning by encouraging them to make a mathematical assumption (conjecture) about, for example, a strategy or a solution. She also stressed the importance of advancing a plausible mathematical justification for the assumption that can be explored and verified. This dynamics exemplifies how reflection group members returned to the analysis and its results.

The textual content of strategies for mathematical reasoning in teaching suggested by from Lampert (1990; 2001) and the National Council of Teachers of Mathematics (2008) can be global theories transformed into local ones (Fig. 2). During discussions and activities participants aligned and developed local theories into a practical experiment (Fig. 2), which they sought to align for implementation in their own mathematics teaching. The teachers attempted to support their students in using the strategies for mathematical reasoning and to conceptualise mathematical reasoning as a cyclic process of exploration, conjecture and justification. The quote bellow is from the reflection group. The students have worked with equations and to concretize that  $x$  can have different values, the students used boxes with different amounts of beans.

*Irma:* [...] the strategies for "the reasoning cycle" (conjecture, justification and exploration) helped both me (in grade 4) to understand the students' mathematical thinking. The students worked with the equation  $3x + 3 = 2x + 5$  and the students had to determine the value of  $x$ . I saw differences between students who made a wild guess and students who argued for their assumptions e.g. [...] if we imagine that  $x$  represent the boxes with beans. In each box there is same number of beans, we don't know the amount yet. We need to balance the left and right side... if we reduce the same amount of boxes ( $2x$ ) from the both side of the equal sign, what will happen then?]

Irma gives a student example of an initial mathematical reasoning. Later on the reflection group discussed situations from their own mathematical teaching in terms of how and when mathematical reasoning occurred and interpreted why. In the reflection group the negotiation of meaning centered on teachers' awareness of stimulating students to "become involved in the reasoning cycle of"

exploration, conjecture and justification (Lampert 2001; the National Council of Teachers of Mathematics 2008). The teachers reflected on and interpreted their own teaching and used a thought experiment as a form of individual experience and reflection (Fig. 3). Ongoing analysis revealed how participants' discussions and shared repertoire about the key issue changed over time. As a participant researcher, my strategy was to focus on questions that arose in the reflection group and search for mathematical education theories that problematized the teachers' challenges and questions (Goodchild 2008) in thought experiments (Fig. 2).

## Results and conclusions

I investigated how the reflection group developed their meaning making and shared repertoire related to mathematical communication and reasoning, which promoted a change in the members' ways of communicating about mathematics teaching in relation to students' mathematical communication and mathematical reasoning. Four relevant changes in the mathematics teaching were identified in the reflection group's discussions and learning. The changes ranged from understanding communication and reasoning to identifying, interpreting, applying and practising that reasoning. Teachers in the reflection group also changed their approach to discussion. In the initial stage, they achieved consensus, but gradually adopted a positive yet critical approach in which they problematized the process of learning in and from daily practice (Sterner 2015). The three levels of reflection (individual and shared reflections and the researcher's reflection on the preliminary outcome in the reflection group) resulted in discussions that promoted new and meaningful ways to communicate mathematically and stimulate mathematical reasoning in algebra. This methodology could be a way of linking the activities of students and teachers.

Ultimately, in response to Potari et al.'s (2015, p. 2,972) 'How can we link students' activity to teachers' activity', the present study demonstrates the importance of linking research and development in order to enable teachers to learn about their own mathematics teaching and students' learning. Moreover it provides a response to Sowder's (2007, p.158) questions; 'How do teachers learn from their professional communities about teaching mathematics' and 'What can teachers learn from investigating their own teaching of mathematics' by indicating the combined method of the developmental research cycle (Goodchild 2008) and the theory of communities of practice (Wenger 1998), along with reflection on three levels (Fig. 3) allowed using the results and questions that emerged in the reflection group.

## Implications and further research

The main study, between March 2013 and January 2014 (Fig. 1) focused on a group's learning process, the group's meaning making of the key issue. The third question from Sowder (2007) 'What can be learned from research on teacher change' found a partial answer. Results of the study demonstrate what can happen in the change process when a reflection group begins to work actively. On that note, other questions are whether mathematics teachers' activities and shifts in collaborative learning change their mathematics teaching and whether teachers' meaning making and their shared repertoire about communication and reasoning in mathematics teaching influence their teaching and persisted three years later. Since I am curious about teachers' learning from a long-term, sustainable

perspective, one question I will continue to carry with me comes from the last meeting in the reflection group, when one of the teachers, Clara said:

*Clara:* I'm worried about myself. It's very easy to sit back and fall into old habits when we no longer meet for reflection. What will my teaching be like now?

As Clara suggests, a question not answered in this study is whether teachers' activities and the shift in their approach in the discussion can change their mathematical teaching shortly after and also three years later.

### **Possible new routes and issues three years after the completion of the reflection group**

The research in the reflection group involved the group's process of learning about the key issue of communication and reasoning. The teachers' meaning making and shared repertoire (Wenger 1998) about that issue shifted from understanding to identifying, interpreting, applying and practising mathematical reasoning. The present study does not provide answers about what happened in the light of the grey ellipse representing mathematics teaching in Figure 2 or what happened to the teachers' thoughts and their mathematical teaching three years later. What questions will arise when the five teachers listen to the interviews they gave in 2014, after the completion of work in the reflection group and what thoughts will they have on hearing their own narratives? Will it be possible to use the same theory of communities of practice (Wenger 1998) to analyse the teachers' individual reflections when they listen to their own voices from those interviews? Further research is necessary to understand sustainable, long-term learning in this case whether the mathematics teachers' activities and shifts in their collaborative learning actually changed their mathematics teaching over time. What roles, if any, do teachers' discussions changed meaning making and changed shared repertoire about mathematical communication and reasoning play in their teaching in a long-term sustainable perspective?

# Teachers' decisions and the transformation of teaching activity

Konstantinos Stouraitis

National and Kapodistrian University of Athens, Greece, [kstouraitis@math.uoa.gr](mailto:kstouraitis@math.uoa.gr)

*In this paper I study teachers' decisions as a response to emerged contradictions in the context of enacting a new set of curriculum materials. The way these decisions are framed and the potentials they have to transform the teaching activity are analysed. Our data come from discussions in teachers' group meetings through one year. I use activity theory to capture social and systemic aspects of decision making and to interpret teachers' decisions. Future-oriented envisioning of the deliberate outcomes of teaching and action-based decisions about the actions to be undertaken are two different aspects of decision making. Both are traced in the data of this study as two necessary aspects for decisions that create possibilities to broaden the horizon of teaching activity.*

*Keywords: Activity theory, contradiction, decision making, teachers.*

Last decades, in the context of curriculum reform efforts, teachers are seen as active agents and designers, whose instructional actions are influenced by curricular materials, but also shape the enacted curriculum alongside their students (Remillard, 2005). Considering teacher at the centre of the curriculum enactment, highlights the importance of teacher's decision making. Thus, a number of studies focus more or less explicitly on teachers' decisions. For example, Lloyd (2008) follows a teacher for two years and finds that his perception of students' expectations and his own discomfort associated with using the new curriculum were key factors in his decisions. A large number of studies are focused on in-the-moment decisions made by teachers. ZDM special issue 48(1–2) on teachers' perception, interpretation, and decision making, is indicative. Schoenfeld (2011) uses the notions of resources, goals and orientations to "offer a theoretical account of the decisions that teachers make amid the extraordinary complexity of classroom interactions" (p. 3).

The studies examining in-the-moment teacher decisions, focus on the classroom context and emphasize the individual dimension of deciding. Nevertheless, the broader social, temporal and cultural dimensions of decisions a teacher makes in his planning or in the classroom are not addressed. In this study I seek a better understanding of how decision making process develops and how is shaping the teaching activity, drawing on cultural historical activity theory. The study is conducted in two secondary schools in Greece at the time of the introduction of a newly prescribed mathematics curriculum. In Stouraitis, Potari, & Skott (2015) and Stouraitis (2016), we have analysed the contradictions emerged in this context and how teachers' decision-making is framed and develops considering social and systemic dimensions. In this paper I study how and why teachers' decisions, may or may not have a transforming effect on teaching activity. The decisions in focus are discussed in group meetings and refer to planned actions undertaken in the classroom. I examine three teachers' decisions, the different ways these decisions shape the teaching activity and I interpret these differences. Although sociocultural perspectives have been used in research about teachers' decisions in mathematics education (see for example, Skott, 2013), activity theory has not been used so far. Thus, although empirically based, the paper is methodologically oriented, giving an account about the affordances of using activity theory in studying teachers' decisions.

## Theoretical considerations

Cultural historical activity theory (AT) offers a lens that tries to capture the complexity of teaching, by integrating dialectically the individual and the social/collective. The activity is driven by a motive and directed towards an object (Leont'ev, 1978). In our case, teachers (the subject) are involved in teaching activity with the motives of students' learning of mathematics and the fulfilment of other professional obligations. The unit of analysis is the activity system (Engeström, 2001a) incorporating social factors (rules, communities, division of labour) that frame the relations between the subject and the object with the mediation of tools (Figure 1). In our case, a tool with considerable influence in the teaching activity is the new curriculum.

Activity is carried out through actions which are "relatively discrete segments of behaviour oriented toward a goal" (Engeström, 2001b). I conceptualise teaching action as discrete instructional acts or clusters of acts that constitute the teaching activity, e.g. the selection or creation of a task, the enacting of a lesson plan, etc.

**Figure 1: The activity system**  
(adapted from Engeström, 2001a)

Every activity system is characterised by contradictions which are the driving forces for the development of every dynamic system (Ilyenkov, 2009). They may create learning opportunities for the subject and may broaden the activity, for example leading to reconsideration of the actions and goals (Engeström, 2001a; Potari, 2013). In our study, the introduction and enactment of the new curriculum produced or revealed contradictions in teaching that emerged in group discussions (Stouraitis, Potari, & Skott, 2015).

Dealing with contradictions involves decisions about the goals and the actions to be undertaken. Of particular importance are decisions related to the "discrete individual violations and innovations" (Cole & Engeström, 1993), that is the search for novel solutions as the first, individual response to the emerged contradictions. Thus, although teachers' decisions are part of the teaching activity, they may have a transformational effect on this activity. Engeström (2001b) identifies four dimensions of decision making: social, temporal, moral and systemic. The systemic dimension is particularly concerned with the way "this [decision] shape the future of our activity?" (Engeström, 2001b, p. 281). This dimension is connected to expansive learning, the activity theoretical notion in which the learners are creating new ways to carry out the activity, reconceptualising its object.

Engeström, Engeström, & Kerosuo (2003) make a distinction between action-based decisions about the actions to be undertaken, and future-oriented envisioning, which is the imagination of the deliberate situation of the object as outcome of the activity. Drawing from their interventional study in health sector, they argue that intertwining these two aspects is necessary in any attempt to transform the activity stating that "history is made in future oriented situated actions" (p. 287).

## Methodology

A new set of reform-oriented curricular materials was introduced and piloted in a small number of schools in Greece in 2011-12 and 2012-13. The new materials emphasize students' mathematical reasoning and argumentation, connections within and outside mathematics, communication through

the use of tools, and students' metacognitive awareness. It also attributes a central role to the teacher in designing instruction. In 2012-13 I collaborated with teachers in three of the lower secondary schools that piloted the new materials. The collaboration took place in group meetings at the respective schools, where the teachers discussed about their lesson planning and reflected on their experiences from teaching some modules of the designed curriculum. I participated in these meetings, providing explanations about the rationale of the materials, as I was a member of the team that developed the curriculum. I was also discussing their reflections provoking their explanations about the rationale of their choices. In this paper, I refer to two reflection groups, one of five teachers working in school A and one of two teachers working in school B.

School A is an experimental school with an innovative spirit. Our focus here is on the teaching decisions of two teachers, Marina and Linda. They both have more than 25 years of teaching experience and additional qualifications beyond their teacher certification, as Marina has a masters' degree in mathematics and Linda has one in mathematics education. They both have experiences with innovative teaching approaches and both have strong views about their instructional choices and a critical stance on teaching innovations and materials introduced by various agents.

School B is a normal school with a culture open to innovations. Peter, the teacher in focus, is teaching in public schools about 15 years. Before this, he was teaching in private education preparing students for examinations. Peter is assistant principal of the school, he attends master studies in education and he is educator preparing teachers to use digital tools in teaching mathematics. He is open to the new curriculum, but he bases his teaching on the old textbooks. In the year of the study Peter is questioning the teaching practices he was involved for many years.

The data material consists of transcriptions of audiotaped group discussions and interviews conducted with each teacher in the beginning of the study and six months after the end of the group meetings. The transcriptions were analysed with methods inspired by grounded theory (Charmaz, 2006). The initial open coding resulted in the identification of the discussion themes for each meeting and the corresponding contradictions that emerged in the context of enacting the curriculum. Seeking an understanding of these emerging contradictions I used AT which provided me a lens to study them and a language to discuss about their dialectical nature, integrating social, cultural and historical aspects. Analysing the ways teachers decide to deal with contradictions, I traced shifts in teachers' discourse across different meetings and interviews and I used AT and the relevant literature to interpret these decisions and the factors influencing them. In this paper I focus on the part of my analysis concerning the relations between the action based decision making and the future oriented envisioning, and the potential of transforming the teaching activity.

## Results

Below I present two examples selected as illustrative cases for the relations of action based decisions and future oriented envisioning. In the first one, Marina and Linda make contrasting decisions, both addressing their perspectives about their students' learning. In the second one, Peter makes action based decisions without a clear articulation of his envisioning about his students' learning.

### **First example: teaching congruence involving geometrical transformations**

Geometrical transformations are introduced as a distinct topic in the new curriculum with the rationale of supporting students' development of spatial sense and of using transformations when tackling issues of congruence and similarity. The use of transformations as a proving tool is an alternative to the Euclidean perspective in school geometry: the intuitive use of the moving figure is seen as incompatible with the rigorous deductive rationale of Euclidean geometry. This contradiction between the two proving tools is a manifestation of the dialectical opposition between intuition and logic. In Stouraitis (2016) I discuss in details the two contrasting ways Marina and Linda deal with this contradiction in the discussions in school A. Below, I briefly describe their decisions to highlight the different future-oriented envisioning they hold for the object of activity.

In the fourth meeting (A4), Marina discusses her thoughts to use geometrical transformations in teaching triangle congruence in grade 9. She considers using tasks with geometrical transformations in parallel to or in combination with criteria of triangle congruence. She describes her goal saying "I want them [the students] to understand that when we compare angles or segments, we have two tools. One is transformations and the other is the criteria of triangle congruence". On the other hand, although Linda appreciates Marina's approach as a "nice idea", she prefers not to intertwine the two topics. She refers to "the purpose [students] to learn how to write [a justification], to observe the shape, to distinguish the given data from the required claims, to make conclusions, and to prove", implying that these goals can be achieved through teaching congruence with a Euclidean perspective, without involving transformations. Although Marina's response is that the same goals are relevant in every geometrical topic, Linda states that in teaching congruence she wants to focus on Euclidean geometry and not transformations.

In next meetings (A5, A6) Marina describes how her students work with both geometrical transformations and congruence of triangles, discussing also emerging epistemological issues. She explains her decision as creating an "opportunity to change the framework [of proving] in grade 9" and to "get away from Euclidean geometry". Linda contributes to the discussion with her opinion and ideas, but she does not change her decisions. In other meetings, Marina mentions a seminar on transformations she attended three years ago in the university and her experimental teaching of transformations in a school she was previously working.

Analyzing Marina's and Linda's decisions across Engeström's (2001b) four dimensions, I conclude (Stouraitis, 2016) that, although Linda and Marina share similar experiences and perspectives and participate in the same school community and in the same reflection group, there are significant differences between the goals they set, the decisions they make and, consequently, the actions they undertake. Marina appears more fluent with the mathematics of geometrical transformations to use them as a proving tool alternative to Euclidean geometry, and this may possibly and in part be explained by her involvement in past activities like the seminar on transformations and her experimental teachings. Linda has not such experiences. Moreover, her goals are based on the affordances of the Euclidean perspective.

Focusing on the possibilities their decisions have to shape the future of teaching activity, I look at the way the teachers envision the future of their students learning. All the aforementioned extracts of Marina's discourse reveal a future-oriented envisioning of the object of the activity she is

engaged in: she imagines her students working fluently with both approaches and consciously about the differences between them and she notes their development in this direction. In the interview conducted in the next year, Marina says that she uses the same approach, with more elaborated tasks for her students. Like Marina's envisioning, Linda is showing her motive in the relevant extract: she imagines her students in the future to work having developed understandings and proving abilities based on Euclidean perspective in school geometry.

### **Second example: the use of modelling in teaching algebra**

The new curriculum materials recommend mathematical modelling as an important aspect in students meaning making in algebra. Generating algebraic expressions and equations to represent realistic situations and problems is introduced in grades 7th, 8th and 9th. In group discussions about teaching polynomials in grade 9, a common contradiction was about introducing polynomials and operations in a formal, abstract way or involving realistic situations and modelling procedures. This contradiction is a manifestation of the dialectical opposition between the abstract and the concrete. Below I describe Peter's dealing with this contradiction as appeared in group discussions of school B with Manolis (Peter's colleague) and the researcher.

In the 3<sup>rd</sup> meeting (B3) Peter describes his introductory lesson of monomials using only definitions, examples and counterexamples. He says "we begin with the algebraic expression, they [the students] read the definition, and I give them examples to discuss ... then to monomials [with the same way]". After researcher's and Manolis' questioning about the "why" of teaching polynomials, Peter refers to a similar student's question. He is reflecting that "he begins with the definitions", but "we must pay more attention ... to the practical use of monomials". Again in the discussion with Manolis and the researcher about modelling, Peter starts thinking the potentials of it. After some turns, he says that he likes the word "modelling" because "it shows exactly what we are doing: we transform real situations to mathematics, verbal expressions to mathematical ones". With modelling "you give [the students] a motive, a goal. Ok, you must first pose the problem to create questions"

Although Peter finds modelling a useful idea, he is involved in a discourse emphasizing the role of mathematics and his own teaching but not the deliberate students' development. For example, he describes what "he did" and what he "usually does", and that modelling is what "we do in mathematics". In this discourse, no explicit or implicit longitudinal objective appears related to the way his students should deal with modelling. This can be interpreted as absence of any clear articulation of his future-oriented envisioning that could lead his decisions.

In another meeting (B7), Peter refers to classroom discussions about functions where students and teacher modelled realistic situations and phenomena (mostly from physics) leading to linear and quadratic functions. He says that his goal is "[the students] to understand that a function shows a relation between two interdependent things. And that everything is a potential function". These formulations reveal Peter's future-oriented envisioning about students understanding of functions and connecting them to realistic situations and also physics. But again, there is not any similar envisioning about students' work on modelling per se. The modelling processes Peter involved in classroom discussions were limited at the level of actions subordinated to his teaching of functions.

In the interview conducted in the next year, the researcher asked Peter if he uses modelling in teaching polynomials this year. Peter responded that although he thinks it is useful and keeps it in

mind, he “hasn’t the time to do all this”. This response shows that there is not any movement in the way Peter carries out the teaching activity about modelling.

Peter's adoption of the idea of modeling in teaching polynomials and functions can be interpreted as adoption of elements introduced by the new curriculum, based on Peter's reflection about teaching and on the group discussions with Manolis and the researcher. But this adoption did not give rise to actions involving students in modeling procedures, especially in teaching polynomials. Peter's previous involvement in practices, like preparing students for examinations in the private education, seem to have strong influence on his decisions. Moreover, his decision about modelling had not any systemic influence on the teaching activity, since it was not connected with future oriented actions.

## Discussion and conclusion

The introduction of the new curriculum created or revealed contradictions that provide opportunities for teachers to engage differently in mathematics teaching and learning. The analysis exemplifies these opportunities and the teachers' decisions to make or not shifts in their teaching.

In both provided examples, all three teachers seem to be aware of a contradiction of the introduction of the new curriculum. Marina and Linda appear to be more consciously aware of its epistemological and dialectical nature. Peter also shows an understanding of some aspects of the relevant contradiction. Teachers' awareness of the contradiction is the necessary but insufficient driving force for the development of the teaching activity. From this point, teachers' decisions can lead to one or the other direction.

On the contrary of "traditional views [that] locate decision making in the heads of individuals at a given point of time in a particular place" (Engeström, 2001b, p. 282), searching, under an activity theoretical view, what makes teachers to set goals and what creates the horizon for possible actions, contributes to our understanding of teachers' decisions. Although activity is collective and the object is socially formulated, different teachers can have "different positions and histories and thus different angles or perspectives on their shared general object" (Engeström, 2001b, p. 286). In the first example provided in this paper, Marina and Linda make different decisions about the same contradiction. The difference may in part be explained by their different histories, including Marina's attending of the seminar and her experimental teachings. In the second example, Peter's decision seems to be influenced by his previous activities in the private education sector.

In the two provided examples three possibilities appear for teachers' decisions and the way these decisions may or may not influence the future of the activity. Marina's decision to combine geometrical transformations with Euclidean geometry is an attempt to overcome the contradiction synthesizing dialectically the opposing poles. On the other hand, Linda decides to keep the two opposing poles separated, pursuing the affordances of Euclidean geometry. Somehow in the middle, Peter decides to deal with the contradictions using aspects of modelling in teaching functions, but not to use modelling as meaning-making introductory activity in polynomials.

Marina's decision has the potential to transform the teaching activity, broadening the horizon of the possible modes this activity is carried out. The dialectical overcoming of the contradiction is a discrete individual innovation, although its evolvement is not already known. Linda's approach does not transform the activity, but clarifies and strengthens some objectives of teaching Euclidean

geometry. Linda's decision reinforces aspects of the existing way activity is carried out, showing that every learning is not necessarily expansive (Engeström, Engeström, & Kerosuo, 2003). Peter's decisions have not any shifting effect to the way the activity is carried out, neither reinforce any existing practice. Somehow this decision seems to have not the power to affect the activity.

What is the difference between Marina's and Linda's decisions on the one hand, and Peter's decision on the other, that provide the different power on them? The difference could not be the attempt to overcome or not the contradiction, since Marina's and Linda's decisions differ at this point although both are strong enough to have an effect on the teaching activity. The difference is grounded on the connections made between action-based decisions and future-oriented envisioning of the object. Marina and Linda underpin their decisions about the actions they undertake with a strong future-oriented projection of their students' understanding. This adds fluency in deciding among the possible actions realizing the relevant goals. At the same time it generates decisions with the potential to be stabilized, even if initially the stabilization refers only to individual modes of carrying out the activity. On the other hand, Peter's decisions seem to be restricted to action level, without a grounding on future envisioning of the object, namely the deliberate modelling processes his students should be able to involve as outcome of the sequential actions undertaken. The absence of future-orientation restricts the horizon of possible actions and reduces the potentiality of stabilizing them. Our conclusions appear in line with Engeström, Engeström, & Kerosuo (2003) who, researching developmental work in the health sector, write that "professionals make history in future-oriented discursive actions" (p. 286) and "to overcome the gap between action and imagination in history-making, it may be necessary to bring them closer to one another" (p. 305).

Summing up, one can argue that for decisions to affect the activity the following elements seem to be necessary: the emergence of a contradiction and some degree of awareness about it, a willingness to deal with it and a future-oriented envisioning about the outcomes of the activity. If there is to have a transformation of the activity, the decision must aim to a dialectical overcoming of the contradiction by searching new solutions. Although schematic and perhaps simplistic, this sequence may represent some crucial aspects of decision making, especially the relations between action-based decisions and the future of the activity.

Our developmental intervention was not designed on an AT basis. However, based on AT, our analysis traces aspects of the path leading from the contradiction to the transformation of the teaching activity. In this analysis, AT seems to offer two particularly important aspects. Firstly, the four dimensions capture social and historical aspects of teachers' decisions, which is critical in our interpretations. Secondly, the distinction between action-based decisions and future oriented envisioning, provides a lens to interpret the possible power of teachers' decisions. The not-predetermined nature of the intervention might be seen to provide the analysis with a potential to interpret more naturally some snapshots of the trajectory of transforming the teaching activity. More research could be useful for a more holistic, but also detailed view of this trajectory.

# A commognitive lens to study pre-service teachers' teaching in the context of achieving a goal of ambitious mathematics teaching

Gry Anette Tuset

Western Norway University of Applied Sciences, Norway; [gry.tuset@hvl.no](mailto:gry.tuset@hvl.no)

*This paper investigates how Sfard's (2008) commognitive framework might inform the investigation of pre-service teachers' (PSTs') teaching in the context of achieving a goal of ambitious mathematics (AM) teaching. In particular, I will show how the commognitive framework can be used to foreground the mathematical talk when analyzing qualities in PSTs' attempts in forms of opportunities and needs created and exploited. I use the commognitive framework and especially the distinction between rituals and explorations to conceptualize qualities of PSTs' attempts at AM teaching on two levels. The first level points to PSTs' use of teaching tools provided in a teacher education program in Norway to support AM teaching. The second level points to characteristics of the mathematical discourses manifested in the attempts of PSTs to utilize these tools. On both levels I investigate students' opportunities for explorations.*

*Keywords: Teacher education, mathematics teaching, commognitive framework, geometry.*

## Preparing for ambitious mathematics teaching

Over 25 years ago, Lampert (1990) described a possible approach to bring the practice of knowing mathematics in school classes closer to what it means to know mathematics within the discipline. Her vision is in contrast to what is viewed in most classrooms, where doing mathematics means following the rules laid down by the teacher; knowing mathematics means remembering and applying the correct rule when the teacher asks a question; and mathematical truth is determined when the answer is ratified by the teacher (Lampert, 1990, p. 32). Sfard (2017, p. 125) calls this memorized-symbolic-manipulation type of activity *ritualized* participation in a mathematical discourse. Such participation is connected to ritualized instruction and it is characterized as performance for the sake of connecting with or pleasing others (Heyd-Metzuyanim & Graven, 2016).

The term *ambitious* is used by Lampert, Beasley, Ghousseini, Kazemi, and Franke (2010, p. 129) to distinguish this kind of classroom discourse from a classroom discourse that is more aligned with Lampert's vision. They define the work teachers need to do to manage the complicated interactions between the teacher, the students, and the mathematics in classroom environments as *ambitious mathematics teaching* (AM teaching). The most important and challenging work of AM teaching is allowing students to exercise authority for mathematical ideas while staying accountable to the discipline (Lampert et al., 2010). Students are expected to participate in a discourse in which they strive to learn more about the mathematics involved. Such activities are called by Sfard (2008) *explorative* participation in mathematical discourse, in contrast to ritual participation. Explorative participation is connected to explorative instruction and is characterized as performance for its own sake (Heyd-Metzuyanim, Smith, Bill, & Resnick, 2016).

In a practice-based teacher education program in Norway, pre-service teachers (PSTs) were provided among others the following teaching tools to support their attempts in AM teaching: A set

of talk moves to increase the mathematical talk in the classroom (Chapin, O’Conner, & Anderson, 2009), and some screen manipulable shape-making quadrilaterals constructed in GeoGebra with the potential to develop more sophisticated geometrical discourses (e.g., Sinclair & Moss, 2012). The figures (e.g., squares, rectangles, rhombi, and parallelograms) are constructed to hold certain properties of the diagonals (see Figure 1).

**Figure 1: Four of the seven shape-making quadrilaterals**

It is within the context of this teacher education program that I study the mathematical talk, the extent to which it becomes explicit for the students through the PST’s use of the provided teaching tools, and how this affects student’s opportunities to participate in the discussion. I explore Sfard’s commognitive framework regarding these relations because of the comprehensive set of conceptual tools it provides for capturing both mathematical discourses and social participation patterns (e.g., Heyd-Metzuyanim & Graven, 2016; Sfard, 2017). This paper is a contribution to the general need to develop analytical approaches for conceptualizing and analyzing interactional and content-related aspects of classroom discourse (Sfard, 2008).

In the following, I will first briefly outline key concepts from the commognitive framework and report how they are used to conceptualize qualities of PST’s attempts at AM teaching in discursive terms. Finally, I will show how the analytical framework is used to foreground the mathematical talk when analyzing qualities in one PST’s attempt in the form of opportunities and needs created and exploited. The PST is named Andy and he is in his second semester studying mathematics in a Norwegian teacher education program for lower secondary school. He leads a classroom discussion about quadrilaterals in ninth grade (14–15 years). This is his first attempt to lead a classroom discussion in the context of achieving a goal of AM teaching.

## Analytical framework

Sfard’s (2008) *commognitive* framework is rooted in the claim that *thinking* is a form of communication and that mathematics is defined as a *discourse* where *mathematical objects* are abstract discursive objects. *Discourse* is a special type of communication, set apart by its objects (*word use*), all kinds of mediators created and acted on for the sake of communication (*visual mediators*), a set of meta-level rules followed by the participants (*routines*), and the outcomes of their processes (*endorsed narratives*) produced within the *community of the discourse* (Sfard, 2008, p. 93). Sfard does not explicitly define teaching. However, she talks about ways teachers can provide opportunities for different kind of mathematics learning and participation through their communicational activities (Sfard, 2017, p.44). In AM teaching the communicational activities aim to bring students’ mathematical discourses closer to disciplinary mathematical discourses in such a way that they are able to participate in an explorative way.

Sfard (2017, p. 45) describes distinctions between ritual and explorative mathematical discourses when she talks about the historically established mathematical discourses we aim at in schools. I use the work of Wang (2016) and Sinclair & Moss (2012) in redefining and refining van Hiele’s levels

of geometric thinking into discursive terms to make distinctions between ritualized and explorative geometrical discourses. In ritualized discourses (levels 1 and 2) a “square” is often used as a proper name on a concrete thing or a family name of disjoint discursive objects. Thus, in ritualized discourses it is difficult to call a shape by a different name, because names represent different families. In contrast, mathematical definitions guide the use of the name “square” in object-driven explorative discourses (levels 3 and 4). A shape can be called by several names if it has the necessary and sufficient properties described in several definitions. A characteristic in explorative discourses is therefore the possibility of hierarchic classification by definition. The identification routines are also different in the two discourses. In explorative discourses, one strives to use definitions as criteria to identify geometric figures instead of direct visual recognition or just checking some partial properties. In ritualized discourses, there is often no need for substantiation routines, because claims seem to be self-evident. If they are not, one tends to use the concreteness of the figures to endorse the narrative, for example, by using measuring and dragging routines to check and verify the sides and angles in a figure constructed in GeoGebra. In contrast, explorative discourses emphasize deductive reasoning to substantiate the endorsement of a narrative by using previously endorsed narratives. The more ritualized checking routines are still used, but mainly to modify the justifications. Engagement in explorative geometrical discourses can therefore be related to qualities in AM teaching.

Supporting transitions from ritualized to explorative geometrical discourses is central in AM teaching. It involves what Sfard (2008) calls *meta-level development*, so called because the meta-level rules change. The inevitable point of departure for meta-level development is imitation of the moves of an expert discursant (Sfard, 2017). If everything goes well, the participation will gradually become explorative. However, this transition is demanding for the students and for the teacher. According to Sfard (2017, p. 44), there are two ways in which the teacher can support such transitions. The first way is to take leadership in the new discourse in appropriate learning-teaching situations and model how words are used and what routines count as acceptable within the new discourse. For example, the teacher may demonstrate the use of definitions as a way to enhance direct visual recognition in appropriate situations (Sfard, 2008, p. 254). In order to succeed, the students need to show confidence in the expert, be willing to take the role of the learner, and make changes that bring them closer to explorative geometrical discourses. The second way is to explicitly encourage the desired discourse by using appropriate teaching moves. In order to succeed, the teacher needs to elicit contributions from the students to identify and analyze their geometrical discourses up against ritualized and explorative discourses. Then, the teacher must respond in such a way that students become aware of possible differences in the use of words and routines. In addition, the teacher may expose them to situations in which their discourses would prove insufficient and support them in the process of understanding the advantages of the new way of doing or saying things instead of the method with which they have been so familiar. For example, students may drag the shape-making figures, creating opportunities to widen the range of shapes students are ready to call the *same* (Sinclair & Moss, 2012).

The provided teaching tools have the potential to take into account the complexity of the goals in AM teaching and support such transitions (Lampert et al., 2010; Sinclair & Moss, 2012). However, the choice of appropriate teaching tools involves more than just the use of a tool. It involves making judgments about when and where it is appropriate to use the tool. The PST’s use of the provided

teaching tools could therefore be characterized as ritualized or explorative (Heyd-Metzuyanim et al., 2016). A ritual performer would be concerned about how to proceed when a specific tool has been chosen (Nachlieli & Katz, submitted). The use is often rigidly defined and dependent on others' decisions in order to achieve social goals. For example, talk moves may be used to reward ritual participation as appropriate behavior, or they may be used to follow a prescribed list of possible properties of diagonals regardless of students' responses. In contrast, an explorative performer is concerned about choosing the appropriate tool in order to achieve her intended goal (Nachlieli & Katz, submitted). For example, she may use the shape-making figures to create situations for potential explorations or use talk moves to explicitly support transitions from ritualized to explorative geometrical discourse. PST's explorative use of these teaching tools can therefore be related to qualities regarding AM teaching.

It is important to stress that the distinction between ritual and exploration is not a categorization of students' participation or PST's use of teaching tools as such. It is meant to serve as a way to better understand qualities in PSTs' attempts at AM teaching in learning-teaching situations. In this paper, I explore how the use of this distinction points to the different qualities of PST's attempts at AM teaching; the characteristics of ritualized and explorative geometrical discourses; students' opportunities for ritualized and explorative participation in these geometrical discourses; and PST's ritualized and explorative use of the provided teaching tools to create and exploit these opportunities.

### **An investigation of Andy's attempt**

In this paper, I use the transcription of a video recording of Andy leading a ninth-grade classroom discussion about quadrilaterals. I use it to show how the analytical framework informs the investigation of qualities in PSTs' attempts at AM teaching. I also present findings from a three-tiered analysis design.

**Tier 1:** The transcription was first organized into mathematical episodes in which Andy and students discuss an endorsable mathematical narrative as a claim about one of the shape-making figures or a relation between them. Each episode encompasses the whole discussion around one claim, including the routines of construction and substantiation. I chose Andy's attempt out of four PSTs' discussions because of the nature of the claims in the ten identified mathematical episodes. In episodes 1, 2, 3, 7, and 9, the talk is mainly about identifying and describing potential properties of the shape-making figures. However, in episodes 4 and 8, Andy challenges students to explain how necessary conditions are linked to the naming process (e.g., "Is this (perpendicular diagonals) one thing that needs to hold for it to be a square?" [48]). In episode 5 a student identifies figure B in Figure 1 as a rectangle and Andy prompts the student for further explanations ("Why is it a rectangle?" [75]). Andy also challenges students in episodes 6 and 10 to extend their thinking about the possibility of a figure having several names (e.g., "But, here (figure A in Figure 1) are two and two sides equal as well (5s). Is it a rectangle too?" [85]).

These examples show that Andy's use of the provided talk moves (see Table 1) managed to create several opportunities for explorative participation in a geometrical discourse. The examples also revealed teaching-learning situations where Andy was given opportunities to support transitions from ritualized to explorative geometrical discourses. Understanding whether these opportunities

were exploited requires further investigation. The mathematical episodes were therefore examined qualitatively using the analytical framework on two levels described in tiers 2 and 3 and inspired by the work of Heyd-Metzuyanim et al. (2016).

**Tier 2:** The first level points to Andy's use of teaching tools and the opportunities created and exploited for students' participation. I separated Andy's and students' talk and coded their talk moves on a turn-by-turn basis. I used a modified coding scheme based on the set of teacher's talk moves provided by Chapin et al. (2009) and created codes for students' talk (see Table 1).

Andy's talk moves	Say more	Revoice	Repeat	Press for reasoning	Challenge	Agree/Disagree	Add more
	14	2	7	1	6	1	6
Students' talk	Narrative	Justify	Explain	Judge	Repeat	Clarify	Question
	6	6	4	18	5	3	3

**Table 1: The amount of talk moves used by Andy and students' talk**

Table 1 presents an overview of the amount of talk moves used by Andy and students' contributions. The findings show that Andy makes use of the recommended talk moves to promote student engagement in the leading geometrical discourse and in relation to each other's contributions. The table also shows that students contributed to the geometrical discourse by constructing geometrical endorsable narratives (e.g., "It is a rectangle" [74]). They tried to verify narratives (e.g., "Because two of the sides are longer than the other two" [76]) and they contributed further explanations (e.g., "Yes, but all sides are equal there...In a rectangle there are only two and two equal sides" [88]). It is difficult to determine whether students' intentions were to produce new mathematical narratives for their own sake or to please Andy. However, they show examples of explorative use of talk moves. However, the amount of talk moves did not provide answers concerning whether and how Andy's use of talk moves supported students in the meta-level development towards explorative geometrical discourses.

**Tier 3:** The second level of analysis therefore points to opportunities and needs created and exploited for students to engage in explorative geometrical discourses. I screened the episodes for signs of ritualized and explorative geometrical discourses in the forms of word use and routines. The aim was to identify appropriate learning-teaching situations for meta-level development. I then investigated Andy's use of teaching tools in these situations in order to study how their use supported students in their transitions.

Due to limited space, I present an analysis of one episode regarding a more detailed investigation of the geometrical discourse and PST's use of talk-moves. In episode 1, Andy starts to drag figure A in Figure 1 and asks if anyone has something to say about the shape-making figure on the smartboard.

- 1 Andy: We start with figure A (2s). Does anyone want to say something about figure A? (4s) Yes? (*Andy points at a student who has her hand up.*)
- 2 Student: The sides are always of equal length
- 3 Andy: The sides are always longer (.) of equal length?
- 4 Student: Mmm.

- 5 Andy: Yes (2s), can you explain why they are of equal length?
- 6 Student: Because it is a square.
- 7 Andy: Yes?
- 8 Student: And if you change the size, the sides will change. They are still of equal length.
- 9 Andy: Yes (2s), it is said it is a square. All sides are of equal length; therefore, it is a square. All sides are equal because (*Andy is waving his arm at the figure on the smartboard*) (4s) Does anybody disagree? Does anybody have anything else? (4s) Let's look at the diagonals (*Andy points at figure 1 on the smartboard*), the ones which intersect. We have four criteria here (*he removes the figures and puts a scheme up on the smartboard*). Now you have the figures on your computers, OK? What do you think? (5s) Can anyone repeat what has been said? (4s) (*Andy points at some students in the back.*) You in the back.
- 10 Student: Oh OK, yes, it is a square=
- 11 Andy: =Square, yes=
- 12 Student: =and all sides are equal
- 13 Andy: Yes? What do you want to say? (*Andy points at a student*)

Andy invites the students to participate in the discussion with an open question [1]. One student contributes with an identifying narrative about the length of the sides [2]. The student has therefore created an opportunity to discuss variant and invariant properties in figure A. Andy exploits the opportunity and prompts for an endorsement by asking why ("say more") [5]. Instead of relying on immediate visual recognition, the student provides the justification "because it is a square" [6]. The use of "it" refers to the concreteness of the figure on the smartboard. The identifying narrative "it is a square" [6] has not been previously endorsed by the use of definitions. It is established by the student as something that is already known. The student provides a correct deductive inference: If figure A is a square, then the sides are of equal length. Andy signals that he wants her to "say more" by asking "yes?" [7]. The student supports her justification by explaining a more ritualized checking routine [8]. The student draws on ritualized routines but her contributions also show explorative characteristics in the ritualized discourse.

This is a teaching-learning situation in which Andy has the opportunity to either demonstrate how definitions are used in explorative discourses or choose appropriate teaching tools to create a situation in which the suggested routines prove to be insufficient. Instead, Andy confirms the narrative "it is a square" [9]. He then restates the construction of the narrative suggested by the student but changes the premise and conclusion [9]. His deductive inference is: If all sides in figure A are of equal length, then figure A is a square. This endorsement would not have been accepted in explorative discourses because equal sides are not sufficient properties to define a square. Andy starts to explain why the lengths of the sides are equal, but he stops talking and waves his arms without touching the smartboard [9]. In this situation Andy shifts from being an explorative user of talk moves to a ritual user. Instead of trying to solve the problem or cope with the difficulties within the geometrical discourse, he chooses talk moves that help him to redirect the discussion in order to go on. In this situation, Andy uses "disagree" ("Does anybody disagree?") and "add more" ("Does anybody have anything else?"). The students do not respond. He then redirects the talk towards the

properties of the diagonals. He then uses “repeat” (“Can anyone repeat what has been said?”) to activate the students. The student repeats what is said without adding anything new [10], [12]. Andy invites another student to participate (“add on”) and the talk shifts to the properties of the diagonals. Thus, the opportunities that were given for students shifted from explorative to ritual participation in the geometrical discourse.

This analysis shows how Andy struggles to respond appropriately when he has created opportunities for students to participate exploratively in the geometrical discourse. The analysis of the other episodes revealed similar patterns. Andy manages to make use of the shape-making figures and talk moves to create opportunities and needs for explorative participation, which are important qualities in AM teaching. However, he struggles to stay accountable to the discipline and take leadership in the explorative geometrical discourse when needed. Instead of exploiting the teaching-learning situations to engage students in explorative geometrical discourses, he tends to use the provided talk moves such as “repeat,” “agree/disagree,” and “add more” as shortcuts to overcome the difficulties and keep the discussion going. In these situations, Andy’s use of talk moves shifts from explorative to ritualized, which affects the students’ opportunities to participate in the geometrical discourse. Even more importantly, students were not offered the necessary opportunities to engage ritually or in an explorative way in the explorative geometrical discourse in order to modify their thinking and bring them closer to accepted ideas of the discipline. Without knowing it, they were stuck in a ritualized geometrical discourse (Sfard, 2017).

### Some concluding remarks

AM teaching is characterized by its deliberately responsive and disciplinary-connected instruction which complicates interactional and content-related aspects of classroom discourse (Lampert et al. 2010). The purpose of this paper was to show how the commognitive framework and particularly the distinction between rituals and explorations foreground the mathematical talk when investigating qualities of PST’s attempts at AM teaching. Analyzing the mathematical episodes and the amount of talk moves helped to uncover qualities regarding students’ opportunities for explorative participation in the PSTs’ teaching attempts. Students’ talk provided some evidence of students’ uptake of these opportunities. However, it was the more detailed analysis of the geometrical discourses in the episodes that revealed if and how the PST’s use of talk moves provided opportunities for participation in explorative discourses.

The analysis of Andy’s attempt in AM teaching uncovers just some of the complexity that a PST must attend to in the challenging moment-by-moment interactions with students and mathematical discourses. It also shows the critical need for teacher education programs to provide PSTs with opportunities to learn and reflect upon their use of potentially powerful teaching tools in such learning-teaching situations. Sfard (2008, p. 223) argues that if one only focuses on how a teaching tool should be performed and neglects the question of *when* and *where* this performance is appropriate, it is most likely to result in ritualized rather than explorative participation.

*Our focus in this paper is on locating ways of working with teachers’ use of conventional example spaces to include a focus on structure, abstraction and generality in primary mathematics teaching in South Africa. We share the ways in which we have worked with trajectories of working with example spaces in two strands within our framework for analyzing teaching in terms of teachers: ‘mediating primary mathematics’. We discuss the ways in which this work with example spaces differs from previous writing where emphasis is placed on moving beyond conventional example spaces towards the realms of boundary examples. The ways in which attention to structure and generality might be retained in the context of conventional example spaces are discussed, with focus too on why this might be useful to do in a developing country context marked by very low mathematical performance.*

*Keywords: Example spaces, primary mathematics teaching, South Africa, mathematical discourse in instruction, generalization.*

### Introduction

The background for this paper rests upon two bodies of writing that are interpreted as pushing in somewhat opposite directions in relation to the kinds of examples that are in focus. The first evidence base is located in mathematics education writing on ‘example spaces’ (Watson & Mason, 2005). These authors, over nearly two decades now, have produced an extended evidence base arguing for learning to be seen in terms of extensions in the example space that students are able to work with and construct. On the pedagogic side, they have focused on both teacher-set example spaces (Watson & Mason, 2006a) and student-constructed example spaces based on prompting for ‘another example’ of something or ‘a different kind of example’ of something (Watson & Mason, 2005). In both teacher-set and student-constructed cases, the focus on example spaces is driven towards attention to the abstractions and generalizations inherent in the idea of ‘examplehood’ – the attributes that make an example an ‘example of’ some class or category. Goldenberg & Mason (2008) describe such attributes as critical ‘dimensions of possible variation’, and the extent to which variation in the dimensions of these attributes can allow students to see the boundaries or extents of application of properties or structure defines the ‘range of permissible variation’ in their terms. As Watson and Mason (2005) put it:

‘[Example] spaces can be explored by finding out what can vary and how far it can vary, identifying new variables, working from first principles, building objects from definitions, and using alternative modes of representation to see what is possible in one and relating it to another and in other ways.’ (p.52)

Within their work, critiques of pedagogy are directed towards what they see as the overemphasis on ‘conventional’ or ‘central’ examples that commonly contribute to unhelpful abstractions on the part of students – for example, that triangles are three-sided shapes with acute angles that have the base edge parallel to the bottom of the page, or multiplication only with positive integers. Instead, they call for a pedagogy in which there is encouragement for the construction of examples that extend students’ existing ‘boundaries’ through attending to dimensions of possible variation and range of permissible change, and focusing discussion on the ‘tipping points’ at which ‘examplehood’ appears to end. Illustrating this approach are tasks relating to questions such as ‘Can we multiply by a number and end up with an answer smaller than the one we started with?’ And ‘What kinds of numbers produce this result?’ Pedagogy in mathematics, in this formulation, is consistently directed towards tasks functioning in ways that expand the boundaries of the example spaces associated with particular ideas:

‘one of the important roles for tasks inviting learners to construct examples is to broaden their range of permissible change in the images they associate with concepts’ (Watson & Mason, 2005, p.56)

In this pedagogy, the emphasis is on the boundaries of example spaces related to the concept in focus – on what Askew & Wiliam (1995) describe as ‘only-just examples’ on the example side and ‘very nearly examples’ on the non-example side.

Sitting with somewhat different emphases to this attention on example spaces is a second body of work, located in developing country contexts, but with parallels in contexts of disadvantage in developed country contexts as well, that is focused on learner performance. In this narrative, there is extensive evidence of a lack even of limited forays towards success in the restricted purview of the conventional or central example spaces associated with key concepts. Pritchett & Beatty (2012), working in the policy terrain and overviewing mathematics (and reading) performance data across India, Pakistan, Uganda and Kenya, identify what they describe as almost ‘flat learning profiles’ when looking at mathematical performance in items across grades. For example, in a study carried out in one state in India, Pritchett & Beatty note that while just over half of Grade 2 children were able to correctly answer  $697+505$  presented as a vertical addition, less than 10% of Grade 5 children were able to correctly fill in the missing number in this horizontal equivalence sentence:  $200 + 85 + 400 = 600 + \underline{\hspace{1cm}}$ . Further, it was noted that performance on ‘mechanical’ procedures was generally higher than performance on even-low level conceptually oriented items, with one of the overviewed studies showing that less than 30% of a Grade 4 learner sample were able correctly answer the question:  $3 \times \underline{\hspace{1cm}} = 3+ 3+ 3+ 3$ .

What interests us here is that the examples identified in this latter body of work fall well within the realms of ‘conventional’ example spaces, with the ‘multiplication as repeated addition’ example above also possible to interpret as a ‘reference’ example (examples that ‘somehow contain information about a whole class of objects’, Watson & Mason, 2005, p.84).

While Watson & Mason's pedagogic approach emphasizes the need to focus on expanding students' example spaces, which are viewed as personal, and locally situated, these authors' exemplifications of ways of working with sets of examples point to a relatively fast skip beyond the conventional and central example spaces towards the boundary examples.

But why is this difference of emphasis of interest to us? We answer this question in the next section.

## Background

Our work over the last five years in South Africa has focused on primary mathematics knowledge and teaching development, set in the context of the Wits Maths Connect-Primary (WMC-P) research and development project, located in Johannesburg, and working in partnership with ten government primary schools. The South African primary teaching context is marked by an emphasis on oral, chorused responses to closed questions, weaknesses and gaps in the teacher knowledge base, and concerns related to coverage, connections & coherence, and pacing within primary mathematics teaching (Hoadley, 2012). The national context is one that is marked by low performance in mathematics at all phases, reflecting many of the concerns about limited progress and significant learning deficits raised by Pritchett & Beatty (2012). A key problem that has been widely written about in primary mathematics is the ongoing use of highly inefficient counting based methods for solving number problems well into the middle years (Fleisch, 2009).

In this context, we have worked on a combination of interventions aimed at supporting development in terms of both 'primary mathematics knowledge for teaching' and of primary mathematics teaching itself. Quasi-longitudinal data on learner performance in the early primary 'Foundation' years (Grades 1 -3) has pointed towards some improvements in early number learning, with broad evidence of moves from highly rudimentary 'count all' strategies used for early additive relations problems to the more efficient 'count on'/'count down' strategies underpinned by some initial reifications of number (Sfard, 2008). With interventions in place focused on working with teachers to develop number sense, our attention has started to turn towards working to understand whether, and, if so, how, changes in learning might be linked to changes at the level of teaching. We have found the work on example spaces, and seeing expansions in teachers' ways of working with example spaces useful for thinking about the changes in teaching that we have observed. But these explorations have focused firmly on the middle ground of conventional example spaces, rather than on the boundaries. In this sense, they are more aligned with supporting mathematical learning in the middle ground rather than at the boundaries of particular topic spaces, with the examples selected grounded in expanding the boundaries of personal and situated example spaces, rather than mathematical boundaries of concepts in any more disembodied, objective sense. Our considerations of changes in teaching have led to the development of a framework for exploring differences, focused on primary teachers 'mediating primary mathematics<sup>1</sup>' (MPM). Empirically, our attention within this framework centres on teachers' mediation of mathematics as enacted in the context of their selected example spaces across episodes in lessons through their use of artifacts, their inscriptions and their talk, with focus on the following strands:

- 1 Mediating with artifacts
- 2 Mediating with inscriptions

- 3 Mediating with talk & gesture in a) methods for generating/validating solutions; b) building mathematical connections; and c) building learning connections: explanations and evaluations of errors/ for efficiency/ with rationales for choices

The concepts and theories underlying the aspects in the MPM framework have been detailed in other writing (Venkat & Askew, under review). Expansions in teachers' personal, situated example spaces, as seen in observed lessons, feature within two key strands of our overall framework – 3a and 3b – and our attention in this paper is on detailing the ways in which expansions in example space are considered in relation to the two bodies of literature discussed at the start of this paper, with the illustration and discussion in this paper focused on our ways of thinking about expansions within these strands. We remain interested in the notions of abstraction and generalization that Mason (1989) has written about over an extended period of time, and have looked at ways of retaining a focus on these elements drawing from a base in highly conventional example spaces. Our illustrations of levels of mediation for structure and generality in these two strands draw from excerpts of teaching and teacher explanations seen across our work supporting teaching development in Foundation Phase classrooms, and also, in this paper (and for the purposes of exemplification of the levels), from teacher responses to tasks in our primary mathematics for teaching courses.

## Analytical discussion

### Strand 3a: Method for generating/ validating solution

We have formulated expansions in teaching related to this strand as follows:

	0	1	2	3
Method for generating/ validating solutions	No method or problematic generation/ validation  (Mixing of knowns and unknowns)	Singular method/validation  (provides a method that generates the immediate answer and can produce answers in the immediate example space)	Localized method/validation  (provides a method that can generate answers beyond the particular example space)	Generalized method/validation  (provides a strategy/method that can be generalized to both other example spaces AND without restriction to a particular artefact/inscription)

Our earlier work pointed to problems with the coherence of teachers' ways of generating solutions to the problems that they set in the context of their teaching or that were set to them in our mathematics knowledge for teaching courses. At the lower extreme, lack of coherence manifested itself in a range of ways. We saw the mixing of knowns and unknowns in teachers' solution processes, with unknowns sometimes drawn into the problem-solving process prior to their actual generation, and questioning sometimes treating 'knowns' as if they were unknowns. For example, we saw episodes where, in adding 10 to a number on a 100 chart, the teacher counted on from, e.g. 17, saying 18, 19, 20, etc, and stopping at 27, without any overt demonstration of keeping track of how many she had counted on. Knowledge of the answer – the unknown value – was assumed in this kind of working. There was also evidence of teacher talk that connected poorly with the artifacts and inscriptions in use during

the focal episode, disrupting possibilities for generating or validating a solution to the tasks in the example space being worked with.

In the middle ground of this strand, we focused on the extent of applicability of the methods that teachers communicated for solving problems in, and related to, the example space being worked with. An excerpt of teachers' responses to a task we used in our teacher development work helps us to illustrate some of the range in this strand. The question in focus was:

Is  $-8 < -5$ ? What diagrams and explanations might you use to help to explain your answer?

Almost all teachers from a group of 50 we were working with responded to this by drawing a number line and marking  $-8$  and  $-5$  in the correct positions on their number lines. The explanations linked to this inscription varied between two key justifications. Some stated that  $-8$  was less than  $-5$  because it was further away from 0, with many teachers marking 0 and annotating the two respective distances for the immediate example on their number lines. In some instances, this 'particular' statement was accompanied by more general statements like: 'Numbers further from 0 are smaller'.

Other teachers had annotated their number lines with the words: 'Further to the left, numbers are smaller. Further to the right, numbers are bigger.' The first formulation remains applicable if both (or all) of the numbers being compared are of the same sign, i.e. both negative or both positive, but is not necessarily true if the numbers under consideration have different signs. The latter statement, in contrast, is more generally true across the real number example space and the number line convention. We code the latter formulation as a Level 3 offering, but we still have questions about whether the first formulation should be coded as a Level 1 or Level 2 offering, and whether this should be interpreted in relation to the example space that is being worked with in the empirical terrain. If the example space only contains pairs of negative numbers, we could argue that while the method offered is 'localized' (in the sense that the method can also be applied to pairs of positive numbers as well), there are limitations in the example space that can be critiqued. The broader point remains valuable though: that it appears useful to think about teachers' offers of methods for solving or validating problems in relation to their extent of applicability to example spaces related to the concept in focus. Further, this appears important in a context of broad evidence of a lack of move beyond unit counting strategies – which we have usually coded at Level 1 due to their inefficiency for use as the number range being worked with increases.

In a sense, what we are focusing on in this strand relates to the range of permissible variation in the example space that can be managed within the constraints of the solution procedure that has been taught. This range is considered pragmatically rather than strictly mathematically: for example, at one level, even large additive relationship calculations can be carried out using the unit counting strategies that we have noted as prevalent. In practice though, such methods are both inefficient and error-prone, and therefore represent solution choices with pragmatic limitations as the number range increases. In larger number ranges, 'structured' representations of number – i.e. representations of number underpinned by properties and relations, offer much greater purchase for both range of applicability, and for flexible efficiency. While not the focus of this paper, we code 'structured' representations (representations underpinned by structural properties of number) more highly in the artifact and inscription strands than 'unstructured' representations of number. In the 3a strand, a focus on solution

procedures employing numerical structure provides an important feature within the possibility for attention to procedures with more extensive scope of applicability.

### **Strand 3b: Building mathematical connections**

Expansions in relation to building mathematical connections have been conceptualized as follows:

	0	1	2	3
Building mathematical connections	Disconnected and/or incoherent treatment of examples  OR  Oral recitation with no additional teacher talk	Every example treated from scratch	Connects between examples or artefacts/ inscriptions or episodes	Makes vertical and horizontal (or multiple) connections between examples/ artefacts/inscriptions / episodes

This strand was built into the framework on the basis of common evidence of disconnections. These disconnections sometimes occurred, as noted in the previous strand, within teachers' handling of examples, leading to incoherent explanations. Further, in our observations, and noted as prevalent in the broader South African landscape, is evidence of extensive chorused oral recitation, for example of skip counting in multiple sequences, with no input from the teacher. Both of these phenomena were coded at the lowest level of the building mathematical connections strand.

Example spaces figure within this strand in terms of the nature and extent of the connections between the examples seen. Watson & Mason (2006b) have described these kinds of connections in terms of vertical connections between elements of examples – which they describe as ‘going with the grain’ and horizontal connections within examples (e.g. equivalence structures within relationships) – described as ‘across the grain’ connections. Linked focus on several examples allows for attention to invariances amongst the variation between examples, with these invariances forming the grounds for abstraction and generalization. Keeping vertical and horizontal, and more generally, multiple connections between examples in focus, allowed us similarly to pay attention to shifts in the possibilities for building awareness of generality in pedagogic mediation.

Our way of attending to example spaces in this strand contrasts with our focus in the previous strand where the emphasis was on the extent of ‘reach’ into other examples and example spaces of the methods for solving problems that are communicated within the focal example space. At Level 1 of this scale, we placed episodes where examples within the focal example space were dealt with as individual and separate instances. Venkat & Naidoo (2012) describe an episode involving finding pairs of numbers adding to 16, where each offered pair is verified as correct by concrete unit counting, with very limited reference to any of the partitions that were established previously in the episode as correct. In this ‘extreme localization’ there is no opening for a focus on ‘examplehood’ as thinking about instances as ‘examples of’ some property necessarily requires some invoking of either other examples from which abstractions can occur, or juxtaposing the instance with the property or generalization or definition of which it is an instance. In our observations and analyses, we noted that

this invoking could occur through teachers making connections between examples in the example space as noted here, but could also occur more multi-directionally through connections made between artifacts, inscriptions and episodes as well. Importantly for us, this way of considering the possibilities for generality can, once again, be worked with in the context of conventional example spaces. Askew (2015) has analysed one teacher's ways of working with multi-directional connections in lesson episodes focused on early place value, noting her working with the example space as a connected set of instances with fluid vertical and horizontal links, as well as links to place value artifacts involving ten strips and unit squares, and the inclusion of symbolic inscriptions. While the teacher's working with the examples was entirely coherent, the conventional nature of the example space contrasts, for example, with Watson & Mason's (2006a) 'stretching' of what looks, initially, like a conventional example spaces (related to co-ordinate plotting to fractional values) in the context of a single exercise, as a key aspect of hypothesizing a generality related to a given constraint.

## Discussion

Working in this way with the concept of example spaces has allowed us to develop attention to structure and generality in somewhat different ways to those presented in Watson & Mason's writing. Specifically, the base for generalizations is located in conventional example spaces, with limited – if any – move towards boundary examples. We would acknowledge that concepts are less fully rounded out in this way of working. But we would also argue that these more mundane expansions are important to thinking about developing primary mathematics teaching in contexts of the flat learning profiles described in Pritchett & Beatty's overview. At the lower extremes of both of the strands we have delineated in this paper, there is attention to students being able to reproduce coherent procedures that have been presented or offered and accepted in class. This kind of move already represents some potential for forward moves in relation to students' existing problem-solving repertoires. Further moves upward in the strands discussed start bringing other example spaces into the realms of possibility for learners. Our early analyses show moves towards coherence and connection in teachers' work with example spaces, coupled with greater inclusion of structured artifacts and inscriptions. The concurrence of these fledgling moves towards coherence and generality in pedagogy with improvements in students' performance on conventional and central example spaces suggests that our ways of working with example spaces may be useful to carry further into our research and development activity.

<sup>1</sup> In previous writing developing this work, we have used the term 'Mathematical Discourse in Instruction – Primary', or MDI-P. The history of this work is a co-development of MDI frameworks between Hamsa Venkat and Jill Adler, that shared roots in socio-cultural theory but differed in specific formulations across work in secondary and primary mathematics. In order to avoid confusions between the secondary and primary level models, we have changed our titling of the framework to MPM. Writing with Adler and her team is underway, detailing the histories and trajectories of development of both MPM and MDI.

# Self-scaffolding students' problem solving: Testing an orientation basis

Joana Villalonga Pons<sup>1</sup> and Paul Andrews<sup>2</sup>

*It is known not only that young students have difficulty solving mathematical problems but also that appropriate scaffolding can support them in the process. In this paper we describe the development and pilot implementation of a device for self-scaffolding grade 6 Catalan students' mathematical problem solving. Called an orientation basis (OB), the OB, which addresses cognitive, metacognitive and affective aspects of problem solving, drew on research describing the actions of an expert problem solver. The evidence indicated that the OB, while in need of refinement, had a positive impact on the problem solving behaviours of many participant students.*

*Keywords: Mathematical problem solving, scaffolding, orientation basis, Catalonia.*

## Introduction

Mathematical problem solving is difficult, both for students (Mason, Stacey & Burton, 1982; Pólya, 1945) and teachers trying to create appropriately conducive classroom environments (De Corte & Verschaffel, 2004; Schoenfeld, 2013). When children solve problems without being conscious of the relationship between their actions and their solutions their ability to transfer their solution processes to new situations will be limited (Coltman, Petyaeva & Anghileri, 2002). However, appropriate adult intervention can help children become aware of these processes (Coltman et al., 2002). Such interventions, known as scaffolding, build on what learners already know in order to close the gap between current learner competence and task objective (Bruner, 1985; Greenfield, 1984; Wood, Bruner & Ross, 1976). Moreover, given time, scaffolding can be provided by peers and, ultimately, students themselves (Holton & Clarke, 2006). In this paper we describe the development and use of a device, which we have called an orientation base (OB), for use in Catalan sixth grade classrooms. The OB's role is to support the transition from where teachers scaffold learner's problem solving to where students scaffold their own.

## Problem solving

As a human activity, problem solving can be understood as an example of goal-directed behavior (Schoenfeld, 2007). It is a dynamic, but not necessarily linear, activity requiring the organization and activation of multiple skills and strategies (Mason et al., 1982; Pólya, 1945). At the heart of problem solving lies an appropriate mathematical knowledge, an awareness and experience of solution strategies, self-regulatory or metacognitive competence and a belief not only that the problem is worth solving but also that the solver can solve the problem (De Corte, Verschaffel & Op't Eynde, 2000; Schoenfeld, 2007, 2013).

A key aspect of the above, at least from the perspective of providing scaffolding for the learner, is the encouragement of students' metacognitive competence. For example, expert solvers spend more time understanding and analyzing the problem and solution process than calculating, and they continuously reflect on the state of the problem solving process (De Corte et al, 2000), behaviours that are typically absent with weak problem solvers (De Corte et al., 2004). Such students need

scaffolded support with respect to interpreting a task, identifying its sub-objectives and planning a strategy (De Corte et al., 2000; Mason et al., 1982). They need to learn how to reflect on their existing knowledge and thought processes; that is they need to learn how to evaluate and regulate their own thinking (Sanmartí, 2007). This regulative competence is not acquired automatically but emerges over time (De Corte et al., 2004). Thus, with support in understanding how things work, students can become more efficient and self-regulated problem solvers (Schoenfeld, 2013).

## **Scaffolding**

### **Scaffolding in an educational context**

Drawing on Bruner's (1975) initial observations with respect to the ways that parents scaffold their infants' learning, Wood, Bruner and Ross (1976) argued that knowledgeable adults can scaffold students' problem solving activity. Here, the adult seeks to reconcile implicit theories of the task components, the necessary steps to solution, and the child's capabilities (Stone, 1998). In this way, acknowledging a socially imitative process, six ways of assistance were differentiated; recruiting the child's interest, reducing the degrees of freedom, maintaining goal direction, highlighting critical task features, controlling frustration and modelling preferred solutions paths (Wood et al., 1976). Recent work has continued this theme, examining how teachers can best provide (temporary) support that enables learners to complete tasks they would otherwise not have been able to complete independently (Smit, van Eerde & Bakker, 2013; van de Pol, Volman & Beishuizen, 2010). In this process, whereby the learner becomes incrementally independently functional (Smit et al., 2013), both teacher and learner actively share and build common understanding (Stone, 1998; van de Pol et al., 2010).

### **Scaffolding strategies**

Scaffolding is not a 'technique' that can be applied in every situation in the same way (van de Pol et al., 2010). As in the construction industry, where each scaffold is unique to a specific building, learning scaffolding can be provided at different ages and in a variety of ways, addressing learners' knowledge gaps as part of an ongoing progress (Wood et al., 1976). Significantly, effective scaffolding is thought to comprise three components, involving the six processes of feeding back, giving hints, instructing, explaining, modelling and questioning (van de Pol et al., 2010), which are

- Contingency: Support should be adapted to the student's current level of performance.
- Fading: Support is gradually withdrawn over time.
- Transfer of responsibility: Task completion is gradually transferred to the learner.

Moreover, effective scaffolding not only promotes learners' cognitive and metacognitive activities but also positive affect. Finally, acknowledging different agents in the process, whether they are informed adults, a group of learners or the individual student, scaffolding is progressively relocated to the learner, whereby the external dialogue of scaffolding becomes the inner dialogue of metacognition (Holton & Clarke, 2006).

### **Orientation basis for problem solving**

One means of encouraging self-scaffolding of students' problem solving-related self-monitoring skills is to use an orientation basis (OB) (Sanmartí, 2007). Here we understand a problem solving-

related OB to be a necessary sequence of actions based on the problem solving behaviour of experts. An orientation basis leads the learner to a solution in ways that structure an emergent independence and problem solving autonomy. An OB is not a ‘one size fits all’ tool but tailored according to learners’ requirements and achievements. At every age and according to the learner’s needs, an OB can be presented through different statements.

Dimensions	Actions	Track
I understand the problem	A1. I have read the question twice, at least.	
	A2. I understand what the question wants.	
	A3. I have identified and understood the data.	
I devise a plan	A4. I have played with the data from the question.	
	A5. I have prepared a strategy.	
	A6. I have checked that my strategy fits the data.	
I apply my plan	A7. I have implemented my strategy.	
	A8. I have recorded all my actions in ways that I understand.	
	A9. I have recorded all my actions in ways others can understand.	
I review my task	A10. When I get stuck I go back to the beginning.	
	A11. When I have finished I have checked my answer(s).	
	A12. I have checked for other answers or better solutions.	

**Table 2: The orientation basis (OB)**

In this paper we discuss the development and implementation of an OB for grade 6 Catalan pupils. At this age, pupils are typically expected to have acquired a minimum background in problem solving. However, experience has shown that they lack regulative and problem solving competence, especially in understanding and analyzing the problem, and planning and implementing a solution process. Therefore, drawing on Pólya’s (1945) problem solving principles, the OB depicted in Table 2 was developed. Each of Pólya’s four dimensions comprised three particular actions, which can be tracked in the right hand column. The inclusion of each action was a consequence of earlier observations of the problem solving behaviours of grade 6 Catalan pupils and the problem solving strategies found in the literature (e.g. De Corte et al., 2004; Mason et al., 1982). The OB shown in Table 2, translated from the original Catalan, was designed to be a contingent, hint-giving, feedback tool focused on facilitating both fading and transfer of responsibility (van de Pol et al., 2010). As indicated above, the aim of this paper is to present an initial evaluation of the efficacy of the OB shown in Table 2 for scaffolding grade 6 students’ mathematical problem solving.

## The study

The participants were students in a 6<sup>th</sup>-grade class of a Barcelona primary school. Their teacher was an experienced generalist primary school teacher. Such teachers, who receive relatively little subject knowledge instruction during their pre-service education, typically acquire their mathematical knowledge in practice, a situation much criticised (Egido, 2011; MECD, 2012). Data were collected during a regular, 50 minute, lesson at the end of the second quarter of the academic year 2015-2016. They derived from 22 students’ initial use of the OB as they tried to solve the mathematical problem posed in Figure 1, which was originally posed in Catalan.

**Problem: My grandmother's blanket**

My grandmother is a crochet expert. She loves doing crochet blankets. I haven't seen yet the last one she made, but she told me how she did it: "I joined squared pieces. Their styles are different but all of them have the same size."

She explained me that the boundary of the blanket is made with a dozen of green squares with a white rhombus, and with a dozen of white pieces with green dots. She set them up alternately: one green piece with rhombus, one white piece with green dots,... and she managed so that in the four corners there is always a green dotted blank piece.

She also told me that the interior part of the blanket is really different. It is made with different coloured pieces, but all of them have the same size of the external ones.

So,

1. How could my grandma distribute the pieces to make the boundary of the blanket?  
Explain how you know it.
2. I wonder how many pieces she used to end the interior part of the blanket. How can I know it?

**Figure 1: The Problem translated from Catalan**

Before solving the problem, the teacher explained the purpose of the OB carefully and together with the class discussed and clarified the meaning and purpose of each element. This ensured, as far as is practicable, that students understood its vocabulary and overall purpose. Students were each given a copy of the OB's rubric, which included a grid in which they recorded their engagement with the OB as well as a paper copy of the problem on which their solution was to be written. Students were instructed to solve the problem, using the OB to guide their activity, and then record the OB actions they addressed. They were also told that their teacher would not intervene in the problem solving process but check, as they worked, that they completed their OB tracking.

## Results

Table 3 shows the data from all 22 students' use of the OB as they worked on the problem. It can be seen that only one student, Student 21, failed to engage with the OB, while all others used it in varying degrees. Nine students obtained correct solutions for both parts of the problem, a further five managed just one part and eight failed to complete either, including the one who failed to complete any OB actions. Four students indicated some difficulty with respect to understanding some OB actions. In this respect, all four found A3, 'I have identified and understood the data', difficult to understand. The only other action that caused uncertainty was A6, 'I have checked that my strategy fits the data'. Thus, in the light of an OB being necessarily adaptive (Sanmarti, 2007), these issues would be addressed in the next iteration of its development. Importantly, even when faced with uncertainty, each of these students was able to continue the problem solving process to at least the next step. Student 12, the only student who found two statements difficult, completed 11 of the OB's stages but failed to complete either part of the problem. Importantly, from the perspective of the OB's development, Student 9 completed all the OB's actions but failed to solve either part of the problem, pointing, perhaps, to the need of cognitive interviews to determine in depth the nature of the difficulties encountered in completing the task.

**Table 3: OB-related data for each student. An asterisk shows a difficult but completed OB action**

### Was the OB effective and did students take it seriously?

As is typical of classroom interventions, eliciting evidence of their efficacy and their being taken seriously is not straightforward. With respect to its efficacy, it is interesting to compare the number of completed OB actions with the number of completed problems, as shown in Table 4. A Fisher exact probability,  $p = 0.008$ , indicated not only that the figures of Table 4 were unlikely to have been due to chance but, importantly, that students who failed to complete the OB tended not to complete the tasks. Indeed, Table 4 shows that a necessary but not sufficient condition for the completion of both tasks was that students completed seven or more OB actions.

		Number of correct solutions		
		0	1	2
Completed OB activities	0-6	5	3	0
	7-12	3	2	9

**Table 4: Number of completed OB actions and number of successfully completed problems**

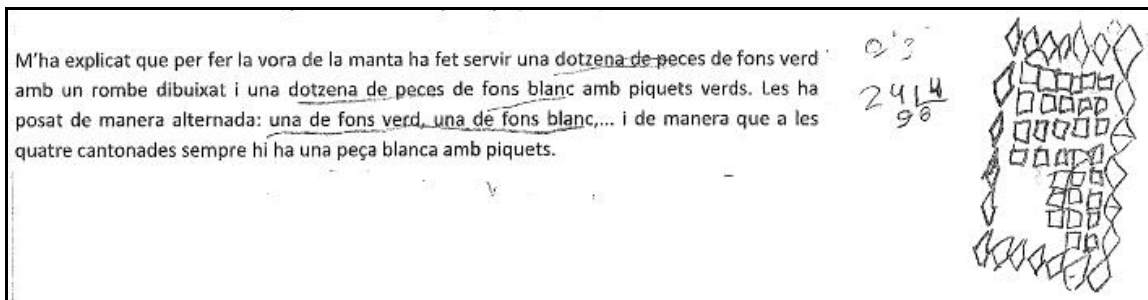

When viewed as four dimensions rather than as individual actions the data offer further interesting insights. For example, while probably not surprising, the data of Table 3 show that as they move down the OB, the number of students completing each dimension gets smaller. With respect to the first dimension, ‘I understand the problem’, 21 students began its three actions, of which 19 (90.5%) completed all three. With respect to the second dimension, 17 began with the first action, of whom 12 (70.6%) completed all three. The third dimension, ‘I apply my action plan’, was begun by 13 students (one more than completed the second dimension), of whom 9 (69%) completed the dimension. Finally, of the 12 students who began the final dimension, ‘I review my task’, 11 completed (91.7%) it. These figures tell two stories. The first is that students who begin working on a dimension can typically be expected to complete it. The second is that once they reach the final dimension students seem almost guaranteed to complete it. In other words, an in-depth examination of the four dimensions can also inform future developments of the OB; the first and last dimensions seem less problematic with high completion rates in comparison with the middle two.

Looking at the data qualitatively, it can be seen that students' solution attempts tended to show that they took the OB seriously. Students were able to connect OB actions to their own activity, and did not confirm those actions until after they had been completed.

**Figure 2: A solution of the problem and related OB tracking**

For example, Figure 2 shows a student solution and his OB tracking. The picture confirms that he had read the problem and understood what the first question required. For example, his arithmetical operations and note, 'on each side there are 6 squares', indicate not only that he had identified and understood the required data but that he had also played with the data which let him to prepare a strategy for the first part of the problem. In short, the solution the student presented corresponded with the OB actions he claimed to have completed.

**Figure 3: Solution of the pupil who failed to complete explicitly any OB action**

Even when students failed to complete any OB action, there was evidence of its having influenced their solution attempts. For example, Figure 3 shows how the single pupil who failed to complete any OB action attempted to address the OB's first action.

### Student response to the OB

Several students attempted to communicate with the OB, particularly when uncertain as to its intentions. Figure 4 shows, in the underlining of the word *quefer*, uncertainty as to its meaning and, essentially, an invitation for someone to explain. In similar vein, students annotated their OB in ways indicative of doubt or just a desire to comment on their response, both cognitively and affectively. Figure 5 shows comments inserted alongside the ticks indicating the student's completion of the various actions. The top two comments are the same and translate as, 'yes, but it takes me a great effort'. The lower comment, while similar in its intention, translates as, 'regular, because it takes me a great effort'.

## Discussion

In this paper we have outlined the development and trial of an orientation basis, designed to support 6<sup>th</sup> grade-students' problem solving-related self-scaffolding. Derived from the literature the four dimensions, and their respective actions, provided evidence suggesting that the OB has a role to play. The four dimensions and the means of their operationalisation make real for students the actions that guide problem solving (Holton & Clarke, 2006). The evidence supports earlier findings that appropriate scaffolding may have a beneficial impact on cognition, metacognition and affect (van de Pol et al., 2010). However, with respect to the extent to which the OB for problem solving is contingent, exploits fading and encourages transfer of responsibility (van de Pol et al., 2010) is variable. With respect to contingency, our view is that students were able to connect OB actions to their own activity and those who were affected by typically persisted until at least the next step. Also, students took the OB seriously, indicating initial support for both fading and transfer of responsibility, although a longitudinal study would allow these to be better examined. The dimensional structure and the ways in which students use the actions embedded within it point towards a productive cycle of refinement. Despite its linearity, based on the behaviours of an expert problem solver, students' engagement with the final dimension confirmed not only the cyclic nature of problem solving but also the role of the OB in supporting students' awareness of it. Finally, the OB comprised short statements written in the first person. Our view is that it helps learners' not only understand what problem solving expects of them but also anticipate possible actions.

Finally, this paper has reported on the first iteration of an emergent study. Since the completion of this first task students have solved two further problems using the OB. Their teacher has commented, anecdotally, that students are becoming more familiar with and confident in their use of the OB. Therefore, a longitudinal analysis of students' OB-related problem solving would seem an appropriate next step. As found with previous studies, the impact of scaffolding is difficult to evaluate (van de Pol et al., 2010) and this will remain a key objective of future work.

*We present a new tool – Realization Tree Assessment (RTA) for assessing the mathematical quality of lessons and the ways in which the whole classroom discussion expose students to mathematical concepts. The tool, built upon the commognitive framework, depicts the different realizations of a mathematical object treated in a lesson, and then uses different shades to signify who articulated the realization – the teacher or the students. We exemplify the tool on two lessons implementing an identical Hexagon pattern generalization task. The RTA visualizes the manner in which one lesson gave students sufficient opportunities to “same” different algebraic expressions, while the other lesson did not. We show how this visual presentation of the mathematical ideas complements existing assessment tools, particularly, the Instructional Quality Assessment and Accountable Talk. We conclude by discussing the potential of the tool as an aid for lesson planning.*

*Keywords: Teaching practices, Realization tree, commognition, cognitive demand, lesson assessment tools.*

## Introduction

Recent years have seen increasing efforts to train teachers to teach exploratively – provide students with opportunities to engage with cognitively demanding tasks, problem solve, and participate in rich mathematical discussions (Schoenfeld, 2014). Within such efforts an important role lies in the tools that are used to examine lessons enacted by the trained teachers (Boston & Smith, 2009; Schoenfeld, 2015). Scoring and evaluation tools (such as the Instructional Quality Assessment tool or TRU math) can be used both for evaluating lessons and thereby examining the effectiveness of the training program, as well as tools for teachers’ professional development. A common difficulty with these tools, however, lies in operationalizing their criteria for evaluating the quality of mathematical ideas dealt with in the lesson. In this paper, we propose an analytical tool – the Realization Tree Assessment tool which is based on the “commognitive” framework (Nachlieli & Tabach, 2012; Sfard, 2008). This tool enables drawing a succinct yet sufficiently meaningful picture of the mathematical concepts surfaced in a specific lesson in such a way that lessons can be both compared with each other as well as planned ahead more accurately.

## Theoretical background

Tools for the examination and evaluation of classroom instruction can be categorized into three types: scoring tools such as Instructional Quality Assessment, or IQA (Boston, 2012b) and the Teaching for Robust Understanding of Mathematics summary, or TRU math (Schoenfeld, 2014); “coding and counting” tools, such as Accountable Talk (O’Connor, Michaels, & Chapin, 2015); and qualitative analytical tools (e.g. commognition, Sfard (2008)). Scoring and coding measures have the benefit that they are quantifiable. They thus enable both the comparison of teachers with each

other, as well as comparison of within-teacher change from lesson to lesson, for example, as a result of professional development. Scoring tools, however, have a drawback. They are heavily based on extensive training of scorers for the development of inter-rater reliability. This, because of their high-inference nature. Coding and counting tools, which are based on coding talk moves, necessitate lower inferences and are therefore easier for achieving reliability. However, these tools are mostly good for capturing non-mathematical aspects of the discourse.

The difficulty in assessing the surfacing of “important mathematical concepts” (Boston, 2012a) or “important content and practices” (Schoenfeld, 2015) in a lesson is not surprising, given that the definition of “mathematical concepts” has been under much dispute for decades (Sfard, 2008). To our aid, we draw on commognition (ibid), which we have extensively used in the past as a qualitative tool for describing learning-teaching processes. In the present work, we simplify this tool, to attune it with the demands of coding and scoring schemes that seek to evaluate lessons in a relatively short period of time, for the goal of comparing large sets of lessons.

### **Realization trees**

Mathematical learning, says Sfard (2008), is a process whereby students gradually become able to communicate about *mathematical objects*. These objects are produced by discourse (or communication), and are made up of different “realizations” (ibid, p. 165). The term realization is used by Sfard instead of the more common term “representation”, to emphasize the fact that nothing is, in fact, “there” to be represented. All mathematical objects are products of human discourse and come to life by being different realizations being “samed” and alienated from human agency so that they are talked about as existing of themselves. For example, the signifier  $\frac{1}{2}$ , the process of dividing a pizza into two pieces, and the process of shading 3 circles out of 6, are all samed into the object “one half”. Children often learn each of these realizations separately and only later come to relate to them all to one object. This is the heart of a process Sfard calls “objectification”. Objectification, or talking about mathematical signifiers as “standing for” mathematical objects that “exist” in the world, is a major and necessary accomplishment for advancing in the mathematical discourse. Sfard used the term “realization tree” to illustrate the fact that realizations are usually hierarchical. A half is made of different realizations ( $\frac{1}{2}$ , 0.5, 50%,  $\frac{3}{6}$  etc.) but the whole numbers making up these realizations also have endless realizations (3 apples, 3 fingers, etc.). Nachlieli & Tabach (2012) used realization trees to visually explain the complexity of the object *function* and to relate to the historical development of this object, as well as to make explicit students' development of the discourse of function. Before moving to explain our use of realization trees as tools for assessing the conceptual quality of a lesson, let us briefly describe the two other tools that have been serving us for quantifying and comparing mathematics lessons.

### **IQA**

The IQA (Instructional Quality Assessment tool) has been designed by Boston and Smith (2009; Boston, 2012a) to evaluate the *cognitive demand* of mathematical lessons. This, based on the “task framework” put forward by Stein and her colleagues (1996), which differentiates between the cognitive demand of a task, the way it is presented to the classroom, and the way students eventually engage in it. Every rubric in the IQA is scored on a scale from 0 to 4. For reasons of space, we will concentrate here only on two rubrics: AR-2 (implementation) and AR-X

(mathematical residue). Regarding the implementation rubric, 1 means students engage only in rote memorization and producing facts, 2 means they engage in the application of procedures explicitly taught, 3 means cognitive demand is not lowered but mathematical reasoning is not sufficiently explicated, and 4 means full engagement in a cognitively demanding mathematical task. 'Mathematical concepts' or 'ideas' are mentioned almost in every rubric in the IQA. For example, in the rubric that refers to the mathematical residue, the highest score should be given when: "The discussion following students' work on the task surfaces the important mathematical ideas, concepts, or connections embedded in the task" (Boston, 2012b, p. 20). However, IQA does not provide any clear guidance on this matter, besides giving a few examples of high and low level lessons.

### **Accountable Talk**

Accountable Talk coding (Resnick, Michales, & O'Connor, 2010) is a tool originating in socio-linguistic analysis of classroom talk (O'Connor & Michaels, 1993). It provides teachers with a set of specific *talk moves* they can make during whole classroom discussions, to hold students accountable to the community, to knowledge and to reasoning. Our version of Accountable Talk coding (Heyd-Metzuyanim, Smith, Bill, & Resnick, 2016) includes eight codes for teacher moves (e.g. press for reasoning, revoice, restate, agree/disagree) and four codes for students' moves (e.g. student-agree, student-justification). These moves track the amount in which teachers attempt to make students' thinking public, help students to reason mathematically, and hold them responsible for attending to the reasoning of others. Though the manual does contain examples of mathematical statements, Accountable Talk's basic framework does not deal specifically with content. It has no clear indicator of what consists as more important or "conceptual" reasoning, and what does not.

### **The study**

In what follows, we first describe the setting of the study on which we developed the Realization Tree Assessment tool (RTA). We then describe the results of analysis using the IQA and AT, showing what could be achieved by them and what was missing or difficult to agree upon. We follow this by describing the RTA results for the data, showing where they agree, complement and elaborate on the findings obtained by the IQA and AT.

### **Setting**

The study reported here was performed in the context of a project for training Israeli teachers to implement explorative instructional practices in middle school mathematics classrooms, using methods inspired by Smith & Stein's (2011) "Five Practices for Orchestrating Productive Mathematics Discussions". In this report, we focus on two teachers: Dani and Sivan. Dani was teaching a 7th grade classroom in a school serving a community of middle-high socio-economic background. Sivan was teaching an 8th grade classroom in a school serving a community mostly from a low-middle socio-economic background. Both teachers participated in training sessions where the instructor planned together with each of them separately a lesson according to the "5 Practices". In both cases, the lesson centered around an identical task: the Hexagon Task. The main session in the task was to write description that could be used to compute the perimeter of any train in the pattern of hexagons (See Figure 1):

**Figure 1: The Hexagons Pattern**

The reason this task was used, was that it has proved in a previous study (Heyd-Metzuyanim et al., 2016) to be very productive for teachers who are beginning to implement the “5 Practices”. We observed, video recorded, and transcribed both lessons. In addition, Dani and Sivan were both interviewed before and after the lessons, and their lesson planning sessions were recorded. In what follows, we present the IQA and AT measures of the two lessons, as well as what was still missing from them for a full understanding of the task implementation.

## Findings

**Accountable Talk in the two lessons.** Both Dani and Sivan’s lessons were conducted over a double period (90 Minutes) and both included work in groups (or pairs) where the teacher was walking between the groups, followed by a whole classroom discussion. The two whole classroom discussions took similar time (in Dani’s classroom 28 minutes and in Sivan’s lesson 26 minutes).

Overall, there were many more AT moves in Dani’s lesson (98) than Sivan’s (46). In particular, Dani’s lesson had much more student talk moves coded as AT moves, either as student agree/disagree ( $N_{\text{Dani}}=22$ ,  $N_{\text{Sivan}}=0$ ), or as student justifications ( $N_{\text{Dani}}=20$ ,  $N_{\text{Sivan}}=11$ ). Dani was also higher than Sivan in pressing for students’ reasoning ( $N_{\text{Dani}}=23$ ,  $N_{\text{Sivan}}=14$ ). The overall picture drawn from the AT measure is, thus, that Dani’s lesson had more accountability to reasoning and to the community than Sivan’s lesson. Using the AT measure alone, however, does not enable learning about what mathematical concepts were dealt with, and which mathematical ideas surfaced through the discussion.

**IQA scoring of two lessons.** According to the IQA, Dani’s lesson got higher scores than Sivan’s lesson on all the rubrics, except the potential of the task, which was given in both cases by the teachers’ trainer. In the Implementation rubric, we scored Dani’s lesson as a 4, since multiple solutions were found and presented by the students; the teacher did not lead the students towards any particular solution; solutions were linked to each other both by the teacher and by the students; and there was no proceduralization of the task. In contrast, Sivan’s implementation scored a 2. Though students generalized the Hexagon pattern into a expression, this was not done through the visual Hexagon’s representation, only through the table; connections were not made with other algebraic expressions; in particular, students seemed to be well rehearsed in producing a table, algebraic expression from it and a graph of that expression, thus the task was proceduralized.

In the mathematical residue rubric, the results of the scoring were similar. Dani’s lesson received a 4 since: the mathematical idea of equivalence of algebraic expressions was driven through the different algebraic solutions student presented. Evidence for students’ understanding could be seen in one of the girls’ exclamation “so they’re all the same!” In contrast, Sivan’s lesson scored a “2” on the mathematical residue rubric, since although the discussion dealt with some mathematical ideas, it did not touch upon the main idea behind the Hexagon task. The teacher did not focus on the different algebraic expressions but rather on the different representations of a linear function (graph,

table and algebraic expression). However, as will be shown later, even this idea was not treated fully and appropriately.

Of all the Academic Rigor rubrics, we found the “Mathematical Residue<sup>1</sup>” most difficult to operationalize. It appeared Dani and Sivan had different ideas regarding the mathematical goals of their lessons and this had consequence for the way they led the lesson. While Dani seemed to be well aligned with the goal of showing the equivalence of algebraic expressions, Sivan seemed as though she was mostly aiming at ideas related to linear functions (which are, indeed, part of the 8<sup>th</sup> grade curriculum). We therefore searched for a tool that would aid in explicating the mathematical ideas explored in the two lessons. For this end, we developed the RTA.

### Realization Tree Assessment tool

The first step in RTA is examining the task and explicating the *mathematical object(s)* that can be surfaced through engagement with the task. This includes the different realizations that are reasonable to expect from students at a certain grade level. In our case, we built our realization tree based on a lesson plan provided by the Institute for Learning ([http://ifl.pitt.edu/index.php/educator\\_resources](http://ifl.pitt.edu/index.php/educator_resources)), where the different solutions, expected from middle schoolers for this task were drawn out. This produced a “blank” tree, with nodes as seen in Figures 2 and 3. We then proceeded to shade the tree nodes with four different colors, as follows: Shade no. 4: the student's explanation was complete and accurate; Shade no. 3: the student's explanation was not complete and accurate but the teacher helped explicating the idea; Shade no. 2: the student did not articulate the realization, but the teacher did; Shade no. 1: The realization was partially mentioned, but neither the student nor the teacher explained it fully.

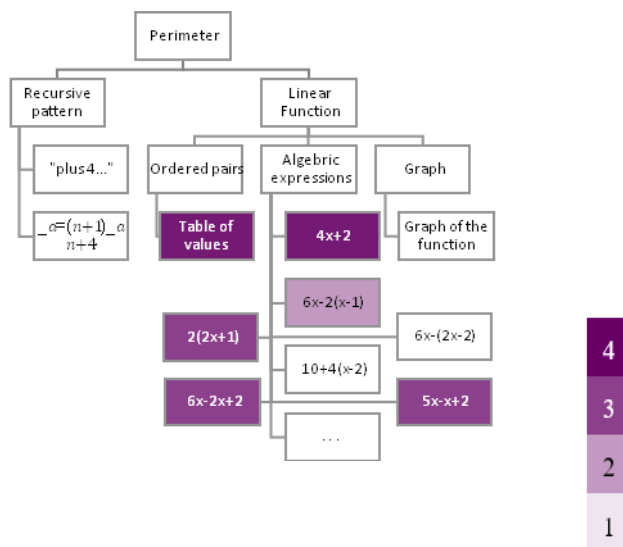

Figure 2: The RTA of Dani's lesson

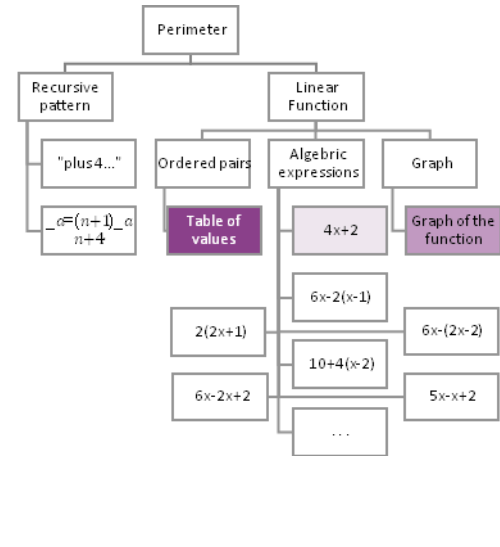

Figure 3: The RTA of Sivan's lesson

<sup>1</sup> The Mathematical Residue rubric appears in our manual as “under development”.

Finally, if the realization was not mentioned at all, but was hypothesized to be relevant to the lesson and the grade level according to the lesson plan, it was shaded white (no. 0).

As can be seen in Figures 2 and 3, the main branch of our realization tree (“algebraic expression”), branches out on the multiple realizations of the algebraic expression. This, in accordance with the potential of the task to explore the different ways in which the visual representation of the hexagon sides can be generalized into a pattern and expressed algebraically.

Figure 2 describes the RTA for Dani’s lesson. It shows that three realizations were explained fully and completely by students, three were explained by students, but the teacher filled in some gaps in these explanations, and one realization was explained only by the teacher. This full treatment of the “algebraic expressions” branch led students to endorsement of the narrative that “they all (all the algebraic expressions describing the pattern) equal to”, thus to the saming of different realizations, which was the goal of the lesson, as expressed both by Dani and by the teacher trainer.

In contrast, the RTA for Sivan’s lesson (see Figure 3) is much lighter and sparser. It shows that only three realizations were treated in the lesson, and none of them was fully explained by the students. Moreover, the main branch of the tree – the “algebraic expressions” branch, is particularly empty. Only the realization was treated, and even that one was not explained accurately by the teacher or the students. The relative “emptiness” of Sivan’s RTA corresponds well with the relatively low IQA and AT scores her lesson received. Still, it puzzled us, since Sivan was prepared in the PD very specifically for a lesson that was envisioned as similar to that of Dani. “What went wrong?”, we asked ourselves. In order to answer that, we went back to the planning session, as well as to the post-lesson interview with Sivan, conducted right after the lesson. We found that, despite the PD instructor’s conviction that she and Sivan were “on the same page”, Sivan, in fact, had different goals for the lesson. She was focused on connecting the lesson to the previously learned unit on linear functions, where she had taught students to connect the concept of “slope” with the term “ $m$ ” in  $y = mx + n$ , as well as connect it with the visual slope of a linear graph:

“I wanted the students to see that every time it rises by four so that they will connect it with the slope that we have done with functions... I deliberately divided the board into three sections, to show the different stages in reaching the function itself - the graph that combines all the various representations of the function”. (Sivan, Post-lesson interview)

It appears, then, that Sivan had a *different* mathematical object in mind (though probably only tacitly) when she planned the lesson – the “linear function” object<sup>2</sup>. Within the linear function object, the “slope” attribute of that object was her focus of attention. This could have been an appropriate goal for the lesson, had it been explicated and thought through. In particular, the following realization tree (see Figure 4) could have been appropriate for discussing slope and linear functions.

---

<sup>2</sup> Though she named it inaccurately simply a “function”, we understood from the context and from the curriculum she was referring to linear functions.

**Figure 4: Alternative Realization Tree for discussing slopes and rate of change**

However, the Hexagon task, especially as written for this lesson, was probably not the optimal task for talking about “slope”. This, since it depicts a situation where the function is discrete and cannot be described using a linear line. In practice, Sivan neglected very early the connection to the Hexagons drawing. Thus even the “rate of change” (which could have been visualized as the addition of four sides with the addition of each hexagon) was not connected to the “slope” on the graph.

## Discussion

Our goal in the present report was to present a new analytical tool for the evaluation of mathematical lessons – the RTA. Though this tool does not give a numerical value such as scoring and “coding and counting” tools do, it still enables relatively easy qualitative comparisons between lessons. We have used this tool to enable comparison between two more lessons that were performed on the Hexagon task, and the results give a quick overview of the mathematical opportunities to learn in each lesson. The RTA can also serve as an aid for determining the quality of mathematical content (or “mathematical residue”) that is sought after in coarser grained assessment tools such as the IQA. In addition, the RTA can give us information about the potential of the task to engage students in explorative mathematical learning and about the relation between this potential and the actual implementation of the task in the classroom.

In the two cases reported here, the application of the RTA was done post-hoc, after the lessons were planned, implemented and recorded. However, we believe there is much potential for using this tool as an aid for planning lessons and training teachers for explorative mathematics instruction. Such a tool is particularly needed in light of previous findings which point to the difficulty of teachers to explicate to themselves the *mathematical goals* of the lesson (Heyd-Metzuyanim, Smith, Bill, & Resnick, submitted). We also believe that drawing realization trees with teachers will help them plan tasks and whole classroom discussions that provide sufficient opportunities for explorative participation. Often, when teachers talk about explorative instruction, their focus lies on the social or socio-mathematical norms of the classroom, such as students talking and listening to each other

(Heyd-Metzuyanim, Munter, & Greeno, submitted). We believe no less emphasis should be put on the nature of mathematical objects that students get exposed to, and on the paths for objectification that are opened through sufficiently rich mathematical discussions.

# A study of readiness for the integration of 21<sup>st</sup> century practices in mathematics classrooms

Aibhín Bray, Elizabeth Oldham and Katriona O’Sullivan

Trinity College Dublin, the University of Dublin, Ireland; [braya@tcd.ie](mailto:braya@tcd.ie), [eoldham@tcd.ie](mailto:eoldham@tcd.ie) and [osullik14@tcd.ie](mailto:osullik14@tcd.ie)

*This poster explores the complex process of integration of 21<sup>st</sup> Century (21C) teaching and learning practices into mathematics classrooms, reporting on mathematics teachers’ perceptions of the predictors for, and barriers to, their integration in European post-primary schools. Data are drawn from teachers’ responses to a questionnaire for an Erasmus+ project that addresses readiness for the integration of 21C practices. Responses from 52 Irish, Swedish, Estonian and German practitioners listing mathematics as one of their teaching subjects are considered. For quantitative data, descriptive and inferential statistics were used; a directed content analysis approach was taken for qualitative data. Findings indicate that system restrictions and resources are major barriers, and that classroom management and teacher beliefs impact on confidence with and frequency of use of 21C practices. We propose that this work form the basis of a broader study.*

*Keywords: Teaching practices, 21<sup>st</sup> century learning, mathematics education.*

The perceived importance of a ‘21<sup>st</sup> Century’ (21C) approach to teaching and learning is well documented (Dede, 2010; Voogt & Roblin, 2012). In terms of mathematics pedagogy however, while there is considerable research into the use of technologies for teaching and learning (e.g., TWG15 and TWG16), the broader field of 21C practices in the classroom is less considered. This research explores responses to a survey instrument developed for an Erasmus+ project, Teaching for Tomorrow (TfT). TfT is a partnership between institutions in four countries (Ireland, Sweden, Estonia and Germany) that are working to develop a model of 21C teaching and learning across subject areas. The poster reports on the responses of 52 teachers who name mathematics as one of their teaching subjects. The aim is to identify what they see as the predictors for and barriers to usage of 21C practices in the classroom, with a view to larger-scale research.

The theoretical framework underpinning the model for 21C practices being developed by TfT draws on the work of Ravitz, Hixson, English, and Mergendoller (2012), which emphasises a project-based, collaborative, and student-led pedagogic approach. “Readiness for integration” is taken as involving *confidence* in using and encouraging, and *frequency* of using, the 21C practices of: Critical thinking, Collaboration, Communication, Creativity & Innovation, Use of Technology, Self-direction, Global and Local Connections.

The questionnaire used to gather data was developed by the Irish partners, with items drawn from the validated instruments of Euler and Maaß (2011), Ravitz et al. (2012), and the OECD (2010). It involved 4 main sections: (1) *Background information*; (2) *Teachers’ beliefs about the nature of teaching and learning (direct transmission versus constructivist)*; (3) *Orientation towards, usage of, and barriers to 21C teaching and learning*; and (4) *Confidence with and frequency of integration of 21st skills in practice*. Apart from section 1 and an open-ended item in the Barriers section, all items used 5-point Likert-type scoring system.

Multiple regressions were performed to identify whether the categories of *beliefs*, *opinions and usage*, and *barriers* had a significant bearing on teachers' *confidence* with, and *frequency* of, integration of 21CL practices in the mathematics classroom. Also, *t*-tests and one-way ANOVAs were used to compare the mean ratings across the four participating countries. Directed content analysis was undertaken for the qualitative data.

Results indicate that teachers' mean *orientation* towards 21C practices is quite high, with respondents tending to agree that 21C teaching and learning has a positive impact on student motivation. However mean levels of *confidence* are less positive, and mean *frequency of usage* is rather low, pointing to a lack of readiness for integration. Respondents' mean scores for self-reported direct transmission beliefs are lower than those for constructivist beliefs, the latter being predictors of confidence in 21C practices.

In the qualitative analysis, students' and teachers' direct transmission beliefs are reported by respondents as barriers to the integration of 21C practices, with "*teacher inertia and general reluctance to move from traditional methods*" emerging as a common issue. Barriers at the system level, particularly those associated with time, and curriculum and assessment, also appear important. In addition, both quantitative and qualitative analysis reflects that classroom management issues act as barriers to teachers' implementation of 21C practices: "*Students are not used to 21CL, because most of the time they do not have to do it, so at first it takes a lot of time.*"

In order to encourage teachers to integrate 21C practices in the mathematics classroom, it is essential to address some of the barriers identified. The features of the TtT model, outlined above, are intended to provide guidance for teachers and students, a structured approach to the development of 21C activities, and relevant assessment practices.

It should be noted that although the samples from each country are small and not representative, and that there were variations in the criteria for participant selection, the results across counties show surprising commonality. Thus, we propose to conduct a larger study, involving representative groups, uniformly selected in each country, to see if such trends arise outside the confines of TtT.

<sup>5</sup>Norwegian University of Science and Technology (NTNU), Norway

<sup>6</sup>Brock University, Canada

### **Rationale**

The variety of papers presented in TWG 20 at CERME 2017 connected to the growing field of teacher education. There were total of 27 papers and 4 posters that had been presented. The number and heterogeneity of the research foci, contexts, methodological and theoretical approaches, provided opportunity for in-depth discussions and reflections around the presented papers. Although the core topic proposals were expected to embrace three intertwined domains, the focus of the presented papers at TWG20 was mainly on teachers' knowledge, while the topic of teachers' beliefs and teachers' identity would appear implicitly or in the background of some of the research.

### **Main topics**

The priority given to teachers' knowledge can be seen throughout the unbalanced number of proposals which included the 27 papers presented (30 were submitted). For the development of the work three thematic strands have been considered: (i) knowledge in mathematics education (3 papers); (ii) lesson study context and beliefs (5 papers) and (iii) teachers' knowledge" (19 papers). It is interesting to note that the differences between (i) and (iii) concerns the aims of the research (even if not perceived explicitly), and not necessarily the theoretical perspectives considered.

**(i) Knowledge in mathematics education.** This thematic strand included three papers, focusing on aspects different from the specificities of teachers' knowledge, even when the context was teachers' education. Although the theoretical dimensions of the presented researches addressed teachers' knowledge conceptualizations the research focused on the knowledge of prospective teachers' that is revealed at the very beginning of teachers' training.

**(ii) Lesson study.** The second thematic strand included five papers and one poster, dealing with mathematics teachers' professional development (PD), in the context of the development of Lesson Studies (LS), and (prospective) teachers' learning with regards their own teaching practice and students learning, as well as on how teachers perceive themselves as participants in such LS context. Although there is evidence that PD contexts can lead to improvements in teaching practices and students' learning, less is known about what and how teachers learn from PD and about its further impact on students' learning outcomes (Borko, 2004), and also some other intertwined variables.

Common to the presented research were the perspective of considering teachers as learners, where the research is looking at the relationships between these two elements. In this thematic strand, two particular issues arise; how can theories/approaches/perspectives on teachers' knowledge be used to analyse the impact of teachers' participation and involvement in LS for teaching practices and professional development; concerning questions around the incorporation of theory in a methodological approach for LS in order to analyse the different phases and cycles.

Further, the research developed in the context of the implementation of a LS (or a research on the LS process), needs to take into account the particularities and specificities of the cultural contexts in which it is implemented – in order to acknowledge, the differences of those cultural contexts and the one where it is originated. In, and for doing so, one needs to take into account different aspects, such as the type, nature and impact of the affordances and constraints that takes into consideration; the influence of the researchers' background in the implementation, development and design of the research in the LS context; to what extent, in the context of a mathematics education research, the *mathematics* features of teaching is effectively the focus of attention.

(ii) **Teachers' knowledge.** Similar to previous CERME's, the explicit focus on teachers' knowledge has been given a major importance in the context of most of the presented proposals. The papers were grounded on teachers' knowledge conceptualizations that have already been discussed extensively in previous CERME conferences (Mathematical Knowledge for Teaching (Ball, Thames & Phelps, 2008); Mathematics Teachers' Specialized Knowledge (Carrillo, Climent, Contreras & Munoz-Catalan, 2013); Knowledge Quartet (Rowland, Huckstep & Thwaites, 2005); Ontosemiotic Approach (Godino, Batanero & Font, 2007)). We observe that, within a period of four years (from CERME 8 to CERME 10) a certain shift related to the focus of attention occurred, namely a shift from discussing the need for different conceptualizations towards an effort to deepening on the nature of teachers' knowledge when assuming a certain conceptualization.

In CERME9, Ribeiro, Aslan-Tutak, Charalambous and Meinke (2015) suggested that the use and development of diverse conceptualizations could be perceived as both a richness of the research field and as a constraint. The richness concerns possibilities for gaining a better insight into factors that influence the development of teacher knowledge. However, there are challenges of finding a common ground for discussing the core aspects of the research field. At the current conference, the issue of a diverse conceptualization was addressed in discussions on how to investigate mathematics teachers' knowledge when assuming it to be in interplay with students' learning. In other words, the need to pay "close" attention to how we, as researchers, take into consideration the aspects of mathematics teaching and learning, being connected to teachers' intertwined knowledge as well as to the role and impact of teachers' knowledge in practice concerning the use of resources (where the focus was the teachers' knowledge involved in/for preparing and using such resources – in a broader sense – in practice and not the resources itself).

The research, and the associated discussions and reflections in the group, also brought forward one of the recurrent items in the group discussions: the need for the research on teacher education to move from a prevalent focus on what teachers do not have (the deficit perspective – in term of knowledge) to a focus on what teachers actually know, how they know it, and possible different hows that can contribute to the development of teacher's knowledge, specifically related with teacher's work of teaching. Along the discussions, and aligned with some of the presented papers, a

possible direction for future research emerged on area of teachers' knowledge sustaining teachers' noticing and "earing" ability. For example, future research focusing on how mathematic teachers' pay attention to and make sense of what happens in the complexity of instructional situations (see e.g. Sherin, Jacobs & Philipp, 2011). Also on what aspects of one's knowledge do teachers' ground their decision making – in order to develop mathematically demanding practices, aiming at developing critical mathematical thinking for deeper mathematical understanding. One other possible focus concerns on how and why (the impact) the teachers' and researchers' knowledge influence their foci of attention and awareness.

## **Emerged themes and future perspectives**

We have considered three thematic strands for an operational reason, but one need to have in mind the intertwined nature of such strands. Thus, in our case, the connecting element was teachers' knowledge. Some of the discussions were grounded in ideas already discussed in previous CERME's, aiming at deepening the understanding on those aspects/dimensions while other discussions seek for an alternative and complementary path for getting such a broader understanding. A particular sensitive aspect was the need for a deeper understanding on the relationships between teachers' knowledge and practice, and for gaining such a deeper understanding some new approaches to research on teachers' knowledge were discussed, in particular studies that investigate how teachers use their knowledge to give meaning to others' solutions or to anticipate students' answers. Moreover, the role of task design in and for assessing, accessing and developing teachers' knowledge and improving practices was emphasized in the discussions. We have grouped the main research trends emerged in three groups:

### **- Deepening research into teachers' knowledge, beliefs, identity, and noticing**

- Taking into account that in some contexts mathematics teachers knowledge specificities are perceived mainly in the domain of PCK, how is the "weight" of PCK perceived in the field of research in mathematics education and how it intertwines with the specificities of the teachers' content knowledge, beliefs and identity?
- How to take into account teachers' noticing?

### **- Research on interactions with fields of practice**

- How can the focus of research be intertwined with practice and education in a more explicit manner, perceiving practice in a broader sense?
- How can we investigate whether and how teachers' knowledge affects students' learning and transitions throughout student's education? How to design and develop research aimed at approaching "simultaneously" teachers' knowledge and students learning?
- How to move from frameworks for analyzing, describing, understanding and/or evaluating teachers' knowledge, to the use of frameworks by teachers (for analyzing teaching practice)?
- How the teachers' knowledge conceptualizations take into account the notion of assessment, and how does knowledge on assessment contribute to students' learning in mathematics?
- What are the roles and knowledge (e.g., features, nature, content) of mathematic educators in teacher education (e.g. facilitator in LS; teacher trainer)?

**- Research on methodological (and theoretical) challenges:**

- How can we deal with (and what are the implications for) similarities and differences of aims and challenges in mathematics teacher education in different cultural contexts?
- How to clarify the findings we have, when using a particular theoretical lens for analyzing teachers' answers, comments and/or practices?
- How to develop research that emphasize teachers' potentials instead of teachers' deficiencies, and how to design approaches for grounding teachers' knowledge development in such potential?
- As many of the researchers developing research on teachers' knowledge – in multiple contexts, including lesson study – are educators, how do we deal with such fact (a recurrent issue); what significant does researcher's role as an educator play on the research itself and what is the actual impact of research in improving teachers' education (in what terms is the research one does implying on the ways teachers' education occur)?

*Responsibility for evaluation is assigned to teachers so that they can critique their own work and follow each of their students' progress. To succeed, teachers must build an appropriate means of assessment by themselves. This study examines the ability of pre-service and novice mathematics teachers in secondary schools to do so, using a questionnaire that requires them to make a connection between teaching objectives and mathematical tasks. The results show difficulties in matching teaching objectives to a given task and vice versa, with no significant differences between the pre-service and novice mathematics teachers. Interviews show how their beliefs, and their lack of mathematical and pedagogical knowledge, influence the teaching objective and assessment task they choose.*

**Keywords:** *Pedagogical mathematical knowledge, assessment, mathematical knowledge, pre-service mathematics teachers, novice mathematics teachers.*

## Introduction

The aim of evaluation is to provide teachers with reliable information so they can make decisions regarding their teaching methods as well as track their students' learning (NCTM, 2000). To achieve that aim, teachers must design and construct assessment tools on a routine basis (Magnusson, Krajcik, & Borko, 2002). This means that teachers should have the capacity to find or develop assessment tasks that align with their teaching objective, and that have the potential to accurately reflect their students' knowledge and understanding (Siegel & Wissehr, 2011). They should also have the reverse capacity: they must know how to find the teaching objective behind a given mathematical task. The two capacities integrate pedagogical knowledge with mathematical (content) knowledge, which has been defined as a part of pedagogical mathematical knowledge in assessment which teachers should have (Tamir, 1988). This study attempts to examine the pedagogical mathematical knowledge in assessment of pre-service and novice mathematics teachers by checking their ability to draw a connection between teaching objectives and mathematical tasks.

## The theoretical framework

Teaching as a profession is characterized by the existence of a unique knowledge base for those involved in it. Shulman (1986) defined categories of knowledge that teachers need in order to be professionals. Among these, he listed content knowledge (in this case, of mathematics), pedagogical knowledge, and pedagogical-content knowledge. Toward the end of the last century, the assessment of students' achievement was placed in the teachers' hands, with the hope they would have the knowledge to develop a reliable and valid assessment methods aligned with the teaching objectives (NCTM, 2000). Thus, the topic of assessment became part of the knowledge base teachers have to have. Tamir (1988), followed by Magnusson, Krajcik, & Borko (2002), expanded the definitions of

pedagogical knowledge and pedagogical-content knowledge for the topic of assessment. **Pedagogical knowledge in assessment** means knowledge of general rules related to assessment that can be applied to every subject-matter, such as familiarity with the various means of assessment. **Pedagogical-mathematical knowledge in assessment** refers to the knowledge teachers need in order to implement the general assessment rules in mathematics, and also to the ability to build a means of assessment that aligns with their teaching objectives.

Connecting teaching objectives and mathematical tasks is the foundation upon which pedagogical-mathematical knowledge in assessment is based, and particularly all means of assessment, formal as well as informal. This capacity should be acquired by every teacher from the time he/she starts to work. To the best of our knowledge, research that examines teachers' ability to connect between tasks and objectives has yet to be done in any field. This study is the first attempt to explore this ability in general, and particularly in mathematics, among novice and pre-service mathematics teachers. This paper is aimed to check this ability in an innovative way.

## Methodology

The data analyzed below derives from a research program about assessment that examines the pedagogical knowledge and pedagogical mathematical knowledge in assessment of pre-service and novice mathematics teachers for primary and secondary schools (Hoch & Amit, 2013; Hoch & Amit, 2011).

### The research questions

The aim of this paper is to examine the ability of pre-service and novice mathematics teachers to find the most suitable teaching objectives to associate with a given mathematical task. The research questions are:

- a. Given a mathematical task, to what extent do the participants know how to match it to a suitable teaching objective which can be checked by that mathematical task?
- b. What are the sources of mismatching in selecting the appropriate teaching objective?

### The population

The study focused on sixty-six participants: thirty-two pre-service teachers, who were taught in five teacher training colleges, and thirty-four novice teachers, who had also been trained in one of those colleges.

The pre-service teachers were near the conclusion of their studies, and about to become secondary school mathematics teachers (grades 7-10). The novice teachers were already teaching mathematics in secondary schools (grades 7-10), and had up to three years of teaching experience (Vonk, 1993).

All the participants had taken a one-semester course in student achievement assessment during their studies at the teacher training colleges. None of the novice teachers took any additional course besides the one in which they had trained.

### The research approach

This study used the Mixed Method approach. First, quantitative data was gathered; then, on the basis of the gathered data, qualitative data was collected (see below).

## **The instruments**

The research was conducted by means of a questionnaire, followed by interviews.

### The questionnaire:

This study is innovative in that it examines assessment pedagogical-content knowledge in mathematics by checking teachers' ability to draw connections between teaching objectives and mathematical tasks. Specific questionnaires were created for this purpose. In this paper we shall focus on one of these, which checks the participants' ability to match a suitable teaching objective to a given mathematical task. Every question starts with a mathematical task followed by three teaching objectives that can be assessed by that task. The participants were asked to rate those teaching objectives according to their suitability to the given mathematical task on the scale of 3 (= the most suitable) to 1 (= the least suitable) (see Figure 1 below).

The questions focus on three central subjects in the curriculum of grades 7-10: algebraic expressions, equations and functions. All the mathematical tasks appear in the most widely used textbooks and in national tests. The teaching objectives were taken from the mathematics curriculum and from these textbooks, in order to simulate live classroom situations.

The questionnaire was given to a panel of judges which included seven experts in mathematics assessment. All have a PhD. in mathematics education, except for one who has an M.A. in mathematics education. All are familiar with the topic of assessment, and some of them even teach this topic in teacher training colleges. The panel of judges was asked to rate the teaching objectives in each question according to their suitability to the given mathematical task (just as the respondents would be, on a scale of 1-3). To ensure reliability (see Burstein et al., 1995/1996) each one of the judges was given the questionnaire discretely and did the assignment independently, without knowing who the other judges were.

After all the judges had completed the questionnaire, their ratings for each question were checked. Only questions that were given the same rating by at least five judges were left in the final version of the questionnaire. For the remaining questions, all the judges agreed which was the most appropriate teaching objective, but did not agree about the order of the other tasks.

### The interviews:

Interviews were conducted with eight participants (four pre-service teachers and four novice teachers) a maximum of two days after they completed the questionnaire. The interviews were done in order to gain a deeper understanding of the participants' way of thinking and to find explanations to and elaborations for the results obtained from the questionnaire (see Burstein et al., 1995/1996; Ercikan & Roth, 2006; Luft & Roehrig, 2007). The interviewees were therefore chosen according to the degree of incompatibility between their own rating and the experts' rating, and subject to their willingness to be interviewed. The interviews were semi-structured so that for each item in the questionnaire the interviewees were asked: "Can you explain your considerations for the rating you gave?" Each interview was recorded rather than hand written so as to avoid interruptions and delays during the interviewing process. Later the interview was transcribed.

## Data analysis

**Quantitative analysis:** For each question, each participant's rating was compared to that of the experts and received a mark indicating the degree to which it matched the experts' rating. The mark was on a scale from 4 to 0 following the rules: 4 points - the participant's rating is equal to the experts' rating; 3 points - the participant found the most suitable teaching objective but confused the order of the two other objectives; 2 points - the participant marked the most suitable teaching objective as the second and the second suitable teaching objective as the most suitable one; 1 point - the participant marked the most suitable teaching objective as the second and confused the order of the other two; 0 points – any other option. As a result of this process each question got a score, thus enabling the use of common statistic tests.

**Interview analysis:** The material obtained from the interviews was coded and analyzed using content analysis (Bauer & Gaskell, 2010), with the explanation for each question used as an analysis unit. At the initial stage of the analysis, the participant's rating was compared to that of the experts for each question and the explanation for the rating was checked. In cases where the rating did not match that of the experts, or the interviewee's explanation for the rating (even when it was in alignment with the experts' rating) did not correspond to the experts' reasons, the causes that led to those mistakes were identified. Finally, all the causes which were found to have a common source were grouped together, thus creating several categories. Since similar research has not previously been undertaken, there were not yet any known categories.

## Findings and interpretations

### General results for the questionnaire

On average, the participants obtained 2.5 points (out of 4) in this questionnaire. This means that they managed to answer correctly an average of 6 questions out of 9. No significant differences were found between pre-service and novice teachers.

**"Substitute Set" Question** (see Figure 1 below).

In this question the participants obtained 2.51 points (out of 4). No significant differences were found between the two groups. Less than 50% of the participants correctly chose the most appropriate teaching objective.

For this question the causes that led to a mistaken rating were divided into four categories.

### Difficulties in content knowledge

Interviewer: Which algebraic expressions are suitable?

Sara: b, c, d

Interviewer: b, c, d, all right

Sara: And e

Interviewer: And e

Sara: Even though in e you can substitute (-5)

Interviewer: So what is the right answer?

Sara: I really do not know .....

The right answer is b and d, but many students of all ages have problems with the algebraic expression given in c. They need more than a few minutes to understand that c is a wrong answer. The one which is written in e caused problems for some interviewees, and one interviewee gave it as a correct answer without realizing that there was a problem. The fact that  $(-5)$  cannot be substituted, while 5 can, caused problems. This algebraic expression shows that the ability to find the substitute set is not sufficient for providing the right solution. Those interviewees who had difficulty with mathematical knowledge chose the second objective as the most suitable one or rated the teaching objectives in the same order as the experts.

<p>In a test that was given to 7<sup>th</sup> grade students the following question was asked:          Find the algebraic expressions where the set <math>\{x   x \neq \pm 5\}</math> is the substitute set.          (There is more than one correct option.)</p>	
<p>a. <math>(x-5)(x+5)</math>      b. <math>\frac{4}{(x-5)(x+5)}</math>      c. <math>\frac{x-5}{x^2+25}</math>      d. <math>\frac{x}{x^2-25}</math>      e. <math>\frac{7}{x-5}</math></p>	
The teaching objective: To check if the student	Degree to which the objective fits the task
Knows how to substitute numbers in an algebraic expression	1
Knows how to find a substitute set to an algebraic expression	2

**Figure 1: "Substitute Set" Question (with the experts' rating)**

### Difficulties in pedagogical knowledge

The results showed that the participants did not clearly and unequivocally understand how a teaching objective should be determined. As a result, they made their choices based on several different criteria. Some of the interviewees chose the suitable teaching objective according to the order of the syllabus. In this case, for instance, finding a substitute set to an algebraic expression topic is learnt after the students know how to substitute numbers and practice doing so. According to Orna, "Here the student does not try to substitute numbers because this stage is already known, it is something obvious". Thus the teaching objective that would be suitable in this case is the second one, with the additional reasoning "that is the way I would do it" (Orna). Osama's rationale, on the other hand, led her to choose the first teaching objective, saying "Here the student first has to substitute in order to know if the denominator is equal to zero... [Therefore] I think this task checks very well if the student knows how to substitute". Others, like Yelena, based their determination of the most suitable teaching objective on a strict adherence to the exact phrasing of the assessment task. She declared that "the student does not have to know the idea behind the term 'a substitute set' because no one asks for this".

She thinks that a teaching objective should be determined according to what is specifically asked for in the written question.

### Difficulties in pedagogical content knowledge

Some of the interviewees did not take into consideration the difficulties students have when the substitute set of the algebraic expression is not the same as the given one. "Even those who do not understand the learnt material can substitute numbers and succeed in solving the question and the teacher will think he/she understands" (Osama). "In 'e' the student finds that the substitute set is all numbers except 5, so he will not mark this ['e'] because [it is given that] the substitute set should be different from 5 and also from (-5)" (Sharon). Knowing how to find the substitute set or knowing how to substitute numbers does not ensure that the student will come to the right conclusion because an additional step is required, namely comparing the result obtained from the finding of the substitute set with the given substitute set and coming to a conclusion.

### Beliefs/conceptions

The interviewees raised concerns about whether a task like this could in fact accurately reflect their students' understanding at all, or whether it just reflected their ability to follow instructions. Their responses addressed questions like: What is the nature of the rules that are provided by teachers or books? Do these rules replace the need for understanding the subject matter? Can students follow the rules and succeed in solving tasks without understanding? Anat, for example, pointed out that "If the teacher wrote down the rules on how to find a substitute set...all kinds of rules, the students may not understand what a substitute set means, but they will be able to solve exercises without such understanding." Anat expresses the belief that knowing the rules and using them correctly can cover up a lack of understanding, and that therefore this task cannot check the understanding of a substitute set.

## **Discussion and conclusions**

This study attempts to give a preliminary idea of the mathematics teachers' pedagogical-content knowledge of assessment. It examined two groups: pre-service teachers in secondary schools just prior to their entering the educational system, and novice teachers in secondary schools. The example presented here shows the participants' difficulties finding the teaching objective behind the given mathematical task, dividing them into four categories: a. difficulties in mathematical knowledge, b. difficulties in pedagogical knowledge, c. difficulties in pedagogical mathematics knowledge and d. beliefs/conceptions teachers hold. The first three categories have already been discussed extensively by many researchers as an acknowledged part of the knowledge base all teachers must have (e.g. Shulman, 1986; Turner-Bisset, 1999). As this example shows, an incomplete knowledge base also influences the quality of the assessment teachers carry out. The application of beliefs in the teaching process has been well documented in the literature (Eren, 2010; James & Pedder, 2006; Turner-Bisset, 1999) and arose in the context of assessment as well. In this case, it was the teachers' belief that providing students with rules could cover their lack of understanding. This issue has been dealt with by many researchers for many years (e.g. Skemp, 1976). The belief that teaching students to follow a set of rules can be a substitute for teaching them the underlying ideas for those rules may be the result of what has, until recently, been the prevalent Israeli method of learning mathematics – a

method that demanded low levels of thinking from the students. Various researchers (e.g. James & Pedder, 2006) have recommended encouraging the pre-service teachers to express their beliefs by opening them up for discussion. Hearing and addressing these beliefs that can influence future behavior, can lead the holder to undergo a process of professional development.

Finally, this study showed that the abilities of the novice teachers are no better than those of pre-service teachers. Both groups demonstrated the same problems, suggesting that experience in practice does not rectify problems that originate in training. This forces the assessment course's lecturers to focus on how to connect between teaching objectives and mathematical tasks. Moreover, every teacher educator should encourage preservice teachers to express their presumptions or beliefs, since discussing them can eliminate wrong beliefs and lead to a professional development (James & Pedder, 2006).

### **The study's limitations**

Although the number of participating in this research is small, and despite the fact that this research was restricted only to novice teachers, it is nevertheless important, since there is no study to date that examines the ability of teachers to identify a suitable teaching objective for a given mathematical task. Understanding the sources of the mismatching in selecting the appropriate teaching objective can help teacher educators focus their efforts on these problems, thus improving the training program's changes of preventing them.

The study looked at the participants' ability to connect between teaching objectives and mathematical tasks in three themes, limiting each theme to very few questions. These alone could not encompass all the aspects to be addressed in each theme. Further studies of this ability (and its opposite) should be done, preferably with every study conducting an in-depth examination (including interviews) of only one teaching theme.

# Differences in the forms of content teachers are seen to offer over time: Identifying opportunities for teacher growth

Nick Andrews

University of Oxford, Department of Education, UK; [nicholas.andrews@education.ox.ac.uk](mailto:nicholas.andrews@education.ox.ac.uk)

*In this paper, I report on a study into differences in how teachers make content available to learners over a series of lessons on a topic of their choice. The study highlights significant differences in the forms of content made available between lesson series, with the taught topic being a critical factor. It also highlights significant differences between the forms of content made available during classwork and seatwork, but these differences are independent of both topic and teacher. The implications of these findings are discussed, including their potential along with the analytic research tool for prompting teacher knowledge growth.*

*Keywords: Teacher knowledge, instructional design, teacher education.*

## Introduction

Findings of research into classroom practice have clear impact when they draw attention to features of a classroom situation that teachers might not otherwise attend. This impact can be particularly powerful if it affords deep psychological investment: if findings are presented in such a way as to promote an awareness of choice, if a reason to choose to act differently can be harnessed and if alternative actions can be imagined (Mason, 2002). In this paper I focus on an exploratory study of four cases of classroom practice over a series of lessons, and in particular differences in the manifestations of mathematical concepts offered by the teacher over time (a phrase I will define in due course) revealed through quantitative content analysis of teacher talk and classroom tasks. I draw on and adapt ideas from international comparative studies in order to inform the research design of this local study. I express the findings of my analysis as rhetorical questions about teacher knowledge that shapes decision making around the sequencing of content over time (a contributory code of the connection element of the Knowledge Quartet (Rowland, Huckstep & Thwaites, 2005)).

## Background to the study

### Differences in how content is made available to learners

The notion of differences in teaching methods is well established through comparative research (e.g. Stigler & Hiebert, 1999). Such studies have tended to use the lesson as the unit of analysis, yet Clarke, Emanuelsson, Jablonka & Mok (2006) propose a series of lessons on a topic as more appropriate for the purposes of comparison. The nature of teaching can change over the course of a lesson series, with the decisions that teachers make in planning and teaching individual lessons shaping the way they act over time but also being shaped by the classroom situation of which the teacher is part. Furthermore, teachers make decisions at the lesson series level when preparing to teach a topic and so analysis at this grain size affords focusing attention on such decisions as well as alternative choices that might be available. What is not known is whether particular forms of content are emphasised, and whether this emphasis might differ between series of lessons taught in different contexts.

Differences between lesson time given over to the teacher speaking with the whole class and to students engaged in seatwork have been researched (e.g. Stigler & Hiebert, 1999). Serrano (2012) underlines the emphasis placed on application/practice during seatwork in classrooms in USA and German, contrasting this with greater opportunities for exploration offered in Japanese classrooms. Hino's (2006) within-country comparisons offer an account for this, highlighting how seatwork activity frequently precedes explicit presentation of the main content in lessons in Japan rather than following it. From these studies, some variation in the forms of mathematics being offered during seatwork in different contexts might be anticipated, but are these differences as significant as those between the forms of content emphasised when the teacher speaks with the whole class and those emphasised during seatwork?

### Case study design

I purposefully designed the current study so that it involved four cases of teachers teaching a series of lessons on a topic of their choice, which allowed me to explore the role of the teacher and the topic. In Clarke et al.'s (2006) study the length of a lesson series was set by the researchers as ten lessons (or equivalent), but in the current study the length was determined by how long the teacher intended to work on the topic and was between three and five one-hour lessons. This ensured that the stretch of lessons included a start, middle and end, and I report elsewhere on the notable lesson-to-lesson differences that were revealed in each case (Andrews, 2016). Figure 1 shows the convenient selection of three experienced mathematics teachers (Ashley, Bernie and Courtney) from two local secondary schools (King's Meadow School and Bishop Langton School) that generated the four case studies for my investigation.

Figure 1: Tree diagram representation of the multiple case study design

Figure 1 also shows that classes were from school years 9 to 11 in England (learners aged between 13 and 16). Classes were set by prior attainment in both schools, with the average teacher-predicted attainment of learners in each class by the age of 16 being in line with the national average for mathematics. The broad topics that were the focus of each lesson series are also given in Figure 1. Thus cases involving Ashley and Bernie had the school context in common, the two cases involving Bernie had the teacher in common and the two cases involving linear equations had the age and predicted attainment of students and the topic in common. For convenience, I generally refer to cases through teacher and topic, but it is important to have in mind the significance of all four dimensions (teacher, class, school and topic) and not let this notation obscure the contribution of school and class to the classroom environment.

## Conceptualising forms of content offered by teachers

In this section I clarify what I mean above by ‘forms of content offered’. Firstly, I view the teacher’s role within the classroom situation as making content available to learners, where by content I mean the material dealt with in teaching rather than its form; it is the content that brings teachers and learners together. In the context of mathematics teaching, content is made up of the mathematical phenomena that constitute a topic. But it is precisely the ‘form’ of content that I observe the teacher offering learners – rather than the content itself – that is of interest to me. The emphasis on “I observe” here is deliberate, since this is a researcher’s stance. In the current study I am not seeking what the teacher perceives as the form of content they are offering, for which I might use the term *instantiation* of a mathematical concept. Rather it is my own perception of what is being offered from the position of observer, for which I use the term *manifestation* of a mathematical concept. This also explains why more familiar terms used to describe learner activity such as ‘prepare’, ‘apply’ and ‘explore’ (Serrano, 2012) and Clarke et al.’s (2006) codes are inappropriate from a methodological perspective, since attending to what the teacher says and makes available as tasks allows for neither assertions regarding teacher intentions nor learner activity.

The notion of manifestation requires further exemplification. When observing a teacher working with a class on linear equations, I might see the teacher offering diagrams of bars as in Figure 2, mathematical symbols such as “ $5x + 3 = 24 - 2x$ ”, or word problems such as “My father is currently three times my age. In five years’ time the sum of our ages will be 50. How old am I now?”

**Figure 2: A problem featuring bars**

I see each as a manifestation of a linear equation, but each is a different manifestation. I classify the manifestation in Figure 2 as *visual*, the mathematical symbols as *technical* and the worded problem as *functional* (in the sense that a solution is likely to be arrived at through modelling the problem mathematically). There are parallels here with the three strands of *Structure of a Topic*: awareness, techniques and emotion (Mason & Johnston-Wilder, 2004). These three components of manifestation may be combined, for example if the teacher was observed offering the worded problem above and heard saying “Solve this by forming and solving an equation,” this would be both a functional and a technical manifestation of a linear equation. In other cases, the spoken instruction may not be so explicit but nevertheless clearly implied in the context of the lesson. Either way, I would classify what is offered as *functional-technical*. Similarly manifestations might be classified as *visual-functional* or *visual-technical*, or indeed *visual-functional-technical*.

Although this classification of manifestations has been established here through focusing on linear equations, it is transferable to the other topics under consideration in this study. For example, when teaching geometric constructions, the teacher may seek to evoke an image of a perpendicular bisector of two fixed points as the locus of points equidistant from the fixed points (visual) or ask learners to construct a perpendicular bisector using a straight edge and compasses (technical). Or when teaching

division in a given ratio, the teacher may offer a pile of coins for learners to experience sharing in a given ratio visually (visual) or pose a worded problem (functional) such as: “On starting up a company, Sasha invests £25000 and Tina £40000. At the end of the first year they make a profit of £19500 that they agree to share based on their original investment. How much does Sasha receive?”

To add texture to these descriptions and to consider implications for learners, I cautiously associate visual, technical and functional manifestations with opportunities to focus learners’ attention on image having (Pirie & Kieren, 1989), procedural fluency (Kilpatrick, Swafford & Findell, 2001) and confident manipulation (Mason, 1980) respectively. I associate visual-functional, visual-technical and functional-technical manifestations with opportunities to shift the focus of learners’ attention; these are likely to be formative, and afford learners new ways in which to encounter a mathematical phenomenon working from what is already familiar.

### **Focus of the investigation**

The multiple case studies provide broad instantiations of teachers teaching over time, so afford localised responses to my research questions:

When comparing series of lessons, what differences are discernible in the forms of content that the teacher is observed offering (manifestations) over time?

Within and across series of lessons, what differences are discernible in the forms of content that the teacher is observed offering (manifestations) when speaking with the whole class (classwork) and through tasks (seatwork)?

In posing these questions, my intention is to explore features of classroom situations that may go beyond those which teachers routinely attend. But if they are features to which teachers *could* attend, then this opens up opportunities to act differently.

### **Method of analysis**

The transcript of the teacher’s voice, field notes, screen-shots of information displayed on boards, hand-outs, worksheets and text books were all used in order to infer how the teacher made content available to learners. In the process of coding, I considered the mathematics-related utterances made by the teacher when speaking with the whole class during classwork or with individuals during seatwork, which together I refer to as teacher-talk. I also considered whether learners were working on a particular task, which might have been made available for example through a worksheet or spoken instructions from the teacher. I refer to such tasks as given-tasks.

Each lesson was parsed into half-minute intervals, which were then coded for manifestation taking account of the teacher-talk and given-task present during the interval. Selecting half-minute intervals as the smallest unit of analysis afforded reliable and manageable coding while still allowing sufficient sensitivity to discern small differences in how content was made available. Each interval was coded with a Barycentric co-ordinate  $(x, y, z)$ , where  $x$ ,  $y$  and  $z$  represent the relative emphasis between visual, functional and technical manifestations respectively observed during the thirty seconds with  $x + y + z = 1$  (c.f. Swan, 2006). For example, an interval featuring only technical manifestation was coded  $(0, 0, 1)$  and an interval featuring visual-functional manifestation was coded  $(\frac{1}{2}, \frac{1}{2}, 0)$ . Coding was based on presence of a manifestation in the half-minute interval rather than the proportion of time, and given-task and teacher-talk were weighted equally. Further, if in a particular half-minute

interval of seatwork the given-task was classified as visual-functional but the teacher made an brief articulation that was classified as technical, the overall interval would be coded ( $\frac{1}{4}$ ,  $\frac{1}{4}$ ,  $\frac{1}{2}$ ), being the mean point of ( $\frac{1}{2}$ ,  $\frac{1}{2}$ , 0) and (0, 0, 1). More details of the coding rules and approach to analysis, including the strengths and limitations of this approach, are provided in Andrews (2016).

The *series centre* for manifestation for each case was calculated through finding the mean point over the whole lesson series. Further analysis allowed for the calculation of series centres for each case for classwork and for seatwork. Differences between lessons were explored by treating the  $x$ ,  $y$  and  $z$  values as separate variables. Each variable is ordinal-valued, and as such only non-parametric approaches to statistical analysis are appropriate. The Wilcoxon rank-sum test (Wilcoxon, 1945) was selected for this purpose. It was found that this test was sufficiently sensitive in order to detect even small difference between cases, and so I use the term *materially different* to describe the situation where the effect size ( $r$ , calculated from the Wilcoxon test statistic) of case comparison on one of the variables satisfies  $r > 0.3$ .

The use of Barycentric co-ordinates as a method of coding half-minute intervals afforded representing series centres as points within an equilateral triangle. This may evoke a sense of the series centre representing a point of ‘electromagnetic attraction’ to three differently charged ‘poles’ – visual, functional, technical – positioned at the vertices of the triangle. With this imagery in mind, I refer to the triangle as the *tri-polar space for manifestation*.

## Results

### Comparing series centres for manifestation

The series centres for manifestation highlighted differences in how content was manifested across each of the four lesson series. Figure 4 presents the four series centres in the tri-polar space for manifestation, indicating clear differences between some of the cases.

**Figure 4: The four series centres plotted in the tri-polar space for manifestation**

The three components of manifestation were most evenly stressed in Ashley’s series on geometric construction. Functional and particularly technical components were stressed in Bernie’s series on sharing in a given ratio, while visual and particularly technical components were stressed in the two series on solving linear equations (Bernie and Courtney). Table 1 quantifies the between-case differences seen in Figure 4 by presenting the effect sizes on the three components of manifestation when comparing lesson series.

<b>Case comparison</b> (Topic; half-minute intervals)	<b>Effect size on component of manifestation</b>		
	<i>Visual</i>	<i>Functional</i>	<i>Technical</i>
Ashley (Constructions; $n = 488$ ) to Bernie (Ratio; $n = 383$ )	<b>-0.45</b>	0.03	<b>0.38</b>
Ashley (Constructions; $n = 488$ ) to Bernie (Equations; $n = 289$ )	-0.10	<b>-0.57</b>	<b>0.57</b>
Ashley (Constructions; $n = 488$ ) to Courtney (Equations; $n = 416$ )	-0.11	<b>-0.46</b>	<b>0.50</b>
Bernie (Ratio; $n = 383$ ) to Bernie (Equations; $n = 289$ )	<b>0.42</b>	<b>-0.65</b>	0.30
Bernie (Ratio; $n = 383$ ) to Courtney (Equations; $n = 416$ )	<b>0.41</b>	<b>-0.51</b>	0.17
Bernie (Equations; $n = 289$ ) to Courtney (Equations; $n = 416$ )	-0.01	0.20	-0.14

N.B. Material differences are highlighted in bold.

**Table 1: Quantification of between-case differences in the components of manifestation**

The series of lessons taught by Ashley on constructions and Bernie on ratio were marked out as materially different to the two series on equations, and different to each other. However, the analysis did not highlight significant differences between the two series on equations. This led me to infer that within this study the topic had an impact on the forms of content the teacher offered.

### Comparing classwork and seatwork

Combining the four cases, there were differences in the forms of content the teachers were observed offering during classwork and seatwork (see Figure 5). On average, the visual component was stressed more during classwork whereas the functional component was stressed more during seatwork, which aligns with Serrano's (2012) findings about American and German classrooms.

**Figure 5: The across-case centres for classwork and seatwork plotted in the tri-polar space**

Focusing now on each case, the difference in emphasis of the visual component between classwork and seatwork was statistically significant, although the difference was only material in Courtney's lesson series on equations (see Table 2). Greater emphasis on the visual component during classwork was observed regardless of the particular teacher, topic or class.

Case (Classwork intervals, seatwork intervals)	Effect size on component of manifestation		
	<i>Visual</i>	<i>Functional</i>	<i>Technical</i>
Ashley (Constructions; $c = 77, s = 411$ )	-0.21	0.26	-0.02
Bernie (Ratio; $c = 82, s = 301$ )	-0.17	<b>0.38</b>	-0.24
Bernie (Equations; $c = 81, s = 208$ )	-0.18	-0.06	0.19
Courtney (Equations; $c = 146, s = 270$ )	<b>-0.34</b>	0.21	0.17

N.B. Material differences are highlighted in bold.

**Table 2: Comparison of classwork to seatwork across the four cases based on the relative stressing of the three components of the manifestation**

Only in Bernie's series on equations was there no statistically significant difference in the functional component between classwork and seatwork. Yet the only difference in the functional component between classwork and seatwork to be material was in Bernie's series on ratio (see Table 2), suggesting that the teacher was not a critical factor here but that the class may be.

## Discussion

This investigation has highlighted differences in the teaching of topics over a series of lessons. Material differences were discernible in the forms of content that the teachers were observed offering over time. In the current study, the topic was a critical factor and this contrasts with Clarke et al.'s (2006) study since although their analysis was of a series of lessons on a topic, the topic itself was not foregrounded in their findings. My findings raise the question of why the forms of content Bernie offered in a lesson series were so different when teaching ratio compared to equations. In particular, the findings lead me to ask whether opportunities associated with functional manifestations of equations were considered or not and, if they were, why these manifestation choices were not enacted.

Differences in the forms of mathematical content offered during classwork and seatwork gets to the heart of the purpose of these two types of engagement from a didactic perspective. From other perspectives, classwork may have a specific purpose such as offering learners extrinsic motivation to engage in mathematical activity. Yet this study prompts the question: what forms of content is it necessary for the teacher to make available through classwork rather than seatwork, if any? The small sample in this study raised the conjecture that making available visual manifestation might be better served by classwork rather than seatwork, and that the class – rather than the topic – being taught would shape the extent of this.

In the introduction, I spoke of how the impact of findings “might be particularly powerful if there is an awareness of choice, if a reason to choose to act differently can be harnessed and if alternative actions can be imagined.” The above prompts along with the tri-polar space for manifestation offer opportunity for such activity, for the interior triangular space suggests the possibility of choice and invites actions associated with particular positions within it to be imagined. This activity in turn invites new research opportunities to explore teachers' knowledge, attitudes and beliefs.

# How do prospective teachers imagine mathematical discussions on fraction comparison?

Kristin Krogh Arnesen, Ole Enge, Yvonne Grimeland and Torkel Haugan Hansen  
Norwegian University of Science and Technology, Department of Teacher Education, Norway;  
[yvonne.grimeland@ntnu.no](mailto:yvonne.grimeland@ntnu.no)

*Prospective teachers plan a short mathematical discussion on comparing fractions by writing lesson plays. We analyse how their mathematical knowledge for teaching surfaces in their written scripts, using three dimensions of the Knowledge Quartet: foundation, transformation and connection. Our findings give insight into the prospective teachers' knowledge of fractions and comparison strategies, their perspectives on mathematics and mathematics teaching, and insight into how they transform their knowledge to make it accessible to middle school students.*

*Keywords: Mathematics knowledge for teaching, representations of teaching, classroom discussion, lesson planning, rational number sense.*

## Introduction

Several recent studies call for a practice-based approach to research on teacher education (e.g. Ball & Cohen, 1999; Grossman & McDonald, 2008). An integral part of teachers' work is planning for teaching. Recently, several researchers have advocated writing lesson plays as a means of learning how to plan for instruction (see Zazkis, Liljedahl, & Sinclair, 2009). Lesson plays are imagined mathematical discussions written verbatim. Zazkis et al. (2009) argue that lesson plays can give a "window" for researchers to investigate mathematical knowledge for teaching. We have collected and analysed prospective teachers' (PTs') planning documents for a practice assignment in their school placement. The assignment was to write a lesson play on fractions. Several studies show that many PTs struggle to understand fractions (Newton, 2008; Ma, 1999). Siegler et al. (2010) recommend, "[p]rofessional development programs should place a high priority on improving teachers' understanding of fractions and of how to teach them". With this in mind, our research focuses on the following question: *How does PTs' mathematical knowledge for teaching surface in their lesson plays on fraction comparison?*

## Lesson plays

This study reports our efforts to develop practice assignments in our teacher education courses with respect to the notion of high-leverage practices. Ball, Sleep, Boerst, and Bass (2009) define "high-leverage practices" to be those that, when done well, are likely to lead to improved student learning. High-leverage practices are practices which novice teachers need to learn to do, and from which they will learn more about teaching (Lampert, 2009). Further, a high-leverage practice is such that novices can begin to master it (Grossman, Hammerness, & McDonald, 2009). Lampert, Beasley, Ghouseini, Kazemi, and Franke (2010) give several instructional activities that could be part of high-leverage practices in mathematics, which can be realised in a relatively short time, typically 10-15 minutes, through classroom discussions. The PTs used coursework literature to analyse and discuss a series of videos and transcripts of classroom discussions concerning computational strategies. We asked the PTs to plan a similar short mathematical discussion with a group of middle

school students, age 9 to 13. This was part of a practice assignment, intended to be implemented during their school placement towards the end of the term. The PTs were asked to plan for the mathematical discussion by writing a *lesson play*.

Lesson plays, introduced by Zazkis et al. (2009), are proposed as a way to plan teaching by writing a script for (part of) a lesson. An envisaged interaction between a teacher and a group of students is given verbatim, as an alternative for the traditional lesson plan. Zazkis et al. (2009) argue that lesson plays can give an opportunity for in-depth discussions of crucial aspects of mathematics teaching *before* the lesson, while such discussions can only take place after the lesson if the lesson is planned using a traditional lesson plan. As such, lesson plays are not affected by John's (2006) claim that traditional lesson plans do not give insight into "the substance of the particular activity" (p. 487).

Zazkis et al. (2009) typically give their PTs a prompt representing a mathematical error or misinterpretation, and ask the PTs to write the script of a discussion, which resolves the prompt. We asked our PTs to plan all aspects of the discussion, including formulating a mathematical aim for the discussion and a task, or a sequence of tasks, to achieve this aim. Our requirements for the discussion were that the mathematical topic was fractions, and that the aim should be to discuss some calculation or reasoning strategy on fractions. Furthermore, the script should include argumentation and some type of generalisation of concepts and/or strategies. Generalisation, argumentation and reasoning was a major focus in the coursework. The duration of the discussion should be 10-15 minutes.

## Mathematical knowledge for teaching

We are interested in how PTs' mathematical knowledge for teaching surfaces in their lesson plays, and we use the Knowledge Quartet (KQ) (Rowland, Huckstep, & Thwaites, 2005) as a framework for our analysis. The KQ consists of four dimensions, three of them resting on the first, named *Foundation*. Foundation concerns the teacher's or PT's knowledge of mathematics and mathematics teaching as acquired in their education. It underpins a teacher's ability to make rational, reasoned choices and decisions about instruction based on knowledge of mathematics and mathematics pedagogy. The second dimension of the KQ, *Transformation*, is about how the teacher transforms her own subject matter knowledge of mathematics into forms which enable others to learn it. Such transformation is informed by the teacher's choice of examples and representations and how these support learning of the intended mathematical topic. *Connection* is about the choices a teacher makes in order to ensure the consistency of planning and teaching a topic or concept through a lesson or lessons. As such it concerns anticipation of what students will find problematic, and decisions about sequencing. Crucial is the teacher's understanding of connections between mathematical concepts and between concepts and procedures as well as anticipation of complexity when planning and teaching a topic. *Contingency* concerns a teacher's responses to events that were not anticipated or planned for. Since we are considering planning for teaching this dimension will not be relevant to our analysis.

As the lesson plays analysed concern comparing fractions, it is useful to clarify the implications this has for the foundation dimension of the KQ. When describing number sense, researchers state that it manifests in flexible mental computation, understanding number magnitude, making judgements about calculations, using benchmarks, and having an inclination to use and develop understanding

of numbers and operations (McIntosh, Reys, & Reys, 1992; Sowder, 1992). Researchers have identified several strategies for comparing fractions based on number sense (see Yang, 2007). The *parts* strategy can be used when comparing fractions with the same numerator or denominator. The *benchmark* strategy refers to comparing two fractions to some well-known third fraction, typically  $\frac{1}{2}$  or  $\frac{3}{4}$ . When using *residual thinking* one builds up the fractions to 1. There are also “standard” ways of comparing fractions, which do not overtly depend on number sense, such as finding a common denominator or converting to decimals. Since the task for the PTs was to write a lesson play about reasoning with fractions, we expected the planned discussions to contain more than performing an algorithm. Using visual models of fractions can be a legitimate strategy, but researchers also warn about the limitations of relying on a visual strategy alone (Petit, Laird, Mardsen, & Ebby, 2015; Lamon, 2012). Thus, we expected strategies beyond visual strategies in the planned discussions.

## Method

The participants in the study were PTs following a 4-year teacher education programme, for age 6-13, at a university in Norway. The data were collected from their responses to a coursework assignment given during their first mathematics education module, in their first year of study. Of the 178 PTs in this cohort, 32 had chosen tasks on comparing fractions for their written classroom discussion. These 32 scripts are the data analysed in this paper, in particular they were chosen for analysis because fraction comparison has good potential for reasoning based on number sense (Yang, 2007). The excerpts presented in this paper are chosen to exemplify general trends identified in the 32 lesson plays.

All four authors conducted the analysis. Together, we first analysed in detail two lesson plays, using the descriptions of the dimensions from the KQ in our analysis of the two scripts. We then individually analysed the rest of the lesson plays looking for occurrences of similar and contrasting forms of mathematical teacher knowledge related to the KQ. After this independent analysis, we compared similarities and differences in our analyses, and agreed on an interpretation of different aspects of the lesson plays, using notions included in the KQ framework.

## Analysis

Of the 32 scripts, 6 used no strategies based on number sense, instead relying on visual “parts of shapes” strategies, or on algorithms such as finding a common denominator or converting to decimal numbers. In the remaining 26 scripts, the PTs used a number sense-based strategy at least once. 9 PTs used *benchmarking*, 13 used *parts* and 17 used *residual thinking*. In the following, we analyse some examples from the scripts in light of the mathematical content.

Anne was one of the PTs who based most of the imagined discussion on number sense-based strategies. Her stated goal of the discussion is to build understanding of the strategies of benchmarking and residual thinking. She gives two tasks designed to encourage the students to

utilise these strategies, and we quote here<sup>1</sup> two excerpts from the imagined discussion between Anne's teacher and her students while discussing the sorting of  $\frac{7}{8}$ ,  $\frac{3}{4}$ ,  $\frac{2}{10}$  and  $\frac{3}{6}$  by magnitude:

Ola: Yes, at least you see that  $\frac{3}{6}$  is the same as the half of something, that was where I started.

Teacher: OK, so you believe that it is one half. But how can that help us?

Ola: Well, since it is one half, we also see that  $\frac{2}{10}$  is less than one half.

Teacher: Per, can you try to elaborate Ola's thinking?

Per:  $\frac{2}{10}$  is sort of lacking 3 parts to become one half. Because 5 parts is half of 10 parts. So then  $\frac{2}{10}$  is less than  $\frac{3}{6}$

Teacher: Right, do the rest of you agree? Yes. OK, what do we do next?

We see that Anne, in Ola's words, uses one half as a benchmark when comparing  $\frac{2}{10}$  and  $\frac{3}{6}$ . We note that Ola's explanation is incomplete; it does not state why  $\frac{2}{10}$  is less than one half. The PT seems to be aware of this, as she asks Per to *elaborate* Ola's thinking, from whom she receives the completed reasoning. In the next sample from Anne's script, a residual argument is pursued:

Teacher: All right, so now we know that  $\frac{2}{10}$  is the smallest, and then comes  $\frac{3}{6}$ , but which is the biggest of  $\frac{7}{8}$  and  $\frac{3}{4}$ ?

Per: Since  $\frac{1}{8}$  is smaller than  $\frac{1}{4}$  then  $\frac{7}{8}$  is the most

Mia: But why is that when  $\frac{1}{4}$  is a lot bigger than  $\frac{1}{8}$ ?

Teacher: Good question Mia, does anyone want to explain?

Ola: When we looked at  $\frac{1}{8}$  and  $\frac{1}{4}$  we were looking at how much was missing to fill one whole. The one that miss the biggest part is then missing the most, and therefore that fraction is the smallest. Because  $\frac{7}{8}$  is only missing a small  $\frac{1}{8}$  to become one whole.

Mia: Oh yes, now I understand, because we are looking at what is missing.

Anne does not acknowledge any students' claim without a justification. Through the whole of Anne's script, the teacher is encouraging the students to utilise their number sense when reasoning about the tasks. Similar approaches are also apparent in the rest of the 26 scripts, but not always as comprehensive as in Anne's case. One typical feature is that even though a mathematically correct conclusion is reached, there is no valid argument given by the students, and the PTs tend to accept this without comment. This is evident in Alice's script, when the students are comparing  $\frac{4}{8}$  and  $\frac{3}{4}$ .

---

<sup>1</sup> The original scripts were written in Norwegian, with translation to English by the authors of this paper. In the translation we have retained linguistic inaccuracies and imprecise use of terms, as in the original Norwegian.

Fredrik: Yes, me and my group decided that  $\frac{3}{4}$  is the biggest. I think that 3 is closer to 4, than 4 is to 8.

Teacher: That was good thinking. [Proceeds with a different task]

Our analysis shows a general tendency in the scripts that strategies based on number sense have some kind of justification, while strategies based on algorithms and rules are more likely accepted without justification. The above excerpt from Alice's script is one of few exceptions, where she gives a correct conclusion with an attempted justification that is not valid as an argument. Judging by the teacher's response, it seems that Alice regards Fredrik's argument as valid.

The following excerpt from Christine's script shows another problem.

Sindre:  $\frac{3}{6}$  must be the biggest, because that fraction is only missing 3 parts to become one whole, while  $\frac{3}{8}$  is missing 5 parts to become one whole.

Teacher: Yes, that's right Sindre. Did the rest of you understand what Sindre was thinking? Nina, can you explain what Sindre meant?

Nina: Yes, you can also say that  $\frac{3}{6}$  misses one half to be whole, while  $\frac{3}{8}$  lacks more than half to be whole, since it is lacking 5, and half of  $\frac{8}{8}$  is  $\frac{4}{8}$ .

Teacher: That was a good explanation, Nina. Did the rest of you also understand what Nina meant? (The class agrees.)

In this excerpt, we notice that Sindre's argument is wrong even though the conclusion is correct. Christine (in the role of the teacher in the discussion) does not comment upon this, instead simply accepting Sindre's argument. Interestingly, Nina subsequently gives a valid residual argument, but Christine does not draw attention to the difference in the two arguments in her script. Our analysis shows that similar arguments that "work" on the fractions in question, but where a counterexample would prove the argument not generally valid, are typical for many of the lesson plays.

Another aspect of our findings was the PTs' choice of tasks used in the discussions. Returning to Anne's script, she uses only two tasks. They both underpin the strategy in focus, and have a natural progression in complexity: The fractions involved seem to be carefully chosen to make her target strategy suitable, and residual thinking is further highlighted by Anne asking the question "Which of the fractions are missing the most to become one whole?" at the start of the discussion. In contrast to this, Molly's choice of tasks and the sequencing chosen, seems less appropriate: Compare  $\frac{3}{5}$  and  $\frac{3}{7}$ ;  $\frac{7}{7}$  and  $\frac{7}{9}$ ;  $\frac{2}{4}$  and  $\frac{3}{4}$ ;  $\frac{2}{4}$  and  $\frac{4}{8}$ ; and  $\frac{1}{2}$  and  $\frac{3}{6}$ . Molly does not state explicitly a mathematical goal for the planned discussion, and her imagined discussion covers several ideas in a brief way. Moreover, the progression of difficulty in the sequence of tasks does not seem to be well thought through: in the lesson script on the first tasks, Molly's fictive students use benchmarking with one half, indicating that one half is a well-known concept for them. To then proceed with the final three tasks focusing on equivalent fractions to  $\frac{1}{2}$ , seems exaggerated.

## Discussion

We now relate the findings presented in the analysis to the dimensions of the Knowledge Quartet.

## Foundation

For the foundation dimension, the most visible aspects are the PTs' mathematical knowledge of fractions and comparison strategies, as well as their beliefs about mathematics itself, and about mathematics teaching. In general, the PTs try to use strategies relying on number sense to compare fractions. This could indicate that the PTs value developing understanding rather than focusing on an algorithmic approach. The strategies attempted in the scripts are not always followed through in a mathematically valid argument, and some of the PTs fail to recognise the difference between valid and invalid arguments. Christine's script is an example of this.

Another finding is that very few scripts contain any attempt at discussing the *generality* of the strategies used. This indicates that the PTs' beliefs about mathematics might not include this as an important aspect of doing mathematics. Instead, the PTs seem to be satisfied as soon as the problem at hand is solved, as in Christine's script when neither Sindre's or Nina's arguments are investigated further from a general point of view. Recall that the task given to the PTs particularly required them to emphasise the development of their students' understanding and reasoning.

## Transformation

The PTs' scripts afford good insight into their choice of examples to elicit an idea. With very few exceptions, the tasks chosen by the PTs are suitable comparison tasks where it is clear that there is at least one number sense-based strategy that could be applied.

We proceed to consider the PTs' use of questions. In the context of PTs writing an imagined discussion, we regard this as a form of teacher demonstration, and thus consider it a part of transformation. We find in most scripts a use of certain techniques and types of questions known from their coursework literature on orchestrating mathematical discussions. For example, in Anne's script, the teacher's questions structure what her students have discovered and then seek to develop their ideas further. When Anne's teacher asks Per to elaborate Ola's thinking, she succeeds in bringing to light an argument. In other scripts, the PTs seem to emphasise the use of discussion techniques in itself to such an extent that it suppresses the attention on connecting the mathematical ideas. This can be seen e.g. in the excerpt from Christine's script above, where the teacher asks a student to repeat another student's reasoning without connecting the different explanations. Sometimes the PTs fail to notice when a clarifying question is needed. This can be seen in Alice's script above, where Fredrik's attempted justification is an invalid argument in general, and yet the teacher accepts it and proceeds without further enquiry.

## Connection

The *sequencing of tasks*, how one task should connect to the previous task, and the anticipation of what students will find problematic, is part of the connection dimension. We find that in most scripts, the sequencing of tasks is appropriate. However, we find examples of situations where the PTs do not seem to anticipate the complexity of the sequence of tasks. An example is Molly's script as discussed above. Other scripts seem to have too many tasks, given the time allotted. In these scripts the discussion moves forward smoothly with students giving the desired response quickly and effortlessly. This may indicate that these PTs do not anticipate complexity in the discussion and that the conceptual challenge for the students is underestimated. Thus, these discussions take more the form of numerous repetitions of the same procedure, which relates to the foundation dimension

of the KQ and perspectives on how mathematics is learned: These PTs seem to emphasize procedural repetition as an important aspect of learning mathematics, perhaps on behalf of unpacking the mathematics of the procedures. However, some scripts include deliberate mistakes and misconceptions made by the students, which are then discussed. We see this as an anticipation of complexity.

## Conclusions

Following the discussion above, we claim that lesson plays encourage the PTs to use and develop several aspects of their mathematical knowledge for teaching. For the foundation dimension, we claim that the insight we get from the scripts, is more than what we would get from simply assigning the PTs fraction comparison problems for them to solve. We note that several PTs write discussions including both valid and invalid arguments and both are accepted without further probing. For instance, Christine knows what a valid argument for comparing fractions looks like, but at the same time she accepts an invalid one. Such inconsistency in the PTs' thinking might become more visible when they plan teaching by imagining a detailed mathematical discussion.

We also claim that our findings show the importance of emphasis in mathematics teacher education on generalisation and argumentation, and how classroom discussions concerning generalisations could play out. Our PTs were asked to have those aspects in mind when writing their lesson plays, and yet it is rarely found in the scripts. How to develop the PTs' ability to emphasise this aspect more needs to be studied further. Managing classroom discussions is a complicated task for novice teachers. However, due to its high leverage on students' development of mathematical understanding it is a critical factor in mathematics teaching, and thus in teacher education.

## Acknowledgment

The authors thank Tim Rowland for many helpful comments and discussions, as well as for organising for us to come to Cambridge to work on our data in May/June 2016.

*The purpose of the current study is to provide findings of a follow-up study on a content course developed to improve specialized content knowledge of high school teachers. Elif was chosen to be interviewed among the participants of the content course according to certain criteria of sampling. Elif graduated within a year of taking the course and have been teaching in high school since. The individual semi-structured interview on her perceptions of how the content course influenced her teaching was conducted. The interview was transcribed and coded. Two themes emerged about the influence of the content course; using same examples or proofs, readiness to implement tasks for teaching. The findings show the participant's self-report of how she transformed her SCK experiences from university to her instruction. Furthermore, her answers revealed the relationship between SCK and PCK, how this unique knowledge of mathematics (SCK) forming basis for PCK.*

*Keywords: Specialized content knowledge, mathematical knowledge for teaching, novice teachers, content course, secondary mathematics teaching.*

## Introduction

Teacher knowledge has been in central position for teacher quality. Not only Shulman's (1986) work and emphasis on pedagogical content knowledge (PCK) but also further studies (e.g. Ball and her colleagues) on understanding nature of knowledge needed for effective mathematics teaching have been shedding light on role of teacher knowledge. In addition to studies to develop different models on teacher knowledge, there are many researches on understanding or improving teacher knowledge. However, most of those studies investigate either preservice teacher education (content or pedagogy courses) or in-service teachers (professional development). In this study the authors will share findings from a case study of a novice secondary school mathematics teacher's perception on influence of taking a content course focusing on Specialized Content Knowledge (Aslan-Tutak and Ertas, 2013) on her teaching. Authors will shortly review literature on mathematics teacher knowledge that guides this research.

## Mathematical Knowledge for Teaching

The theoretical framework of this study is mathematical knowledge for teaching (MKT) model developed by Ball et al. (2008). According to MKT model, there are six sub-domains of teachers' knowledge for mathematics teaching. Three sub-domains of subject matter knowledge are Common Content Knowledge, Specialized Content Knowledge, Horizon Content Knowledge, and sub-domains of pedagogical content knowledge are Knowledge of Content and Students, Knowledge of Content and Teaching Curriculum Knowledge. Since this model is very well known, in literature review part of this paper, authors will focus on only Specialized Content Knowledge (SCK). Further information about these domains can be read from Ball et al. (2008).

SCK is a type of subject matter knowledge; it is defined as mathematics knowledge which is unique to teaching. Indeed, it is about knowledge about mathematics, not teaching, but for teaching. Ball and her colleagues stated the role of SCK as follows:

What caught us by surprise, however, was how much special mathematical knowledge was required, even in many everyday tasks of teaching— assigning student work, listening to student talk, grading or commenting on student work. Despite the fact that these tasks are done with and for students, close analysis revealed how intensively mathematical the tasks were. (Ball et al., 2008, p.398)

Due to nature of SCK it may be omitted in university mathematics courses and also in pedagogy courses (Ball, et al., 2008). Especially in secondary school teacher education, mathematics courses are advanced and require teachers to study mathematics from a different perspective than teaching. Since MKT model was developed based on a study of elementary school teachers, it was necessary to revise definition of SCK for high school preservice teachers. In an attempt to improve high school preservice mathematics teachers the first author developed a mathematics content course. The course content was developed by addressing not only MKT but also Advanced Mathematical Knowledge model of Zaskis and Leikin (2010), Advanced Mathematics for Secondary School Mathematics Teachers by Usiskin and his colleagues (2003), and SCK task development perspective of Suzuka and her colleagues (2009). Usiskin and his colleagues emphasized three types of mathematics experiences for secondary school mathematics teachers; concept analysis, problem analysis and mathematical connections. Lastly, the content course practices were developed to allow preservice teachers to unpack their already existing knowledge and to develop a flexible understanding of concepts (Suzuka et al., 2009). How these models and perspectives were merged together to form a content course can be read in detail in author's previous paper for CERME 8 (Aslan-Tutak & Ertas, 2013).

Since our research is a follow up study, it is needed to mention about aforesaid content course's ingredients. The mathematical tasks which were used during the course can be categorized under four approaches; unpacking concept definitions, applications and modeling, procedures and generalizations, and historical perspective of concepts (Aslan-Tutak & Ertas, 2013).

Unpacking concept definitions practice was identified by participants as eye-opening experience. One example is the activity focusing on geometric definition of imaginary number " $i$ ". Almost all of the students stated that they had seen geometric representation of " $i$ " for the first time and they were really surprised. The instruction which focused on geometric representation of " $i$ " was discussed in Aslan-Tutak and Ertas (2013) as;

In order to explore number " $i$ ", instruction started with discussion on the roots of an equation as its constant terms changes (Usiskin, et al., 2003). Then graphs of the equations were plotted on Cartesian plane (geometric representation of the equations) and their roots showed on a number line (geometric representation of real numbers). The number line was sufficient for the roots of first two equations but participants realized that they could not show the roots of third equation on number line. Then, the definition of the imaginary number  $i$  was discussed by rotation of  $90^\circ$  perspective (Lakoff & Núñez, 2000; Trudgian, 2009; and Usiskin et al., 2003) which provides a geometrical understanding of the imaginary number.

Second categorization of the course was applications and modeling. In the content course, there were some modeling problems for the topic of functions and also alternative definition of function. An example of modeling activity was about oil spill and its cleaning procedures. At the beginning of the problem there were some discussion about oil spill incidents in Gulf of Mexico and France and its effect on environment. After discussion part, the students were taken the problem as: *If there was 8000 gallon oil due to a spill, and the crew can clean only 80% of oil for a week. So how much oil would remain after a week? And how long will it take to clean until there is 10 gallon of oil is left?* Erbas et al. (2014) discussed two approaches in use of modeling: as a means of teaching mathematics and modeling as an aim of teaching mathematics. In this current study, the authors used modeling in content course as a means of teaching mathematics. This practice was aimed to introduce preservice teachers to use mathematical modeling in instruction while examining definition of functions. In addition to modeling, history of mathematics was used for examining functions. For example, history of logarithm and Napier's problem were studied. The historical approach was not limited to functions but almost all the topics, such as history of irrational numbers.

Participants of the content course stated that, the proof of equality  $0,9999\dots=1$  was also one of the surprising tasks of the course. Seven different approaches to show it were posed to preservice teachers and then the relationship between the aforesaid proof and converting infinitely repeating decimals to fraction without any formula were established. This mathematical task was used with preservice teachers in different settings. Conner (2013) used this task to promote argumentation with preservice teachers. She stated that "Engaging prospective secondary teachers in mathematical argumentation is important so that they can learn to engage their own students in creating and critiquing arguments." (p. 172).

The second author of this current paper was a student at the time of the study. He graduated from the program and has been teaching for three years. The purpose of the content course was to improve participants' SCK which can be used during teaching. Therefore, the authors examined perceptions of participants, actively teaching in high schools, about how their learning from the undergraduate course transferred into their teaching.

## Methods

The two-year long study, SCK development of high school teachers, was conducted at a mid-size, western public university in Turkey. The content course was offered in 2011 fall semester and 2012 fall semester. Based on students scores on national central university entrance exam, this high school mathematics teaching program had the highest rank among all of the mathematics education programs in Turkey. Students of this program had to take advanced level mathematics courses such as calculus, linear algebra, and complex analysis. Seventy percent of the courses are mathematics courses. Pre-service teachers also took general pedagogy courses, mathematics teaching courses and school practicum courses. At the time of this SCK project, there was no content course in mathematics teacher education program. The content course that developed based on this project was therefore elective for students. There were 31 students who enrolled to this course in 2012 fall semester.

The sample of the current study was determined based on three criteria; graduation from the program and starting teaching in spring 2013, teaching in high school, and living in Istanbul. Some of the students did not pursue career in teaching but other professions such as economics. Also, not all

students graduated in 2013. This condition was necessary in order to allow minimum time between taking the course and starting teaching. The second condition of teaching in high school was used because the topics of the content course were high school topics. The topics of this course are not covered in middle school. In order to investigate how novice teachers' transfer their SCK learning into their practices, it was important to choose participants according to grade levels they teach. The last condition of living in Istanbul was for convenience, in order to be able to conduct interview easily. There are some novice teachers who fulfill the first two conditions but they were living in other cities. Considering all of these conditions, there are only two novice teachers. Since one of them is the second author of this paper, the only other novice teacher (Elif, pseudonym name) was the sample for this study.

Indeed, all these conditions are also helping researchers to establish trustworthiness of the study. The conditions allow clear examination of transferability of the study. The findings of the study can be transferred into settings where preservice teachers study mathematics content for SCK in context of teaching and start teaching afterwards. Furthermore, in order to improve trustworthiness of the study researchers did member-checking with the participant. In addition to asking Elif to confirm interviewer's interpretations during the interview, later researchers also contacted her to discuss about findings of this case study. The member-checking also aided for the conformability of the study. For conformability, after the completion of analysis done by the first author, the second author went through the analysis. After this two-stage of analysis, Elif's member-checking was helpful to finalize findings. Elif approved most of the findings and she improved what we called "completeness". This phenomenon of "completeness" is discussed in findings section.

Yin (2013) explained the rationale of using case study research methodology as explaining "how" or "why" questions in-dept. The purpose of this study is to investigate how a novice high school mathematics teacher uses her SCK experiences in the content course. How does this course influence her teaching practices? Since teaching is a complex practice, it was necessary to examine this research question through case study methodology. The authors conducted a semi-structured interview with the participant, Elif. The interview questions were in two parts (i) background questions (e.g. years of teaching), (ii) her experiences in the course as a student and how these experiences influence her teaching.

Elif's interview was first transcribed and the open-coded. After open-coding, Elif's answers on how the SCK tasks in the course influenced her teaching practice were emerged into two themes; (i) using same example, proof in the classroom, (ii) readiness for implementing tasks of teaching (understanding student misconceptions, answering student questions, material development).

## **Findings**

The first part of the interview was to understand Elif's teaching experiences and the environment that she has been working in. The school environment and possible mentor-mentee relationship is important in novice teachers development of practice. Elif took the content course in fall 2012 and graduated from university on June 2013. Right after her graduation, she started to work at a private high school, Baris Schools. Baris Schools is a school of a foundation which has more than 100 years background in education. Baris Schools have three K-12 campuses in Istanbul. In other words, Elif started to work at a well established school, a good opportunity for a novice teacher. After her first

year, she transferred to another campus and has been teaching for two years at that campus. So, she has been teaching high school (9-12 grades) for three years. In the interview, she stated that her school is a good place to learn about teaching. Considering how she transferred what she learned in content course in her teaching, she stated that mathematical exploration in the course provided her “completeness” for the topics/concepts that were covered in the course.

Elif: You can guide, direct the students to understand concept because you know that concept.

Interviewer: How do you direct them?

Elif: You construct the concept together, like  $i$  square to be -1, by asking questions, when you are complete for content.

Especially as a novice teacher, she valued this feeling of completeness both when preparing instructional material and during the instruction.

Elif: When teaching, for the concept, you can be prepared. Your explanations are complete, select materials and put them in order.

According to Elif, completeness is a broad term which includes readiness to unexpected questions, constructing relationships between mathematical concepts and having deep understanding of the concepts. Her answers on how she transferred what she learned in the course to her teaching practice will be discussed in detail according to two themes that were emerged from data.

### Using same examples or proofs

She stated that she kept all of the course materials, book, notebook, activities and presentations. She said, for some topics, she specifically used same examples. Her answers on what she kept same for her teaching reveal that she used alternative definitions (number  $i$ , mathematical functions), proofs (irrationality of  $\sqrt{2}$ , quadratic formula), and examples given for concepts (examples for exponential functions). For example, she had been teaching complex numbers for two years, she stated that she always introduced number  $i$  by the same geometric definition from the content course. But she made a differentiation about using materials from the course. Elif stated that while she was teaching geometric definition of number  $i$  for whole class instruction, she used many proofs only when certain group of students asked for further mathematical knowledge. She said that she decided to use a definition/proof/example based on students’ mathematics level. In the following quote from the interview, she described how she used “deriving the quadratic formula” that she learned in the content course.

Elif: When I explain it (quadratic formula) to students, even the order of doing it was stuck in my mind because we teach it this way, we give formula at the end. Before that to make square formula...It make sense, you get quadratic formula from making square formula. Discussing  $b^2 - 4ac$  from the beginning, why there are two roots, or one root...Yes, it’s a terrible formula but we derive it together, of course with the ones who are good at math

## Readiness to implement tasks of teaching

Content course, in other words SCK tasks that were done in the content course, aided Elif's teaching during the instruction when answering student answers. In the individual interview, Elif discussed about using her mathematical experiences from the content course. Many of Elif's answers to interview questions were emerged to form the theme, readiness for teaching. However, her answers were similar to mathematical tasks for teaching addressed in MKT model (Ball et al., 2008). So, in order to put emphasize on Elif's differentiation of demands of teaching, we merged her answers together and named them *readiness for implementing tasks for teaching*. As it was stated before in her feeling of completeness, she emphasized *knowing what to prioritize in teaching a concept*. She explained knowing and realizing the big idea in concepts several times. For example, while she was getting ready for teaching a concept, she knew what to emphasize in instruction even before thinking about how to teach it.

Elif: In complex numbers, maybe students didn't get why square of  $i$  is  $-1$ , but I checked my notes (from content course) in order to get 180 degree rotation thing in my mind so I can teach it. This was for me actually.

The second code is *building awareness*, and directing her to find other resources. Elif didn't have to use same examples from course in her instruction. Mathematical tasks provided some awareness to her and she did further research about certain concepts. She stated that based on mathematical tasks in the course, she searched and found other tasks/examples from Khan Academy or YouTube. The third code is *directing students to understand concepts*. Elif emphasized the role of mathematics that she learned in course to help her ask mathematical questions to guide student thinking. In a sense, this is related to first code, identifying and knowing big idea of a concept. Further to that identifying big ideas, in this code, she is using that knowledge for directing student thinking.

Elif: In the class, maybe I didn't use exactly same example but when there is a student question, if it is related to mathematical concept, I can just direct student to reach the concept. Because I learned that content.

The fourth code under readiness to implement tasks of teaching is *answering student questions and addressing their misconceptions*. This code is related to previous one but Elif made explicit differentiation between directing students and answering students' questions.

Elif: When someone asks, or what does quadratic formula mean, why do we need it. I know these. When there is a question like these I can answer them easily.

Here, Elif focuses on her state of being confident in her mathematics knowledge when answering student questions. The last code, fifth one is related to her *implementation of curriculum*. As a novice teacher Elif stated using textbooks and course materials from other experienced teachers. However, she realized differences between her and experienced teachers in terms of implementing curriculum. In her first year, the national curriculum was revised extensively. One of the changes was how functions were introduced in 9<sup>th</sup> grade. In previous curriculum, first mathematical relations were introduced and then set theory approach of functions was given. In revised curriculum, functions should be taught through mathematical modeling without an introduction with mathematical relations. The covariation definition gains importance in this new curriculum. Elif realized that knowing alternative definitions of function (including covariation) helped her to easily adapt her

instruction to new curriculum. The SCK experiences of the content course provided basis for her use of the new curriculum. Furthermore, she was able to implement certain features of the curriculum while experienced teachers omitted.

Elif: Maybe, they don't think it (proof of  $\sqrt{2}$  irrationality) is important. Because other teachers also analyzed the new book, but I said we need to do this. They didn't want to spent time on it. This actually give information about what do we need to give importance conceptually.

## Discussion

The purpose of this study was to investigate perception of novice teachers on how they transfer what they had learned in the content course into their practices. Elif, a former student of this course and with 3 years of teaching experinece, was volunteer to participate this follow up study. She stated that the course and mathematical explorations (SCK tasks) clearly helped her in teaching. The most expected influence would be using mathematics examples, tasks from the course. Usiskin and his colleagues (2003) discussed that "Often the more mathematics courses a teacher takes, the wider the gap between the mathematics the teacher studies and the mathematics the teacher teaches" (p. 86). So, based on findings from Elif's case study, it should be explored further if a content course with SCK tasks provides mathematical explorations that preservice teachers will be teaching in their profession. Furthermore, these SCK tasks also allowed Elif to unpack her knowledge of mathematics (Suzuka et al., 2009) so she could identify mathematical big ideas and prioritize important concepts.

It is important to note Elif's feeling of readiness in her first three years of teaching. There are various demanding tasks of mathematics teaching such as selecting appropriate mathematical task, using proper representations, answering student questions, and leading student discussions. Elif mentioned five different tasks (themes emerged from data analysis) of teaching that influenced by her experiences in the content course. Her discussion of these tasks may be used to depict how SCK is taking role in classroom instruction. It can be used to discuss the link between SCK and PCK. For example, when Elif discussed role of knowing mathematics in directing students to understand concepts, she was actually talking about PCK. She explained and clearly discusses the role of specialized knowledge of a teacher. Without this type of mathematics knowledge, she will be lacking directing students. Similarly, in using curriculum materials, she uses her SCK knowledge.

There are some limitations of this study such as sampling only novice teachers in Istanbul, and also relying on participant's self report on how she transferred what she learned in the content course. Even though, interview questions were specifically asking about the content course, there is still a limitation of influence of all other teacher education courses/practices on Elif's transfer from university to her teaching. Furthermore, Elif also has been teaching at a prestigious high school which provides various resources for a novice teacher to improve herself. In order to investigate further how preservice mathematics teachers transfer what they have learned into their teaching, researchers are planning to extend the study to include other participants who possess different characteristics.

# Study of primary school teacher's practices for a lesson after a Lesson Study process in mathematics

Valérie Batteau

HEP Lausanne-University of Geneva, Switzerland; [valerie.batteau@hepl.ch](mailto:valerie.batteau@hepl.ch)

*This study presents the analysis of primary school teacher's practices in mathematics for a lesson that has taken place after a professional development training called lesson study (LS) in Lausanne, Switzerland. Practices are analysed in a double didactical and ergonomical approach. The methodology used is a case study of the particular teacher's practices. Results about the teacher's practices after the LS process are discussed.*

*Keywords: Teacher's practices, problem solving, lesson study.*

LS is a field of research and professional development developed principally in Asia, in US and in Northern Europe (Lewis & Hurd, 2011; Yoshida & Jackson, 2011). LS is a collective and reflexive process that involves a group of teachers and facilitators meeting to improve instruction.

This study concerns practices of a teacher who participated to a LS process and this study falls within the "double approach" (Robert & Rogalski, 2002, 2005).

## Theoretical framework: The "double approach"

Teachers' practices are analysed using the following theoretical framework: the "double approach" based on a French didactical approach (Robert & Rogalski, 2002, 2005) and an ergonomical approach based on activity theory (Leontiev, 1975; Leplat, 1997).

This "double approach" distinguishes the task, the "goal to be attained under certain circumstances" and the activity, what the teacher engages in during the completion of the task (Rogalski, 2013, p. 4). The prescribed work fits the *prescribed* task (in our context: what the teacher must do according to Teacher's Handbook and the official program) and the real work fits the *conducted* task (in our context: what the teacher does in reality during the lesson). To appropriate the *prescribed* task, the teacher should modify it. Thus, a gap exists between the *prescribed* task and the *conducted* task: the reasons can be a lack of the necessary competencies or an inappropriate representation of the task for example (Ibid.). Leplat (1997) adds two levels of tasks: the *represented* task (in our context: how the teacher represents the *prescribed* task and what he thinks we attend of him) and the *redefined* task (in our context: the teacher redefines his task according to the *prescribed* task and his own professional goals). These levels of tasks are neither hierarchical nor time: the teacher can represent the *prescribed* task and can redefine a new task before and during the lesson in taking into account different sources (students' activity, his own activity, institutional constraints).

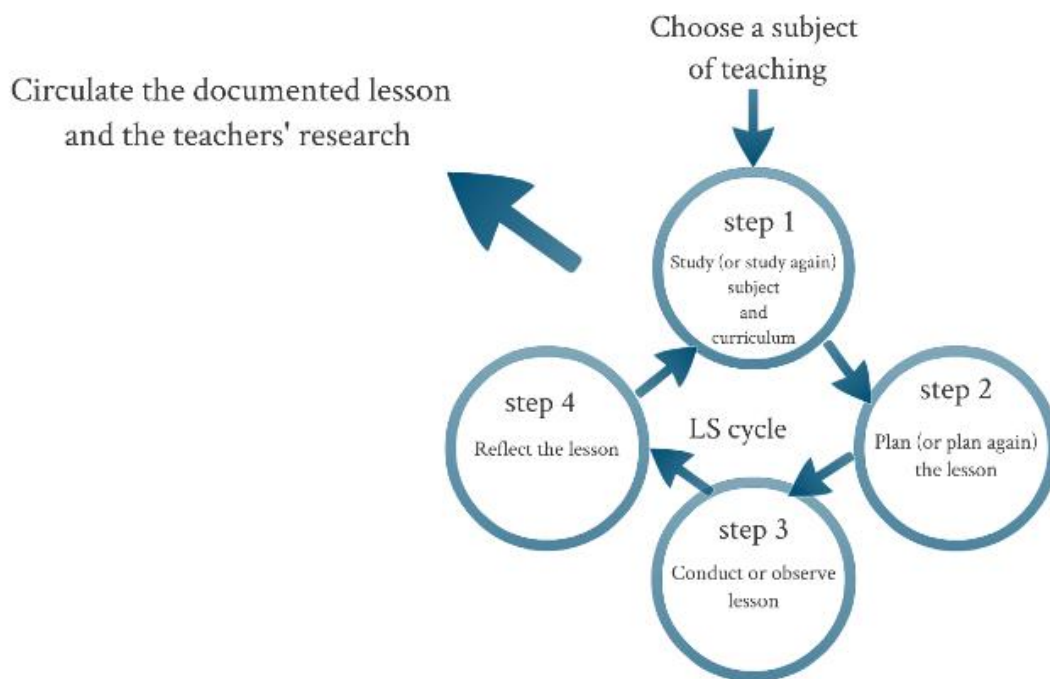

The teacher combines professional acts and knowledge (mathematical, didactical, pedagogical) in his representation of the *prescribed* task and in his redefinition of the *represented* task. This study focused on these professional acts and knowledge at stake in these representation and redefinition. Thus, the teacher's activity is analysed as a process of modifications between the *prescribed* and *conducted* tasks (Leplat, 1997; Mangiante, 2007).

## Research question

This case study aims to provide elements to respond to the following question: what are the sources of the process of modifications between the *prescribed* and *conducted* tasks?

## Methodology and data

This qualitative study used a case study to analyse teacher's practices. A LS process (see Figure 1) can be decomposed four steps (Lewis & Hurd, 2011, p. 2): the group studies a mathematical subject, standards and sets instructional goals (step 1), the group prepares a research lesson based on their study of the topic and standards (step 2), the group selects one teacher to conduct the research lesson while others observe and collect student data (step 3), and finally, the group analyses and reflects on the research lesson (step 4), with the option of teaching it again (Batteau, 2016).

**Figure 1: A LS cycle (Lewis & Hurd, 2011)**

In the Swiss context, some researchers chose to implement this form of LS process without modify the structure in four steps because this model fits a French didactical point of view (Clivaz, 2015): the Theory of Didactical Situations (Brousseau, 1997; Warfield, 2014). In the TDS, the methodological research tool consists of an *a priori* analysis of the possible teaching of a mathematical subject: the steps 1 and 2 fit a deepen *a priori* analysis with a study of the mathematical subject, the didactical variables, the student's strategies, and difficulties. A second methodological research tool (in the TDS) consists of an *a posteriori* analysis, who takes place during the step 4, which compares what would be anticipated and what is happened. Thus, a LS process in mathematics began in Lausanne in September 2013 and occurred over two years with two

collective sessions occurring per month (Clivaz, 2016). The group consisted of eight primary school teachers ranging in experience, voluntary, and generalist<sup>1</sup> teachers, and two facilitators<sup>2</sup>.

This study focused on Océanes' practices for one lesson observed after the end of this LS process. For this teacher, data were collective sessions during the LS process (cycles *c* and *d* about problem solving), one lesson after the LS process (about problem solving), informal meetings after this lesson, all written documents produced during the lesson, and student work. Video data (lesson and collective sessions) were transcribed. This teacher has seventeen years of experience and students eight to ten years old.

To operationalise the theoretical tools presented for this study, the *prescribed* task fit the aim of the problem chosen by Océane, the Teacher's handbook, and the planning material for this problem. The *prescribed* task is analysed *a priori*, which means the mathematical knowledge at stake in the problem, the possible resolutions, and the didactical variables were analysed. We analysed the modifications between the *prescribed* and *conducted* tasks. To explain these modifications, we analyse the representation of the *prescribed* task and the redefinition of the *represented* task with using the informal meetings and collective sessions.

This paper presents first the mathematical subject worked during the LS cycles *c* and *d* before this lesson.

## Analysis

### Cycles *c* and *d* of the LS process

During the cycles *c* and *d*, the group worked on problem solving and how to help students represent a problem. The group relied on an article (Julo, 2002)<sup>3</sup> in which the main idea was explained during a collective session.

Facilitator: (quoting Julo) “this help doesn't give clues about the answer, doesn't guide to a strategy and doesn't suggest a modelling”. But it's difficult to achieve, it's written just after that. It is an ideal [...] but if we don't follow this ideal, it means that we do precisely a part of what students have difficulty to do.

The research lesson of the cycle *d* was based on this problem: examine the matchstick pattern represented below. How many matchsticks are needed to align 99 squares?

---

<sup>1</sup> In the French speaking part of Switzerland, primary school teachers teach several school disciplines (mathematics, French, sciences...).

<sup>2</sup> In this particular LS process, the two facilitators were researchers in Mathematics Education and in teaching and learning (Clerc-Georgy & Clivaz, 2016). They had the role of trainers and « knowledgeable others » (Lewis & Hurd, 2011, p. 30;33).

<sup>3</sup> During the first collective session of LS process, teachers said to facilitators which subject they wanted to work according to their teaching difficulties and/or students' difficulties. The subjects were numeration (cycle *a*), isometries (cycle *b*), and problem solving (especially how to help students represent and model a problem, cycles *c* and *d*). Then, the facilitators proposed reading this paper to teachers, in order to find elements of answer to this issue.

**Figure 3: Problem “99 squares” (Teacher's handbook of 6H, Danalet, Dumas, Studer, & Villars-Kneubühler, 1999, p. 187)**

The mathematical function at stake was  $u(n)=3n+1$ , where  $n$  is a whole number. The group worked on this problem focussing on how to help students represent and model this problem.

### Context of the lesson observed after the LS process

For this lesson, Océane chose to manage problem solving and she explained it during a collective session at the end of the LS process.

Océane: There is a lot of problem which I think oh I don't dare to try [...]

Océane: I think, this year with my students, I take the textbook and I do a lot of things I never did before.

Anaïs: Oh, you dared.

Océane: Yeah, I did.

### The prescribed task: some elements of analysis

For this lesson after LS, Océane chose the problem “Fold”: Fold a strip of paper in half, here are two parts. Fold a strip of paper in half, then a second time, here are four parts and so on. How many parts are there with a folded strip of paper ten times?

How many parts are there with a folded strip of paper ten times?

*Avec une bande de papier*

**Figure 4: Problem “Fold” from (teacher's handbook, Danalet et al., 1998, p. 96)**

The aim of this problem is to develop reasoning capacities and research strategies (Ibid.). In this problem, students should go from handling to representation in order to predict the result of acts (Ibid.). To determine the number of parts when the strip of paper is folded 10 times, we should

calculate  $2 \times \dots \times 2$  with ten factors 2 (or 2 power of ten). Thus, to find the number of parts with a strip of paper folded  $n$  times, it's not necessary to know the answer when the strip of paper is folded  $(n-1)$  times.

The problem solving “Fold” is similar to “99 squares” in that sense these two problems rely on functions (power function or affine function). The kind of functions and the context of these problems are different but the idea of function is the same and the idea that it's possible to determine the number of matchsticks whatever the number of squares or the number of parts whatever the number of times we fold the strip of paper.

### **Modifications between the *prescribed* and *conducted* tasks**

Some significant elements of modifications between the *prescribed* and *conducted* tasks are summarized about the mathematics at stake in the problem. Océane took over the modelling of the problem: she realized a two-column table, then students had to complete it by calculating doubles. Thus, she modified the aim of the problem. During informal meetings, she said that she chose this problem to introduce the multiplication. The issue of the problem is not the same for her (involving the multiplication) and for the designer of the problem (modelling a problem). During the lesson, she took over the modelling of this problem instead of students. Furthermore, she reduced the problem to calculations of doubles of numbers as in this characteristic extract of the lesson.

Teacher: doubles. Here, we double. We double every time. The double of two, four. The double of four, eight. The double of eight, sixteen. The double of sixteen, thirty-two. The double of thirty-two, sixty-four. The double of sixty-four? All right? So Nadège, the double of sixty-four is? It folds in seven times. [...] It's as if we calculate sixty-four more sixty-four. Is it? (*Nadège looks all the folds in her strip of paper*).

Nadège: one hundred twenty-six. One hundred twenty-eight.

Teacher: great. [...] Next, Luc?

Luc: two hundred fifty-six.

Teacher: very well. Yes? If we fold it nine times, it should be?

Romuald: five hundred six.

When Océane prepared her lesson, she did not identify the mathematical knowledge at stake in the problem (power of two). She validated students' strategies only with calculations (see extract), and she did not link strategies together. In this extract, she said “the double of sixty-four is? It folds in seven times”. However, she did not explain why it's necessary to multiply by two when the strip of paper is folded half. Her strategy of doubling could not allow to respond directly to the problem. With her strategy of doubling, in order to find the number of parts with a strip of paper folded ten times, it's necessary to know the answer when the strip of paper is folded nine times and eight times, ..., until two times (see Figure 5). With the “expert” strategy, to find the number of parts when the strip of paper is folded  $n$  times, the students should calculate the product  $2 \times 2 \times \dots \times 2$  with  $n$  factors 2.

Using a similar problem solving activity than for the research lesson of the cycle  $d$ , Océane could not identify the mathematical function at stake.

Another modification of the *prescribed* task was to propose to students to calculate the number of parts when the strip of paper is folded 11, 12, 13, and 14 times (see Figure 5). This modification was coherent with the teacher's strategy because it was not possible to propose to calculate the number of parts when the strip of paper is fold 100 times for example without the "expert" strategy.

FOLD	PARTS		
1	2		
2	COUNT UP TO 4	2+2	
3	8	4+4	
4	16	8+8	
5	32	16+16	
6	64	32+32	
7	128	64+64	
8	256		

9	512
10	1024
11	2048
12	4096
13	8092
14	16384

**Figure 5: Reconstitution of the blackboard**

In the blackboard, Océane wrote only additions to fill in the table, but nor multiplication neither "double of a number". To fill in the second line of the table, she wrote two strategies without linking: count up to 4 and  $2+2$ .

This modification illustrated the focus of the lesson on calculation of double (with additions) and nor on modelling the problem, neither on the explanation of strategies and the links between the different strategies.

### Representation of the *prescribed* task

Océane represented the *prescribed* task in according to her mathematical analyses. Before teaching, she prepared her lesson and realised mathematical analysis. The issue of the problem (modelling) took over by the teacher. In her analysis, the mathematical knowledge at stake in the problem are multiplication and doubling of a number. In the teacher's handbook, the aim is to represent, to model a problem, to develop reasoning capacities and research strategies. Her analysis was in contradiction with the teacher's handbook. Thus, she took freedom in relation to institutional constraints of the Teacher's textbook.

### Redefinition of the *represented* task

Océane anticipated the two-column table to fill in, so she anticipated to take over the representation of the problem and his modelling before this lesson. During this lesson, she taught vocabulary, "double of", and she focused only on calculations. In her redefinition of the task, she modified the problem in a problem of calculation when the strip of paper is folded 2 until 14 times.

In her redefinition of the task, she modified the problem according to her mathematical analysis and her representation of the task.

### Process of modification between the *prescribed* and *conducted* tasks

The process of modification between the *prescribed* and *conducted* tasks had its origins in her representation of the *prescribed* task for this lesson. Océane took into account the students' activity for the first time she taught this problem (last year). Then, she adapted her teaching when she taught this problem for the second time (for this lesson after LS): she took over the modelling and imposed

a two-column table to fill in. She did not take into account students' activity during this lesson but by anticipation.

## Conclusion

This case study proposed an analysis of particular teacher's practices during a lesson after a LS process. After the LS process, this teacher has self-confidence over teaching problem solving. In teaching problem solving, it should be able to identify mathematics at stake in the problem. Mathematics at stake should be given by the mathematical textbooks, but it was not the case. In the French part of Switzerland, official textbooks lack mathematical analysis for the teacher to use while planning lessons. For this lesson, the representation of the *prescribed* task relied on the Océane's mathematical analysis which were not sufficient. Thus, her representation and her redefinition of the *prescribed* task did not allow to reach the mathematical learning intended by this problem. To conclude, the sources of the process of modifications for this lesson were her representation of the *prescribed* task and her mathematical analysis. This case study highlighted a gap between the *prescribed* and *conducted* tasks due to the teacher's representation and mathematical analysis.

# Developing student teachers' professional knowledge of low attainments' support by "learning-teaching-laboratories"

Ralf Benölken

University of Münster, Germany; [rben@wwu.de](mailto:rben@wwu.de)

*This paper presents a study that is part of a project named MaKosi ("Mathematische Kompetenzen sichern"). It aims at the conception and evaluation of a program in which primary student teachers and children who are low attaining in arithmetic work together. The organization refers to a specific form of project seminars called "learning-teaching-laboratories". The study investigates how knowledge of identifying and supporting low attaining children develops by participating in such a program. Qualitative data were generated by learning maps in a pre-post-design and analyzed by a reconstructive pedagogic-icnological image interpretation. The results indicate a sustainable positive development of student teachers' knowledge.*

*Keywords: Professional development, learning-teaching-laboratories, low attaining students.*

## Introduction

Concepts of teachers' professionalization are an important focus of current research in mathematics education (e.g., DZLM, 2015). Regarding a specific professional knowledge of teachers, the development of pedagogical content knowledge (PCK) including, in particular, the development of abilities to analyze children's thinking and learning is reputed to be one of the main goals (Sowder, 2007). Moreover, beyond cognitive aspects, some recent approaches on teachers' knowledge consider affective components like beliefs (Kuntze, 2012). Questions that arise from this are, e.g., how student teachers' education on analyzing children's learning trajectories can be realized, and as a result how cognitive and co-cognitive components of student teachers' knowledge develop. In this paper, the attention will be given to the aspects mentioned above by a synthesis of different approaches within a qualitative study: With regard to analyses of children's thinking and learning, the development of primary student teachers' knowledge about the identification and support of low attainments (ISLA) is focused on, since analyzing mistakes is assumed to be a valuable resource in this context (e.g., Ribeiro, Mellone, & Jakobsen, 2013). As to a suitable organization of a professional development program, the approach of "learning-teaching-laboratories" (LTL) is applied, which reflects an important part of current discussions on student teachers' education in Germany (Roth, Lengnink, & Brüning, 2016). Summarized, LTL provide project seminars intertwining student teachers' theoretical and practical education by working with children, i.e., via learning by teaching. The following questions will be investigated: *How can a development of student teachers' knowledge about analyses of children's thinking and learning in mathematics be organized by a connection of ISLA- and LTL-concepts? How does their knowledge by taking part in an ISLA-LTL develop?* First, brief overviews of the theoretical frameworks will be given. On these bases, a LTL-concept will be outlined. Finally, the study's design and results will be subsumed and discussed.

## Theoretical frameworks – brief overviews

As to *teachers' professional knowledge*, the classical concept distinguishes between subject matter knowledge, PCK and curricular knowledge. Summarized, PCK refers to knowledge of possibilities regarding teaching subject matters (Shulman, 1986). Independent of certain approaches, there seems to be a consensus on the fact that PCK bridges subject matter knowledge and teaching, and it designates a specific-distinctive manner of teachers' professional knowledge (Brown & Borko, 1992). According to Ball, Thames and Phelps (2008), PCK covers knowledge of content and students, knowledge of content and teaching, and knowledge of curriculum. In particular, the first mentioned aspects provide facets that are connected to analyzing children's thinking and learning as well as to providing an adequate support (Sztajn, Confrey, Wilson, & Edgington, 2012). Because drawing an exact distinction between cognitive aspects regarded by knowledge and affective aspects like beliefs is felt to be difficult, some current research combines both aspects to describe teachers' professional knowledge; inter alia, pedagogical content beliefs (PCB) are described as an equivalent to PCK: Convictions about handling specific instructional situations (Kuntze, 2012) like ISLA. Recent competence frameworks of professional development programs are in line with such approaches. Beyond mathematics-related beliefs, self-oriented ones are considered including components like self-efficacy (e.g., DZLM, 2015), which produces a more holistic view. The study's framework refers to Kuntze (2012). Thus, a combination of cognitive (PCK) and affective aspects (PCB) is assumed. Additionally, self-oriented beliefs are considered in the context of PCB, since in this way a holistic base to describe changes of knowledge by taking part in a LTL is given.

Research on individual *problems in learning mathematics* covers a large range: Beyond approaches that describe such problems as a social construct, or approaches focusing on learning difficulties or disabilities in a narrower sense (for a survey: Scherer, Beswick, DeBlois, Healy, & Moser Opitz, 2016), different approaches focus on previously low achievements (e.g., Watson & De Geest, 2012). The perspective mentioned last mostly concentrates on arithmetic and in this context on typical phenomena such as rigidified counting (and a unilateral ordinal understanding of numbers) and an insufficient understanding of mathematical operations or the place value system (for surveys: Benölken, 2016; Denvir & Brown 1986). Mostly, a group of children is addressed which can be supported within a school's infrastructure, i.e., which does not show learning difficulties in the outlined narrower sense. As to identification or support, recent research independent of certain approaches demands a holistic view considering both cognitive and co-cognitive parameters (e.g., Nolte, 2009). Against the background of student teachers' education, the theoretical framework of both the LTL and, thus, the study corresponds to different aspects of the above outlined approaches: As to problems in learning mathematics, low attainments in arithmetic are focused on considering both typical phenomena and a holistic view in the identification and support procedures.

As to the development of PCK, practical situations that demand, e.g., scaffolding skills are assumed to be adequate opportunities of extending knowledge (Prediger, 2010). Existing findings indicate that one-to-one-interactions of a student teacher and a child might be a promising organizational form (e.g., Kilic, 2015). Against this background, "*learning-teaching-laboratories*" aim at a mutual growth and practical application of knowledge by a specific form of academic studies combining three dimensions: First, the support of children regarding a certain topic; then, the education of student teachers in this context, e.g., as to diagnostics and support; third, research aims like theory

building in the content focused on (Roth, Lengnink, & Brüning, 2016). Recent research mainly concentrates on a clarification of LTL-types and on an interdisciplinary consensus about defining the term of LTL. An example is given by the following definition:

LTL define a specific form of organization as to student teachers' academic studies combining children's learning with student teachers' professional development in a holistic way. In contrast to, e.g., standard lectures, seminars or practice lessons, LTL offer student teachers opportunities to develop, to enhance and to apply iteratively various skills of diagnostics, support and, thus, both teachers' professional acting and knowledge with regard to specific focuses in authentic, but complexity-reduced learning situations. (Brüning, 2016, p. 1274; translated by the author)

Hence, LTL include aspects and influences that are considered as most important by approaches on teachers' professional growth like the individuality of their learning in mutual reflection and enactment processes (e.g., Clarke & Hollingsworth, 2002). Even if LTL are conducted at more and more German universities in different "STEM"-disciplines, ongoing studies still focus on their evaluation. First impressions indicate that LTL are highly valued by student teachers and they are suited to ensure a sustainable growth of their knowledge about the respective topic (e.g., Brüning, 2016). The study's framework refers to Brüning's definition. Its cornerstones are transferred to the context of ISLA. The demanded complexity-reduction is realized by one-to-one-interactions.

### **Survey of a LTL-concept in the context of ISLA**

The presented study is part of the long-term project "MaKosi" that focuses on the conception and evaluation of a professional development program connecting ISLA- and LTL-approaches (for details: Benölken, 2016). Summarized, the aims are the support of children low attaining in arithmetic and the development of student teachers' knowledge of ISLA. The student teachers' education is organized as a combination of a theoretical course and a project seminar with children. The theoretical course covers information about approaches in the field of problems in learning mathematics as well as concepts of diagnostics and support. While the theoretical course is a regular seminar at university, the project seminar takes place at a primary school once a week about 15 times per semester. Against the outlined framework of ISLA, diagnostics triangulate different tools: In a first step, teachers are given information about the framework and they elect children providing a justification in written form. Then, parents have to fill in a declaration of consent. In a second step, children, student teachers and scientists come together to get to know each other in a playful first session. In a third step, process-diagnostics follow considering both cognitive and co-cognitive parameters; mostly, non-standardized tools such as observations on children's task solving using rating sheets or guided interviews with children, teachers or parents are applied. Every project seminar session is divided into three parts: First, a preparing workshop where student teachers and scientists come together for 15 minutes in order to highlight specific aspects of observation or other determining factors; second, a 90-minute-children-session; finally, a reflecting 75-minute-workshop, in which each child's problems and possibilities as to an appropriate support are discussed. Within this schedule, the children's session is divided into three stages: In the beginning, a playful problem task is offered avoiding arithmetic contents to provide an adequate imagination of mathematics or to support both a positive self-perception of mathematical abilities and joy of problem solving (for example, the problem of "a ferryman, a wolf, a sheep and a head of cabbage").

At this stage, children can organize themselves considering ideas of a natural differentiation. Subsequently, one student teacher and one child turn into one-to-one-interactions of diagnostics and support in established teams for 60 minutes. Thus, the student teachers can develop, e.g., scaffolding abilities in a complexity-reduced situation. Tasks and activities applied in this context are taken from well-proven examples of literature (for examples see: Benölken, 2016), which the student teachers got to know in the theoretical course. They develop suggestions on both their compilation and detailed planning which are discussed during the reflecting workshop with all participating student teachers and the supervising scientists in order to ensure sustainable conducts. Each session closes with a game to support the children's joy of participating in the LTL.

## The study

The study focuses on the *question* how student teachers' knowledge of ISLA develops by taking part in an ISLA-LTL. The *participants* were 25 primary student teachers; 11 (10 females, 1 male) took part in the winter semester 2015/2016, and 14 (only females) in the summer semester 2016. Mostly, they were in their third year of undergraduate studies. The study's character is explorative, i.e., generalizations were not intended, but existential propositions (Lamnek, 2010) about possible developments of knowledge by participating in the LTL. Thus, a qualitative *design* was advisable. As to the *method*, qualitative data were generated according to Rott (2017) by applying learning maps in a pre-post-comparison which were anonymized by codes to ensure unbiased interpretations. In the head, the student teachers were given the impulse to craft their way between their current status and their future work at schools: "Dealing with low attainments will be a challenge as to your work as a teacher, especially due to the knowledge of identification and support: What does this mean to you personally? Which way have you covered or which way will you have to cover in the future? Please lay out your way." (translated from German) All participants designed the maps for the first time, and they had to do it before taking part in the LTL at the beginning of a semester, and, again, at its end. As to the *analysis*, the pre- and post-maps were compared by a reconstructive pedagogic-iconological image interpretation, which becomes more and more accepted in different scientific disciplines. Its characteristic steps were observed: (1) Discussion of previous history and selection of key images, (2) image description and analysis (with regard to the factual, expressive and form-related sense), (3) context analysis, and (4) comparative analysis (Schulze, 2013). Data were interpreted within two meetings at the end of the summer semester 2016: The 14 participants analyzed in groups of two or three at least one, but for the most part two pairs of maps. Afterwards, the results were presented, and major observations were discussed in a plenary session.

## Results

As to *key images*, their *description* and *analysis*, three types were identified: (1) An interrupted path, (2) a continuous path, and (3) a system of paths. The first type was found only within the pre-, the third one only within the post-, but the second type within both the pre- and post-drawings. Subsequently, we focus on the reconstructions of the examples shown by the Figures 1 and 2, which were conducted in the group meetings mentioned above and which reflect typical main features.

**Figure 1: First example of a pre- (left) and post-map (right)**

**Figure 2: Second example of a pre- (left) and post-map (right)**

As to the factual sense of the first example's pre-map (Figure 1, left), a lack of details is obvious, which might reflect that the creator is unfamiliar with the context. The expressive sense is characterized by monotony as to, e.g., colors, which might indicate the creator's uncertainty. Regarding the sense of form, the interrupted way seems to reflect that the creator cannot (yet) imagine how to achieve the purpose. As to the factual sense, the post-map (Figure 1, right) contains more details: Different remarks are phrased; thus, the creator seems to connect many thoughts to the path. Merged stars seem to reflect interdependent experiences that influenced the creator positively, but a question mark seems to indicate obscurity about future requirements. The expressive sense is characterized by a use of different colors highlighting the significance of the experiences' connection, for instance. As to the sense of form, the continuous path obviously reflects that the creator now perceives a way to achieve the purpose, even if it is flanked by the question mark. The path precedes the current status; thus, the creator seems to have developed a more holistic view on the way he or she passed. As to the factual sense of the second example's pre-map (Figure 2, left), a main feature is a wide range of remarks, which seems to reflect that the creator already connects several aspects to the path. An important detail is the remarks' phrasing in the form of questions in most of the cases; thus, the creator rather seems to ascribe uncertainty or just a small level of recognition to him- or herself. Moreover, clouds seem to emphasize particular past and future experiences. The expressive sense is rather monotonous, e.g., as to the coloring, which might indicate that the creator refers to a matter-of-fact way. Regarding the sense of form, the continuous path is drawn as a stairway; thus, the creator obviously distinguishes different steps of his or her knowledge's complexity. Arrows emphasize secondary objects, which might reflect that the creator at least considers different complex patterns. As to the factual sense of the post-map (Figure 2, right), a wide range of remarks still can be observed, but now they are put forward in the form of declarative sentences. Signposts seem to describe possible intentions and their connections. Clouds

and boxes seem to highlight important (mostly past) theoretical and (especially future) practical experiences. A computer seems to indicate an intertwining of the regarded focus with other domains. Finally, sections which the creator already had passed are characterized by continuous, but future sections by dotted lines. The expressive sense is characterized by different colors which underline the significance of main experiences; overall, a great confidence seems to be reflected. Aspects related to the sense of form confirm this impression: In contrast to the circle drawn in the first section of the map, the path continues afterwards directly, but winding to school, flanked by some concrete imaginations. The final part of the path system is drawn slightly broader compared to previous sections which might reflect that the creator will feel well prepared to enter school. In the creator's view, practical work seems to bridge impressions of running in a circle within theoretical studies, which are not connected directly to work at school, and achieving the objective, which is supposed to be a complex, but positive and manageable challenge.

As to a *context analysis* of the first example, the interrupted way of the pre-map (Figure 1, left) seems to reflect that knowledge on ISLA is assessed to be nonexistent or at least superficial by the creator (PCK), and he or she cannot imagine how to cope with ISLA at school (PCB). Comparing the post-map (Figure 1, right) indicates that the creator now reflects to have knowledge on ISLA (PCK), and that he or she perceives ways of handling ISLA at school (PCB). This impression is confirmed by concrete aspects and intentions given by the detailed remarks (e.g., top right, “self-responsibility”, “perspective of hope to face the topic in the future”), which were missing in the pre-map, and by elements like stars or colors, which underline the significance of taking part in the LTL as to developing knowledge of ISLA and, thus, of bridging theoretical knowledge and practical work. Regarding the second example, the continuous path shown by the pre-map (Figure 2, left) indicates that the creator already knows about some aspects of ISLA, even if this knowledge seems to be rather superficial (PCK) and he or she seems to be rather uncertain (PCB). Comparing this with the post-map (Figure 2, right) suggests that the complexity of the system of paths reflects an increase of knowledge (PCK), and the creator can well imagine to cope with ISLA at school (PCB). Questions posed in the pre-map (e.g., on the first step, “What has to be done?”) turned to concrete intentions and planning steps (e.g., top left, an intention as to the practical semester of academic studies “Enriching scientific knowledge by specific focuses of observation.”); particular attention is given to emphasize the significance of practical experiences, like taking part in the LTL, as to developing knowledge of ISLA and as to intertwining theoretical knowledge and practice.

Based on these examples, a *comparative analysis* of all pre- and post-maps suggests that both the student teachers' ways and their location on the ways changed. Their PCK of ISLA developed to more profound patterns, and their PCB to more confident characteristics. Put more precisely, the comparisons indicate mainly the following typical changes: As to cognitive aspects, before taking part in the LTL the student teachers' knowledge about ISLA seemed to be rather fragmentary and superficial for the most part. Moreover, most of them seemed to equate problems in learning mathematics unilaterally with learning difficulties in a narrower sense. In contrast, after participating in the LTL, the student teachers developed a complex knowledge of the entire field: They distinguished different approaches and considered phenomenology-related issues. Regarding affective aspects, before taking part in the LTL, the student teachers rather seemed to express uncertainty as to dealing with ISLA, which seems to reflect disadvantageous characteristics of self-efficacy. In contrast, after participating in the LTL, the maps indicate more proactive views: The

student teachers declared more complex perceptions of problems in learning mathematics, in particular as to a child's individuality, and they proposed precise plans to develop their knowledge. Moreover, they seemed to connect ISLA closer to teachers' responsibilities, and emphasized the significance of practice as to the development of aspects such as self-efficacy. Finally, as indicated by the discussed examples, there seem to be different types: A first one representing an "optimistic novice" (Figure 1), and a second one representing an "expectant expert" (Figure 2).

## Discussion

The results indicate that participating in an ISLA-LTL and, therefore, an intertwining of theory and practice contributes sustainably to a positive development of both student teacher's knowledge about ISLA and their abilities to analyze children's thinking and learning in mathematics. This observation is in line with reports emphasizing the benefits of practical work with children as to the development of knowledge, and one main reason for this might be seen in the student teachers' constructivist learning (Sowder, 2007). Thus, beyond the context of ISLA, the results suggest the hypothesis that LTL provide an appropriate professional development program for student teachers to develop their abilities in analyses of children's thinking and learning. Of course, the study's character is explorative, and it has obvious limitations; for instance, the reconstructions as to interpreting the use of colors (or, e.g., their absence) were conducted within a group, but it remains uncertain, if a consensus view is the right one (Lamnek, 2010). Subsequent research might focus on a deeper clarification as to evaluations of ISLA-LTL, and as to the benefits of LTL in general; in particular, different LTL-focuses like support of mathematics interest should be taken into account.

*The aim of this paper is to present what are the criteria used by a teacher when performing the didactic analysis in its final master thesis. For that matter a case study was performed, whose object of study is the master thesis conducted by a Math teacher in service. The analysis was based on didactical suitability criteria proposed by the Onto-Semiotic Approach (OSA) to mathematical knowledge and instruction (Godino, Batanero & Font, 2007). As a result of the analysis it was possible to notice that the teacher, in addition to using all didactical suitability criteria proposed by the OSA implicitly, highlights the importance of finding a balance among the suitability criteria to achieve the learning of the didactic proposal carried out by him.*

*Keywords: Didactic assessment, suitability criteria, masters thesis.*

### Introduction

The tendency to achieve an international convergence in the planning of College programs and, particularly, those related to the Professional Master education centered on the education of teachers, has fostered a series of reforms in different countries, so that there is a model organized by a sort of refinement and evolution around professional skills. In the Brazilian context, in an attempt to train Mathematics teachers who were currently working in the area, the Professional Master Program in Mathematics in the National Network (PROFMAT) was launched in 2010 by recommendation of the *Conselho Técnico-Científico da Educação Superior da Capes*. The program is an on-site and long-distance program, offered throughout the Brazilian territory, coordinated by the *Sociedade Brasileira de Matemática* (SBM), which has a main objective to support Mathematics teachers who work in the primary education level, especially in public schools. It is important to highlight that, although PROFMAT's main objective is to foster teaching of mathematics at all levels (Brasil, 2013) it is configured as a program composed almost entirely of mathematical disciplines. In addition, at the end of the course, the students must present a final work (ETM) consisting of design a sequence of tasks, not assigning the mandatory implementation.

The work presented in this document is part of a larger research (Breda & Lima, 2016; Breda, Font & Lima, 2016; Breda, Pino-Fan & Font, 2016; Breda, Pino-Fan & Font, *in press*), in which, through the analysis of 29 Master's Thesis Works (EMTs) of PROFMAT (Breda, 2016) and was concluded that the teachers who implemented the design of their sequence of tasks performed a much more refined and balanced didactic analysis compared to the teachers who did not implement the proposal. In addition, it was evidenced that when the teachers' opinions were clearly evaluative, they were organized implicitly using some characteristics of the components of the didactical suitability criteria proposed by the Onto-Semiotic Approach (OSA) to mathematical knowledge and instruction (Godino, Batanero & Font, 2007).

So, the objective of this paper is to present a case study that analyses what are the criteria used by a teacher in his reflection process (explained in his EMT of PROFMAT), who will be addressed as Mr. Lopes, in order to improve the design and implementation of new contents related to the Riemman integral in Elementary School.

## Theoretical framework

In the field of Mathematics Education there is no consensus on the notion of “quality” and, in particular, there is no consensus on the “methods for assessing and improving the teaching and learning of mathematics”. There are basically two ways to address this problem, from a positivist perspective or from a consensual perspective (Font & Godino, 2011). From the first, the scientific research in the area of Mathematics Education tell us what are the causes to be modified to achieve the effects as objectives to be achieved, or at least tell us what are the conditions and restrictions that must be taken into account to achieve them. From the consensual perspective, that tells us how to guide the improvement process of mathematics instruction, which must come from the argumentative discourse of the scientific community, when it is aimed at achieving a consensus on “what can be considered as the best”.

The notion of didactical suitability criteria proposed by the Onto-Semiotic Approach (OSA) to mathematical knowledge and instruction (OSA, from now onwards) (Godino, Batanero & Font, 2007) is positioned in the consensual perspective. Such notion is a partial answer to the following problematic: What criteria should be used to design a sequence of tasks to assess and develop mathematical competence of students and what changes should be made in its redesign to improve the development of this competition? Suitability criteria can first serve to guide the teaching and learning of mathematics and, second, to assess their implementation. Suitability criteria are rules of useful correction in two stages of the processes of mathematical study. A priori, the suitability criteria are the principles that guide “how things should be done”. In hindsight, the criteria used to assess the study process effectively implemented. According to these authors, the didactical suitability criteria are: 1) Epistemic suitability, to evaluate if the Mathematics being taught are “good Mathematics”; 2) Cognitive suitability, to evaluate, prior to the beginning of the instruction process, if what is intended to be taught is at a reasonable distance from what the students already know, and after the process, if the knowledge acquired is any close to what was intended to teach; 3) Interactional suitability, to evaluate if the interactions contribute to clear doubts and difficulties students encounter; 4) Mediational suitability, to evaluate the adaptation of material and time-related resources used in the process of instruction; 5) Emotional suitability, to evaluate the implications (interests, motivations,...) of students during the process of instruction; 6) Ecological suitability, to evaluate the adaptation of the instruction process to the educational project of the school, the curricular guidelines, the social and professional environmental conditions (Font, Planas & Godino, 2010, p. 101).

## Methodological aspects

We chose to conduct a case study (Ponte, 1994) where the didactic analysis performed by a mathematics teacher in service, as part of his master degree, is investigated. To analyse our case, we used the *indicators of didactical suitability* proposed by the OSA (Godino, Batanero & Font, 2007; Godino, 2011; Breda, Font & Lima, 2015), as theoretical model to analyse the reflections

performed by the teachers regarding ways to improve their teaching practices, related to the implementation of the didactical activities proposed as part of their EMT.

### **Research context**

According to the guiding document of the PROFMAT, the EMT should, preferably, consist of a project with direct application to the mathematics classroom in Basic Education, thus contributing to the enrichment of the teaching of said discipline.

In this work we proceed on the assumption that the End of Master's Thesis (EMT) is a task that involves, implicitly, a didactical analysis exercise, since in their EMTs teachers must explain a didactical proposal and justify why it represents an improvement in teaching. In this sense, the reason for choosing the case of Professor Lopes is that, in addition to having applied the sequence of tasks with the students, he presents in his reflection aspects that "did not work" or that should be improved in future implementations.

### **Professor Lopes' didactical proposal**

Professor Lopes' EMT (2014), entitled "A review of the introduction of Riemann's sums into High School Education", presents the design and the implementation of a didactic proposal for a group of third-year high school students (students aged 16 to 17) in order to intuitively introduce the integral calculus through the study of the areas of 2D geometric forms. Lopes (2014) explains that it is possible to introduce methods and notions of the integral calculus in High School Education intuitively, starting with area-calculation problems for curvilinear shapes. That is, the aim is to broaden the calculation of areas habitually studied in Elementary Education through the study of area-calculation of curvilinear shapes, using both Archimedes' and Riemann's methods.

To be specific, Lopes' EMT (2014) is organized into four chapters; in the first, the professor presents, using literature reviews, the argument: "Should integral calculus be used in Elementary School?" On the basis of this question, the professor seeks to justify- through the study of literature- the use of two methods: Archimedes' method (used to calculate the area of a circle) and Riemann's method (used to calculate the area of three curvilinear shapes: circles, eclipses and polynomial shapes with an x axis). In the second chapter, Lopes (2014) explains the didactic unit which was implemented with a group of third-year students from a state secondary/high school in Brazil. The group was formed of 41 students but at the beginning of the year, only 36 students attended the classes and participated willingly in the project. In this second chapter, the professor also explains in detail the initial self-evaluation he performed with the students and, in particular, he explains the method for evaluation previous knowledge on certain geometry topics, on mathematical software knowledge and also on the expectations of the project.

In the third chapter, professor Lopes describe the implementation he carried out. This section is a sequential report in which the author explains what happened during the implementation of the didactic sequence, placing emphasis on the set tasks, what the students learnt and the interactions made during the implementation. We are looking at a review written from the perspective of the professor but, in his very review, the professor ensures he presents evidence of the statements he makes. In the fourth and last chapter, the professor presents his reflections and conclusions on the implementation he carried out. In this way, it can be said that Lopes' proposal (2014) covers the four phases of didactic design (preliminary study, design, implementation and evaluation), which

other models of mathematics teachers' knowledge also cover, in order to answer the most fundamental question: "What knowledge should a mathematics teacher have to be able to appropriately manage their students' learning?" (Pino-Fan, Assis & Castro, 2015).

### **Professor Lopes' analysis on his own implementation project**

When teachers have to reflect on a didactic proposal that implies a change to or an innovation in their own practices, they implicitly employ some of the *didactical suitability criteria*. Lopes' EMT (2014) has also allowed us to deduce the use of some of these criteria in the justification and reflection on the suggested proposal. In the following subsections, we show the extent to which the author considered- implicitly and explicitly- the suitability criteria put forward by OSA in attempt to defend his didactic proposal as improvement for mathematics teaching.

#### **Epistemological suitability**

Lopes (2014) justifies the 'innovative and creative' nature of his proposal by pointing out that it encourages students to perform relevant mathematical processes, in particular that of mathematical modelling. In his own words, he explains: "*In this way, the application process, divided in three stages, aims to build knowledge through the use of mathematical models. Starting with the first construction, on the basis that the topic is studied in depth and new elements arise, other models are built based on the previous ones [...]*". (Lopes, 2014, p. 22)

The professor also considered that his innovative proposal allows students to perform other relevant mathematical processes such as connections, meaningful constructions, problem-solving, etc. "*In this sense, the aim is to (...) awaken the student's creativity and enthusiasm to learn geometry, to create geometrical models with the students, making connections with reality, and to provide situational problems with a geometric focus...*" (Lopes, 2014, p. 21).

It is evident in his review that some of the processes mentioned were in fact developed during the implementation of his proposal. In his thesis, the professor generally presents explicit reflections on the fact that his didactic proposal for teaching area-calculation is more representative (since it thoroughly explores the area-calculation of curvilinear figures) than the proposals that are commonly implemented at high school level.

#### **Cognitive suitability**

In Lopes' work (2014) there are comments, reflections, etc., that allow concluding that the author takes into account, in an implicit way most of the times, the indicator of cognitive suitability.

*Background knowledge.* The teacher carries out an initial evaluation in order to find out if the students had the necessary background knowledge for the study of the intended content. Furthermore, he makes sure that the students have such background knowledge, and specifically, he dedicates part of the time intended for the implementation, to revise the calculation of the area of triangles and quadrilaterals, and the study of trigonometric ratios. On the other hand, the learning objectives were attained by the students, "and there is confirmation that the Archimedes and Riemann methods are in the students' zone of proximal development" (Lopes, 2014, p. 19).

*Curricular adaptation to individual differences.* With the narration of the teacher it is not possible to conclude if he considers at some point complementary or reinforcement activities. However, when he assesses the learning related to the Riemann method, he concludes that many students will

not achieve such learning and adds: “...it would be necessary to have a more extensive study period, to be able to ask the students (...) to interpret results more thoroughly, considering that each student is unique and as such, needs a shorter or longer time to learn” (Lopes, 2014, p. 92).

Regarding the *learning* intended, the teacher states in a very clear way that he has to carry out evaluations to verify that his innovative proposal helps the students to achieve the learning objectives. Therefore, apart from the initial evaluation, the teacher carries out three formative evaluations that show the acquisition of the competences/learning implemented. With these evaluations, the teacher concludes that the learning related to the calculation of areas of quadrilaterals and triangles, and the Archimedes method was acquired, but the same cannot be said about the learning of the Riemann method, which he justifies with lack of time.

*High cognitive demand.* The author considers that his proposal requires a high cognitive demand from the students, since it activates relevant cognitive processes.

### **Interactional suitability**

*Teacher-Student interaction.* The teacher describes a “teacher-large group interaction”, through a dynamic of questions asked by the teacher and answers given by the students, which, according to him “facilitates comprehension among students” (Lopes, 2014, p. 32). He also presents some examples of how this type of interaction helps to clarify doubts that the students might have.

*Interaction among students.* In his narrative, the teacher also mentions that the students worked in small groups and although he did not comment if such dynamic has solved the student’s semiotics conflicts, he concludes that this organization allowed some students that hardly participated in the classroom to express themselves in a larger group.

*Autonomy.* It is possible to conclude that there were moments in which the autonomy of students was encouraged. On the one hand, “the students had to do homework” (Lopes, 2014, p. 67); on the other hand, there were some moments in which it was possible to observe that the responsibility to study (exploration, formulation and validation) was assumed by the students.

*Formative evaluation.* As mentioned in the cognitive suitability section, the teacher carried out a formative evaluation that allowed a systematic observation of the cognitive process of the students.

### **Mediational suitability**

It was possible to observe the use of *material resources* such as calculators and computers. The teacher explains that he used the *GeoGebra* software and the calculator during the teaching process. Regarding *GeoGebra*, he presents some implicit evaluative comments about the advantages of including this software of dynamic geometry in the teaching process.

*Number of students, Schedule and classroom conditions.* Regarding this aspect, the teacher makes several comments. In a relevant way, he explains that the number of students and the conditions of the classroom (both the physical space as well as the computer laboratory) somehow determined the use of *GeoGebra*. Thus, the software was mainly used by the teacher to illustrate and show mathematical practices (e.g., the calculation of the areas of quadrilaterals and triangles).

Regarding the *time – of group teaching and learning –*, the teacher makes comments and assessments about three indicators of this component: the adaptation of intended meanings in the

available time, the time spent in the most important and relevant contents, and the time spent in the contents that were more difficult for the students. In connection to the first indicator, the teacher states very clearly that he could not adapt the intended meanings in the time that was available. Particularly, he states that he did not have enough time to finish explaining all he had planned regarding the Riemann method. For the second indicator, the teacher states that it took him a lot of time to ensure the required background knowledge, and that, on the other hand, he did not have time to solve the initial problem that was contextualized in order to later introduce the Archimedes and Riemann methods. Finally, regarding the third indicator, it is possible to infer from the teacher's comments that it was impossible to carry out the whole study due to lack of time (e.g., there was not enough time to explain the Riemann method in depth).

### **Emotional suitability**

In connection to this suitability indicator, no comments regarding the *interests and needs of the students* were found in Lopes' EMT (2014). No comments about *the attitudes* of the students were found neither. Regarding *emotions*, the teacher states that the implementation he carried out promotes the students' self-esteem.

### **Ecological suitability**

According to the criteria and objectives that the teachers had to consider for the elaboration of their projects, professor Lopes adds that his proposal is a *didactical innovation* that adapts to the *Elementary school* curriculum and, according to his students, contributes to social and professional integration (*social and labour utility*) and that presents an intra-mathematical *connection* to higher level Mathematics (*intra and interdisciplinary connections*).

### **Final reflections**

The analysis of the EMT of Professor Lopes shows how the indicators of *didactical suitability* proposed by OSA are -implicitly- present in his reflection processes on their own practice. An important aspect to highlight is that this EMT clearly demonstrates the issue of finding a balance between each of the suitability criteria. On one hand, the author plans an innovation with high epistemic suitability and he demonstrates in his review that he also made a substantial effort to achieve high cognitive suitability. On the other hand, however, he also demonstrates that he was obliged to neglect part of the content he had planned; in particular he could not solve the initial problem which was the very motive of his didactic proposal and the learning was not complete (in particular, the Riemann method) due to the fact that the suitability of means was not adequate; to be precise, there was not enough time.

We could say that, in terms of the suitability criteria, Lopes concludes that if in future implementations, cognitive and epistemic suitability are not to be neglected, and then it would be necessary to allow more time. One aspect, which is difficult to explain, is the reason why the criteria of didactic suitability function as implicit patterns in the Lopes' discourse, when he has to evaluate instruction processes without specific training on the use of this analysis tool. One possible explanation is that the training that he has received in the PROFMAT allows him to do, implicitly, this type of analysis. However, Caldatto's research (2015) and Caldatto Pavanello and Fiorentini (2016), leads us to believe that the characteristics of the PROFMAT do not encourage this kind of

reflection. Now, other answer to this very question is related to the origins of this construct. In the OSA, the didactic suitability criteria, its components and characteristics were constructed on the basis that they should be constructs which rely on a certain amount of consensus within the Mathematics Education community, albeit the local one. Therefore, one of the plausible explanations that the suitability criteria can be considered as teachers' reflections patterns is related to the extensive consensus that they themselves generate amongst persons involved in Mathematics Education. Therefore, another possible explanation, for Lopes case, could be based on his previous training and his experience, which would lead him to participate in this consensus.

The analysis of the EMT of Professor Lopes shows that, when the teachers' opinions were clearly evaluative, they were organized implicitly using some characteristics of the components of the didactical suitability criteria proposed by the OSA. This result has been evidenced in other investigations (Breda, 2016; Seckel, 2016; Breda, Pino-Fan, Font, *in press*) in which it is also suggested that the suitability indicators can be taught as powerful methodological tools to organize the teacher reflection –as it has already been done in different processes of teacher training in Spain, Ecuador, Chile and Argentina (Giménez, et al., 2012; Valls & Vanegas, 2015; Posadas, 2015; Pochulu, Font & Rodriguez, 2016; Seckel, 2016) –, that aim at the fostering of the “meta” dimension of didactical-mathematical knowledge (DMK) of Mathematics teachers (Pino-Fan, Assis & Castro, 2015; Pino-Fan, Godino & Font, 2016).

# Describing a secondary mathematics teacher's specialised knowledge of functions

Dinazar Escudero-Avila<sup>1</sup>, Eric Flores-Medrano<sup>1</sup> and José Carrillo<sup>2</sup>

<sup>1</sup>BUAP, Puebla, México; [eadinazar@hotmail.com](mailto:eadinazar@hotmail.com); [ericfm\\_0@hotmail.com](mailto:ericfm_0@hotmail.com)

<sup>2</sup>University of Huelva, Huelva, Spain; [carrillo@uhu.es](mailto:carrillo@uhu.es)

*Taking a case study into the specialised knowledge of linear functions demonstrated by a secondary teacher, we aim to demonstrate, and to raise discussion about, a set of methodological tools for organising and representing mathematics teachers' knowledge. The results are art of an ongoing study which employs the model of professional knowledge known as Mathematics Teacher's Specialised Knowledge. We also believe that the use of these tools help to demonstrate the effectiveness of the division of this knowledge into subdomains, and affirms the relevance of the descriptors defining their boundaries.*

**Keywords:** Secondary, mathematics teacher's specialised knowledge, functions.

## Introduction

Since the CERME 8 conference in Turkey, the University of Huelva research group has presented a series of papers demonstrating an analytical model that is being developed to aid the study of mathematics teachers' specialised knowledge (e.g. Montes, Aguilar, Carrillo & Muñoz-Catalán, 2013; Vasco, Climent, Escudero-Ávila & Flores-Medrano, 2015; Flores, Escudero & Carrillo, 2013), we outlined the model currently under development, known as Mathematics Teacher's Specialised Knowledge (MTSK). In this model, each subdomain is described in terms of mathematical concerns, an aspect which represents a significant move away from other models (Carrillo, Climent, Contreras & Muñoz-Catalán, 2013).

Continuing the group's work on this model, this paper illustrates the application of various methodological tools to studying and understanding mathematics teachers' knowledge, as brought into play in the classroom. At the same time, we consider developments in the theoretical foundations of the model, and present adjustments that have been made in the light of empirical studies and fruitful discussion in various academic platforms. We illustrate the use of these tools by means of an analytical study of the knowledge employed by a secondary school mathematics teacher in the process of planning classroom activities.

## Mathematics Teacher's Specialised Knowledge (MTSK)

The distinguishing feature of the MTSK model is that it incorporates elements of knowledge which, considered as a unit, are uniquely relevant to mathematics teachers. It contemplates two chief knowledge domains – Pedagogical Content Knowledge and Mathematical Knowledge, each divided into three subdomains.

For its part, Pedagogical Content Knowledge is composed of Knowledge of Features of Learning Mathematics (KFLM - the teacher's knowledge of the processes involved in the students' assimilation of mathematical content), Knowledge of Mathematics Teaching (KMT - the teacher's stock of

resources and strategies for teaching such as examples, tasks, analogies and so on), and Knowledge of Mathematics Learning Standards (KMLS - the teacher's knowledge of the performance targets set for different educational stages). Meanwhile, Mathematical Knowledge comprises Knowledge of Topics (KoT - knowledge of the mathematical content pertaining to any particular course, along with the associated foundations, properties, definitions, phenomenological associations and so on), Knowledge of the Structure of Mathematics (KSM - the teacher's knowledge of mathematical connections between concepts), and Knowledge of Practices in Mathematics (KPM - knowledge of the syntax of mathematics and the procedural logic at the heart of the discipline) (Escudero-Ávila, Carrillo, Flores-Medrano, Climent, Contreras & Montes, 2015).

In addition to the division into subdomains, the MTSK model also places emphasis on beliefs about mathematics and about mathematics teaching and learning, as the relationship between beliefs and knowledge is a significant consideration, influencing, for example, how a teacher might deploy his or her knowledge. This provides a base to interpret knowledge evidences that we found and gives us sensitivity to interpret some elements that allow to contextualize David's teaching decisions and the exchange of opinions with his colleagues.

### **Methodological tools for studying and understanding the specialised knowledge of mathematics teachers**

In this section we present an example of an analysis using MTSK, which we hope will demonstrate a deeper understanding of the nature of each of the subdomains involved and illustrate some interesting methodological tools.

We analyse the case of David (fictitious name), a secondary school mathematics teacher working in Colombia, who, at the time of the data collection, was studying an online Master's degree. His first degree was in Chemical Engineering, and he had been involved in education for over 25 years as a teacher of Mathematics, Physics and Chemistry. He had also participated in several teacher training courses and similar programmes. The bulk of his experience was in upper secondary (14-18 year-olds), but for the previous eight years he had worked in lower secondary (12-14 year olds), teaching Mathematics.

Our analysis focuses on David's participations in forums and his written productions as part of the Master's course. David plans a lesson for teaching linear and quadratic functions. The task required the teacher to devise an exercise for use with the class, and then to discuss aspects of it with the group tutor and the other course participants in various sessions of an online forum, with the aim of evaluating the task and making any modifications deemed necessary as a result.

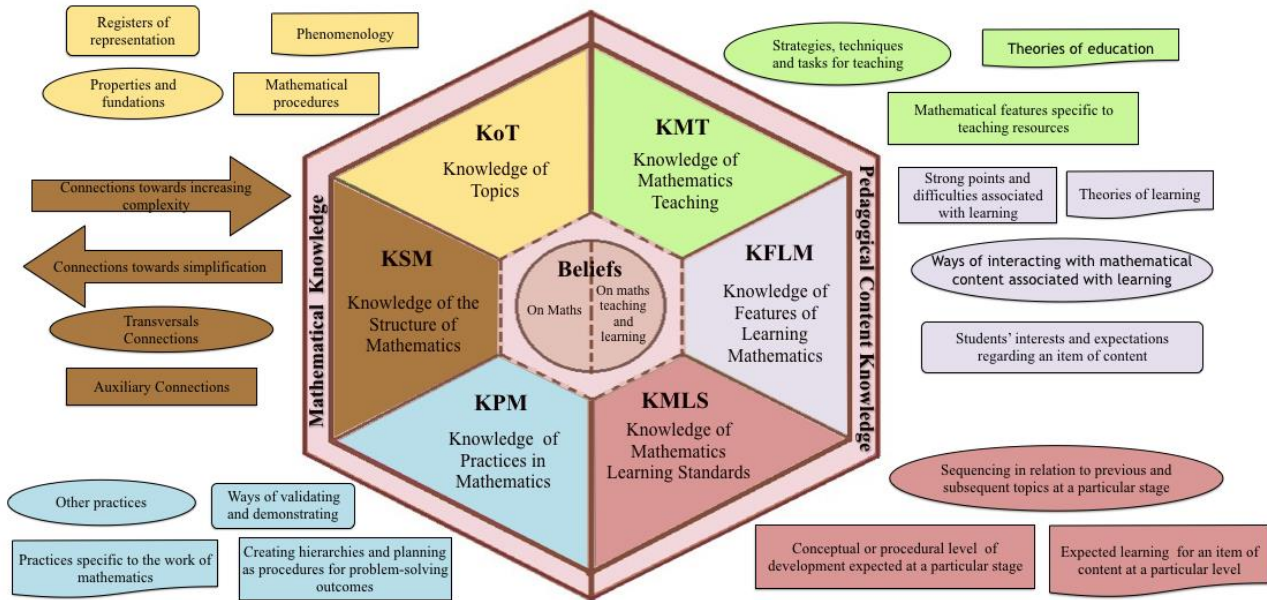

David came up with two exercises, one dealing with linear functions, the other with quadratic, both aimed at pupils in eighth grade. In this paper, we focus on the specialised knowledge we were able to identify relating to the exercise concerning linear functions. It should be noted here that although David was given several opportunities to incorporate modifications to his planned activity, he ultimately decided to stick with the same plan through to the end of the course.

The Master's programme which forms the background to our analysis encouraged teachers to explore aspects of their day-to-day classroom practice. This required them to articulate their pedagogical and mathematical knowledge in order to explain to the other teachers and the tutor the decisions that had led to their particular activities.

Our system for classifying and organising the knowledge displayed by David was based on units of analysis drawn from his written discourse in forums and tasks over the duration of the course. These were assigned to a particular category within the subdomains making up MTSK. In order to establish these categories and refine the analysis, we used Grbich's *top-down* and *bottom-up* methodology (Grbich, 2013). This approach enables researchers to move from theory to data (top-down) by opening provisional categories suggested by the literature review, and from data to theory (bottom-up) by eliminating, merging and opening new categories consistent with the results obtained from empirical study.

With respect to the potential of this methodological approach, we propose the following example. In Escudero (2015), it is mentioned that the KFLM and KMT subdomains contain a category that reflects the knowledge that teachers have about learning and teaching mathematics, respectively. With this information we analyze the data collected from David to find elements related to teaching/learning theories. When David mentions Socio-Epistemological Theory, it is clear that he has knowledge about the theories we are looking for (top-down). On the other hand, when David refers to Socioepistemology, we could notice some differences with the “formal” constructs, therefore we think of the possibility to explore knowledge of formal theories and personal knowledge base in formal theories whose nature corresponds with the knowledge of teaching/learning theories (bottom-up).

As a result of this procedure, we developed a range of categories for each of the subdomains, enabling specific aspects of each one to be considered, and giving a fuller description of the MTSK model. These categories are illustrated alongside the model in Figure 1.

**Figure 1: Mathematics Teacher's Specialised Knowledge**

Once units of David's knowledge had been identified from his contributions during the course, we wanted to be able to describe and understand the specialized knowledge deployed in each instance. To do so required a tool that would allow us to determine the type of knowledge, the connections between different subdomains, and the nature of this knowledge in terms of the different categories within each subdomain. At the same time, we wanted to keep in sight the holistic character of this

kind of knowledge, and to maintain an awareness that the placing of boundaries around discrete areas of knowledge is a (necessarily) artificial procedure serving analytical purposes. To this end, we devised a coding system using shapes and colours, whereby subdomains were represented by colours and categories by shape. In addition, associations between different types of knowledge were schematized by a series of arrows joining the two elements. The result can be seen in Figure 2 below.

## David's specialised knowledge of Mathematics

The task which we will analyse below concerns filling a tank, in the shape of a rectangular prism, with water.

David: There is a rectangular tank with a volume as shown in the figure, which is to be filled with water at the rate of  $1 \text{ cm}^3$  per second.

Draw a table in which the variables are height and time.

If the inflow varies, what happens to the graph, if it increases and if it decreases?

What type of function do you get if you model the two situations?

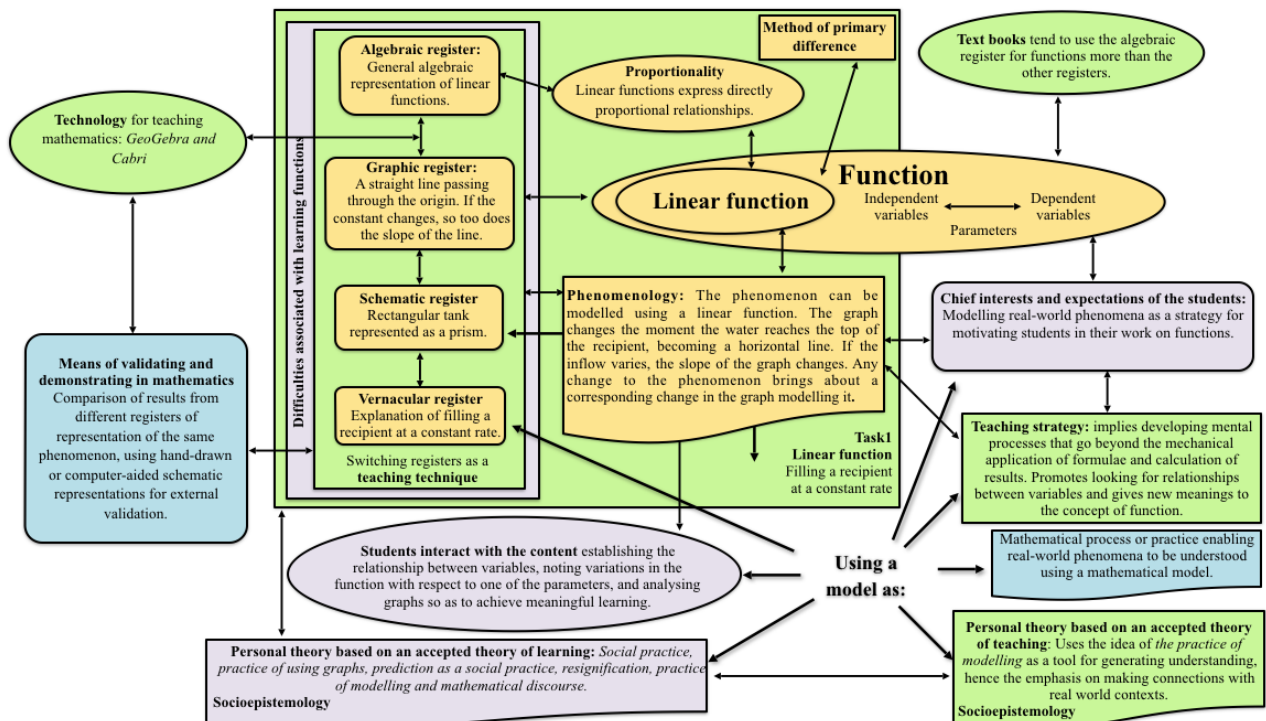

Figure 2: A representation of David's specialised knowledge regarding the concept of functions

An interpretation of Figure 2 is presented below. The aim is to reach an understanding of David's specialised knowledge, as identified in his contributions during the course, and of the connections between the different subdomains and categories which can be detected.

David goes on to specify the objectives of the task, underlining the importance of designing appropriate activities for the topic of functions, and gives a list of the resources to be used with suggestions for conducting the activity. These include a series of exercises aimed at guiding the students towards analysing the problem, establishing the relationship between the variables and modelling the process in order to arrive at a function modelling the behavior. In the final section, he makes various observations about the use of the teaching resources.

Although David does not write explicitly about his **knowledge of the properties** of linear functions (yellow ovals), the design of the exercise and his comments about it provide indications of the elements he considers fundamental to them, such as the parameters and concept of dependent and independent variables, and noting that directly proportional magnitudes are also linear functions.

Nor does David explicitly solve the activity, although he does talk about different ways the problem can be solved. One method he mentions is that of primary difference for calculating the parameters of the functions modelling the phenomenon in question. This indicates **knowledge of mathematical procedures associated with the mathematical content** (yellow rectangle), which represents evidence that he knows a specific mathematical process associated with the concept of linear functions.

David: [...] using differences to find out the parameters of the functions; the primary difference for the linear, and the secondary difference for the quadratic; that is for when I need to find out the parameters using the given data.

The students are encouraged by the task to employ different semiotic registers of representation (Duval, 1995) for the function, that is, the pictorial, numerical, graphical and algebraic. This provides us with evidence that David has knowledge of different registers of representation (yellow rectangles with rounded corners) associated with the concept of functions.

Regarding **knowledge of the mathematical characteristics specific to teaching resources** (green rectangles) used by David in his design, and which are located in KMT, we identified that he knows a specific mathematical task for dealing with the concept of linear functions, such as filling a receptacle at a constant rate, and also a specific technique for teaching the concept – the transition between registers of representation. Questioned about the exercise, David demonstrates a connection between understanding registers in terms of mathematics and understanding them in terms of teaching, when he considers the transfer from one register to another as a teaching strategy, thus making a connection between KoT and KMT:

David: Generally, we, teachers, prefer to work in the *algebraic register*; but to a large extent we can also recognise the different variations a function can undergo using *tables* and *graphs*, by giving the dependent variable different values to the ones originally set.

[...] By moving from one register to the other [from the algebraic to the graphic], I hope that, by making graphs, [the students] establish the relations between the

dependent and independent variables, and can see how this resource, that is the use of graphs, could be put to use in modelling.

A connection to KFLM is also made that contemplates potential errors, obstacles and difficulties to learning, as well as, conversely, areas that might offer an advantage when David considers **potential difficulties in learning the concept** of function (mauve rectangles):

David: [I acknowledge] a high degree of complexity in learning the concept of function, because of the variety of its representations in different contexts, and its algorithmic nature.

Awareness of these potential difficulties in representing functions is inherent to the concept of function itself.

Elsewhere, another connection between KoT and KFLM can be seen when David shows that he is aware of how modelling real world phenomena can be a motivating factor in work on functions as the students can establish the relationship between dependent and independent variables through making graphs, thus providing a meaning linked to a tangible context for the linear and quadratic functions. It is precisely this kind of knowledge – understanding how drawing up graphs can help students learn about functions – which we consider **knowledge of the students' interests and expectations** regarding the teacher's approach to the concept in question (mauve rectangle with rounded corners).

As might be expected, David's KoT is the foundation on which the task is constructed, providing him with the background knowledge for sequencing activities and setting his goals. One important aspect is his knowledge of phenomena which can be modelled by linear functions, such as the rate at which a rectangular-shaped vessel fills with a constant inflow, which we have denominated **knowledge of the phenomenology associated with the concept** (yellow labels), on the basis that understanding the mathematical features of the phenomenon and the effect of its variation on the different modes of representation, enables David to make connections between the variables involved, and to model the phenomenon via the transition from one register to another, using modelling as a teaching strategy for generating “new” meanings of the concept of functions.

David: [I recognise] the importance of learning this concept [function], and its significance as a tool for modelling different phenomena in mathematics, physics, chemistry and economics amongst others.

As can be seen in Figure 2, modelling plays an important role in the task design. Deconstructing David's understanding of modelling, we can see that he imbues it with different meanings, and we can duly recognise the different ways that David understands and recognizes modelling. Hence, on the one hand, we can locate David's knowledge of modelling as a **teaching strategy** (green rectangles) within KMT. On the other, within KPM, we can identify David's knowledge of modelling as a **mathematical practice or process** (blue labels), directly associated with the concept of functions which enables real world phenomena to be interpreted. Finally, within KFLM, David identifies the concept as a **means of getting students to interact with mathematical content for educational purposes** (mauve oval).

At the same time, KFLM includes **knowledge about theories of mathematics learning, whether formal or personal** (mauve label). In David's case, he was able to draw on various theoretical constructs at the design stage of his materials so as to supply a solid foundation for his work. Some of these constructs derive from Sociopistemological theory (Cantoral & Farfán, 2003). In the excerpt below, David makes reference to some socioepistemological constructs (marked in bold):

David: One of our aims is to achieve the concept of function **resignification** using the **modelling practice**.

Asked about the origin of terminology, David replied:

David: **Socioepistemology** allows me not only to view mathematics education as a practice in which we convey knowledge, express postulates, solve problems and do demonstrations, but also to see beyond the concepts to what lies behind them, to transform them and to transpose them to other contexts and so get closer to real life [...] From the perspective of linguistics, we can note significant learning and **resignification**. Both attempt to modify the meanings of a concept, but Significant Learning is the process followed to achieve learning of value, and where our behaviour changes, while **resignification** is the means by which I achieve this learning.

Given the lack of rigorous definition of the constructs (it could even be said that some are not totally accurate, in that modelling and making graphs are not actually defined as social practices) we can say that David has a certain personal knowledge of this theory, which allows him to take a position in terms of how the concept of function is to be learnt (re-signified). That is to say, drawing on his knowledge of formal theory, David has developed a personal theory of the relevance of learning about functions based on the "practice of modelling". His personal theory extends to regarding education as a tool for creating specific meanings about functions by enabling connections to real world situations to be made.

Regarding KPM, as can be seen in Figure 2, David's **knowledge of the processes of validation, reasoning, and checking** via software (blue rectangles with rounded corners) is directly connected to teaching technique chosen for his lesson plan. It also links to his knowledge of technology specifically designed for teaching Mathematics (green ovals), namely GeoGebra and Cabri.

David: The use of the software is to show the students that their work is not only checked by their classmates, but also by a tool which in addition to helping them show their results, is like an external agency which can tell them whether what they have done is right or not.

## Final reflections

We can conclude that David's knowledge of various teaching resources, such as software and teaching strategies, and the use to which he puts this knowledge could be connected to his understanding of the ways of proceeding and producing in Mathematics, possibly as a result of the tendency of KPM to organize mathematical work, as discussed above.

The main connections that this analysis has brought to light are those between KoT, KMT and KFLM. As underlined above, these connections illustrate the interdependence between the different

categories within the subdomains, and highlight the holistic and indivisible nature of teachers' knowledge of the teaching and learning process. What a teacher knows about interacting with content, or about learning theories and possible difficulties that might arise in a specific topic, has a significant influence on how the teacher plans the lesson. However, it is important to distinguish between the influence that this knowledge brings to bear on the planning process and the teacher's knowledge of planning itself a teaching resource.

We hope that this study serves to open a debate within the group about the relevance, potential and shortcomings of using categories to analyse Mathematics teachers specialized knowledge, and likewise the use of colour-coding and shapes as a means of aiding the assimilation of the information and facilitating the analysis of the connections between subdomains and categories.

*This paper addresses the knowledge about the function concept and the knowledge on how to teach this concept using an analogy. The analysis of an episode of one lesson in which the analogy between a washing machine and the concept of a function is shown allows identifying specialised knowledge about the function concept and teaching strategies. The study findings reveal links between knowledge of the topic and knowledge of mathematics teaching, permitting identification of potentialities and limitations of the analogy used.*

*Keywords: Function concept, mathematics teachers' specialised knowledge, analogies.*

## Introduction

Function is one of the most important concepts in mathematics, fundamental for development of mathematical analysis and mathematics in general (Ponte, 1992). This concept is not only present in many areas of mathematics, but is prevalent in the school curriculum and is, of course, studied as a part of the mathematics teacher training programs. Given its importance and great complexity (Dubinsky & Harel, 1992), it is essential that the mathematics teacher's knowledge considers both the discipline-specific knowledge of the function concept, as well as knowledge about how it is taught and learned.

Teachers' knowledge has been widely studied from different perspectives, using a wide range of theoretical models (e.g., Shulman, 1986; Ball, Thames, & Phelps, 2008; Carrillo et al., 2014). The Mathematics Teacher's Specialised Knowledge (MTSK) model is presented both as a conceptualisation for mathematics teachers' knowledge and as an analytical tool for acquiring this knowledge (Flores, Escudero, & Aguilar, 2013). Studying the subdomains and categories proposed by the MTSK model, and their relationships, allows us to advance the understanding and analysis of teachers' knowledge (Sosa, Flores-Medrano, & Carrillo, 2015). Part of this knowledge is related to the depth of the teacher's understanding of a concept (in this case the function) as a mathematical concept and as an object of teaching. Several studies conducted to date focused on the understanding of the function concept on students, pre-service teachers, and practicing teachers (e.g., Even, 1990; Breidenbach, Dubinsky, Hawks, & Nichols, 1992). Other studies highlight the importance of fully understanding the concept (e.g., Sierpiska, 1992), identification of its representations (e.g., Even, 1990), as well as difficulties in learning (e.g., Dubinsky & Harel, 1992) and relating their different representations (e.g. Ponte, 1992; Figueiredo, Contreras, & Blanco, 2015). The focus of the present investigation is on the relationship between teachers' knowledge about the function concept and the knowledge about its teaching from the perspective of the MTSK, particularly when a teacher uses an analogy to make the function concept understandable. In this study we ask what knowledge about

functions and their teaching can be inferred from the use of an analogy? How are these knowledge types related?

## Analogies

According to Treagust, Duit, Joslin, and Lindauer (1992), analogy is achieved through a comparison of structures in two distinct domains, one of which is familiar (source or analogue), while the other is unfamiliar (target).

An analogy refers to comparisons of structures between domains. An analogy is a relation between parts of the structures of two conceptual domains and may be viewed as a comparison statement on the grounds that these structures bear some resemblance to one another. (Treagust et al., 1992, p. 413)

The use of analogies in teaching, particularly as a didactic strategy in the teaching-learning process, has been extensively studied (e.g., Duit, 1991; Treagust et al., 1992). For example, Curtis and Reigeluth (1984) analysed instructional text and provided a classification of the ways in which the relationship between the source and the target domain is established. According to the authors, the relationship can be (1) *structural*, referring to physical similarity or similar construction; (2) *functional*, referring to the way of functioning of both structures; and (3) *structural-functional*, formed by combining the previous two. They add that analogies occur in two forms: verbal and pictorial-verbal, whereby the former is achieved solely via the use of words, while in the latter words are complemented by an image.

Teachers tend to produce analogies automatically when answering questions or explaining the concepts they are teaching (Ünver, 2009). According to Figueiredo et al. (2015), function as a machine is an example of such analogies and this comparison will show only some aspect of the concept. Function can be describing operationally as a computational process or structurally as a set of ordered pairs (Sfard, 1991). To present the function through this analogy conducts to understand the concept as an input-output process in an operational way.

## Mathematics Teacher's Specialised Knowledge

The MTSK model (Figure 1), in the spirit of contributions by Shulman (1986) and Ball et al. (2008), proposes, within the teacher's knowledge, a discipline-specific component (MK, mathematical knowledge) and a didactic component (PCK, pedagogical content knowledge). A further component related to beliefs about mathematics and about teaching and learning it is introduced in the middle of the model.

According to Carrillo et al. (2014), MK corresponds to knowledge specific to the discipline being taught, and comprises of three subdomains: *Knowledge of Topics* (KoT), *Knowledge of the Structure of Mathematics* (KSM), and *Knowledge of the Practice of Mathematics* (KPM). KoT considers the phenomenology, definitions, properties, procedures, and foundations of the topic, as well as the ways of recording and representing it. On the other hand, KSM pertains to the conceptual connections among mathematical concepts, relating a concept to prior contents (simplification), later contents (adding complexity), or to contents with a common property (transverse connections), and the auxiliary connections among objects. Finally, KPM is related to knowledge about the characteristics

of mathematical work, namely how to proceed and create knowledge in mathematics, practices linked to mathematics in general, and practices linked to a specific topic.

**Figure 1: Sub-domains of the MTSK model (Carrillo et al., 2014)**

PCK corresponds to didactic knowledge specific to teaching work in the process of teaching and learning mathematics. Once again, it comprises of three subdomains, namely *Knowledge of Features of Learning Mathematics* (KFLM), *Knowledge of Mathematics Teaching* (KMT) and *Knowledge of Mathematics Learning Standards* (KMLS). KFLM considers teachers' knowledge of their students' learning styles, strengths and difficulties associated with learning, way of interacting with mathematical content, students' conceptions of mathematics, and personal or institutional theories of mathematics learning. KMT is knowledge about mathematical content conditioned by its teaching, including knowledge about personal or institutional teaching theories, physical and virtual resources, and strategies, activities, examples, and help. Finally, KMLS pertains to knowledge about required mathematical concepts to be taught, knowledge about the level of conceptual and procedural development expected, and the sequencing of the various topics.

The aforementioned division into subdomains allows us to deepen our understanding of the elements of knowledge that are utilised in an integrated and interconnected manner. The MTSK model is a suitable analytical tool for meeting the objective of the present study because, in addition to highlighting mathematics, its categories, and subdomains, it allows focusing on teachers' knowledge about the function concept and its teaching (for example, the definition, its properties, representation, and the strategies used when teaching).

## Methods

This research is grounded in an interpretative paradigm and is based on the instrumental case study design (Stake, 2007). The aim is to investigate from the perspective of MTSK the knowledge manifested by a high-school teacher when teaching the concept of function. The teacher that is in the focus of the study, henceforth referred to as Arturo, has ten years of teaching experience, teaching classes from fifth to twelfth grade. He is also a university teacher in first-year classes for engineering students and for pre-service teachers. He has also worked as a teacher in continuing education courses for primary-school teachers and has taken courses connected to university teaching, curricular updates in geometry, and curricular reform. At the time of this study, Arturo was teaching ninth-grade classes,

where he had planned to introduce the function concept. According to the information provided by Arturo, his group of students is familiar with the use of algebraic language, equation solving techniques, and Cartesian plane, among others.

To collect the data, classes in which Arturo planned to introduce the function concept were observed and video-recorded. The videos were transcribed and the transcripts served as the principal source of information. The resulting data was subjected to content analysis (Bardin, 1996), whereby class episodes were determined according to the tacit or explicit goals of the teacher. The units of analysis correspond to the teacher's interventions and responses provided by his students. In addition, only those that present evidence of teacher's specialised knowledge have been considered (Flores et al., 2013). In the first class, Arturo introduces the concept of function and its definition, and provides some examples of functions. An episode was selected from this class, in which the teacher uses an analogy to promote students' understanding of the definition of function. The episode was analysed in relation to the KoT and KMT sub-categories of the MTSK.

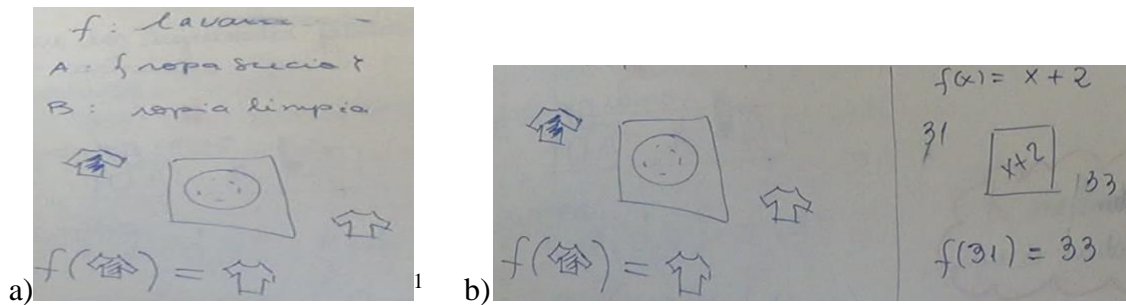

## Results and discussion

Arturo defined function as *a correspondence between elements of two sets in which each element of the input set corresponds to a single element in the output set*. Knowledge of this definition is part of his KoT. To make this definition understandable, Arturo introduces a washing machine as an analogy for a function, alluding to a family context for his students. To know this context is not part of the MTSK, but it allows us to reflect on the scope and applicability of the analogy according to the type of students to whom they are presented. In the following extract, Arturo presents the analogy between function and washing machine:

- Arturo: Before giving you more names, the function works like a kind of machine. An example could be a washing machine. A washing machine carries out a function. What is its function?
- Student: Washing!
- Arturo: What do you do? You take an article of clothing. It's dirty. You put it in the washing machine. How does it come out?
- Student: Clean.
- Arturo: Did the washing machine fulfil its function? Yes. The dirty article of clothing would be a member of the input set, and the clean article of clothing would be a member of the output set. This is what the function does. Here [he points to a diagram] we would have the dirty article of clothing. The function does what it does, depending on the machine, and arrives at the other side. In the case of a washing machine, it arrives clean.

Knowledge of analogies, as elements that enhance the teaching of a concept, is part of the teacher's specialised knowledge (Carrillo et al., 2014). The use of analogy shows teacher's knowledge about when to give any specific help to his students (KMT). The use of analogy favours the understanding and visualisation of abstract objects in students, besides being a motivation for a new theme. This analogy presents the function as a *process* and allows the students to better understand this concept (Sfard, 1991; Figueiredo et al., 2015). Moreover, different components can be identified, namely

domain, co-domain, pre-image, and image explaining the connection between the source and the target domain.

**Figure 2a: Presentation of the analogy. 2b: Relationship between the source and the target domain.**

The analogy is presented in two formats: in the intervention described (verbal) and when the teacher draws a washing machine on the whiteboard (pictorial). This illustration (Figure 2a) shows the function as an input-output process, in which the object that enters is modified (in this case, a dirty article of clothing comes out clean). In this example, the objects are the same at entry and exit (T-shirts in both cases). Other analogies for this concept can relate objects of different nature. For example, function can be represented as a coffee dispensing machine into which money is entered in order to obtain a cup of coffee, highlighting the arbitrariness of related sets (Even, 1990). In this sense, the analogy of the washing machine impedes the association of arbitrary sets, which may result in students gaining a partial understanding of the concept. Likewise, the washing machine does not show other conceptions for the function as, for example, the co-variation of magnitudes. Similarly, it does not facilitate representation of more complex functions or the complexity of the concept itself (function algebra, composition).

Arturo takes advantage of this relation between input and output to clarify the definition of the concepts of image and pre-image, which are parts of his KoT. Similarly, evidence of his knowledge about the domain and co-domain of the function appears in the analogy as "dirty clothes" and "clean clothes." This knowledge and the exposed relations between the source and target domains account for the use of analogy as a strategy for teaching the function, evidencing a relationship between its KoT and its KMT. Figure 2a shows Arturo's knowledge of the notation  $f(x) = y$  (knowledge about representations as a part of his KoT) that allows him to show the relationship between two domains of the analogy (as knowledge of strategies - KMT) and to introduce new ways to represent the function.

In the following excerpt, Arturo explains the relationship between the linked domains, source and target, using the analogy, in which we interpret the *structural* and *functional* character of the analogy presented (Curtis & Reigeluth, 1984).

Arturo: In our context, our function was the washing machine, washing. Set A would be dirty clothes and Set B clean clothes. If this is our washing machine, and it carries out its function; dirty clothes go in, and how do they come out?

<sup>1</sup> f: washing machine A: dirty clothes B: clean clothes

- Student: Clean!
- Arturo: The same as what we did here. The function was applied to this kind of T-shirt that I drew that was dirty. What will it equal?
- Student: Clean, clean clothes.
- Arturo: The same T-shirt, but clean. These two elements also have names. This element here is called the "image" of what I sent in. [...] And these elements here are called "pre image." What is the clean T-shirt?
- Student: Image.
- Arturo: The image of what?
- Student: Of the dirty T-shirt.

The *structural* characteristic is shown in establishing the correspondences of the Set A with the dirty clothes, the Set B with the clean clothes, and the washing machine with the arithmetic process carried out by the function. That is, the structure of the laundry process is analogous to the evaluation process in the function. When Arturo presents the analogy "function as a washing machine," he also refers to its functional character, as he establishes a comparison between the operation of the machine and the function. After this intervention, Arturo represented verbally and as an algebraic expression (representations in his KoT) an example of function (Figure 2b), thus deepening the analogy between machine and function.

- Arturo: With numbers, the function isn't going to do the washing. It's going to add two to whatever comes in [he writes " $f(x) = x+2$ "]. Whatever comes into the function, to the machine, I add two to it. If this is my machine that adds two to whatever comes in, if a one enters, how does it come out? [Student: Three.]

It should be noted that, when Arturo teaches "with numbers," he aims to work in the target domain of functions. Consequently, the situation created becomes an example (knowledge of examples - KMT) that will allow him to present the *functional* characteristic of the analogy and propose a two-way process for understanding the relationship between a function and a washing machine (Figure 2b).

The relationship between an algebraic expression (function) and a washing machine presents functions as an input-output process, meaning of the concept that we consider part of his KoT. In the same way, the articulation and selection of representations for the function (the analogy,  $f(x) = y$ , algebraic expression and natural language) accounts for Arturo's KoT, relating to his KMT.

In this last intervention, by associating a function with a machine, Arturo highlights the process role of a function (part of his KoT). We do not have evidence of Arturo highlighting the object role of a function supported by the analogy studied here, although the structural character of the analogy may be the first approach to this conception.

## Conclusion

According to the results yielded by the analyses presented above, the relations between the teacher's KoT and KMT are demonstrated in the articulation between knowledge of representations of the function and the choice and use of these representations as examples and analogies for teaching the

concept. In addition, the choice of analogies and examples given by Arturo reflect his KMT, which is nurtured and influenced by his KoT. The analogy shows the function as a correspondence in coherence with the definition given, while also permitting articulation of different representations: sagittal and algebraic diagram (Figure 2b). They also allow the teacher to produce other representations as a Cartesian graph or a table of values, thereby expanding the concept image for the students. Likewise, the analogy allows the students to appreciate the univalence character of the function (Even, 1990) and to extend the range of situations in which the concept of function is present (phenomenology - KoT).

The analogy utilised in this case is suitable for teaching and learning given that it is connected to the students' prior everyday experience. Moreover, its functional and structural character allows them to understand the concept from different perspectives and using different representations. Establishing a bidirectional relationship between the function and the washing machine can allow students to utilise the concept of a function they have learned to identify the concept in other areas of mathematics and other areas of knowledge. It should be noted that, in spite of the benefits presented by this analogy, students may have a partial notion of function if the conception of function as a machine is maintained. Thus, it is essential that other aspects of the concept be highlighted, such as the arbitrariness of the sets involved (Even, 1990). It is also important to relate it to other representations (Figueiredo et al., 2015). Lack of articulation between representations can cause a limitation in the development of the conception of function from the *structural* perspective (Sfard, 1991; Breidenbach et al., 1992). On the other hand, this presentation of the concept may constitute an obstacle to learning, for example, the algebra of functions or its composition (How do I sum two machines?). Likewise, students' direct experience with the laundry process can be detrimental in understanding the function: "the function did not fulfil its function." However, it is not the purpose of the study to evaluate the methodological proposal or Arturo's knowledge, but rather to approach it with the intention of improving our understanding of such knowledge, that of subdomain relationships in particular. In that sense, the analysis using the MTSK model is useful for advancing this understanding.

# Pre-service teachers using the Knowledge Quartet as a tool to analyse and reflect on their own teaching

Sindre Syversen Flesvig<sup>1</sup>, Tim Rowland<sup>2</sup> and Elisabeta Eriksen<sup>3</sup>

<sup>1</sup>Inland Norway University of Applied Sciences - INN University, Norway; [sindre.flesvig@inn.no](mailto:sindre.flesvig@inn.no);

*This paper reports a qualitative study of the post-lesson reflections of two pre-service teachers in Norway. During their third school placement, Nora and Mia volunteered to use the Knowledge Quartet to analyse and reflect on their own mathematics teaching. Comparing the nature of their reflections at the start and at the end of the placement, we find that Nora and Mia exhibit some development, focusing more on mathematical content at the end of the study than in the beginning. Factors that can influence their reflections are discussed: their own experience of mathematics and their beliefs about mathematics seemed to play an important role in how they interpreted and made use of the framework.*

*Keywords: Mathematics teacher education, teacher background, elementary school mathematics, teacher practicum placement, Knowledge Quartet.*

## Introduction

The apparent disconnect between teacher education and the practice of teaching is of great concern to teacher educators (e.g., Solomon, Eriksen, Smestad, Rodal, & Bjerke, 2015). Systematic reflection on teaching might reduce this fragmentation, providing an educational experience based on genuine classroom experiences. However, teacher educators face the challenge of encouraging pre-service teachers to engage with classroom data in a meaningful way. In mathematics, in particular, research efforts have been made to find ways of focusing attention on mathematics as opposed to general pedagogy, with the ultimate goal of helping mathematics teachers (both pre- and in-service) to develop their teaching. The Knowledge Quartet (KQ) is an example of a research-based theory that resulted from this research effort (Rowland, Huckstep, & Thwaites, 2005). Through two case studies (Flesvig, 2016), this paper explains and exemplifies the situated challenge of using the KQ to reflect on mathematics teaching.

The research questions are: “To what extent does using the KQ as an analytical tool influence what pre-service teachers' (PSTs') attend to in the analysis of their own mathematics teaching? How do PSTs describe their experiences of using the KQ for lesson analysis?”

## Literature review

Teacher education programmes prioritize increasingly the ‘core practices’ of teaching. The debate as to what these might be and what it means to focus on these in teacher education is ongoing (McDonald, Kazemi, & Kavanagh, 2013). We support the view that analyzing teaching is one such core practice:

[it] involves learning to decompose instructional practice, to attend to particular events and interactions that are considered consequential for student learning, and to interpret the meaning behind those events to make informed teaching decisions. (Sun & van Es, 2015, p. 201)

The underlying assumptions are that engaging in analysis of teaching, and focusing on the details of the mathematical aspects involved and on students' mathematical thinking, will result in development of mathematical knowledge for teaching, as well as in more responsive teaching. There is evidence that the first assumption holds true both for PSTs (Turner, 2012) and for in-service teachers (Llinares & Krainer, 2006). While the second assumption is yet not well documented, Sun & van Es (2015) confirm it in their study of secondary PSTs exposed to a course with a focus on analysis of video recordings of the participants' own mathematics teaching.

Providing PSTs with opportunities to analyse teaching is not enough. PSTs need tools to direct their attention to salient aspects of teaching episodes. While focusing their reflections on the taught content (mathematics) is not a given either for in-service teachers or for PSTs, research provides examples to show that this is a trainable skill (Turner, 2012; Star & Strickland, 2008; Sun & van Es, 2015). Examples of 'tools' that support the process include frameworks for analysis of teaching (Rowland et al., 2005, Star & Strickland, 2008), routines for discussion of videos (Sun & van Es, 2015), and experienced mentor support to direct post-lesson review to focus on mathematics (Nilssen, 2010).

In theory, school 'practicum' placements should provide PSTs with excellent opportunities to reflect on the details of teaching, under the supervision of experienced teacher mentors. However, research has shown that there are significant differences in the experience of school placement of individual PSTs and that school placement is mostly about managing and doing the teaching, less about learning systematically from it (Solomon et al., 2015). This makes it all the more interesting for teacher educators to explore ways of supporting, with minimal involvement, PSTs' structured reflections on mathematics teaching in their school placements.

## **Theoretical underpinnings of the study**

### **The nature of reflections on mathematics lessons**

While we argued for the value (and difficulty) of attending to mathematics content in PSTs' lesson analysis, we recognise other salient aspects are likely to feature. To capture these aspects in PSTs' reflections, we turn to the five-category framework of Star & Strickland (2008): classroom environment (class size and level, room layout, equipment, etc.), classroom management (classroom events and procedures), tasks (worksheets, presentations, homework, etc.), mathematical content (the topic, representations, examples, problems) and communication (questions asked, suggestion offered). The framework has been used as an instructional tool in two separate studies based on analysing video, leading to improved skills in observing classroom environment and communications (Star & Strickland, 2008; Star, Lynch & Perova, 2011). However, attention to the categories 'tasks' and 'mathematical content' seems harder to promote, and did not improve in the second study. For this reason, we chose another instructional tool for our study.

## The Knowledge Quartet

The Knowledge Quartet (KQ) is a framework that classified the situations in which mathematics teachers' knowledge comes into play, in four broad categories: foundation, transformation, connection and contingency. The framework is empirically grounded in classroom observations, and the four categories encompass in total 20 different codes (Rowland, 2014). For example, foundation includes codes such as overt display of subject knowledge, adherence to textbook, concentration on procedures. Transformation encompasses ways of making the mathematics accessible to learners, such as choice of examples and choice of representation. Connection includes, for instance, both connections between concepts and sequencing within a lesson. Contingency is the dimension capturing unexpected events in the lesson, for instance in responding to students' ideas.

The KQ is used to analyse mathematics teaching with a focus on teacher knowledge, and is an appropriate tool to analyse and develop mathematics teaching when used in cooperation by PSTs, teacher mentors and teacher educators (Rowland, Huckstep & Thwaites, 2005). It has been successfully used as “an analytical framework to identifying mathematical content knowledge revealed through observations of practice” in a study with in-service teachers (Turner, 2012, p. 256). The participants, who collaborated closely with the researcher and were given considerable support in using the framework, saw the KQ as a tool to support them in reflecting more critically on their own teaching (Turner, 2012). This focus on the mathematics stands in contrast with the general pedagogical and organisational features of the lesson typically addressed in post-lesson review sessions between teacher mentors and PSTs (Solomon et al., 2015). The KQ is a means “to support focused reflection on the mathematical content of teaching” (Turner, 2012, p.253).

## Methodology and methods

This paper reports on case studies of two PSTs' reflections on their mathematics teaching in school *practicum* placement. At the time of the study, the participants, called here Mia and Nora, were in their second year of a four-year Norwegian teacher education programme for grades 5-10 (age 10-15), specialising in mathematics. They were in the third school placement of their programme, and were based in the same grade 5 class.

Prior to the school placement, Mia and Nora attended a training session with the first author. This included a presentation of the KQ, and a joint analysis of a video from a Norwegian classroom. Nora and Mia were invited to use the KQ to analyse each mathematics lesson in their school placement. Since Mia and Nora were aware of the design of the study when they volunteered to participate, we expect that they attempted to use the framework as faithfully as possible.

Data collection included observations of two mathematics lessons for each participant, the first and the last of those taught in that third school placement (two weeks apart), followed immediately by audio-recorded semi-structured interviews. In the observed lesson, Mia and Nora taught statistics, and in the second they taught decimal numbers. This paper considers data from the interviews, since it is the PST's *reflections* on teaching, rather than the teaching itself, that will be analysed. However, the lessons were videotaped for stimulated recall during the interviews, and to allow recall of episodes discussed in the interviews.

The interview guides for the two interviews had a common core, and some additional questions that differed (regarding participants' background in the first interview, and regarding their experiences of using the KQ in the last interview). The core was structured around the dimensions of the KQ ("Last time we talked you mentioned being concerned with how tasks are sequenced. What about this lesson?"), but also included more open questions about the lesson observed ("Tell me about an episode you remember from this lesson. Why did this episode catch your attention?"). The interviews were transcribed and analysed in the original language (Norwegian), by the first author. The excerpts included in this paper were translated into English by the authors.

Given the design of the interview guide, with some open questions and some directly connecting to the KQ, this framework is not sufficient as the analytical tool. In this paper, our analysis draws on the framework of Star & Strickland (2008). This framework gives insight into the nature of the participants' reflections on their mathematics teaching, and their development during the school placement during which the study took place.

## Participants

At the time of the study Mia and Nora were in their third school placement (lasting 13 days), both based in the same class (grade 5, age 10) under the supervision of the same teacher mentor. Both Mia and Nora had some experience working as (unqualified) substitute teachers.

While confident in her mathematics knowledge, Mia wanted more in terms of mathematics pedagogy and this was her motivation for participating in this study. She had enrolled in her current grades 5-10 teacher education programme after dropping out from a programme for mathematics teachers for grades 8-13 (age 13-18) in disappointment with the courses: "It was all about computations... there was nothing about putting it [the maths] across".

Nora found mathematics "fun, at least in grades 1-7", but to gain admission to the teacher education programme, she had to retake the final mathematics exam (grade 12). In teacher education, Nora experienced a "steep transition from upper secondary, quite a few notches over that". In the first interview she described mathematics as her favourite subject to teach, but was dissatisfied with the course: "A lot of what we learn is not what we will teach, and there is no use for it in our professional lives, while at the same time I miss something on how to teach the very basic stuff".

## Findings

We consider Mia and Nora's reflections on their teaching of the two lessons, and their thoughts on The Knowledge Quartet. Some data from the videos is included by way of context for the interviews.

### Interview 1 - Mia's reflection on her teaching

In the post-lesson interview following Mia's first lesson, some questions were directed towards specific dimensions of The Knowledge Quartet, such as transformation. Mia was asked how she selected tasks for her class. She mentioned that she does look at the textbook first, but she supplements the materials with additional problems that she finds online and selects carefully:

I make sure they target the age group, fifth grade. That one [task on the handout] was actually a challenge for fourth grade, I found it online [...]. But it was about inserting, rather than drawing

the chart, and there are no such tasks in the textbook. I always look for tasks that fit the topic and the age group and that complement the textbook, otherwise there is no point in it.

### **Interview 2 - Mia's reflection on her teaching and on using The Knowledge Quartet**

The last lesson, like the first, had a traditional structure, with Mia showing some examples, then the students worked individually until the lesson ended, without any summary or discussion. Mia was invited to mention something she noticed during the lesson:

I remember best and I was most surprised by how well the students remember from [...] the first lesson about decimal numbers. In that lesson I felt they got something out of it, but not everything, because it was hard. But now I suddenly felt that there were very many who were eager and who knew something about it [decimal numbers].

The interview included questions on the dimensions of The Knowledge Quartet, related to specific situations from the lesson observed. In terms of transformation, Mia commented on the role of the textbook and the choice of tasks and examples:

I only use it [the textbook] to see what it says, given that the students will solve problems from there, so my teaching shouldn't deviate too much from it. But I don't really use it when I teach as such, then I use examples and tasks I prepared myself, that are suitable for the children. And these are [...] examples I choose carefully so that I know them well if I get questions.

At the end of the interview, Mia was asked about her thoughts on the KQ:

I had one lesson that I was really unhappy with, while my mentor thought it hadn't been so bad. But I was really irritated [...] so I used it [the KQ], because I was really angry. I went carefully through all the codes and categories. I'm thinking this should be done when the lesson goes well, too, because it really helped me when it went poorly [...] I discovered that - here is something positive, and here as well. It wasn't all negative, although it felt that way to begin with.

### **Interview 1 - Nora's reflection on her teaching**

Nora's first lesson was in statistics. The lesson had a traditional structure, starting with recalling and writing down definitions, solving a few problems on the interactive board, and then individual work.

Asked about the transformation dimension, about her choice of tasks and their sequencing, Nora explained:

I asked first for the definition of the mode and the median, since they'd learned that earlier. [I asked them] to check if they remembered what they'd been told earlier. [...] They have a rulebook where it's good to write down things like this, so we started there, because I thought at least they have it there.

The interviewer asked her to explain her choice of tasks, why she considered them good, and why they were selected for the session on the interactive board:

Because there was a bit of variation. But after a while ... Well, there were [in the online resource of the textbook] ten levels [of difficulty]. That's a bit much, so I stopped a bit earlier. [...] It would have been too much of the same, but six-seven is okay, a chance to drill.

## Interview 2 - Nora's reflection on her teaching and on using the Knowledge Quartet

Nora continued the lesson on decimal numbers from where Mia left off, continuing with individual work and then the whole class worked on exercises on the interactive board.

In the interview, she was invited to mention something she remembered from the lesson:

The students worked individually for a long time, so I had to find some additional tasks [from the textbook] since they solved them much faster than I thought. So I just let them know [...] that they can carry on to the next page.

Invited to use the KQ to analyse the lesson itself, Nora recalls a contingent moment:

One girl asked [...] if the distance between 0.7 and 1.1 on the number line is 4. Then I answered that she has to think of the whole number line: here's 0 and here's 1, there is a whole between them. Do you think there are four between [0.7 and 1.1]? No, so then it's 0.4.

In this final interview, Nora was asked about her experience using KQ so far and if she thinks she might continue using it. She admitted that it can be helpful in reassessing a situation ("might not think of it without all these points") that might otherwise be overlooked ("so much happens during a lesson") and this will help to revise the teacher's approach next time. However, the traditional post-lesson review session appeals to her:

I think it's helpful to talk about what happened in the lesson anyway, and we [Nora, Mia and the mentor] talked a lot. Then you get some insight in what is good and what could have been different, and so on.

In her experience, the KQ has "an awful lot of codes and dimensions" and using it resulted in:

... talking more about the lessons. And more about the examples. And sequencing, maybe. But not much otherwise.

## Discussion

### Mia

With reference to Star, Lynch & Perova's (2011) framework, the categories *tasks* and *classroom management* are especially prominent in Mia's first analysis/interview, both in response to the open questions, and when directed to use the KQ. A turn towards *mathematical content* occurs with more targeted questions about specific dimensions of the KQ, as in the case of transformation. By contrast, in her second analysis/interview Mia observed and reflected with *mathematical content* in mind, barely touching upon *classroom management*. Answering open questions, she refers to *tasks* and *communication*, without using any of the terms from the KQ. However, this changes when she goes deeper into her lesson using the KQ framework, with Mia using the terminology of the KQ, with attention to *mathematical content*, as well as *tasks* and *classroom management* in general. Questions on the dimensions of the KQ, such as the transformation dimension, direct Mia's focus to the fine grain of *mathematical content*.

Mia is convinced that the KQ supports a focus on the details of mathematics lesson. She pinpoints a specific situation in which breaking down the events of a lesson with the KQ helped her see

strengths, not only weaknesses in her teaching, thus regaining her confidence as a mathematics teacher, at a time when her mentor's more general feedback was not helping her.

### **Nora**

Throughout her first teaching analysis/interview, Nora's reflections focused most on *tasks*, *classroom management* and to some extent *communication*, only superficially touching on the *mathematical content*. Even when the questions directed her to the KQ, she never actively used the terminology of the framework. In the second analysis/interview, Nora focused mostly on *mathematical content*. Although initially focusing on *tasks*, there was a clear change in emphasis towards *mathematical content* when she is asked to use the KQ framework, and even more so when the questions are specific to the KQ dimensions.

There is a tension in Nora's statements about using the KQ for teaching analysis. While she recognizes that the KQ creates an opportunity for development by making visible the specifics of a mathematics lesson, Nora prefers the unstructured form of traditional review sessions, explaining this in terms of the burden of the number of codes.

### **Concluding comment**

Comparing the first and the last interview, we see that both Mia and Nora's reflections exhibited an increasing focus on mathematics. A number of factors could play a part in this, including the use of the KQ for analysis of the lessons, the experience of the school placement, and the mentor's guidance in the post-lesson reviews. The data indicate that the KQ does mediate this change, since even in the last interview we see that the more the questions are anchored in the KQ, the more marked the focus on mathematics was.

Both Mia and Nora described the KQ as a means to explore the details of a mathematics lesson, and an opportunity to improve their teaching. However, we see differences in the degree to which they embrace the use of the KQ, with Nora leaving the door open to use it for troubleshooting, and Mia positive to continuing using it both when lessons go well and when they do not. We recognize that there are differences in the mathematical knowledge and mathematics teaching confidence of the two PSTs, and this might play a part in these differences. For instance, analysing in such detail a lesson that 'went well' (as is often said in unfocused post-lesson reviews) is likely to reveal details that were problematic, an insight causing some emotional discomfort. In that case, Nora might have benefitted from receiving more support when using the KQ, to help her cope. Or, perhaps Nora interprets the KQ as an algorithm that requires her to go through the all 20 codes for every lesson, and finds the time commitment too much, in which case she would benefit from more in-depth training in using the KQ in a more holistic and efficient way, perhaps limiting the framework to low-inference codes (e.g. 'choice of examples') to begin with.

In conclusion, the study indicates that, even with minimal support, the KQ can contribute in some cases to focus pre-service teachers' post-lesson reflections on mathematics. Individual differences between the voluntary participants' willingness to continue using KQ after the end of the study suggest that teacher educators need to be mindful of factors that could deter PSTs from using the framework.

# Subject professional association activity: What can it offer teachers of mathematics and their students?

Jennie Golding

University College London Institute of Education, UK; [j.golding@ucl.ac.uk](mailto:j.golding@ucl.ac.uk)

*Professional association activity is commonly regarded as a professional ‘good’, yet there remains little systematic evidence of its impact. This paper reports on a small study that asked English teachers of mathematics participating in such activity what contribution they believe it makes to the development of their knowledge, skills and affect, and how that then impacts on their students. Participants claimed a range of significant and pervasive benefits, many of which are distinctive to this form of professional development. These include a renewed commitment to their role as teachers of mathematics, refreshment and inspiration, and a deep and lasting impact on both their own learning and that of their students.*

*Keywords: Professional association, professional development, mathematics, affect.*

## Background

Within mathematics education in the UK, there are four national ‘classroom-facing’ PAs, funded entirely from membership and each attracting up to several thousand members: The Mathematical Association (MA), the Association of Teachers of Mathematics (ATM), the National Association for Numeracy and Mathematics in Colleges (NANAMIC), and NAMA, the National Association for Mathematics Advisers. All have a core purpose of supporting the teaching and learning of pre-university mathematics through working with teachers and others.

Their annual conferences, residential for most, offer sessions that might focus on mathematics pedagogic knowledge or skills, learner enrichment or teachers’ own mathematics enhancement and/or enjoyment, or mathematics curriculum, leadership or assessment issues. There is time for networking and also for social activities. Conferences are usually held in teachers’ holidays and teachers who attend often fund themselves, so they clearly value what such activity offers. Between them the PAs also offer a range of day conferences, bespoke courses, professional periodicals, local groups, policy debate, and a variety of social media opportunities, so building professional communities of up to national scale. Additionally, the larger ones operate working days and weekends when resources are developed for publication, and Hodgen (2003) suggests this in itself can develop teacher reflection, knowledge and hence practice. Teachers can therefore personalize the extent and type of their involvement and the professional development (PD) targeted.

I adopt Cobb and Bowers’ (1999) conceptualization of teacher PD as any planned experience intended to develop teachers’ professional functioning (for the ultimate benefit of their students’ learning) – and that process as both enculturation and construction. We know something of what makes PD effective, for example that it has a content focus, is coherent with teacher’s prior learning and needs, active, sustained, features collective participation (e.g. Desimone, 2009). Golding (2017) suggests that for sustained development it should develop positive work-related identity and affect, as in Hodgen (2003) and Hannula (2011) respectively, including self-efficacy, resilience, enthusiasm and feeling valued. The importance of effective PD, job satisfaction and recognition to teacher retention

is also well evidenced (Lynch et al, 2016): critical when, as in England, there is a shortage of effective teachers of mathematics at all levels (Ofsted, 2012).

There are, though, some sizeable gaps in the PD literature, e.g. there is limited evidence of the impact on students' learning (Joubert and Sutherland, 2008), and the affordances of online activity continue to change. Further, I can find no systematic study of the contribution professional association (PA) activity can make to teachers' development, though Chetwin (2010) suggests there are likely to be gains from networking, growth of knowledge and/or skills, and taking responsibility for one's development. This small study therefore investigated the contribution of PA activity as perceived by participant English teachers of mathematics (n=185). It asked

- How is PA activity aligned with what is known about effective PD?
- What contribution can PA activity make to teachers' professional development, and to the development of their students?
- Is any of that distinctive?

## The study

I conducted semi-structured individual interviews with a purposive sample of four anonymized participants from each of the four 2016 PA annual conferences (Table 1), drawing on a variety of phase/experience/PA background from those currently, or recently, active in the profession. Questions (Figure 1) offered opportunity for development of a grounded account (Charmaz, 2006).

All 2016 conference participants were invited to complete a (usually online) questionnaire designed in part to validate interview responses with a wider sample. The interview questions were complemented by Likert-style questions (Table 2) designed to elicit the value attributed to aspects of conference activity known to be particular to this form of PD. Additionally, I scrutinised documents and publications available on PA websites or at conferences. Data consisted of questionnaire responses (n=185), transcriptions of recorded interviews (n=16), and my notes from documents scrutinized. There is no claim to generalisation from this highly selective sample, though the study shows clearly the breadth and depth of perceived impact on some teachers.

Grounded analysis of all qualitative data was by open, axial and selective coding (Charmaz, 2006). Documentary evidence was used to validate participant claims, and interviewees validated all written interpretations of their talk; additionally, a colleague acted as a 'critical friend' - particularly important given I have a history of involvement in PA activity myself.

Throughout, though, the study is framed by its reliance on teacher accounts. The status of such claims has been contested: do teacher narratives represent warranted true belief, and if not, to what extent can they be represented as 'truth'? This issue is addressed in the literature, though Desimone (2009) argues concerns can be over-stated in relation to accounts of PD; I adopt here Doyle's (1997) position applied to teacher development, that the study aims to develop understanding of a highly contextualised and personal phenomenon, through access to participants' stories of intentions, motives, purposes and perceptions of effectiveness, rather than a universally knowable phenomenon susceptible to legislation through policy.

**Table 1: Interviewees**

<i>Source</i>	<i>Pseudonym and teaching context</i>	<i>PA activity(years)</i>
ATM	Alice (11-18, special education), Lara (11-18), Terry (11-18), Billy (11-18, Higher Education, Adviser)	6/8/ 2/'many'
MA	Jackie (5-11, 11-18, Higher Education), Janet (5-11, Adviser), Kim (11-18), Rachel (5-11)	41/35/3/10
NAMA	Charles (11-18, Higher Education), Gail (5-11, Higher Education), Graham (11-18, Adviser), Kathy (11-18)	16/20/16/'many'
NANAMIC	Sally (11-18, 16+), David (11-18, adults), Angela (16+), Susan (11-18, 16+)	'Many'/0/'12/10

1. Tell me about your professional background... and your history of involvement in (*the PA*).
2. What aspects of the conference are you finding/did you find particularly helpful (why)?
3. What are the limitations of a conference like this in terms of your PD – what aspects of your PD are better provided elsewhere? (*prompt*: institution or local opportunities, online affordances)
4. And how do all these different opportunities impact on your students? (*prompt*: and their learning? How do you know? Any conference-specific impact, or not? if not mentioned)
5. So if someone asked you how you stay up to date, maintain your skills, and develop further as a teacher, what would you say?... and has that changed over your career?
6. Any other comments you'd like to make about your PD and its relation to PA activity? Thanks.

**Figure 1: Interview structure**

## Findings

Coding exposed themes around identity and values, specific gains for teachers and/or students, strengths and limitations of professional association activity, including some apparently distinctive benefits, and threats or disincentives to that. I consider each of those in turn. Whilst it was not possible to enact either questionnaires or interviews in precisely comparable ways across the four associations, I argue that differences did not fundamentally influence the nature of responses.

### Identity and values

Interviewees were keen to talk about impact on their professional identity or values, often in terms of affirmation, empowerment and meeting with like-minded people who support and challenge them professionally. For 11 of 16 this was their first focus in response, often centred around face to face participation – a sense of community, sometimes built up over years, and talk about refreshment and renewal, often contrasting that with the draining nature of teaching. Claims were often extravagant: “It’s been a life-changer, it builds me up as a maths teacher so I can do a better job in the classroom” (Kim), and for four teachers this was specifically linked with retention:

PA activity helps me analyse and then be proactive about developing what I value. Hugely empowering, and ... that keeps me in the profession despite the grinding demands. (Lara)

Here is about personal PD, affirmation, values – challenge too, but support for...your long-term growth and enablement, that enables you to go back refreshed and keeps you committed to what can be a ...very draining profession – I just couldn't stay in my job long-term without that injection of positivity and recharging. (Billy)

For interviewees with a background in Further or Adult Education, this identity work was talked about in even more fundamental terms:

In FE, very often you don't even see other teachers of maths... So NANAMIC gives you that identity – there are other people out there struggling with you, valuing some of the same things as you do – otherwise you're just functioning in isolation, far too often. (Sally)

### **Specific gains for teachers and/or students**

Interviewees commonly (10 of 16) talked about the high quality of PA publications, sessions and resources in terms of direct benefit to themselves and to their students:

Support – inspiration - resources: I return brimming over with ideas and enthusiasm, with knowledge about innovations across the country, catholic ideas and approaches that have worked in different circumstances. The resources are creative and engaging, they really probe deep understanding and the students love them. (Terry)

Often the benefit was claimed to spread beyond the interviewee concerned:

I've worked with teachers using these materials and boy are they effective. If they can make the right selection and the right tweaks, and we work on that, then they see real and immediate impact on learning. (Graham)

Many respondents (25 open questionnaire responses and 7 interviewees) greatly valued informal networking opportunities, claiming explicit benefits also to their colleagues and students – both immediate and also for sustained learning and positive disposition towards mathematics:

The specific numeracy ideas, I took them straight back to my classroom and my students are already showing the benefits, in a couple of weeks – to confidence as well as skill. There are also 'seed' ideas, things that ...will come to fruition over a longer timescale. (Susan)

For some (seven interviewees and over 25 open questionnaire responses), the opportunity to be better informed about, and contribute to, national policy debate is valued; for others (in 6 interviews and some 15 questionnaires), the chance to engage with cutting-edge research relevant to their practice and reflect on its application is important. Teachers who engage in local branch meetings claim similar, but less extravagant, benefits. Questionnaire open responses were generally consistent with these interview response strands.

### **Strengths and limitations of PA activity**

As well as the specific benefits to professional skills and knowledge, and to professional affect and identity, teachers identified the eclectic nature of professional association activity, and the fact that they can easily personalise it to their own professional needs, as underpinning its effectiveness. Many described it as 'uniformly high quality – the best professional development I get' or similar. It was often reported as having long-term benefits for both teachers and their students, sometimes in contrast to other courses which "focus on short-term skill or particular knowledge." (Janet).

Five interviewees talked about the benefits of being physically removed from their work environment and the luxury of sustained unhindered time committed to their professional growth. Several teachers described the desirability of also participating in institution-based development alongside colleagues, with access to familiar resources, and with whom they could contextualise new ideas. In three interviews they extolled the particular advantages of engaging in branch or conference activity with at least one colleague. On the other hand, teachers said they found distance learning can be effective and efficient for pure dissemination of information. Four identified PA activity as often limited by a ‘light touch’ for more substantial knowledge or skill development, particularly where there was a need for substantial subject or subject pedagogical knowledge, perhaps better provided in a series of inputs interspersed by classroom embedding. This was true in particular for two of the one-day NANAMIC conference participants. One commented:

And of course then you go back into college and there’s no-one to share it with...so unless you’re really committed, those interesting ideas and good intentions might well get lost. (Angela)

However, all of those interviewed and virtually all of those completing questionnaires identified face to face PA activity as a central and rich component of their effective impact on students. These comments were echoed in questionnaire responses, though typically in less depth. Questionnaire responses added no significantly different responses.

Likert scale items in questionnaires largely concentrated on features of conferences. Table 2 shows mean response, on a scale of 1 (of little importance to me) to 5 (very important to me), together with standard deviations *s*. As quantitative data it is of limited robustness but gives some indication of the ranking of different aspects, similar but not identical for the different conferences. For the range of participants, working with others from a variety of roles and experiences is highly valued, as are opportunities to engage with new ideas or mathematics. These teachers also value opportunities to construct a programme that meets their individual needs.

**Table 2: How important are the following aspects of the conference to you?**

*Association (responses from active teachers or those actively working with teachers)*      *NANAMIC (n=10)*      *NAMA (n=29)*      *MA (n=56)*      *ATM (n=90)*      ***Overall (185)***

Meeting people in comparable roles	4.2	3.7	4.3	4.2	4.2 (s=0.7)
Face to face rather than at a distance	4.4	4.5	4.3	4.3	4.4 (s=0.7)
Meeting people from other phases in education or with different roles or from different areas of the country	4.2	3.9	4.7	4.7	4.6 (s=0.6)
A mix of beginners and experienced colleagues	4.4	4.0	4.5	4.6	4.5 (s=0.7)
Sessions that are grounded in the classroom	4.1	3.4	4.4	4.2	4.1 (s=0.5)
Social activities	-	2.3	3.3	3.9	3.5 (s=1.1)
Immersion – it’s residential	-	2.3	4.5	4.3	4.0 (s=0.7)

Opportunity to do mathematics or engage with new ideas, irrespective of whether I'll use them directly in the classroom	4.3	4.5	4.5	4.6	4.5 (s=0.8)
Being able to choose sessions which fit my needs/preferences	4.6	3.7	4.6	4.7	4.5 (s=0.8)

### Threats or disincentives to such activity

There are, though, some clear threats to participation, of which funding was mentioned by nearly all interviewees. Although “cheaper for several days of exceptionally high quality development than many mediocre commercial courses” (Rachel), teachers routinely talked of schools and colleges prioritising performance-framed one-off courses for funding, and leadership teams not valuing the “deeper, wider learning that is supported by face to face PA opportunities” (Janet). Others said that colleagues “thought they were mad to spend holiday time at a ...conference when there are so many pressures during term time you just want to curl up and die when you get to a holiday” (Kathy). Four interviewees claimed their schools/colleges would not pay for conference attendance because a better-informed teacher was more likely to move. Funding was a particular issue for those working in FE, with a majority of those respondents reporting little or no employer support for subject-specific development, so no choice but to fund such development themselves.

Four interviewees suggested that Primary or FE teachers without a strong mathematical background or a specific mathematics responsibility were unlikely to prioritise, or be confident to participate in, subject specific and self-funded professional development. They suggested incentives for Primary teachers to ‘bring a local friend’ might increase both confidence and impact, and identified day conferences as a good first step “where it’s often desperately needed” (Janet).

### Discussion

It is important to note that there is no claim to generalisability here: these are teachers in an English education culture who choose to attend these conferences in their own time, and often self-funded. They are therefore highly committed to their own development as teachers, but also claim that they gain motivation and energy for their work from PA activity, often in contrast to other opportunities available to their context. It is striking that almost all interviewees privilege talk about values, affirmation of professional identity, and improved self-efficacy in their accounts, together with deep, wide and reflective mathematical (subject and subject pedagogical) learning for the long-term effective exercise of their professional role. They commonly contrast that with much external PD and often generic local provision. With both preservice and inservice education in England increasingly adopting generic rather than subject-specific approaches, Joubert and Sutherland (2008) show such subject-specific opportunities are central to the development of a deeply effective teaching profession.

The benefits described align well with Desimone’s (2009) and Golding’s (2017) criteria for effective PD: showing a clear content focus, active and coherent with teacher’s prior learning needs, featuring collective participation, and contributing very positively to teachers’ affective and identity needs. PA activity can be sustained (sometimes over years) in the sense of offering longitudinal stimulus interspersed with everyday teaching, but not usually in the sense of a critical mass of hours focused on particular knowledge or skills, for which other avenues would appear to be more effective. The

benefits claimed for teachers, and for their students, are significant, deep, wide-reaching and long-lasting, including a renewed commitment to retention in the profession. There is no *a priori* reason why such benefits should not be experienced by far greater numbers, and it is important that perceived threats to participation are addressed. These are not just about funding, but, as in Lynch et al (2016), about the value teachers perceive management to give to PA activity and to teachers' PD beyond the short term specific needs of their school/college.

All teachers in this study were teachers of mathematics, but in the English context there are comparable professional associations in other curriculum areas, and an obvious question is whether the benefits cited here, particularly in relation to subject-related identity, apply also to them.

### **Benefits distinctive to professional association activity**

Some distinctive benefits of PA activity appear to emerge. First, there is the opportunity to mould a PD programme to one's own professional needs, whether in terms of reading, resources or face to face development. Many teachers also referred explicitly to working with mathematics – for its own sake as well as for possible classroom benefits. In England, in contrast to many other jurisdictions, this is unusual after initial qualification, yet this aspect of PA activity was commonly highly valued.

There appears to be a great deal of professional affirmation, networking and identity work taking place. Some teachers particularly value the access to recent research offered by the PAs, and/or the informed policy work facilitated by PAs and based on professional discussion, and I would argue it is healthy for policy systems to be informed by such knowledge and discussion. Finally, through the PAs it is relatively easy for teachers to be able to offer something back to the PD of others, whether through writing about their professional work, giving a session at a conference, disseminating, receiving critique and discussing in a varied but informed peer group, producing resources or developing courses, or engaging in writing work that responds to deep desires to improve mathematics learning. This is itself is recognized to be developmental:

Writing for journals has been very developmental, and the support you get for doing that. Very high quality writing sessions: a richness of ideas from people whose ideas have since shaped my practice, that I admire and aspire to. (Charles)

There are, though, other providers of different subsets of the cited activities, and it is an open question how the affordances and constraints of such provisions compare with those of PA activity.

## **Conclusions**

These English mathematics teachers claim a wide range of benefits from PA activity (especially face to face events), some of which are perceived as either exclusive to such activity or most effectively provided by it. They say it gives them deep and wide professional learning which impacts on their students both through specific pedagogical tools and approaches, and through teacher refreshment and re-commitment. They claim an affirmation of their professional identity through sharing goals and values with others, and increased self-efficacy through peer validation and personalisation of development. Teachers value the subject-specific nature of PA activity, that in the English context contrasts with much school-based, typically generic, development. They appreciate the range of ideas and ways of thinking that far exceed what is available within one school/college or group of institutions. For many, these claimed benefits have been developed and sustained over years.

The study offers evidence to management and policy makers about the value these teachers of mathematics place on subject-specific development that affirms their professional identity and their values, recharges and renews their commitment and enthusiasm, and engages them actively in deep and reflective subject and subject pedagogic learning. With current performance pressures and limited budgets, it is not surprising English schools and colleges often privilege perceived immediate curriculum needs, but the cost of PA activity outside teaching time is small when compared with the costs to students of a stale and drained teacher – or no teacher at all. There is a need to identify politically-acceptable ways to invest in teachers' longer term subject-specific development, so that more teachers are encouraged to participate in such activity.

# Subject matter knowledge and pedagogical content knowledge in the learning diaries of prospective mathematics teachers

Jani Hannula

University of Helsinki, Finland; [jani.hannula@helsinki.fi](mailto:jani.hannula@helsinki.fi)

*In this study, 26 learning diaries by prospective mathematics teachers were analysed in order to describe the characteristics of mathematical and pedagogical knowledge discussed therein and to evaluate the potential and limitations of the learning diary in mathematics teacher education. Conceptualisations of teacher knowledge are typically discussed in terms of subject matter knowledge, pedagogical knowledge and pedagogical content knowledge. A central goal of mathematics teacher education is to strengthen all of these areas of competency. The results of this study indicate that, although the learning diary is a potential learning tool, prospective mathematics teachers tend to emphasise pedagogical content knowledge, placing less stress on subject matter knowledge. Consequently, more structured learning diary tasks could be used to support all the components of mathematical knowledge for teaching.*

*Keywords: Teacher knowledge, mathematics teacher education, learning diaries, subject matter knowledge, pedagogical content knowledge.*

## Introduction

Finnish mathematics teacher education consists of three somewhat distinct parts: subject matter studies, educational studies and practical teacher training at schools. Subject matter studies at mathematics departments form a major part of the mathematics teacher studies. Finnish mathematics teachers, however, report that university-level subject studies in mathematics lack a clear connection to the mathematics taught at school (Koponen, Asikainen, Viholainen, & Hirvonen, 2016). The transition to university-level mathematics requires a major change in mathematical thinking (e.g., Tall, 1992). At university, mathematics courses typically emphasise formal reasoning, meaning reasoning based on axioms, definitions and proven theorems (Viholainen, 2008). Informal reasoning is based on visual or physical interpretations of mathematical concepts (Viholainen, 2008). Some empirical studies (e.g., Chin, 2013; Viholainen, 2008) have shown that prospective teachers may have difficulties connecting formal and informal reasoning.

On the other hand, prospective mathematics teachers may emphasise the importance of a teacher's personal characteristics and pedagogical knowledge, while diminishing the importance of subject matter knowledge (e.g., Hoffkamp & Warmuth, 2015). Subject matter knowledge nevertheless plays a significant role in a teacher's professional knowledge. Firstly, subject matter knowledge is typically seen as theoretically necessary for developing pedagogical content knowledge (Baumert et al., 2010). The quality of prospective teachers' subject matter knowledge also affects their pedagogical choices when participating in practical training (Even, Tirosh, & Markovits, 1996). In addition, subject matter knowledge along with pedagogical content knowledge can be seen as a foundation for effective teaching, as a teacher's professional knowledge affects student achievement (e.g., Baumert et al., 2010).

This study is a part of a design-based research and development project that has been carried out at the University of Helsinki. The aim of the research is to develop instructional practices in order for

prospective teachers to both strengthen their subject matter knowledge and build up their pedagogical content knowledge. The research also aims to give insight into prospective mathematics teachers' conceptions of the relationship between school and university mathematics.

In this study, the specific focus is on learning diaries written by prospective mathematics during a six-week seminar. The seminar focused on finding connections between the mathematics studied both at university and at school and on discussions of mathematical content from the teacher's point of view. That is, the aim of the seminar was for prospective teachers to, first, strengthen their (structural) knowledge of mathematical topics (such as derivative) and, second, enhance their pedagogical content knowledge with relation to these topics. The aim of this study was to examine the potential and limitations of learning diaries as a learning tool in this context and to conceptualise the kinds of knowledge these prospective mathematics teachers discussed in their diaries.

## **Theoretical background**

Theories used in design-based research can be divided into grand theories, orienting frameworks, frameworks for action and domain-specific instructional theories (DiSessa & Cobb, 2004). In this study, the idea of constructive alignment (Biggs & Tang, 2011), which provided the instructional design of the research setting, is used as a framework for action. The data analysis for this study is based on domain-specific conceptualisation of teacher knowledge (Ball, Thames, & Phelps, 2008). In the next two subsections, these frameworks will be discussed in more detail.

### **Teacher Knowledge**

The distinctions between content knowledge (or subject matter knowledge), pedagogical knowledge and pedagogical content knowledge (Shulman, 1987) are an established starting point for conceptualisations of teacher knowledge (Scheiner, 2015). Especially the distinction between subject matter knowledge and pedagogical content knowledge has gained significant attention and generated a great amount of research and further development of the conceptualisations of teacher knowledge. According to the Mathematical Knowledge for Teaching (MKT) model (Ball et al., 2008), a teacher's content knowledge consists of common content knowledge (CCK), specialised content knowledge (SCK) and horizon content knowledge (HCK). In the MKT model, pedagogical content knowledge, in contrast, is divided into knowledge of content and students (KCS), knowledge of content and teaching (KCT) and knowledge of content and curriculum.

The components of MKT model have been shown as important for effective teaching (Jakobsen, Thames, & Ribeiro, 2013). Hence, the model is valuable for this study, which aims to offer insight into prospective mathematics teachers' discussions of their learning diaries and to use this information for further development of instructional practices in teacher education.

### **Constructive alignment and learning diaries**

Present research and development of instructional practices in higher education is typically based on the constructivist view of learning and concepts, such as learner approaches to learning, self-regulation and reflection. Constructive alignment is based on the constructivist view of learning and suggests that the intended learning outcomes, implementation of teaching and assessment should be carefully aligned and support active learning. Biggs and Tang (2011) suggest that by using more

active ways of learning (such as problem-based learning) even ‘less academic’ students can achieve more advanced levels of learning, such as applying and theorising.

In this study, the seminar was designed in the spirit of constructive alignment (e.g., the students worked in groups and specified their own study/discussion topics). The learning diary task was one of the ways to promote active learning and reflection among students. Typically, learning diaries are seen as texts that include both the central arguments of a course or a seminar and the writer’s own interpretation of and reflection on these themes. That is, learning diaries are not supposed to promote *knowledge telling writing* (Bereiter & Scardamalia, 1987), which is understood as writing based on memorised facts. Instead, learning diaries promote *knowledge transforming writing* (Bereiter & Scardamalia, 1987), which is based on problem analysis and reflection.

## Research questions

In Finnish higher education, learning diaries have been used successfully in subjects such as research methodology (Kyttälä, 2012). Journaling has also been found to be useful in studying university-level mathematics (Meel, 1999). There is, however, a lack of research evaluating the use of learning diaries in mathematics teacher education from the point of view of the teacher’s knowledge. Additionally, more insight into prospective mathematics teachers’ mathematical and pedagogical thinking is needed for further development of instructional practices in mathematics teacher education. Thus, the following research questions were formed.

1. Can learning diaries be used to promote knowledge transforming writing in mathematics teacher education?
2. What kinds of professional knowledge do the prospective mathematics teachers discuss in their learning diaries?

The first research question was posed in order to evaluate whether learning diaries have potential as a reflective learning method in mathematics teacher education. The second research question was posed in order to characterise the prospective mathematics teachers’ discussions on teacher knowledge. The question of whether some/certain aspects of teacher knowledge would be emphasised in the diaries was also considered, as prior research has shown that prospective teachers may emphasise pedagogical knowledge and diminish the importance of subject matter knowledge (e.g., Hoffkamp & Warmuth, 2015).

## Method

The data was collected during a seminar held in autumn 2014. The students (prospective mathematics teachers) attending the seminar formed small groups of 4–5 members. All groups prepared an introduction to a topic (such as dot product), so that both mathematical and pedagogical ideas were covered. These introductions led to group discussion and, as homework, the students reflected on their ideas by writing a learning diary. In their diaries, the students were asked to discuss 1) *What was discussed and how do the topics of discussion relate to other contexts?*; 2) *What did I learn and what was its meaning for me?*; 3) *Was something missing or unclear?*

Participants were mainly mathematics students at the end of their studies. Three students were studying another subject (such as physics) with minor studies in mathematics. Also, six students were second- or third-year students and, thus, not yet at the end of their five-year studies. The participants

were studying in a subject teacher programme that qualifies them to work as a teacher in the last years of comprehensive school (with students aged 13 to 16 years) and upper secondary school (with students aged 16 to 19 years).

Student learning diaries (N=26) were analysed using content analysis (Elo & Kyngäs, 2008). The units of observation were first placed in categories from the MKT model using deductive content analysis. Subcategories were then formed using inductive content analysis. In addition, the individual diary entries were classified either as *knowledge telling writing* or *knowledge transforming writing* in order to classify the entire diary either as *knowledge telling* or *knowledge transforming*.

The author of the present article created the coding. As it was not possible to use two independent coders, during the process, the author reread the diaries and the coding to ensure that his thinking remained constant during the coding process. The components of the MKT model may be difficult to distinguish from one another and this boundary problem has been highlighted in the research literature. This poses a challenge for coding, as two researchers may create different categorisations. The most problematic category seems to be HCK. In this study, HCK was understood, as defined by Jacobsen et al. (2013), as ‘an orientation to and familiarity with the discipline (or disciplines) that contribute to the teaching of the school subject at hand, providing teachers with a sense for how the content being taught is situated in and connected to the broader disciplinary territory’.

The coding of *knowledge telling writing* and *knowledge transforming writing* was based on a prior study by Kytälä (2012). When coding each diary entry as either *knowledge telling* or *knowledge transforming*, the former was used if the entry included only repetition of the information discussed in the seminar and the latter code was used if the entry included personal reflection. *Knowledge telling writing* included excerpts such as ‘This week we discussed linear algebra. Firstly, we discussed vectors in  $\mathbf{R}^2$ ’, whereas *knowledge transforming writing* included personal reflection such as ‘I soon realised that I didn’t remember much about dot product. I remembered that it had something to do with lengths and the perpendicularity of vectors.’

If at least half of the entries were labelled as *knowledge transforming* the entire diary was labelled accordingly. This methodology was chosen to ease the comparison of the results of this study to prior studies in the Finnish higher education context.

## Results

The results of the study are presented in three parts. First, writing strategies (*knowledge telling* vs. *knowledge transforming*) are discussed. Then, in the following two subsections, the subject matter knowledge and pedagogical content knowledge observed in the diaries are discussed.

### Knowledge telling writing vs. knowledge transforming writing

23 of the 26 diaries featured *knowledge transforming writing*. This seems to indicate that learning diaries can be used to promote reflective learning in mathematics teacher education as they have in other educational contexts, as Kytälä (2012) has suggested. However, while most of the diaries were categorised as *knowledge transforming*, the content discussed in the diaries varied significantly. In some of the diaries, both mathematical and pedagogical topics/issues were discussed comprehensively, whereas in others, the mathematical content was discussed only cursorily and the

pedagogical issues were discussed in depth. The coding of subject matter knowledge and pedagogical content knowledge aimed to highlight this variation in greater detail.

### Subject matter knowledge

The distinguished subcategories of subject matter knowledge are presented in Table 1. The frequency of each category is indicated in brackets. In the main categories, percentages are also given. Discussing representations of mathematical content was labelled as SCK, as according to Ball et al. (2008), knowledge of 'how to choose, make, and use mathematical representations' belongs to SCK. The category 'nature of mathematics' included utterances such as 'In mathematics you don't prove absolute truths. Instead, the proofs are based on chains where assumptions lead to something.' These can be also seen in connection to HCK, but as these comments were general, they were coded as CCK. Additionally, some discussion of the curriculum, such as 'Does knowing probability require knowing set theory? I suppose so. It would be good if there would be more of that in secondary school', were categorised as SCK instead of KCC. These comments also seemed connected to HCK, but were more focused on rethinking school mathematics and were consequently categorised as SCK.

<b>Common content knowledge (66; 25 %)</b>	<b>Specialised content knowledge (158; 59 %)</b>	<b>Horizon content knowledge (46; 17 %)</b>
<ul style="list-style-type: none"> <li>• Giving a list of concepts (20)</li> <li>• Giving a definition (11)</li> <li>• Giving a theorem (9)</li> <li>• Explaining a property of a mathematical entity (8)</li> <li>• Giving a solution strategy (8)</li> <li>• Giving alternative definitions (7)</li> <li>• Discussing the nature of mathematical knowledge (6)</li> <li>• Giving a mathematical example (2)</li> </ul>	<ul style="list-style-type: none"> <li>• Discussing representations of mathematical content given in textbooks (72)</li> <li>• Discussing alternative representations of mathematical content (65)</li> <li>• Discussing relationship between mathematical knowledge and curriculum (11)</li> <li>• Going through some history of mathematics (6)</li> <li>• Giving and discussing matriculation examination tasks (5)</li> <li>• Reflecting on a mathematical example (2)</li> <li>• Modifying an example (1)</li> </ul>	<ul style="list-style-type: none"> <li>• Discussing the hierarchical relationship of mathematical concepts (28)</li> <li>• Giving an application of a mathematical entity or method (18)</li> </ul>

**Table 1: Subcategories of subject matter knowledge distinguished in the diaries**

Common content knowledge was mainly discussed in terms of giving a list of concepts (related to the subject), giving a definition of a concept (such as limit) or giving a theorem (such as 'If function  $f$  is derivative, then function  $f$  is continuous'). This discussion was typically limited to telling the facts and no explanations or proofs were given. The specialised content knowledge typically focused on discussing the representations of mathematical content. Only one student adapted an example so that different versions of a problem were considered. The least discussed aspect of subject matter knowledge was horizon content knowledge; only 46 units of observation included discussion of the

hierarchical relationship of mathematical concepts or an application of a mathematical entity or method. Overall, discussion of subject matter knowledge was somewhat focused on SCK. More specifically, discussing the different representations of mathematical content was common in many diaries.

### Pedagogical content knowledge

The distinguished subcategories of pedagogical content knowledge are given in Table 2.

Knowledge of content and curriculum (106; 27 %)	Knowledge of content and students (133; 34 %)	Knowledge of content and teaching (148; 38 %)
<ul style="list-style-type: none"> <li>• Upper secondary school curriculum (57)</li> <li>• University curriculum (51)</li> <li>• Comprehensive school curriculum (17)</li> <li>• University of applied sciences curriculum (6)</li> <li>• Vocational school curriculum (2)</li> </ul>	<ul style="list-style-type: none"> <li>• Difficult content for students (45)</li> <li>• Student competence (28)</li> <li>• Student knowledge (23)</li> <li>• Learning process (18)</li> <li>• Misconceptions (10)</li> <li>• Affect (7)</li> <li>• Solving strategies (3)</li> </ul>	<ul style="list-style-type: none"> <li>• Ways to approach mathematical content in teaching (87)</li> <li>• Teaching methods (54)</li> <li>• Encouraging students (5)</li> <li>• Differentiation (2)</li> <li>• Answering student questions (1)</li> <li>• Correcting misconceptions (1)</li> <li>• Mathematical language and notation (1)</li> </ul>

**Table 2: Subcategories of pedagogical content knowledge distinguished in the diaries**

In many diaries, the secondary school and university curricula were compared. Students discussed, for instance, the content of secondary school calculus courses and university analysis courses. The *knowledge of content and students* sections mainly focused on difficulties or misconceptions that school students may have. For example, affect and learning (e.g., emotions) were little discussed and the cognitive studies in mathematics education were mainly used as references. The *knowledge of content and teaching* focused on discussing different means of approaching mathematical content in teaching and different teaching methods. For example, no imaginary learning situations were introduced and only one student pondered the answering of school students' questions.

Overall, PCK was discussed more than subject matter knowledge. However, the PCK typically discussed in the diaries can be described as content-driven, as it was mainly placed in subcategories such as 'Ways to approach the mathematical content in teaching' or 'Difficult content for students'.

### Discussion and conclusion

It is worth noticing that the results of this study cannot be generalised to whole student populations or other contexts. This study contributes only case-specific information, which can, however, be used in further development of the specific learning environment. In addition, the reliability of this study could be enhanced by using two independent researchers in the data analysis phase. Nevertheless, this study found that in this specific context, many prospective mathematics teachers adopted a *knowledge transforming writing* strategy in their learning diaries. The knowledge discussed in the diaries was somewhat focused on SCK and PCK. More specifically, the most discussed topics were representations of mathematical content, curricula, student knowledge and teaching methods.

Some of the learning diaries discussed both subject matter knowledge and pedagogical content knowledge. Some of the diaries, however, were more focused on pedagogical content knowledge. This seems to indicate that some of the prospective teachers emphasised pedagogical topics, while other prospective teachers discussed teacher knowledge more comprehensively. Further research would be needed to discuss this variation in detail and, especially, to compare students who are at different stages of their studies. In addition, it is notable that horizon content knowledge was rarely discussed in the diaries. This was somewhat surprising as the aim of the seminar was to connect the content of university-level mathematics and school mathematics. If HCK is understood as Jakobsen et al. (2013) have presented it, connecting mathematics as a discipline to school mathematics means discussing horizon content knowledge. In addition, some aspects of SMK and PCK (such as modifying tasks) also received little attention. This implies that learning diaries may lead to reflections that are not fully aligned with the intended learning outcomes. Further research is needed to determine whether more structured learning diary tasks would help students to better discuss desired sides of mathematical knowledge for teaching.

# The role of definitions on classification of solids including (non)prototype examples: The case of cylinder and prism

Mine Işıksal-Bostan<sup>1</sup> and Seçil Yemen-Karpuzcu<sup>2</sup>

<sup>1</sup>Middle East Technical University<sup>1</sup>, Turkey; [misiksal@metu.edu.tr](mailto:misiksal@metu.edu.tr)

<sup>2</sup>Middle East Technical University<sup>2</sup>, Turkey; [ysecil@metu.edu.tr](mailto:ysecil@metu.edu.tr)

*The purpose of this study is to investigate prospective middle school mathematics teachers' (PMTs) formal definitions regarding cylinder and prism and the role of these definitions on their classifications of solids involving (non)prototype examples. Data were collected through questionnaire and interview protocol from three PMTs who were 3rd year students in one of the teacher education programs in Turkey. Data analysis revealed that PMTs mostly used inappropriate terminology in defining cylinder and prism. Despite their inappropriate definitions, one PMT could classify cylinders and non-cylinders among the groups of solids correctly. PMTs who could not classify cylinders correctly made incorrect inclusions regarding the cylinders and prisms.*

*Keywords: Definitions, solids, prospective mathematics teachers, middle school mathematics teachers.*

## Introduction

Definitions constitute the indispensable part of mathematical instruction. National Council of Teachers of Mathematics [NCTM] (2000) emphasized the importance of students' understanding of the role of mathematical definitions and students' use of definitions in mathematical practices. Researchers argue that definitions should have some critical attributes. According to Van Dormolen and Zaslavsky (2003), a good mathematical definition should have following necessary characteristics: criterion of hierarchy, criterion of existence, criterion of equivalence, and criterion of acclimatization. In addition to the necessary characteristics, criterion of minimality, criterion of elegance, and criterion for degenerations are classified as the preferred features for the good mathematical definitions (Van Dormolen & Zaslavsky, 2003). Additionally, Leikin and Winicki-Landman (2000) stated that definitions should have necessary and sufficient conditions for the given concept and they should have conditions that are characterized as minimal.

Beginning at early school years, students are encountered with geometric shapes and solid figures. Students' concept images that flourish during that years may support the concept definitions that will be introduced in later years. However, as Vinner (2011) argues, concept definitions and concept images are not always parallel and mismatch may arise between them. Keeping this in mind, educators should stimulate the development of concept images as early as possible that support the concept definitions (Tsamir, Tirosh, Levenson, Barkai, & Tabach, 2015). In other words, appropriate guidance should be supplied before those intuitions are rooted and difficult to alter (Tsamir et al., 2015). Hence, it is a well-known fact that teachers play important roles during the development of those concept structures. Shulman (1986) stated:

Teachers must not only be capable of defining for students the accepted truths in a domain. They must also be able to explain why a particular proposition is deemed warranted, why it is worth

knowing, and how it relates to other propositions, both within the discipline and without, both in theory and in practice. (p. 9)

To state differently, subject matter knowledge (SMK) was related to the structure of mathematics involving definitions, axioms, proofs, theorems and relationships among them (Shulman, 1986). Thus, teachers' knowledge on definitions, classified as one of the components of SMK (Ball, Thames, & Phelps, 2008) plays an important role during the development of students' conceptions of definitions. In addition, teachers' knowledge of mathematical definitions has an influence on didactic approaches in mathematics classes (Leikin & Zazkis, 2010; Zazkis & Leikin, 2008). In other words, teachers' understanding of the definition of concepts in addition to their concept images impact the teachers' way of representing the concept to the students, explanations given during the instructions, way of orchestrating the classroom discussion and their fluency and flexibility in teaching topics (Leikin & Zazkis, 2010). Thus, teachers' knowledge on definitions and to what extent they use these definitions in classifying solid figures deserves further attention for giving evidence for teachers' practices regarding the examples used in mathematics classrooms.

Moreover, an assertion was made that most of the time students do not know the definitions of mathematical terms that they need to use, and thus, they tend to memorize the given definitions without understanding (Edwards & Ward, 2008). Indeed, since stating the correct concept definition is not an indication for the understanding of the concept, critical understanding of definition is needed to apply the definition successfully. With this idea in mind, in this study as a continuation of our early work, we investigate PMTs' knowledge of definitions regarding the cylinder and prism and how their definitions influence their choice of classifications of solids involving prototype and non-prototype examples. Thus, the aim of this study was to answer the following research question:

How do PMTs define cylinder and prism, and how do their definitions influence their classifications of solids involving (non)prototype examples?

### **Framework of the study**

In this research study, we used Leikin and Zazkis's framework developed for the analysis of teacher-generated examples of mathematical concepts (Leikin & Zazkis, 2010). According to the framework teacher-generated examples of definitions of the concepts were analyzed according to four components: 1) Accessibility, 2) Correctness, 3) Richness, and 4) Generality/Concreteness. Accessibility refers to the generation of examples with or without a prompt, whether they are generated easily or with difficulty. By means of generality, Leikin and Zaskis emphasize the use of specific properties pertaining the given concept apart from the general descriptions that belongs to the other class of concepts. In addition, correctness refers to the appropriateness of the logical statement generated for the mathematical concepts. While analyzing correctness of the examples, they make a distinction between appropriate and inappropriate examples. In other words, they classify examples of definitions as appropriately rigorous if the answers consist of necessary and sufficient conditions for defining the given concept and minimal use of correct mathematical terminology and symbols. On the other hand, the answers are classified as appropriate but not rigorous when there are some deficiencies in the definitions or imprecise language was used. When the given examples has deficiency in either satisfying necessary or sufficient conditions, they are categorized under the heading of inappropriate examples. For instance, while defining cylinder as a solid, one of the

necessary condition for the cylindrical surface is that it is generated by a straight line (generatrix) which moves so as constantly to pass through a given curve (directrix) remaining parallel to its original position (Beman & Smith, 1900). In addition, to have sufficient conditions, the curve should be a closed shape which designates the bases of the cylinder that are two parallel transverse sections (Beman & Smith, 1900). Therefore, cylinder is a portion of an enclosed space between two parallel bases created by a cylindrical surface. On the other hand, the definition of cylinder will be inappropriate unless the surface is composed of parallel lines. In addition, having a closed surface is a general description that belongs to other 3D solids and base should be a circle is not a necessary condition for a cylinder.

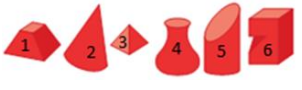

In the framework, richness refers to the number of different examples for a concept that are generated correctly by the participants. In the present study, we focus on cylinder and prism which are geometrical concepts and their examples have figural aspects. Thus, for analyzing richness of the examples, we considered Fujita and Jones's (2007) perspective on prototype examples since prototype images of geometrical objects and definitions of these geometrical concepts are related. Prototype example(s) of a concept are the examples that come first in persons' mind, and they also exist in the participants' concept images. To understand a geometrical object, the associated figure of this certain object would be active in mind. Thus, when a participant has only prototype examples of an object, she can give specific examples of an object with limited images (Fujita & Jones, 2007). On the other hand, when one has non-prototype examples of an object, she can generate different examples for an object. Therefore, in this research we accepted non-prototype examples as indicator of richness for the given definition. Considering the context of Turkish middle school mathematics curriculum (MoNE, 2013), hexagonal prism and rectangular prism are considered as prototypes of prism and circular cylinder is considered as prototype of cylinder. On the other hand, cylinder with non-circular base could be a non-prototype example. However, non-prototype examples are not given a place for exemplifying or defining the solids in Turkish curricula.

## Method

In this study multiple case study approach (Yin, 2003) was used in which data were collected from three volunteer PMTs enrolled in a teacher education program in a public university in Ankara, Turkey. The rationales for selecting these PMTs are as follows: They took the methods of teaching mathematics-2 course, and they were already completed all the geometry courses offered in the program. Thus, they were supposed to give rich data about the definition of geometric shapes.

The data were collected by using a questionnaire and an interview protocol. Therefore, examples of the objects could be analyzed both in oral and written settings. The questionnaire involved items that asked participants to define cylinder and prism in their own words and to show the relationship between cylinder and prism, if any. After the implementation of questionnaire, semi-structured interviews were conducted with the participants using think-aloud method in order to get more information regarding the richness, correctness and generality of the participants' definitions. The semi-structured interview protocol involves questions on definitions of solids and classification of groups of solids as given in Table 1. More specifically, during the interviews participants were given back their questionnaires and they were asked to elaborate on their answers (E.g. Here is your definition for the cylinder. Do you want to change any wordings of your definition? Or will you keep the definition same?). Then, they were asked to name the classification of objects given in Table 1

and to express their reasoning behind this classification. In the Table 1, solids taken from Van de Walle, Karen, and Bay-Williams (2013) are numbered in each group. Group A and Group B involve cylinders with both prototype and non-prototype examples. Further, Group C and Group D involve prisms with prototype and non-prototype examples. Lastly, Group E involves general 3-D objects which are neither cylinders nor prisms.

Cylinders	Prisms	Not cylinders
Group A 	Group C 	Group E 
Group B 	Group D 	

**Table 1: Groups of solids used in the interview protocol (Van de Walle et al., 2013, p. 413)**

The data obtained from questionnaire and interviews were analyzed using Leikin and Zazkis's (2010) framework and Fujita and Jones's (2007) definition of non-prototype examples. More specifically, to analyze generated definitions regarding the cylinder and prism, correctness, richness and generality dimensions of the Leikin and Zazkis's framework were used. While coding the data in terms of correctness criterion, we focus on whether participants' definitions of cylinder and prism satisfy the necessary and sufficient conditions and involve proper terminology. In the analysis of the generality of the definitions, if a participant's exemplification of definition corresponded only to cylinder/prism (e.g. circular cylinder, rectangular prism), it was named as specific. If the definition corresponded to any 3-D solid without critical attributes of cylinder/prism, it was named as general. In addition, in order to evaluate the richness of examples, Fujita and Jones's (2007) definition of non-prototype examples was used. In other words, richness of the examples are determined according to the non-prototype examples expressed/drawn by participants. Researchers analyzed the data until reaching a consensus on the categories of the definitions. Considering that definitions are conventional and contextual, the analysis of the present study was made based on Beman and Smith's (1900) definitions of cylinder and prism.

## Findings

Analysis of PMTs' definitions and their classifications for the cylinder and prism are presented in Table 2. Participants' definitions of cylinder and prism were analyzed according to the correctness, richness and generality criteria. The analysis of PMTs' knowledge of definitions revealed that their definitions were categorized as inappropriate, which satisfy necessary but not sufficient conditions or neither necessary nor sufficient conditions. The dimension of richness included both prototype and non-prototype examples. Analysis regarding generality showed that participants' definitions included specific, partially specific, and general statements. Lastly, the classification of solids are given in Table 2. The symbols '+' and '-' showed that a PMT identified the classification of a group as cylinders, prisms or not cylinders correctly and incorrectly, respectively.

	Correctness		Richness		Generality		Classification		
	Cyl	Pr	Cyl	Pr	Cyl	Pr	Cyl	Pr	None
<b>P1</b>	Inapp. Not N not S cond.	Inapp. Not N not S cond.	Non-pro	Proto.	General	Specific	+	+	Non- cyl
<b>P2</b>	Inapp. With N but not S cond.	Inapp. With N but not S cond.	Non-pro.	Proto.	General	Partially Specific	-	+	Non- pr
<b>P3</b>	Inapp. Not N not S cond.	Inapp. Not N not S cond.	Non-pro.	Proto.	General	Partially Specific	-	+	Non- pr

Note: Cyl: Cylinder, Pr: Prism. P1: Participant 1, P2: Participant 2, P3: Participant 3, N: Necessary, S: Sufficient. Symbol +: participant correctly identified solids. Symbol -: participant do not correctly identified solids

**Table 2: Correctness, richness, and generality in participants' definitions and their classification**

Data analysis showed that P1 defined cylinder as “a 3D shape formed by union of two parallel surfaces with another surface that cover these two surfaces' surroundings” and then she expressed that “the surfaces do not have to be a polygon and one under the other”. In her statements, the definition would be correct if “parallel surfaces” are taken to mean “parallel transverse sections enclosed by closed curves” and “another surface” is taken to mean “surface composed of parallel line segments”. In addition, her use of “surfaces” terminology is not appropriate and lead misinterpretation. This is why her definition was categorized under the example of inappropriate definition with neither necessary nor sufficient conditions. In addition, P1's definition not only include improper terminology but also satisfies general conditions that belong to general 3D objects whose surface is not restricted with a cylindrical surface (e.g. vase). However, analysis of data showed that her drawing of cylinder included a non-prototype example, a cylinder with non-circular closed curve bases. While classifying the group of objects in Table 1, P1 correctly identified the examples of cylinders (group A and group B) which contain both prototype and non-prototype examples. While identifying them, she referred to the attributes that she mentioned while defining cylinder. In addition, she correctly identified Group E as examples of non-cylinders referencing inappropriate examples. For instance, by showing the object #6 she stated that “there is a space here [she showed the surface of the object #6] thus this group cannot be categorized as cylinder”. However, she did not address this critical attribute in her definition of cylinder.

As for the prism, P1 defined it as “a 3D figure formed by combination of two polygon surfaces in two different planes with a surface that covers surroundings of that polygons”. In her definition she did not mention critical attributes like bases and faces. This definition was also considered under the category of neither necessary nor sufficient conditions. While classifying, she correctly identified the groups of prisms through referring visual characteristics and making inclusion as “they are prisms, a special case of cylinders since their bases are polygons”.

P2 defined cylinder as “it is a 3D figure whose top and bottom bases are parallel and congruent closed curves” and then she expressed that “cylinder is formed by combining two identical, parallel and closed curves from corresponding points”. In her statements, although she mentioned about some necessary conditions for the cylinder, they were not sufficient. For instance, she did not mention any information about cylindrical surface. Thus, those characteristics which are general and not specific to the cylinder can be valid for other 3D objects. In addition, the curve that bounds the base should

be planar. Therefore, definition was categorized under the examples of inappropriate definition with necessary but not sufficient conditions. Similar to P1, her drawing of cylinder consisted of non-prototype example which is a cylinder with non-circular bases. However, while classifying, she incorrectly identified the groups of cylinders. She identified objects (2, 3, 4, and 5) in group A as prisms based on their attributes. She also incorrectly identified #1 as pyramid. She stated that “Bases are congruent polygons and parallel. If I take the bases of #5 as polygon, I can say that it is also a prism”. This incorrect identification was also related to her conception of “cylinder is [a special case of] prism”. Besides, she identified group E as non-prisms, based on the assertion that they lack the critical attribute of prism as “their bases are not congruent”, but did not refer to the cylinders.

P2 defined prism as “a 3D object that has top and bottom bases which are congruent and parallel and whose surface area is polygon”. In her definition, while she mentioned some necessary characteristics of bases, she missed that the bases are polygons and overgeneralized faces to polygons rather than parallelograms. Therefore, the definition was categorized under the example of inappropriate definition with necessary but not sufficient conditions. While classifying, she referred to the critical attribute “prisms have top and bottom bases that are congruent and parallel polygons” and correctly identified prisms. Although she confused for a moment about whether object #4 in group D is a prism or not, she identified it as a prism by referring the concavity as “I can consider both concave and convex polygons. Can I think them as polygonal region? Ok, then, I considered polygon bases as both convex and concave and decide that they are prisms”.

P3 defined cylinder as “It has non-polygon bases. It consists of two parallel bases which can be regular or not and combined to each other with infinite parallel lines”. In her statements, she did not mention any information about the congruency of bases. Thus, those properties could be attributed to general properties of 3D solids that are not specific to cylinder. She unconventionally used the term “lines” rather than “line segments”. In addition, she stated that the bases should be non-polygon. Therefore, her statements were examples of inappropriate definition with neither necessary nor sufficient conditions. In addition, she drew a non-prototype example of a cylinder with non-circular bases. While classifying the groups, she incorrectly identified solids in Group A and Group B as prisms. In this process, she considered cylinders as a special case of prisms and identified the objects according to their attributes. In other words, for Group A objects, she stated that “these bases are parallel and congruent. There are parallel lines between them. Thus, these shapes can be classified as prism” and for Group B objects she stated that “these (#1 and #3) are regular cylinders. Can we say whether #2 is non-regular cylinder? But we could not name them as cylinder unless bases are circles. But, we can admitted them as prisms”. In addition, she classified objects in group B as both prism and cylinder since cylinder was included in prisms in her images. Moreover, she identified objects in group E as “non-classified solids and non-prisms”. While explaining her answer, she referred to the critical attribute of prism that “bases should be congruent” and classified them as non-prisms.

P3 defined prism as “a shape formed by infinite parallel lines that pass through two parallel and congruent polygonal bases”. Similar with P3’s cylinder definition “lines” is not appropriate terminology and the definition is insufficient since critical characteristics of bases and faces are not stressed. Therefore, this example was considered under the category of inappropriate definition with neither necessary nor sufficient conditions. In addition, as an example of prism she drew a prototype

example that is a right hexagonal prism. While classifying, she identified prisms correctly by just referring to visual form as “they are all prisms” and not mentioning any critical attributes.

## Discussion and conclusion

In this study, we first examined PMTs’ knowledge of definitions of cylinder and prism through questionnaire and interview data. Then, we analyzed their classification of cylinders and prisms while identifying the 3D objects and how their identification of classes of objects was influenced by their informal definitions. The definition analysis showed that PMTs have difficulty in defining cylinder (Ertekin, Yazıcı, & Delice, 2014; Tsamir et al., 2015) and prism (Gökbulut & Ubuz, 2013) where they mostly used inappropriate terminology that refers to more general attributes of solids rather than attributes specific to cylinder and prism. More specifically, we deduced that PMTs have inadequacy in defining the (sur)faces of the cylinder and prism. This might be the result of their construction of concept definition that depends on the bases rather than cylindrical or prismatic surfaces.

The other finding was that even a PMT did not make a correct definition of cylinder, she identified group of cylinders and non-cylinders correctly. In other words, while PMT did not express some critical attributes that are specific for cylinders in her definition, she correctly identified the group of non-cylinders based on her correct inclusion of cylinder and prism. However, two participants identified cylinder as inclusion of prisms and thus classified non-cylinders (group E) as non-prisms. In other words, participants’ misconception of “cylinder is a special case of prism” arose from the prototype image of circular cylinder let them classify the solids incorrectly. Thus, PMTs’ prototype images of cylinders might be an obstacle that influence their inclusion relations of cylinder and prism. On the other hand, PMTs could identify the group of prisms correctly by referring to the critical attribute of polygon bases in their definitions and making visual judgements. Thus, PMTs easily identified prisms compared to the cylinder. However, we could deduce that PMTs’ preferences toward pedagogical considerations over a rigor definition inhibit their formal definitions and correct classifications of solid figures.

Based on the findings, some implications could be suggested to the teacher educators. The content of courses like methods of mathematics teaching and school practice offered in teacher education programs should be enriched with activities that demand identifying, explaining, defining, and classifying mathematical concepts from both pedagogical and mathematical perspective. By this way, PMTs could have the opportunity to analyze the critical attributes and non-prototype examples of the given concepts and establish the relationships among the concepts through examining general and specific characteristics. In addition, as mentioned above definitions are conventional. Thus, depending on the theoretical perspective 3D solids could be defined differently in different nations. Thus, further research studies could be conducted to compare and contrast definitions and their instructional practices in different nations.

*In this study, we examined whether the Malawian Initial Primary Teacher Education Programme develops teachers' mathematical knowledge for teaching [MKT]. We administered measures adapted from the Learning Mathematics for Teaching project to more than 1,700 pre-service teachers from eight colleges to measure their knowledge for teaching. Paired samples t-test using 725 pre-service teachers whose pre-test ( $M = .049$ ,  $SD = .960$ ) and post-test ( $M = .084$ ,  $SD = 1.043$ ) scores we have paired, showed no significant gains in knowledge overall ( $t(724) = -.808$ ,  $p = .419$ ), and in seven colleges individually. However, mathematical knowledge for teaching for pre-service teachers from college C2 had increased significantly ( $t(165) = -2.062$ ,  $p = .041$ ). While the results showed a significant correlation between pre-test and post-test ( $r = 0.544$ ,  $p < 0.001$ ), we fail to conclude based on the results that the initial teacher education improves mathematical knowledge for teaching.*

*Keywords: Primary teacher education, mathematical knowledge for teaching, number concepts.*

## Introduction

Primary school education sector in Malawi experienced a critical shortage of teachers due to increased enrolments following the introduction of free primary education in 1994 (Ministry of Education Science and Technology [MoEST], 2011). The increased enrolments in primary schools resulted into an exceptional demand for teachers. The government of Malawi responded by recruiting unqualified teachers and recalling retired qualified teachers as a temporary measure. In order to expedite training of the unqualified teachers, the MoEST developed a new teacher education programme called the Malawi Integrated In-service Teacher Education Programme [MIITEP] which begun in 1996/7 and remained until 2005/6 when it got replaced by the current Initial Primary Teacher Education [IPTE] programme. Unlike MIITEP, IPTE is a two year pre-service certificate teacher education programme designed to respond to reforms in primary school curriculum (MIE, 2008). During the first year, pre-service teachers are full time learning in teacher colleges with minimal supervised peer and micro-teaching. In the second year, the pre-service teachers are attached to primary schools for teaching practice with assistance of experienced mentors. To enrol into the programme, prospective students must possess a Malawi School Certificate of Education (MSCE) with a credit pass in English and a pass in Mathematics and one other science subject.

Despite the reforms that have occurred in teacher education since 1997 and curriculum shift to align it with the primary curriculum, pupils' performance and achievement in primary mathematics remain poor. For instance, Malawian pupils have fared poorly on surveys by the Southern and Eastern African Consortium for Monitoring Educational Quality (SACMEQ). In SACMEQ II, Malawi was ranked 13th in mathematics out of 14 Southern African countries (SACMEQ, 2010). The trend in pupils' achievements did not change when SACMEQ III was implemented, with Malawian pupils

being ranked 14<sup>th</sup> out of 15 participating African countries (SACMEQ, 2010). Efforts to explain the underperformance of Malawian pupils in regional surveys have ruled out use of English and increased enrolments as factors responsible for the trend because these factors were not unique to Malawi (World Bank, 2010). Following analysis of the SACMEQ results, the MoEST observed that most teachers did not have sufficient training and/or experience (MoEST, 2011). The analysis therefore recommended strengthening of pre-service and in-service teacher education.

In order to strengthen the current teacher education programme, we need to understand how it operates and identify weaknesses. Therefore, the current study as part of a larger study contributes to efforts to improve the IPTE programme by assessing the extent to which it develops pre-service teachers' mathematical knowledge for teaching. We therefore attempted to address the following null hypothesis: There is no significant change in pre-service teachers' mathematical knowledge for teaching after undergoing initial primary teacher education in Malawi.

## **Related literature**

Issues surrounding teacher preparation are of growing concern in Malawi. In its evaluation report of the IPTE programme, MIE (2008) highlights the importance of basic mathematics and numeracy for teaching of primary mathematics. Through this evaluation and further analyses, MIE identified the following issues relating to IPTE and mathematics teacher education: (1) lack of motivation among trainees to learn mathematics and to become mathematics teachers, (2) mistakes and wrong information in the teaching and learning materials, (3) mismatch between syllabus and content in handbooks, (4) conflict between curriculum and assessment reforms, and foundation studies, and (5) missing illustrations for number operations in student handbooks. The MIE report concludes that these "...will eventually make the student teachers fail to understand what they are supposed to do and even fail to do the activities they are being asked to perform" (p. 54). We consequently observe that, if the goals of the reforms in teacher education are to be met, we must approach the assessment of the current (mathematics) teacher education in a multifaceted and holistic manner. This study is therefore part of that holistic approach.

Although several factors affect a teacher's effectiveness, Hill, Rowan and Ball (2005) argue that teacher's knowledge is one of the biggest influences on teaching and students' attainment. As a matter of fact, they have put forward evidence that show that teachers with sufficient knowledge produce significantly positive changes in their students' learning and attainment after controlling other variables that are believed to influence student achievement. Furthermore, Ball, Thames and Phelps (2008) state that there is nothing more foundational to teacher competency than knowledge of their subject matter. Their assertion concurs with Ma (1999) who contends that a deep understanding of fundamental mathematics affords a crucial base for effective and successful mathematics teaching. We agree with Ball et al. (2008) that the quality of mathematics teaching depends, largely, on teachers' mathematical knowledge. Research in teacher education has considerably changed the way in which mathematical knowledge for teaching development is understood. Traditionally, it can be thought that knowledge for teaching develops during and after formal teacher education. However, Grossman (1990) and Hill, Rowan and Ball (2005) suggest that knowledge for teaching develops from pre-teacher education experiences, teacher education experiences and teaching experiences. Hence our interest in pre-service teachers' mathematical knowledge for teaching before and after their initial teacher education.

Vigorous enthusiasm in knowledge for teaching research followed Shulman's (1986) work to identify, classify and define elements of knowledge for teaching. In mathematics education, the Learning Mathematics for Teaching [LMT] Project at the University of Michigan has made substantial contribution towards identifying and defining the type of knowledge necessary for teaching mathematics. This knowledge is today referred to as MKT (e.g. Ball, 2003; Ball et al., 2005; Ball et al., 2008; Hill et al., 2005). The LMT Project has shown that general mathematics ability does not entirely adjudge the knowledge and skills for effective teaching of mathematics. Ball and colleagues have also defined a special type of knowledge needed by mathematics teachers that is specific, distinct from pedagogy and knowledge of students, and not needed in other professional settings (Ball, et al., 2008; Hill et al., 2005). This is because the tasks of teaching mathematics require knowledge beyond ability to confidently perform algorithms (Ball, 2003; Ball et al., 2005). They argue that teaching mathematics demands of teachers to be able to, apart from thinking pedagogically, fragment mathematical reasoning which is not needed by other professions that use mathematics (Ball et al., 2008). This mathematical knowledge and skill unique to teaching is, in their view, specialized content knowledge (SCK). Conversely, common content knowledge (CCK) is the knowledge which enables an individual to succeed mathematically in terms of "being able to do particular calculations, knowing the definition of a concept, or making a simple representation" (Thames & Ball, 2010, p. 223) and is the knowledge also needed in other professions.

It is our considered view therefore that for the IPTE programme to prepare pre-service teachers for quality mathematic teaching, the programme must offer the teachers opportunities to develop their mathematical knowledge for teaching, among other things, because "improving the mathematics learning of every child depends on making central the learning opportunities of our teachers," (Ball, 2003, p. 9). The programme must embrace deliberate implementation approaches that develop SCK, in addition to CCK, of pre-service teachers within the teacher education cycle.

## **Design and methodology**

The study examined whether pre-service teachers' knowledge for teaching number concepts and operations improved after completing two terms (about 6 months) of their initial teacher education in a pre-test–post-test design. Mathematical knowledge for teaching was examined using measures that were adapted from the LMT measures. The measures were piloted using a different group of pre-service teachers a year prior to the current study (Kasoka, Kazima, & Jakobsen, 2016).

## **Sample**

Pre-service primary teachers were sampled from all the eight public teacher education colleges in Malawi. Only one of the colleges is a single-sex institution. The recruitment and posting of the student teachers to the colleges is centrally done by the MoEST. For the purpose of this study, we identify the colleges as C1 to C8. The pre-service teachers enrolled into the IPTE programme in September 2015 and had covered number concepts and operations in term one that runs from September to December of an academic year. The pre-service teachers had learnt how to teach number concepts and operations by the end of term one. Table 1 shows the composition of the sample.

Age/Gender	Teacher college								Total
	C1	C2	C3	C4	C5	C6	C7	C8	
<21 years	49	65	36	26	28	42	18	20	284
21 – 25	75	81	53	16	34	52	20	16	347
26 – 30	13	12	15	3	6	11	2	3	65
>30 years	9	8	0	0	3	3	4	2	29
Female	84	94	22	45	25	57	17	19	363
Male	62	72	82	0	46	51	27	22	362

**Table 1: Pre-service teachers numbers by college**

### The instrument

For this study, we used adapted MKT measures for number concepts and operations from the LMT measures (see Kasoka et al., 2016). We used the previously validated measures to design an instrument comprising of two forms, namely Form A and Form B. The forms that we designed were intended to specifically measure the pre-service teachers' CCK and SCK of number concepts and operations. The final version of the instrument we administered had 67 items distributed between Form A and Form B. Form A had 38 items while Form B had 35 items. The two forms had six anchoring items.

### Data collection and scoring

The first set of data was collected from the pre-service teachers in the third week (September 28 – October 2, 2015) of term one. The forms were re-administered during the second week (May 16 – 20, 2016) of the third term. Although number concepts and operations are covered in the first two terms, we deliberately collected post-test data at the beginning of term three so as to avoid the pre-test directly affected the post-test. We also noted that there are instances where first term material spills to term two due to some unforeseen circumstances in the colleges. To minimize the test-retest effect further, we swap the forms among the colleges such that the pre-service teachers that took Form A on pre-test, took Form B on post-test and vice versa.

The administration of the forms took place on different days of the same weeks as it was not possible for us to cover all the eight colleges on a single day. Each of the two forms was administered in four colleges. Permission to administer the forms was sort from college management prior to travelling to each college. The pre-service teachers completed the forms during class times without any personal incentives. However, they were briefed about the study and its objectives hence they participated willingly. The participants were allowed to work on the forms for a maximum period of 90 minutes. We had more than 1,700 preservice teachers at each administration. However due to other logistical hiccups, we have only been able to pair pre and post-test scores for 725 pre-service teachers. Hence the sample size,  $n = 725$ . It must be noted that some participants who took the pre-test dropped out of college before the post-test and some participants who took the post-test reported to college late. These missed the pre-test. Table 1 shows the number of pre-service teachers whose scores we have paired so far.

The two tests were scored simultaneously using an item response theory (IRT) software, BILOG-MG. IRT was chosen because of its robustness in analysis of item level data to measure inter-individual variation. For Hambleton and Swaminathan (1985), rich item level information extracted through IRT offers many advantages over classical test theory (CTT). Each of the pre-service teachers got a pair of IRT scores placing them along a standardized ability scale with mean of 0 and standard deviation of 1. The IRT scores were then entered into IBM-SPSS for further analysis.

### Statistical analysis

Pre-test scores were used to calculate Cronbach's alphas to test internal reliability of the test. Form A appeared to have a good internal consistence,  $\alpha = 0.733$  (Pallant, 2007). All the 38 items seemed worthy retaining since the greatest increase in alpha was only .002 after deleting either item FA8 or FA13. Form B had a lower reliability,  $\alpha = 0.656$  and none of the item deletion increased the alpha value significant. To examine the change in mathematical knowledge for teaching between pre-test and post-test, a dependent samples *t*-test was used to compare means of the tests for all the colleges, and within each college. We also compared knowledge growth among the pre-service teacher in the eight colleges using one way analysis of variance (ANOVA). To achieve this, a new score we called knowledge growth was obtained for each participating teacher by calculating the differences between post-test and pre-test scores. ANOVA of the new scores was then carried out. Levene's test confirmed the assumption of homogenous variances,  $F(7, 717) = 2.273, p = .049$ .

	Teacher college							
	C1	C2	C3	C4	C5	C6	C7	C8
<i>T</i>	-.085	-2.062	.951	1.586	-.453	-.873	-1.705	1.590
<i>p</i> -value	.932	.041	.343	.120	.652	.385	.950	.120
<i>Df</i>	145	165	219	44	70	107	43	40

**Table 2: Summary of *t*-test results**

### Results and discussion

A dependent samples *t*-test was carried out to test the hypothesis that the pre-IPTE mean ( $M = .048, SD = .833$ ) and post-IPTE mean ( $M = .960, SD = 1.044$ ) of mathematical knowledge for teaching are the same. Before conducting the test, the assumption of normality for the distribution was ascertain using Q-Q plots. We also observed that there was a significant correlation between pre and post-test scores ( $r = .544, p < .001$ ). This suggests that a pre-service teacher with a high mathematical knowledge for teaching at pre-IPTE was more likely to have a high mathematical knowledge for teaching at post-IPTE. The two assumptions support our use of dependent samples *t*-test. Dependent samples *t*-test returned  $t(724) = -.808, p = .419$  showing that the test was not significant. We therefore failed to reject the null hypothesis and concluded that the teachers' knowledge means before and after teacher education were not significantly different. We also carried dependent samples *t*-tests to test the null hypothesis using knowledge scores for each college. The results are summarized in Table 2.

Teachers' understanding of number concepts and operations is critical to quality teaching of primary mathematics (Hill et al., 2005; Ma, 1999). The poor achievement in primary mathematics and misconceptions are attributed to misunderstanding surrounding number concepts and operations, including counting, ordering, order of operations, associativity, commutativity, and fractions (e.g. Brombacher, 2011). It is critical that pre-service teachers understand and competently use basic number concepts and operations properties for them to effectively teach mathematics (MIE, 2008). The items used in this study were purposively selected to address specific aspects of number concepts and operations that can be considered prerequisite for the learning of school mathematics beyond literacy level. The items examined pre-service teachers' knowledge of whole number operations, subtraction of integers, representation and operations of fractions, decimal representations, prime numbers, and the order of operations. The results of data analysis show that pre-service teachers' knowledge for teaching these essential aspects of mathematics did not improve as a consequence of the participants undergoing teacher education. Similar results are observed from analysis of data from seven individual colleges. These results are surprising and not encouraging since the IPTE programme was developed on the premise of setting the foundations for formal schooling. However, at college level, we observe that mathematical knowledge for teaching number concepts and operations significantly improved among pre-service teachers from college C2.

We noted that the IPTE programme has some effect on pre-service teachers' mathematical knowledge for teaching. However, the effect varied among the colleges. ANOVA test was conducted to understand how the IPTE programme affected mathematical knowledge for teaching growth of pre-service teachers across the colleges. The ANOVA analysis yielded insignificant results ( $F(7) = 1.808$ ,  $p = .085$ ). This result shows that the means of knowledge growth were not statistically different among the eight colleges.

## Implications

The IPTE programme should include aspects related to mathematical knowledge for teaching. These may include use of non-traditional lesson design, improved quality of activities, and classroom engagements of pre-service teachers during their college based education. This study suggests that mathematics teacher educators in teacher education colleges in Malawi ought to understand what mathematical knowledge for teaching is, why it is important, and how they can enhance its development among pre-service teachers. These results encourage teacher educators to network among themselves to learn from each other. The study found that one college had improved MKT. The other colleges can therefore learn from this college.

The significant growth of MKT for college C2 supports the notion that MKT can be developed and enhanced during pre-service teacher education. Mathematics educators in education colleges are encouraged to blend content, pedagogy and practice to develop pre-service teachers CCK and SCK simultaneously. However, the determination of what exactly went on at college C2 to improve MKT is beyond the scope of the current study but a possible direction for future research.

The result also point to pre-service teachers' very poor understanding of basic mathematics and hence their mathematics background. This may have explained the low levels of mathematical knowledge students had on pre-test and the inability for the knowledge to grow in six months. IPTE's minimum

entry requirements for mathematics teachers may need to be revised. Currently, all pre-services primary teachers study mathematics in college and are expected to teach mathematics on completion.

More research is required to identify, understand, and replicate variables affecting growth of mathematical knowledge for teaching in the Malawi context. Although this study is unique in that it implemented MKT measures on multiple colleges and compared knowledge growth, it was limited to MKT growth. There is need to clearly understand how this knowledge is developed and can be enhanced in Malawi. As we continue to make further attempts of pairing pre-test and post-test scores so as to increase our sample and understand how the current results would be affected, the study has been able show that growth in MKT is possible within the settings of the IPTE.

## Conclusion

As more and more research reports highlight poor achievement in primary mathematics in Malawi (Brombacher, 2011; SACMEQ, 2010; World Bank, 2010), it is necessary to assess how teachers are prepared under the IPTE programme to teach mathematics. Research suggests that for student teachers to succeed in their profession, they must have sufficient mathematical knowledge for teaching mathematics. Research has also illustrated that student learning and achievement can be affected by teachers' knowledge for teaching and that this knowledge can be assessed (Hill et al., 2005). According to the framework suggested by the LMT Project, mathematical knowledge for teaching consists of mathematical content knowledge specific to the needs of task of teaching (SCK) over and above what is considered common for other professionals (CCK) (Ball et al., 2008; Thames & Ball, 2010). Therefore, our teacher education programme can meaningfully prepare teachers by ensuring that the pre-service teachers are provided with opportunities to develop both CCK and SCK. We can therefore argue that by assessing student teachers' knowledge for teaching mathematics, we can identify possible gaps that need to be addressed as a contribution towards the provision of quality mathematics teacher education in Malawi.

The current study found that pre-service primary school teachers' MKT did not improve after undergoing IPTE programme. We expected that students' MKT to positively change post-IPTE. However, mathematical knowledge for teaching for students from one college, C2, improved significantly relatively to its pre-test average but not to other colleges.

While the study findings are discouraging, they suggest the need for a review of the IPTE curriculum and its implementation so that it improves pre-service teachers' Mathematical knowledge for teaching

## Acknowledgment

# A preservice secondary school teacher's pedagogical content knowledge for teaching algebra

Florence Mamba<sup>1</sup>, Reidar Mosvold<sup>1</sup>, and Raymond Bjuland<sup>1</sup>

<sup>1</sup>University of Stavanger, Norway; [flothomo@gmail.com](mailto:flothomo@gmail.com)

*This study investigated a preservice secondary school teacher's pedagogical content knowledge (PCK) for teaching algebra. Data were generated using video-recorded interviews and analysed using thematic analysis. Findings indicate that content knowledge was influential in the preservice teacher's PCK. Secondly, the preservice teacher, who was one of the best students in his class, displayed some knowledge of analysing students' errors and anticipating their possible misconceptions. He appeared to be familiar with some methods of handling students' errors and misconceptions. However, it appears that he was not prepared to apply such methods in his teaching of algebra.*

*Keywords: Pedagogical content knowledge, preservice teacher, secondary school, algebra.*

## Introduction

A body of research indicates that teacher knowledge influences the quality of their teaching and student learning (Hoover, Mosvold, Ball, & Lai, 2016). Although there appears to be general consensus that mathematics teachers need to know the content in ways that surpass the knowledge of educated people outside the teaching profession (Ball, Thames & Phelps, 2008), more research is needed in order to investigate the types of knowledge needed for teaching particular mathematical topics at particular levels (Hoover et al., 2016). From her review of literature on teaching and learning of algebra, Kieran (2007) suggests that researchers have barely begun to investigate the knowledge needed for teaching algebra. Some studies have contributed to this area of research. For instance, Bair and Rich (2011) investigated the development of specialised content knowledge for teaching algebra among primary teachers. In the present study, we contribute to the field by investigating pedagogical content knowledge (PCK) for teaching algebra in secondary school.

Our study was carried out in Malawi – a country in southern Africa that experiences severe challenges in the education system. Secondary school students' performance in national examinations continues to be poor with only around 50 percent of students passing end-of-cycle examinations (Ministry of Education Science and technology, 2008), and students' performance in algebra is poor (Malawi National Examinations Board, 2008-2013). While explanations have been proposed concerning system failure, (Ministry of Education Science and Technology, 2008), we suggest that further investigations of teacher knowledge as a potentially relevant factor of influence is necessary. As such, the aim of this study was to investigate a Malawian preservice secondary school teacher's PCK for teaching algebra. Possible implications are discussed.

## Theoretical framework

Two constructs guide the theoretical framework for this study: mathematical knowledge for teaching (Ball et al., 2008) and algebraic thinking (Kriegler, 2007). Ball et al. (2008) distinguish between three sub-categories of subject-matter knowledge and thus extend Shulman's (1986) original category. *Common content knowledge* refers to a kind of mathematical knowledge and skill

that is used in settings other than teaching (Ball et al., 2008). *Specialised content knowledge*, on the other hand, refers to mathematical knowledge and skill that is unique to teaching. In addition, they present *horizon content knowledge* as a third category of subject-matter knowledge. For sake of simplicity, we focus broadly on content knowledge in this study. Ball et al. (2008) also distinguish between three sub-categories of PCK. *Knowledge of content and students* (KCS) is knowledge that combines knowing about students and knowing about mathematics. *Knowledge of content and teaching* (KCT) combines knowledge about teaching and knowledge about mathematics. Finally, Ball et al. (2008) present *knowledge of content and curriculum* as a third sub-category of PCK. In the present study, we focus on content knowledge and two sub-categories of PCK: KCS and KCT.

The second construct of the theoretical framework draws upon Kriegler's (2007) work on mathematical thinking tools of the algebraic thinking framework. Kriegler asserts that mathematical thinking tools are analytical habits of mind. They are organised around three topics: problem solving skills, representation skills, and quantitative reasoning skills. Teachers should be able to solve algebra problems using multiple approaches and problem solving strategies. They should be able to translate among representations and solve problems inductively and deductively.

## Method

The study reported here is part of a larger qualitative study that investigates four preservice secondary school teachers' mathematical knowledge for teaching (see Mamba, 2016a; Mamba, 2016b). In previous publications, the first author reported on results from a task based interview that she conducted with one preservice secondary school mathematics teacher and video lesson observation for one lesson. In the current paper, we explore PCK for teaching algebra, considering the case of Dinga (pseudonym). Dinga was a diploma in education student in a three-year programme at a college of education in Malawi. When data for this study were generated, he was in the final year of study. Being a high-achieving student in mathematics in his class, he was considered an "information-rich" case for in-depth study (Yin, 2014). Video-recorded semi-structured interview was used to generate the data, allowing for multiple, in-depth rounds of analysis of the data (Girden & Kabacoff, 2011). Interview tasks reported here were adapted from a Malawi secondary school mathematics textbook (Gunsaru & Macrae, 2001) and were piloted before the main study.

The first author conducted the interview and transcribed the video recordings. These transcripts were analysed using a combination of inductive and deductive thematic analysis (Yin, 2014). Analysis of the interview transcripts involved identification of the PCK that Dinga displayed as he answered the interview questions. The themes that guided analysis were developed *a priori* from the theoretical framework. Themes for content knowledge were problem solving skills, representation skills, quantitative reasoning skills and justifying. Themes for KCS included predicting students' errors and misconceptions, understanding reasons for errors and misconceptions, and asking questions to reveal or understand students' reasoning and misconceptions. KCT was coded into methods of handling students' misconceptions and knowledge of instructional tasks to be used to enhance conceptual understanding and choosing instructional strategies. Some themes that were not in the theoretical framework were developed *a posteriori* from the data. The themes were further grouped into three categories: CK, KCS and KCT. To achieve credibility of the results, another researcher analysed the data. In all cases we got at least

90% agreement, with no discussion between the researchers. Furthermore, the findings were read and critiqued by other researchers.

## Results and discussion

In the following, we present illustrative examples of results from the analysis of data from the video-recorded interview.

### Content knowledge

During the interview, Dinga was asked to solve the following equation:  $x^2 = 2x + 8$ . He solved the equation using two approaches: factorisation method and the quadratic formula. When asked about other methods apart from the two he used, Dinga explained that he had forgotten the other method. His explanation showed that he had knowledge of completing the square, but he had forgotten how to use this method for solving quadratic equations. Dinga's solution processes revealed that he had procedural knowledge, since he did not display knowledge of the conceptual foundations of quadratic equations. For instance, when he solved the equation  $x^2 = 2x + 8$  by factor method and quadratic formula, his difficulties of explaining the procedures indicated that he knew the “what” of the procedure but not the “why”. For mathematics teachers, knowing both the “what” and the “why” of a procedure is important (Shulman, 1986). Dinga's knowledge of content therefore seemed limited in depth and breadth. Inability to solve the equation, using the other approaches, like completing the square and graphing, also indicated limitations in problem solving skills and representation skills. When solving the equation using the two methods he remembered, however, Dinga used rules of logic to come up with next steps in the procedures he used – thus indicating skills in deductive and quantitative reasoning.

When answering questions in Task 2 (Figure 1), he did not attempt to interpret the graph first, although the interviewer asked him to do so. This also indicates limitations in content knowledge and algebraic thinking skills.

### Knowledge of content and students

Dinga displayed knowledge of predicting methods that students may find easy or difficult, predicting students' errors and misconceptions, understanding reasons for misconceptions, and asking questions to reveal or understand students' reasoning and misconceptions. For instance, the interviewer asked Dinga to assume that he gave this equation  $x^2 = 2x + 8$  to his algebra students to solve. When asked to explain what methods he thought his students would use, Dinga explained that his students would use factorisation because, to him, factorisation method is easy and the other methods are difficult. Our interpretation of Dinga's response is that he based his prediction of what students would find difficult on his own experienced difficulties.

The second task in the interview involved interpretation of a conversion graph between °C and °F (see figure 1 below).

**Task 2:** Suppose you give your students the following problem:  
Below is a graph of an equation  $T_f = \frac{9}{5}(T_c) + 32$  where  $T_c$  = temperature in degrees Celsius and  $T_f$  = Temperature in degrees Fahrenheit. Use the graph to convert the following temperatures:  
(a) 10°C, 40°C and 77°C respectively; (b) 50°F, 100°F and 170°F respectively.

- i. What error(s) may students exhibit as they answer this question?
- ii. What underlying mathematical misconception(s) or misunderstanding(s) might lead the student to the error presented in this item? How might the student have developed the misconception(s)?
- iii. What further question(s) might you ask to understand the student's misconception(s)?
- iv. What instructional strategies and/or tasks would you use during the next mathematics lesson to address the student's misconception(s)? Why?

**Figure 1: Conversion task**

During the discussion extracted in the below excerpt from the transcripts, Dinga was first asked to read, solve and understand task 2. Then, the interviewer asked him to explain the errors and misconceptions that students might display as they attempt to answer this question.

- Dinga: (...) They may misread the scale, or they may not understand the scale and they may come up with different values.
- FM: Ummmm! Hummm!
- Dinga: Some students don't know what horizontal axis is and what vertical axis is. So in this kind of problem, they can easily do the reverse.
- FM: What misconceptions might lead to the errors you presented in this item?
- Dinga: Sometimes, they put forward the belief that mathematics is difficult. So they may think that they may not manage.
- FM: What else apart from the belief that mathematics is difficult?
- Dinga: Teachers also contribute. If a teacher does not understand a topic, he/she does not teach it. He/she teaches a topic that is easy.

By explaining that students will misread scale and come up with different values from the expected values due to misunderstanding of scale, and that students may misallocate a point on the coordinate system, Dinga displayed ability to predict errors students may exhibit as they interpret that graph. However, when Dinga said, "if students do not understand scale, they would find some difficulties about how to come up with a conversion graph", he changed the purpose of the task from interpreting the graph to drawing the graph. Secondly, although Dinga suggested that graph interpretation is easier for Malawian students than drawing the graph, he did not interpret the graph himself, hence what he said contradicted with what he did during the interview. By explaining that graph interpretation is easier than drawing graphs, Dinga displayed limited knowledge of levels of

graph interpretation. According to Cursio (1987), graph interpretation is a cognitive task involving three levels of understanding, namely reading the data, reading between the data and reading beyond the data. Dinga's understanding of these levels may influence students' development of graph interpretation abilities. Thus, Dinga displayed limited ability to predict students' difficulties about interpreting a linear graph – possibly because he struggled to interpret the graph himself. Failure to interpret the graph was also an indication of limitation in representation skills. He was unable to interpret information within a representation. We noted that while algebra students often create graphs from equations, they rarely practice creating equations from graphs and interpreting the graphs – hence Dinga's difficulty.

When asked to explain the misconceptions that may lead to the errors mentioned, Dinga pointed out beliefs and teachers. By explaining that teachers also contribute to errors and misconceptions, Dinga proposes that some misconceptions originate from experiences in school – students' interaction with teachers being one of the experiences. However, his responses indicate that he did not know which causes the other. He identified the errors but was not in a position to understand the misconceptions that could be possible causes of such errors. Instead, Dinga explained the causes of misconceptions. This confusion might have resulted from lack of understanding of errors, misconceptions and their causes. Understanding of each is important for the teacher, because, as with the weeds, the roots must be tackled if the weeds are to disappear. Similarly, teachers must deal with the causes of errors and misconceptions to help students overcome them.

To understand or reveal students' reasoning and misconceptions, Dinga explained that he would ask the students about the meaning and interpretation of scale, and he would identify the misconceptions from their responses. He also explained that he would ask the students to tell him what the horizontal and the vertical axes represent, because some students do not know what horizontal and vertical axes represent. By explaining that students confuse between horizontal and vertical axes, Dinga displayed understanding of students' confusion between independent and dependent variables. Asking him to give examples of probing questions that he said he would ask, we expected that he would mention questions like “explain your answer”, “why do you think so?”, “How did you get that?” Dinga did not suggest such questions. We interpret this as an indication of limited knowledge of what questions to ask in order to identify misconceptions.

### **Knowledge of content and teaching**

The KCT that Dinga displayed included predicting strategies for teaching how to solve the quadratic equation  $x^2 = 2x + 8$ , and strategies for handling students' errors and misconceptions. When asked how he would teach solving quadratic equations using the equation  $x^2 = 2x + 8$ , Dinga explained that he would give them steps to follow for them to come up with the roots of the equation. The procedural knowledge he displayed when solving the equation might have influenced this response. Dinga also explained that he would ask volunteers to solve the equation on the chalkboard in any way they want in order to understand the way students understood the problem. In this case, Dinga decided to use a hybrid of teacher centred and student centred teaching methods. Although, this might be an improved version of teacher centred strategies, Dinga revealed knowledge of teaching the “what” but not “why”. Thus, Dinga displayed lack of an important aspect of subject matter knowledge: “knowing why”. Even and Tirosh (1995) argue that “knowing that” is not enough, and they suggest that “knowing why” enables the teacher to make better

pedagogical decisions. It could thus be expected that Dinga lacks the knowledge necessary for teaching equations effectively to his students. In the closing statements of the interview, Dinga explained his limitations with lack of teaching experience.

In order to handle students' errors and misconceptions, teachers need to use appropriate strategies to create moments of cognitive conflict and help students resolve the conflict (Sayce, 2009). Dinga pointed out that he would use discussion and group work. The transcript below illustrates this.

- FM: What instructional strategies would you use to address the misconceptions you have mentioned?
- Dinga: I will use discussion, grouping, ... (silence).
- FM: How could these methods work in addressing these misconceptions?
- Dinga: If I put my students in groups of 5 or 10, those who understood may assist others.
- FM: Um! Humm!
- Dinga: I will also give a summary of the topic so that students can easily correct their mistakes.
- FM: How else can you address the misconceptions?
- Dinga: Maybe giving my students a lot of exercises to do on the topic which they have problems so that the students understand the concept.

The results in the transcript above concur with Sayce (2009) who asserts that, to induce cognitive conflict, teachers should encourage collaborative working, especially in mixed ability groups. However, Dinga did not reflect on any features of group work that may facilitate this. He also did not reflect on the possibility that cognitive conflicts might be introduced by peers, but he seemed to suggest that the less able students could be passive recipients of the other students' explanations. We also argue that since errors and misconceptions are deeply rooted erroneous conceptions, summarising content covered in a lesson or giving students more exercises might neither be the root to cognitive conflict nor the way out of the conflict. The possible cause for Dinga's limitations in methods of handling students' errors and misconceptions might be that he did not solve the mathematical task (task 2) – possibly because he seemed not to know what it takes to interpret graphs (Cursio, 1987). A teacher needs to be able to solve the mathematical task before presenting it for the students in the classroom. Solving the task enables the teacher to anticipate students' solution methods, errors, misconceptions and questions to ask the students.

## Conclusion

In this study, we investigated the PCK for teaching algebra displayed by one preservice secondary school teacher – Dinga. The findings reveal that content knowledge was the overriding determinant of Dinga's KCS and KCT. For instance, Dinga explained that he would teach solving the equation  $x^2 = 2x + 8$  by giving the students a procedure to follow to solve the equation, probably because he lacked the “why” of the procedure and he solved the equation likewise. He also had some difficulties predicting students' errors and misconceptions because he was unable to interpret the graph. These findings support the fact that PCK involves knowledge and skills that are highly interrelated to each other (Even & Tirosh, 1995). Thus, teachers should possess in-depth content

knowledge, have a rich repertoire of teaching strategies to promote students' understanding of a particular topic and to understand and handle students' errors and misconceptions (Kilic, 2011). The findings also support the fact that preservice teachers possess limited PCK (Kilic, 2011). Although Dinga appeared to be familiar with some methods that can be used to handle students' errors and misconceptions, he seemed to lack conceptual approaches to students' errors and misconceptions because of his limitations in content knowledge and the "why" of his ideas.

It is also worth noting that Dinga's responses to the interview questions might be influenced by several factors. Firstly, it might be that Dinga might be able to solve equations but might not be able to explain his ideas. The fact that the interview tasks were adapted from a textbook might also limit Dinga's explanations and responses during the interview if the textbook was not familiar to him. But I gave the preservice teachers the textbooks a week before the commencement of the data collection for them to study in preparation for the tests and interviews. Furthermore, Dinga's responses might be influenced by the secondary school mathematics curriculum he went through as a mathematics student. The mathematics curriculum did not give students opportunities to explain their reasoning during mathematical problem solving. The way mathematical problem solving is handled in preservice teacher education in Malawi might also influence the results from the interview with Dinga. For instance, there is less practical work on mathematical problem solving in teacher education, yet the preservice teachers are expected to teach their students how to use the approach during teaching practice.

The results from this study cannot be generalized to all preservice teachers at Dinga's institution. Further research with a larger sample needs to be carried out to find out whether results from this case study are generalisable at a large scale. In addition, the measurement of Dinga's PCK was somewhat constrained due to the limitation of not having access to classroom students. In his responses, Dinga had to 'work' within a hypothetical situation. While his limitations in PCK were more evident during the task-based interview, it is possible that additional evidence of PCK could be obtained through a variety of problems and video lesson observations. These results, however, help us to learn that developing PCK and problem-solving skills among preservice secondary teachers by "providing teachers with opportunities to learn mathematics that is intertwined with teaching" (Hoover et al., 2016, p. 12) is crucial for mathematics teaching and learning.

# Analysis of mathematics standardized tests:

## Examples of tasks for teachers

Francesca Martignone

Università del Piemonte Orientale, Italy; [francesca.martignone@uniupo.it](mailto:francesca.martignone@uniupo.it)

*This paper discusses examples of tasks for teachers proposed during some laboratory activities developed in two Italian teacher education courses for middle school mathematics teachers. Following a common script, the teachers carried out and shared an a priori analysis of some items selected from the Italian National Standardized Assessment. The tasks fostered the reflection on epistemological, cognitive and educational aspects: the teachers reflected on the mathematical contents involved, the link with the National Guidelines, and the possible students' answers. The specific tasks and the laboratory approach make these activities well suited for showing and improving some aspects of teacher knowledge and skills.*

*Keywords: Teachers' knowledge and skills, teacher education, tasks for teachers, laboratory activities.*

### Introduction

For some years now, the research on Teacher Education has been concerned with tasks for teachers. Drawing from specific research about the knowledge used by teachers in their work (Shulman, 1986; Ball, Thames, & Phelps., 2008) and about the features that make a task well suited for developing that knowledge (Suzuka et al, 2009), this study presents examples of *meta-didactical praxeologies* (Aldon et al., 2013), which show the ability of the teachers to intertwine the different knowledge that can characterize them as mathematics teachers. The paper discusses a laboratory activity carried out during two teacher education programs for middle school teachers, in which we can identify tasks that aim at bringing out teachers' knowledge and skills and at improving their ability to dynamically relate these knowledge. Teachers carried out *a priori* analysis of items on number line, selected from Italian mathematics standardized tests. These items are assessment tasks but they were chosen and analyzed individually as mathematical problems that could be also become part of learning activities. The fact that they were selected from national tests gave also the opportunity to take into account the statistical results on the national sample. Teachers reflected on the mathematical contents, aims, and students' possible solution strategies, errors and misconceptions. In order to do that, they used different mathematical content knowledge. These activities, by means of shared analyses and collective discussions, put into light some professional skills of the teachers: in particular those related to the use of their *Subject Matter Knowledge* and the *Pedagogical Content Knowledge* (Shulman, 1986; Ball et al., 2008) and to the management of the links between these knowledge.

After a brief presentation of the background and the theoretical framework, the paper discusses examples of activities, tasks, and teachers' reflections developed in two teacher education programs, which involved in-service and pre-service middle school teachers.

## Background and theoretical framework

Making the cultural background explicit is fundamental to understand the goals of a teacher education course (Bartolini Bussi & Martignone, 2013). Therefore, it is important to present briefly the background of the activities analyzed in this paper. In fact, the choices made in the design of the activities are due to factors that are also linked to the Italian context: e.g. the choice of analyzing items taken from the Italian National Standardized tests (<http://www.invalsi.it/invalsi/index.php>). The teachers are interested in the discussion about these items, because all their students faced or will face these tests. For each item the teachers could refer to the quantitative results coming from the surveys on the national sample (these results are annually reported and they are public as well as the test items). Another factor that justifies the choice of analyzing these items is that the teacher educator was involved in a research on Italian national standardized mathematics tests (Branchetti et al., 2015; Lemmo, Branchetti, Ferretti, Maffia, & Martignone, in press) and she wanted to discuss the results of this study with the teachers. The teachers and the teacher educator shared specific *meta-didactical praxeologies* (Aldon et al., 2013) about the analysis of standardized test items. The term “meta-didactical” denotes that the praxeologies shared during the courses deal with the actions and the reflections of teachers about the educational activities. The reflective actions can be fostered by a particular *praxis* that includes different kinds of tasks (in this case the task for teachers about the *a priori* analysis) as well as *techniques* available to face them (e.g. the development and sharing of a common script that takes into account institutional aspects, the mathematical contents involved, the link with the National Guidelines, and the possible students’ answers and mistakes). The *meta-didactical praxeologies* change over time because of the dialectical interactions between the researchers and the teachers communities (Martignone, 2015). This work would lay the foundations of the growth of a *community of inquiry* (Jaworski, 2003) in which the teachers and the teacher educator can share and develop their knowledge. There are aspects of teacher knowledge that many researchers agree on as been characteristic of the teacher knowledge, such as the *Pedagogical Content Knowledge*: “the particular form of content knowledge that embodies the aspects of content most germane to its teachability” (Shulman, 1986, p. 9). There is a wide literature that started from the Shulman idea about the knowledge for teaching. In particular, the studies on the *Mathematical Knowledge for Teaching* (MKT - Ball et al., 2008) propose a refinement of Shulman’s classification of *Content Knowledge*. Ball and colleagues try to define a so called *Specialized Content Knowledge*: “the mathematical knowledge and skills unique to teaching” (Ball et al, 2008, p. 400). As the authors write (Ball et al, 2008, p. 403), often it is difficult to discriminate *Specialized Content Knowledge* (SCK) from the *Common Content Knowledge* (CCK) and from the *Pedagogical Content Knowledge* (PCK), but there are examples in which we can see their different aspects.

“[...] for example, consider what is involved in selecting a numerical example to investigate students’ understanding of decimal numbers. The shifts that occur across the four domains, for example, ordering a list of decimals (CCK), generating a list to be ordered that would reveal key mathematical issues (SCK), recognizing which decimals would cause students the most difficulty (KCS<sup>1</sup>), and deciding what to do about their difficulties (KCT<sup>2</sup>), are important yet subtle” (Ball et al., 2008; p.404)

---

<sup>1</sup> Knowledge of Content and Students.

By means of specific tasks and methodology, some aspects of teachers knowledge and skills can emerge during teacher education programs. Therefore, the tasks for teachers are an important part of teacher learning: they can include “the mathematical prompts, many of which may be classroom tasks, that are used as part of teaching learning” (Watson & Sullivan, 2008; p.109). With regard to the tasks used to develop the MKT, Suzuka and colleagues (Suzuka et al, 2009) make a list of features that make a task well suited for developing MKT:

- “Creates opportunities to unpack, make explicit, and develop a flexible understanding of mathematical ideas that are central to the school curriculum
- Provokes a stumble due to a superficial “understanding” of an idea
- Opens opportunities to build connections among mathematical ideas
- Lends itself to alternative/multiple representations and solution methods
- Provides opportunities to engage in mathematical practices central to teaching (e.g., explaining, representing, using mathematical language, analyzing equivalences, proving, analyzing proofs, posing questions)” (Suzuka et al., 2009; pp.12–13)

These features are linked to the analysis of some examples of tasks (Suzuka et al, 2009). There are shareable critics (Flores, Escudero, & Carrillo, 2013) about the fact that the tasks described can also be faced by individuals who know the topic and, therefore, these knowledge and skills are not identifiable as specialist of the teachers: according to Flores and colleagues there is not sufficient evidence to guarantee that the knowledge, labelled SCK, is exclusive to mathematics teachers. Even if I agree with the critics on these tasks, the list of features about the MKT tasks presented by Suzuka and colleagues seems to well identify some aspects of tasks that characterize the work of a teacher.

This paper will present some examples of tasks for teachers that can be suited for showing and improving the mathematical knowledge for teaching. The methodology is also important in raising the teachers knowledge: in the activities that will be presented, the teachers are involved in laboratory sessions in which they work in small groups, discuss and share their reflections and analysis.

## **The teacher education program**

This paragraph discusses some examples of educational activities carried out in the “Didactics of Mathematics” courses for middle school teachers involved in two Italian post-degree programs for the achievement of the teaching credential: the Active Internship (in Italian “Tirocinio Formativo Attivo” -TFA) and the Special Teaching Certificate Course (in Italian “Percorso Abilitante Speciale” -PAS). These programs follow the indications of the Ministry of Education and they are established by universities. The first one is attended by pre-service teachers and the second one by in-service teachers. The author of this paper is the teacher educator/didactician. During the teacher education programs, the teacher educator had the opportunity to work with teachers and to discuss with them some theoretical tools to analyze tasks from the Italian National Mathematics Standardized Tests. These tests are administered at the end of the school year in grades 2-5-8-10 (grade 6 was involved from 2010 to 2013). Only for grade 8 (the end of middle school in Italy), the

---

<sup>2</sup> Knowledge of Content and Teaching.

test is part of the national final examination, so it contributes to the final assessment of the students. The items aim at assessing students knowledge and skills identified in the Italian National Guidelines.

The teacher education courses analyzed involved 72 in-service teachers and 25 pre-service teachers. The activities followed a laboratory approach in a Vygotskian perspective (Bartolini Bussi & Mariotti, 2008): the teachers learn by doing, seeing, imitating, and communicating with each other within the course community. In these courses, the teachers and the teacher educator shared, discussed and reflected on their *a priori* analysis of mathematics problems, focusing on the institutional, epistemological, cognitive and didactical aspects.

The laboratory activity consists of five phases. In this paper we discuss the first three phases that deal with the *a priori* analysis of the items and that are the same for pre-service and in-service teachers. The last two phases involved only the in-service teachers, because these activities consist in the implementation and analysis of classroom activities carried out with their own students.

At the beginning of the activity, the teacher educator shows an *a priori* analysis of some Italian National Standardized Test items according to a common script (Martignone, 2016). It starts with the analysis of what is necessary for the students to know and how to do it. Therefore, the focus is on the epistemological and institutional aspects. The question is: what is significant from the point of view of the teaching and learning of mathematics? This starting point is necessary, but it is not an innovative task in a teacher education program. It is an activity that all teachers commonly develop. The next step consists in foreseeing the students' possible solution strategies and mistakes. This type of fine grain analysis is common in the educational studies in mathematics, while the teachers more often discuss the student performance after an activity. Afterwards, the teacher educator presents the national sample results about these items, adding also some examples of students' answers collected in the study carried out by her research group (Branchetti et al., 2015). By means of the analysis of these data, during the subsequent collective discussion, the hypothesis shared in the *a priori* analysis are confirmed or rejected. In this first part, the *meta-didactical praxeologies*, related to the analysis of standardized test items, begin to be shared.

## **The activities of the teacher education course**

In the second phase of the course, the teachers, divided into small groups, carry out on their own an *a priori* analysis of other items selected from the Italian National Assessment. During these laboratory sessions, teachers compare and discuss their works and the teacher educator provides other information about possible students behavior, by also quoting some educational research results collected in the literature.

## **The tasks for teachers**

This is the task proposed to the teachers: "Carry out an *a priori* analysis of the item, following the common guidelines shared: (i) the mathematical contents, the necessary skills to face the item, and the links with the Italian National Guidelines; (ii) the possible students solution strategies; (iii) the possible mistakes and difficulties; (iv) the strengths of the task; (v) the critical aspects of the task; and (vi) some proposals for changes".

Figure 1 shows an example of an item analyzed. This item was administered to grade 6 students in 2011, but there were many similar items also in grade 8 tests.

**Place the following numbers on the line:**

**Figure 1: Item D8 administered in grade 6 (2011)**

The in-service teachers have much more experience in predicting students' possible behaviors, but also pre-service teachers manage to foresee the most common mistakes. The written analyses (word documents or Power Point presentations) were shared on the Course Moodle platform.

### **Some excerpts from the teachers' works**

This paragraph presents some excerpts (author's translations) from the *a priori* analysis carried out by teachers on item D8 presented above. The first excerpt shows an example of how the teachers wonder about what the item actually assesses.

"The item assesses simultaneously two different skills: to know how to transform numbers from one representation to another, and to place them on the number line. Because a student may be able to carry out only one of these two actions, he/she gives a wrong answer. Therefore, it is not possible to understand (from the final result) in which part of the process the student made the mistake".

The following are examples of students possible difficulties foreseen by the teachers.

"If students consider only the numerators of the fractions (3 and 5), the way in which the numbers appear in the stem might suggest that they are already written in order"

"The students do not manage the symbol of fraction: they consider only the value of the numerator (or denominator); they put the fraction close to the value of numerator (or of the denominator)"

"The student pinpoints 5/10 counting five hash marks for two possible reasons: he/she makes the straight line longer to obtain ten hash marks and then he/she considers five of these; or he/she considers only the value of the numerator and counts five hash marks".

The teachers have to read the colleagues' works in order to be ready for the next collective discussion, that is orchestrated by the teacher educator.

### **Collective discussion**

All the hypotheses about the possible students behavior are collectively discussed. The student behaviors in these types of items are amply documented in the literature. The teacher educator refers to the studies summarized in the Encyclopedia of Mathematics Education (2014) and to the theoretical framework of the study on the Italian National Mathematical Standardized Tests carried out by her research group (Lemmo et al., in press). All the research papers quoted (or translations of

parts of them) are shared on the platform of the course. Because the items analyzed are taken from Italian national standardized tests, also the quantitative results could be taken into account. The national sample results concerning item D8, administered in 2011 in grade 6, are: 85% of the students gave the wrong answers, 11% the correct one and the remaining 4% either did not answer nor the answers made no sense. The questions faced by the teachers are: which could be the reason for this low percentage of right answers? When all the numbers are well positioned, the item is considered correct; if instead the students make mistakes, then how can the teachers identify the students' difficulties? As a matter of fact, based on the statistical data, we cannot know which mistakes the students made, but only the percentage of wrong answers. For this reason, during the discussion the teacher educator shows some examples of students' answers collected and analyzed in her research project: she wants to intertwine quantitative and qualitative analyses. As we can see in the following examples (Figures 2-3-4), we find the difficulties and the mistakes foreseen by the teachers (showed in the previous paragraph). The teacher educator supports the teachers' interpretations, by quoting some results from educational studies in Mathematics concerning the placing of rational numbers on the number line (Lemmo et al., in press). In fact, many mistakes can be generated by the interlacement of misconceptions about rational numbers and number line management: e.g. some students write the numbers in each hash mark without considering the unit of measure and place the fractions considering only the numerator (Figure 2). In this specific case we are not able to know if the students only copy the numbers as they are presented in the stem.

Figure 2

Other students show difficulties in placing fractions on the number line: they consider  $3/2$  equivalent to  $3+1/2$ , or to  $3.2$ . The same mistake could justify  $5/10$  put over the end of the line (Figures 3-4).

Figure 3

Figure 4

At last, the teachers design new items in order to investigate specific questions raised from the collective discussion. They ask themselves: what would happen if we change/add some numbers? Which ones? Why? What would happen if we change the unit of length or the numbers already written on the number line? Some examples of the proposals for modifications are: to change the order of the numbers in the stem (e.g. to alternate fractions and decimals numbers and do not write 2.5 after 2); to make the number line longer to see where, the students who make a mistake, would place  $5/10$ ; to add more numbers (e.g.  $1/2$ ), etc.

## Conclusions

This paper discusses some tasks for teachers carried out during laboratory activities for middle school teachers. The teachers and the teacher educator share praxeologies concerning the analysis of some items selected from the Italian National Assessment. During the laboratory activities, the teachers analyze and discuss the mathematical contents involved, the link with the National Guidelines, the possible students answers and mistakes, and propose changes in the tasks. The quantitative data of the national sample are taken into account and the teacher educator also provides results from different educational studies collected in the literature. The *shared praxeologies* (Aldon et al., 2013) are made by the intersection of the didactician's knowledge of theory, research and systems and the teachers' knowledge about subject matter, students and school: elements of mathematics, didactics and pedagogy are intertwined. The *meta-didactical praxeologies* (Aldon et al., 2013) presented highlight how some aspects of the MKT can emerge in the analysis of mathematical problems carried out by teachers. The actions that characterized the teachers' activity and their knowledge and skills are: to imagine many possible different solution strategies; to interpret different representations and students' solutions; and to analyze the mistakes thinking about the possible causes. The paper shows how these knowledge and skills can emerge and be improved during a teacher education program by means of specific tasks (e.g. *a priori* analysis of math problems) and methodologies (e.g. laboratory activities that involved teachers and researchers). The tasks presented aim at developing an interlacement among the teachers' *Subject Matter Knowledge* and *Pedagogical Content Knowledge* (Shulman, 1986; Ball et al., 2008): i.e. they highlight the different aspects related to the knowledge of the subject matter to be taught, to the curriculum, and to the possible behavior of students and their difficulties related to specific mathematical content. The ability of the teachers to dynamically relate and intertwine the different content knowledge (among that there are fuzzy boundaries) characterizes their professional skills and therefore it can be identified as typical of the work of teachers. A further development of this research will be the analysis of the actual teachers' actions in the following design and implementation of educational activities (phases 4 - 5 of the teacher education program).

# An exploration of challenges of engaging students in generative interaction with diagrams during geometric proving

Lisnet Mwadzaangati

University of Malawi, Malawi; University of Stavanger, Norway; [mwadzaangatilisnet@yahoo.ie](mailto:mwadzaangatilisnet@yahoo.ie)

*This paper reports from a single qualitative case study which investigated challenges that might arise in a geometric proof lesson involving generative interaction with diagrams. Data consists of video recordings from a 120 minute lesson, taught with a focus on geometric proof in a Malawian grade 11 secondary school classroom. A post-lesson interview was also conducted with the teacher soon after the lesson. The findings indicate that the teacher faced challenge of lack of time, hence he did not complete some planned activities. The students faced the challenge of lack of understanding of the problem. As a result, they were unable to devise a correct plan during their initial involvement in the generative activity. The findings suggest that both the teacher's and students' challenges would have been avoided if problem solving was conducted appropriately.*

*Keywords: Geometric proving, generative interaction with diagrams, empirical activity, geometric diagrams, problem solving.*

## Introduction

Malawi National Examinations Board (MANEB) chief examiners' reports show that students fail to construct geometric proofs because they do not interact with diagrams successfully (MANEB, 2013). The report attributes students' failure to construct geometric proofs to lack of teacher knowledge for engaging students in successful proving activities. The reason suggested by MANEB supports the argument that teachers are responsible for engaging students in activities that involve interaction with diagrams during proof construction (Herbst, 2004). In geometry, to prove means to construct a sequence of argumentation from X (hypothesis) to Y (conclusion) with supportive reasons (Cheng & Lin, 2009). Herbst (2002) describes the work of geometric proving as a didactical contract between a teacher and his/her students. In this contract, the teacher's responsibility is to provide the problem statement and a diagram which contains the givens and the unknown. The students' responsibility is to develop logically connected statements from diagrams by making appropriate geometric interpretations and relationships. Herbst (2004) proposed four distinctive ways of thinking about how students interact with geometric diagrams during proving. These are empirical, representational, descriptive, and generative modes of interaction. Empirical interaction supports hands on geometry in the sense that the student is free to make a variety of operations on the diagram (measuring, looking at, and drawing in the diagram). Representational interaction supports abstract geometry, in the sense that the student is restricted by prescribed rules when making operations on the diagram. In descriptive interaction, the diagram contains features like marks and labels. Students use the features to complete a proof. Herbst (2004) argues that the availability of features in a descriptive diagram reduces students' responsibility for producing the proof and portrays situations of doing proof as only learning of good logic rather than discovering of new mathematics. The author therefore proposes that teachers should engage students in generative activities by using generative mode of interaction with diagrams during geometric proving. In this mode of interaction with diagrams, students are authorised to anticipate operations and results on

the diagram. Depending on the given information and the anticipated result, students can add features like drawing in lines and labels into the diagram. This means that generative interaction with diagrams is supposed to involve exploratory teaching strategies. Despite acknowledging that it is not easy to involve students in generative activities, the studies by Herbst have not focused on clarifying the challenges that might arise during such activities. Likewise, to my knowledge, no study has been done in Malawi to examine challenges of involving students in different modes of interaction with diagrams during geometric proving. Therefore this study has both a local relevance to teaching of geometric proving in Malawi and general relevance to the field of teaching of geometric proofs. The study addresses the following research question: What are the challenges of engaging secondary school students in generative interaction with diagrams during geometric proving?

## **Theoretical framework**

Several investigations have been conducted with an aim of addressing challenges of teaching and learning geometric proof construction. Studies by Jones and his colleagues aimed at developing strategies for teaching proof construction with focus on helping students to understand the proof and appreciate its discovery function (Ding & Jones, 2009). The focus on value of geometric proofs arose because the authors found that there were some students who were able to construct proofs but could not appreciate its discovery function in mathematics (Jones et al., 2009). The authors therefore propose for a shift to exploratory pedagogical strategies. One of these teaching strategies is problem solving approach which involves four stages; understanding the problem, devising the plan, carrying out the plan, and looking back (Polya, 1945). For a geometric proof problem, understanding of the problem involves understanding of the hypothesis and the conclusion. Hypothesis is the given information and conclusion is the statement to be proved. Polya (1945) suggests that when a proof problem is connected to a figure, the stage of understanding the problem must involve helping the students to draw the figure, to introduce suitable notations, and to label in the diagram the hypothesis and conclusion. Devising the plan involves finding the connection between hypothesis and conclusion, deciding on the theorem to use, and making decisions whether to introduce auxiliary elements into the diagram to enable proving (Polya, 1945). Carrying out the plan involves writing of the proving statements logically, each statement accompanied by a valid reason. Looking back stage includes reviewing the solution and checking if the arguments can be derived using a different approach. This study agrees that problem solving strategy can provide opportunities for students to appreciate the value of geometric proving. In addition, this study argues that students' opportunities to involve in generative interaction with diagrams can be enhanced through exploratory activities. This means that teachers require knowledge of problem solving strategy to engage students successfully in generative interaction with diagrams. This study was therefore guided by Polya's (1945) problem solving framework in analysing the data.

## **Methodology**

The study was conducted using qualitative case study design because the goal was to expand understanding of social issues in their context (Yin, 2009). The study was conducted on one Malawian secondary school teacher and one lesson. The teacher, Kim (pseudonym) is regarded as one of the best teachers due to his long teaching experience and because his students perform well

in mathematics during national examinations. Kim was selected for the study on assumption that conducting research on an experienced teacher could offer an opportunity to study the issue in depth. The lesson episode analysed for this study is part of the video data that was collected for a larger project which aims at studying knowledge for teaching geometric proofs. The lesson episode was considered for analysis because it involved moments of generative mode of interaction with diagrams as well as problem solving teaching strategy. Post-lesson interview was conducted and audio recorded in the teacher's office soon after recording the lesson. The teacher was mainly asked to explain his views about the lesson in terms of what went well and what did not go well during the lesson. Although the data for the study is from one lesson, it is considered to be sufficient for illustrative purposes because it was generated from a real-life context (Yin, 2009). The empirical material, both from the video recording of the lesson and the audio recording of post-lesson interview were transcribed and further analysed separately by using thematic analysis. The aim of thematic analysis was to capture and interpret sense and substantive meanings in the data (Ritchie, Spencer & O'Connor, 2004). Polya's (1945) stages of problem solving were used as a priori themes for analysing the data. The transcribed data was read several times to understand it and to identify moments that were related to a particular stage of problem solving. The findings from the two types of data are discussed under each theme for purposes of comparison. Due to space limitations, this paper has mainly discussed findings related to the first two stages of problem solving; understanding the problem and devising the plan.

## Findings and discussions

Kim started the lesson by writing a geometric statement and making a drawing of a diagram on the chalkboard. He told his students that the aim of the lesson was to prove that an angle subtended by an arc at the centre is equal to two times an angle subtended by the same arc at the circumference. After explaining the lesson aim, Kim asked his students to go into their usual small groups to draw a similar diagram and discuss how to prove the theorem. There were six groups in the class and each group contained five to eight students. Table 1 shows the diagram that was drawn and the statement that written by Kim on the chalkboard.

	<p>Given: a circle with centre O, with arc AB subtending angle AOB at the centre and angle AMB at the circumference. Prove that the angle at the centre is twice the angle at the circumference.</p>
---	--

**Table 1: Diagram and statement given to students for proof construction**

It can be argued that the problem statement in table 1 is ambiguous because the teacher has not specified the two angles whose relationship is to be proved. There is one angle at the circumference referred by the statement, but there are two angles at the centre (reflex AOB and obtuse AOB). Furthermore, the diagram in table 1 did not contain any features to indicate the required angles. This means that during group discussion, students were challenged to decide whether to relate the angle

at the circumference to the reflex angle or the obtuse angle at the centre. As such, the diagram required generative mode of interaction. Hence the discussion activity involves problem solving.

After about 10 minutes, Kim moved around to check what students were discussing and doing in the groups. The following lesson segment 1 presents a dialogue between Kim and students in group 6.

- Kim: Okay so what are you going to do, have you discussed?
- Student 1: Yes, we will join MO and prove that these two triangles (pointing at triangle AMO and BMO are congruent). Then relate the corresponding angles.
- Kim: Can you show me how you will relate the angles.
- Student 1: First,  $AO = BO$  (radii), OM is common, and  $AM = BM$  (third side) AOM is congruent to BOM. Then angle MAO = MBO, the two angle here are also equal (pointing at the reflex angle at AOB) and the two angles here are equal (pointing at M). (The student is silent).
- Kim: Go ahead.
- Student 2: Then we add angles here (pointing at the reflex angle at AOB) and angles here (pointing at M) uhhh.... (silence 4 seconds).
- Kim: Yes go ahead what about the other group members, how do you proceed from here to the theorem? (silence for 4seconds) how do you relate the two angles? (silence 6 seconds), how do you arrive at the question that you have been asked using that theorem? (silence 4 seconds). Do you know the angle at the centre referred in the theorem?
- Student 3: Yes this one (pointing at the reflex angle at AOB).
- Student 4: No this one (pointing at the obtuse angle at AOB).
- Kim: Can you try to measure the angles and see if it is the upper or lower angle which is twice the angle at M? After that think of another way, this one might not work.

Then Kim went to check students in other groups and asked questions. When he noticed that most of the groups were not focusing on a correct angle at the centre, Kim interrupted the generative activity and asked all groups to measure the three angles and relate their values to find out the correct angles. The activity took about 15 minutes, students measured the angles and made comparisons. The following lesson segment (segment 2) is a continuation of a conversation between Kim and group 6.

- Student 3: This angle (pointing at angle AMB) was  $52^\circ$  while this one (pointing at obtuse angle AOB) was  $104^\circ$ . So this (pointing at obtuse angle AOB) is twice this (pointing at angle AMB).
- Kim: Okay so how are you going to prove the theorem?
- Student 5: We tried similarity but we found that it was going to be difficult as well because it was not saying anything about this angle (pointing at obtuse angle at O) it was only saying about this one (pointing at the reflex angle at O). So since this angle is outside these two triangles, we agreed to use the property of exterior angle of

triangle. So we extended MO to N to create exterior angles here (pointing at obtuse angle at the centre).

## Understanding the problem

Lesson segment 1 shows that the students agreed to add a feature (auxiliary line) into the diagram by joining MO to form two triangles (AOM and BOM). The students also agreed to construct the proof for the theorem by firstly constructing an in-between proof of congruency of triangles AOM and BOM. This means that in lesson segment 1, the students were devising a plan for the proof. Depending on geometry background at their level, there are two possible approaches that the students could use in developing their plan. The first approach involves joining of MO, then forming two equations using properties of isosceles triangles, sum of interior angles of a triangle and sum of angles at a point, and finally making substitutions to reach the conclusion. The second approach involves joining MO and extending it to some point within the circle to form exterior angles of triangles AOM and BOM, and then use properties of isosceles triangles and exterior angle of a triangle to form two equations, and finally make substitutions. This shows that congruency theorem is not appropriate for both approaches. As such, the students' decision to join MO and then use congruency theorem as an in-between proof was not correct. It can be argued that the students' decision was based on lack of understanding of the problem. This argument is based on several observations. Firstly, in segment 1 the students were unable to explain how they would use the congruency theorem to connect to the conclusion. But segment 2 indicates that after realising that the angle at the centre is the obtuse angle, the students changed their plan, and they were able to justify their decision to use property of exterior angle of a triangle. Secondly, the argument is based on students' disagreements regarding angle at the centre in segment 1. Some students pointed at the reflex angle while others pointed at the obtuse angle when Kim asked them to identify the angle at the centre referred by the theorem. This means that the students were not sure of the correct angle at the centre. The disagreement among the students regarding the angle at the centre provided an opportunity for Kim to shift students' focus from the stage of devising the plan to the stage of understanding the problem. The findings from the lesson segments are supported by the following extract in which Kim expresses the challenges that students faced when constructing the proof:

It was very difficult for the students to come up with relevant constructions when proving. Because I think the main trick in the proof was to know what type of construction and in-between theorem to use for the proof. But after doing the measurements, the students were able to make correct construction and to know the theorem to use. Their reasoning and their work showed that they now understood the statement they were asked to prove.

The extract shows that Kim realised the difference in the students' ability to come up with a correct plan before and after the empirical activity. Kim mentions two challenges that the students faced before the empirical activity. The first challenge involved failure to decide on features to be added to the diagram. The second challenge involved failure to use the diagram to generate a correct in-between theorem and proof. Both challenges involved generative interaction with diagrams as they required students to make explorations with the diagram (Herbst, 2004). The extract also indicates that the students were able to devise a correct plan upon understanding the problem. Cheng & Lin (2009) call the proving of an in-between theorem as construction of intermediary condition (IC).

These authors argue that students can only construct correct ICs if they understand the hypothesis and the conclusion. Polya (1945) advises that solving of any mathematical problem should not be started unless the problem is well understood. Probably, the challenge of understanding the problem could have been avoided if Kim carried out the phases of problem solving before going to the class (Polya, 1945). Through this preparation activity, Kim could have anticipated that students were more likely to regard the reflex angle as angle at the centre due to its location. Thus the reflex angle is close to and in the same quadrilateral (AMBO) with the angle at the circumference. In so doing, Kim could avoid the mistake by helping the students to understand the theorem (which also implies to understand the problem) before asking them to discuss how to develop its proof.

## Devising the plan

Both lesson segments show that students devised the plan for the proof in their groups through exploration. Lesson segment 1 shows that the first attempt to devise the plan was not successful due to lack of understanding of the problem. Lesson segment 2, shows that after the empirical activity, students came up with a proper construction and correct IC for linking angle at the centre and angle at the circumference. The students' suggestions to introduce a line into the diagram confirm that they were involved in generative interaction with the diagram. Lesson segment 2 also shows that the students were able to evaluate their ideas by considering the questions asked by Kim in lesson segment 1. The questions are, "how do you relate the two angles? How do you arrive at the question that you have been asked using that theorem?" The questions helped the students to focus on identifying a construction and theorem that could help them to connect the given information to the conclusion. This is observed in utterance by student 5 who explained that they tried to use similarity theorem but they realised that it was not appropriate because it could not help them to link angle at the circumference and the obtuse angle at the centre. The technique of asking questions that probe students' thinking is regarded as one of the strategies for helping students to devise a plan (Polya, 1945). The findings from analysis of students' explanations in lesson segment 2 show that the empirical activity which focused on understanding angle at the centre helped the students to devise a correct plan for the proof. This observation is also confirmed in Kim's explanation regarding what went well during the lesson. Kim explained that the lesson was generally successful because the students were able to construct the proof independently. Kim explained that his lesson objective was to help the students to understand the theorem and construct its proof on their own. He explained as follows:

If you just start proving without engaging students in an activity like measuring or discussions on how to prove, they just memorise the proof. So to avoid memorisation, I involved the students in discussions. When I found that they were referring to a wrong angle at the centre, I did not tell them the angle, I wanted them to find out on their own by measuring the angles.

The extract shows that during the first activity Kim regarded the students' inability to construct a correct proof as an opportunity for them to understand the theorem which is also the statement problem in this case. Kim's idea of giving students opportunity to do explorations on the problem to be proved is supported by Ding & Jones (2009). But Kim was not supposed to wait until students got stuck in order to suggest the empirical activity. According to Polya (1945) the teacher is

supposed to prevent students from answering a question that is not clear to them, and from working for an end that they do not desire. The author argues that students might be frustrated if they either get stuck or come up with undesirable solution to a problem. As such, teachers are supposed to avoid making students' frustrated by ensuring that they understand the problem before beginning to devise its plan. This suggests that Kim was supposed to first of all engage the students in an exploration activity that could help them to understand the problem before involving them in activity of discussing how to prove the theorem. By doing so, Kim could have avoided the challenge of lack of time that he pointed out when explaining what did not go well during the lesson. Kim explained that he had planned to discuss three examples of how to apply the theorem in solving different geometric problems, but he only managed to discuss one example because some time was spent on the unplanned activity of measuring angles. Apart from examples, Kim also explained that he had planned to give the students an exercise which he wanted to start marking during the lesson, but he turned it into homework due to lack of time. Kim seemed to have planned many activities for the lesson which involved problem solving. But Polya (1945) explains that problem solving might be time consuming because students explore different ways when devising a plan for finding solution of the problem. This means that a teacher is supposed to plan few activities for a problem solving lesson to ensure that students have ample time for explorations. The planning of many activities and the sequence of activities during the lesson indicates that although Kim used problem solving strategy, he was not aware of some of its skills. This agrees with Herbst's (2004) caution that engaging students in generative mode of interaction with diagrams is challenging.

## Conclusion

This study has found that both the teacher and students faced some challenges during the lesson of geometric proving which involved generative interaction with diagrams. The teacher faced the challenge of lack of time hence he did not complete some of the planned activities. The students faced a challenge of lack of understanding of the problem during their first attempt to devise a plan for the proof. Due to this challenge, the students came up with wrong construction and IC for the proof. As a result the students were unable to complete the plan for the proof during their first attempt to devise the plan. However the findings show that the students were able to devise correct plan for the proof after doing an empirical activity which focused on understanding the problem. The study implies that the challenges faced by both the teacher and the students could have been avoided if proper problem solving skills were followed. Thus the first activity could have focused on understanding the problem and the second activity could have focused on devising the plan for the proof. The findings suggest that successful involvement of students in generative interaction with diagrams require knowledge of several problem solving skills including proper planning and sequencing of activities. Lastly, the findings show that empirical interaction with diagrams enhanced students understanding of the problem. Further study is needed to explore whether successful involvement of students in generative interaction with diagrams require a combination with other modes of interaction with diagrams.

*The purpose of this study was to investigate middle school mathematics teachers' knowledge for teaching algebra. The participants of the study were 48 mathematics teachers from various middle schools. A questionnaire was conducted in order to collect data about the teachers' knowledge related to teaching of algebra. The results showed that the participating teachers were competent in making transitions among different algebraic representations. However, they had difficulties in explaining the conceptual bases of some of the algebraic concepts and procedures. In addition, results indicated that some of the teachers had difficulties and misconceptions similar to those of students as depicted in the scenarios provided in the questionnaire.*

**Keywords:** Pedagogical content knowledge, algebra, middle school mathematics teachers.

## Introduction

Teachers' knowledge is considered as one of the most important predictor of student achievement (Hill, Rowan, & Ball, 2005). In recent years, therefore, researchers have focused on the professional knowledge of teachers (Ball, Thames, & Phelps, 2008; Grossman, 1990; Shulman, 1986, 1987). As Knowles, Plake, Robinson, and Mitschell (2001) stated, what teachers should know and be able to do are issues which continuously change and develop as values of the society come up with the changes. Therefore, teachers need different types of knowledge in order to fulfill those expectations. Subject matter knowledge (SMK), pedagogical knowledge, and pedagogical content knowledge (PCK) are among the major components of teacher knowledge referred frequently in the literature (Ball et al., 2008; Cochran, DeRuiter, & King, 1993; Magnusson, Krajcik, & Borko, 1999; Shulman, 1987). Among these, having a strong subject matter knowledge is often considered the central component of teacher competency (Krauss et al., 2008). However, merely having strong mathematics knowledge does not guarantee effective teaching (Ball et al., 2008; Kind 2009).

Effective teaching requires making the content accessible to students, interpreting the questions and productions of students, and being able to explain or represent ideas and procedures in multiple ways (Hill, Sleep, Jewis, & Ball, 2007). In this context, teacher competency is the cognitive ability in order to develop solutions for problems concerning teaching profession and applying these solutions in various situations successfully (Weinert, 2001). Providing meaningful and effective activities for students' learning is considered essential for teacher competency (Knowles et al., 2001). Therefore, pedagogical content knowledge, defined as "the most useful ways of representing and formulating the subject that makes it comprehensible to others" (Shulman, 1986, p. 9), is seen as a core component of teacher competency and an indispensable part of teacher knowledge base. A study conducted by Kind (2009) in which several PCK models were investigated revealed that representations and instructional strategies and students' subject specific learning difficulties were considered as two core dimensions of PCK in most of the studies (e.g., Grossman, 1990; Magnusson, Krajcik & Borko, 1999;

Shulman, 1987). Therefore, among others, the components that are knowledge of students' learning of mathematics and knowledge of teaching mathematics were chosen as the focus in this study.

In the literature, there have been several studies on the pedagogical content knowledge of mathematics teachers concerning knowledge of algebra and teaching of algebraic concepts (e.g., see Doerr, 2004; Güler, 2014; McCrory, Floden, Ferrini-Mundy, Rackase, & Senk, 2012). As the Mathematics Study Panel (2003) indicates, proficiency in algebra is important for students' mathematical thinking and understanding. Moreover, teaching of algebra in middle school is particularly crucial since the algebra learnt there constitutes a basis for the high school and university level mathematics (Mathematics Study Panel, 2003). Thus, teachers' knowledge of algebra and teaching of algebra in middle schools are worth studying as teachers' professional knowledge is one of the most important predictors of student achievement (Hill, Rowan, & Ball, 2005). Thus, the assessment of teacher knowledge is an important step to understand the competency of teachers or the quality of teacher education programs. Although there are several studies based on the algebra knowledge of students, there is limited research on algebra instruction (Güler, 2014; Kieran, 2007; Ladele, Ormond, & Hackling, 2014). Therefore, which knowledge component is required by the teachers and how this knowledge could be developed need to be investigated in order to improve algebra instruction (Kieran, 2007). For this reason, there is a need for theory building on what teachers need to know related to teaching of algebra and how this knowledge could be developed by teachers. In this study, SMK and PCK were considered as separate dimensions of teacher knowledge and PCK of middle school mathematics teachers was investigated for teaching algebra. As for the main theoretical framework, we used "algebraic knowledge for teaching" which was adapted by Güler (2014) from Ferrini-Mundy, Floden, McCrory, Burrill, and Sadow (2005). The framework is a three-dimensional model consisting of three main components: algebra content, algebra knowledge for teaching, and domains of mathematical knowledge. Algebra content consists of two main categories: algebraic expressions, equalities, and inequalities and linear and non-linear functions and their properties. Algebra knowledge for teaching includes advanced algebra, knowledge about learning of students, and knowledge about representations of the content. Domains of mathematical knowledge include basic concepts and procedures, representations, applications, and reasoning and proof. In this study, algebraic knowledge for teaching dimension of the model was focused on. The only difference between the adapted framework (Güler, 2014) and the original one (Ferrini-Mundy et al., 2005) was in algebraic knowledge for teaching dimension which includes school algebra, advanced algebra, and teaching knowledge components. The knowledge about learning of students, and knowledge about representation of the content segments of this dimension were investigated within the study in relation with algebra content and mathematical knowledge context dimensions.

The purpose of this study was to investigate the knowledge of middle school mathematics teachers in relation with teaching of algebra. In this scope, two components of pedagogical content knowledge of middle school mathematics teachers were investigated; knowledge of learning of students and knowledge of teaching mathematics. Moreover, the difficulties and strengths of middle school mathematics teachers were investigated in relation with the knowledge of teaching algebraic concepts. Therefore, the research questions that guided this study were:

- What are the difficulties and challenges that middle school mathematics teachers face in teaching of algebraic expressions, equations, inequalities, and linear and non-linear functions?

- What pedagogical content knowledge do middle school mathematics teachers have about algebraic expressions, equations, inequalities, and linear and non-linear functions?

## Methodology

Participants of the study were 48 middle school mathematics teachers from different public and private schools in Turkey who voluntarily participated in the study. Their teaching experiences (in years) ranged from 1 year to 26 years ( $\bar{X} = 8$ ,  $SD = 5.3$ ). In Turkey, middle school mathematics teachers are responsible for teaching mathematics in grades 5, 6, 7, and 8. All of the participants in this study had at least a bachelor's degree in elementary mathematics education. Based on the current mathematics curriculum in Turkey (MoNE, 2013), formal teaching of algebra starts in 6<sup>th</sup> grade with the introduction of algebraic expressions and the concept of variable. Then, the concepts of equality, equation and linear equation are introduced in 7<sup>th</sup> grade. In 8<sup>th</sup> grade, algebraic expressions and identities, linear equations, equation systems, and inequalities are further dealt.

Developed by Güler (2014) and used with his permission, the instrument used in this study was a 20-item questionnaire comprising of multiple-choice and open-ended items intended to assess teachers' knowledge for teaching algebra at the middle school level. For the instrument, the scores were averaged across 20 items to control the reliability of the instrument ( $\bar{X} = 17.8$ ,  $SD = 5.9$ ). Also, Cronbach's alpha was estimated as 0.81 for person reliability and 0.94 for item reliability. Moreover, in order to ensure validity of the instrument, item analyses were carried out and expert opinion was taken in order to show that the content of the instrument coincides with the conceptual framework. In the questionnaire, the participants were confronted with situations or scenarios related to the work or practice of teaching middle school level algebraic concepts (see Figure 1 for an example). The algebra content tested in the instrument was in line with the mathematics curriculum for the middle school level (grades 5 to 8) in Turkey (MoNE, 2013). The instrument consists of two components in relation with PCK: knowledge of students' learning and knowledge about representation of the content. Moreover, the content of the instrument is constructed under two domains: mathematical knowledge content and algebra content. Mathematics content includes basic concepts and procedures, representations, applications, and reasoning and proof. Algebra content includes algebraic expressions, equality, and inequality, linear and non-linear functions and their properties.

The use of a questionnaire with a survey type design was preferred in order to collect data from a large sample of teachers. There was no time limitation for completing the questionnaire. Descriptive analyses and item based in-depth analyses were carried out in order to have a general overview on algebra related PCK of teachers. Based on the rubric prepared by Güler (2014), analyses were conducted for each item separately. The frequencies and percentages of correct, particularly correct, or incorrect answers were calculated in order to investigate the performances of all teachers for each item. To illustrate, the answers to the 10<sup>th</sup> item (see Figure 1) were categorized as correct if the teachers explained why the inequality sign changed direction by using algebraic expressions or trying out particular values to make generalization, partially correct if the teacher explained it by using particular values of  $x$ , and incorrect if the answer was wrong, invalid, or missing.

Mr. Reyhan gave the inequality  $-x < 7$  to the students and got them find the solution set of the inequality. One of the students divided both sides of the inequality with  $-1$  and got the solution as  $x > -7$ . Then, another student asked why the direction of the inequality sign was changed when both sides of it were divided by  $-1$ . What would you tell to the student if you were the teacher of the classroom?

**Figure 1: The Item 10 in the questionnaire**

In general, answers were coded as correct when the teacher provided correct answers/results to the questions by using algebraic expressions or trying out particular values in order to make generalization in explaining an algebraic topic conceptually, and explained why the answer of the student was wrong in the scenario by providing underlying reasons. The answers coded as partially correct included those in which the teachers gave inadequate explanations and used particular values to show the validity of an algebraic procedure. The answers coded as incorrect were the wrong, invalid, or missing ones. To ensure the reliability of coding, two independent scorers coded all of the open-ended items in the questionnaire for half of the participants (i.e., 24 teachers). The interrater agreement across both scorers was high (*percent agreement* = 92.80%).

## Findings

As the findings suggested, most of the teachers in this study were able to make the transition among the rhetoric, symbolic, and geometric representations of the algebraic expressions. Below we present the findings in relation to the dimensions of knowledge for teaching algebra framework (Güler, 2014), namely algebra content, algebra knowledge for teaching, and domains of mathematical knowledge. In some items, most of the teachers gave correct responses in the questionnaire. The Item 18 ("The difference between an equation and (algebraic) identity") was one of the items that most of the teachers answered correctly (see Table 1). The item 18 was related to three dimensions of the algebra knowledge for teaching model, namely algebra content, algebra knowledge for teaching, and domains of mathematical knowledge.

	Correct		Partially correct		Incorrect	
	<i>f</i>	%	<i>f</i>	%	<i>f</i>	%
Item 6	3	6.3	17	35.4	28	58.3
Item 10	0	0.0	27	56.3	21	43.8
Item 18	33	68.8	12	25.0	3	6.3

**Table 1: Results of the analyses of three items in the questionnaire**

The answer of a participant ( $P_{18}$ ) for the Item 18 item was categorized as correct since it presented the difference of the two concepts effectively.

$P_{18}$ : Equation is an algebraic expression which holds for particular real number(s) while (algebraic) identity is an algebraic expression which holds for all real numbers.

The answer of another participant ( $P_{31}$ ) for the Item 18 was categorized as partially correct since the teacher considered all equations as if they were just first degree equations.

$P_{31}$ : Equations hold for just one value (i.e., If  $3x + 5 = 8$ , then  $x = 1$ ). However, identity holds for all values of the unknown.

Moreover, some of the items got partially correct or incorrect answers by most of the teachers. To illustrate, the results for Item 6 (see Figure 2), which was related to the algebra content and knowledge for teaching algebra dimensions and basic concepts and procedures segment of the model, are presented in Table 1. On the other hand, the results revealed that the teachers were incompetent in some of the areas such as finding and correctly expressing the solution set of equations and identification and correction of students' incorrect ideas and misconceptions.

The teacher gives the equation system to the students and get them to solve it.  
 $2x - 4y = 8$   
 $-x + 2y = -4$   
 One of the students' solution is given below:  
 $2x - 4y = 8$   
 $2(-x + 2y) = 2(-4)$   
*We get  $0 = 0$ . Therefore, the solution set is the real numbers.*  
 Is the solution true or false? If it is false, what would you do in order to correct the misunderstanding of the student?

**Figure 2: The Item 6 in the questionnaire**

The answer provided by one of the participants (P<sub>34</sub>) was categorized as correct since the teacher stated that the solution set could not be real numbers and gave a suggestion on how to show it to the students.

P<sub>34</sub>: The solution set cannot be real numbers since the equations do not hold for each  $(x, y)$  when  $x$  and  $y$  are real numbers. Therefore, this could be shown to students by substituting some  $x$  and  $y$  values which are real numbers but do not satisfy the equations.

The answer of another participant (P<sub>32</sub>) was categorized as partially correct as it stated that the equation could not be solved.

P<sub>32</sub>: The solution is false. The solution set of the equation system should be in the form of  $(a, b)$ . It cannot be real numbers. Those are not two different equations. The first equation is double of the second equation. The two are the same equations. That is, it cannot be solved.

Some of the answers for the Item 6 were categorized as incorrect if the teachers stated that the solution was correct without any explanation or if they gave invalid/missing explanations. The Item 10 where the teachers were asked "Why the direction of the inequality sign is changed when both sides of the inequality  $-x < 7$  are divided by a negative number?" (see Figure 1) was also answered incorrectly by most of the teachers in this study (see Table 1). This item was related to the algebraic expressions, equations, and inequalities, basic concepts and procedures, knowledge about learning of students segments of the model. None of the teachers used algebraic expressions for the solution. Rather, the teachers mostly used particular values for  $x$  in order to show the change of the direction of sign when both sides were divided by a negative number. The answer of one of the participant (P<sub>35</sub>) is categorized as particularly correct since the teacher used particular values for the solution without making generalization.

P<sub>35</sub>: I would give particular values. For example, if we multiply or divide both sides of  $2 < 5$  with  $-1$ , the inequality will be  $-2 > -5$ . By considering the values of the numbers, we can see that the inequality sign should be changed when both sides are multiplied or divided by  $-1$ .

Also, the answer of one of the participants (P<sub>44</sub>) is categorized as incorrect since the teacher stated that it was just a rule to be memorized. In addition, the invalid/missing answers were also categorized as incorrect.

P<sub>44</sub>: I would say that it was a rule to be memorized. Thus, the inequality sign changes when both sides are divided by a negative number. Then, I would give examples with particular values.

## Discussion and conclusion

Results revealed that middle school mathematics teachers presented strength and weaknesses in terms of knowledge for teaching algebra. Most of the teachers in this study show indications of ability and knowledge to make transition among different representations of algebraic expressions. Moreover, most of them were successful at items which required knowledge about particular algebraic concepts such as the difference between an equation and (algebraic) identity or the properties of nonlinear functions. Although some studies concluded that the concept of equation and the concept of identity were frequently confused by pre-service middle school mathematics teachers (Altun, 2006; Güler, 2014), nearly all of the teachers in this study were able to differentiate between these concepts. It might be safe to say that, in general, teachers in this study performed well in items related to algebra content dimension and basic procedures and representations segment of the domains of mathematical knowledge dimension of the model (Güler, 2014).

Analyses of the answers illustrated that some of the teachers had errors and misconceptions similar to those of students, as also observed by Güler (2014). Moreover, most of the teachers presented not only signs of misconceptions beyond the ones given in the scenarios but also difficulties in explaining students' reasoning and proposing an appropriate teaching method in order to guide them in the right direction. One of the basic reasons for teachers' inadequacy to propose an appropriate teaching method might be the lack of knowledge of algebraic concepts. Since the teachers could not provide a valid explanation for students' thinking and reasoning in most cases, they could not provide a suggestion for the teaching of related algebraic concepts (Güler, 2014). In some of the items, teachers were required to give conceptual explanations for the algebraic situations. For example, regarding "How would you explain to your students why  $2^0$  is equal to 1?", only about half of the teachers were able to provide conceptually sound explanations why  $2^0$  is equal to 1. However, other teachers could not give a conceptual answer for that question or stated that " $2^0$  is equal to 1" is just a rule. This indicates that such lack of knowledge lead teachers to teach algebra as a collection of rules to be memorized. Another situation supporting this was Item 10 which required explaining why the direction of the inequality sign changes when both sides of the equation were divided by a negative number. There were nearly no conceptually based explanations provided by the teachers for it. Some of the teachers explained that they were just rules to be memorized like any other mathematical rules, like the multiplication of two negative numbers' being equal to a positive number. Conversely, some teachers explained it by showing that it holds for many different values. However, none of them provided an explanation by using and considering algebra as a tool for generalization (Bednarz, Kieran, & Lee, 1996). Thus, it might be concluded that the teachers in this study had lack of strong knowledge based on representation of the content segment of knowledge for teaching algebra dimension in general. Also, teachers had deficiencies related to the mathematical knowledge dimension of the model.

Results obtained in this study supports that middle school mathematics teachers might be incompetent about the conceptual bases of some algebraic concepts and in identifying and explaining students' errors and misconceptions in order to provide appropriate representations (Ball, 1990; Güler, 2014; Tirosh, 2000). Since teacher knowledge is considered as the first step to provide an effective teaching, it should be investigated and developed. As Cochran, DeRuiter, and King (1993) stated, teacher knowledge has a dynamic form and it develops continuously. Therefore, the results of the current study should simply be taken as a call for teacher educators to strengthen and develop teachers' conceptual knowledge of algebra and its teaching. In this context, for example, a balance should be sought between requiring several advanced mathematics/algebra courses and methods of teaching mathematics/algebra courses in mathematics teacher education programs in order to equip them with the knowledge and pedagogy needed to teach algebra effectively. Furthermore, courses and professional development efforts for learning to teach mathematics/algebra should focus on concepts and big ideas with an emphasis on why to use a particular procedure or why a certain idea/procedure works in some particular contexts.

On the other hand, as assessing in-service teachers' knowledge for teaching (algebra) would require a more carefully constructed instrument and research design, the questionnaire used in this study itself and limiting the research design to survey type might be considered as methodological limitations of this study. Even though the purpose was to collect data from as many teachers as possible, further studies should at least consider collecting data through interviews (with selected participants at least) and require more elaboration on the answers given in the questionnaire and conducting classroom observations when possible. Furthermore, as much as it is challenging, more studies should focus on developing instruments for assessing teachers' knowledge for teaching algebra.

*Similar to countries such as the U.K. and the U.S.A, the Irish education system is divided into four key stages; pre-school education, primary level education, second level education and tertiary education. Transition between each of these phases has its own set of challenges but many believe the most challenging of all is the transition from primary to second level education. This quantitative, national study investigates the transition from primary to second level mathematics education from the perspective of teachers. It investigates sixth class teachers' knowledge of the mathematics curriculum and teaching strategies employed at second level and first year mathematics teachers' knowledge of the mathematics curriculum and teaching strategies favored in primary school. The results of the study highlight low levels of knowledge in these domains amongst both sixth class and first year mathematics teachers. The ramifications of this gap in teacher knowledge are also discussed in detail.*

*Keywords: Primary school mathematics education, second-level mathematics education, transition, teacher knowledge, continuity.*

### Background to the study

As is the case in Australia, the United States and the United Kingdom, Ireland's education system is divided into four phases; pre-school education, primary level education, second level education and tertiary education. The transition from primary mathematics education to second level mathematics education is one of the greatest challenges that young people experience during their school years. According to Bicknell, Burgess and Hunter (2009) the challenge presented by this transition is multifaceted and involves challenges from social, academic and systematic perspectives. As such, this is a pertinent research area and one which has been looked at in depth in recent years.

The overarching finding to emerge from the research carried out to date was that the transition from primary to second level mathematics education resulted in a decline in students' attitudes, academic performance and confidence (Attard, 2010; Economic and Social Research Institute [ESRI], 2007). Furthermore, Bicknell et al. (2009) found that the gap between high achieving and low achieving students widened significantly during this transition period. Due to the serious nature of these consequences, researchers, such as Green (1997) and Attard (2010), have sought to investigate what constitutes effective transition and what are the main factors that contribute to an educationally poor transition for students.

In her study on students' experiences of the transition from primary to second level mathematics education in Australia, Attard (2010) listed curriculum, pedagogy, assessment strategies, social interactions and students' relationships with others, as key factors that dictate the success of transition. Likewise, Barber (1999) describes the transition as a set of five hurdles all of which must

be overcome at once. The hurdles to be overcome to ensure a smooth transition, as listed in this study, are bureaucratic, social and emotional, curriculum, pedagogy, and management of learning. In addition to this, Evangelou et al. (2008, p. 2) stated that a successful transition for children entailed:

...developing new friendships and improving their self-esteem and confidence; having settled so well in school life that they caused no concerns to their parents; showing an increasing interest in school and school work; getting used to their new routines and school organisation with great ease [and] experiencing curriculum continuity.

All research conducted into what constitutes effective transition make some reference to curriculum and pedagogical continuity. Likewise, research conducted in the area of problematic transitions all point to a lack of continuity in this regard. For example, Elkins (1989), Green (1997) and Tilleczek (2007) all found that the attainment and motivational losses that students often experience when moving from primary to second level mathematics education can, in no small way, be attributed to a lack of continuity in terms of both curriculum and pedagogical approaches.

However, in order to ensure continuity between both curriculum and pedagogical approaches it is critical that teachers who are teaching students that are about to enter or have just completed the transition process have an in-depth Mathematical Knowledge for Teaching (MKT). Such knowledge encompasses knowledge of the mathematical content previously studied and that which they will study in subsequent years (Ball, Thames & Phelps, 2008). Ernest (1989) reiterates that a teacher's MKT is not limited to knowledge of curriculum, but also knowledge of students, in order to enable them to teach mathematics effectively. The authors further ascertain that teachers, especially those involved in the transition process, must have a comprehensive MKT comprising of the curricula, students and teaching methodologies utilised before and after the transition process. Teachers who do not possess such knowledge have yet to develop the full range of knowledge domains proposed by both Ball, Thames & Phelps (2008) and Ernest (1989) and as such, their knowledge could be considered inadequate for teaching. It is this belief, in conjunction with existing research, which led the authors to investigate the following research questions.

1. How familiar are sixth class primary school teachers with the second level mathematics syllabus and the teaching methodologies being promoted at second level and vice versa?
2. What are the consequences of these levels of MKT in terms of (a) the fluidity of the transition between primary and secondary mathematics education and (b) the teaching approach adopted by second level teachers when teaching mathematics to first year students?

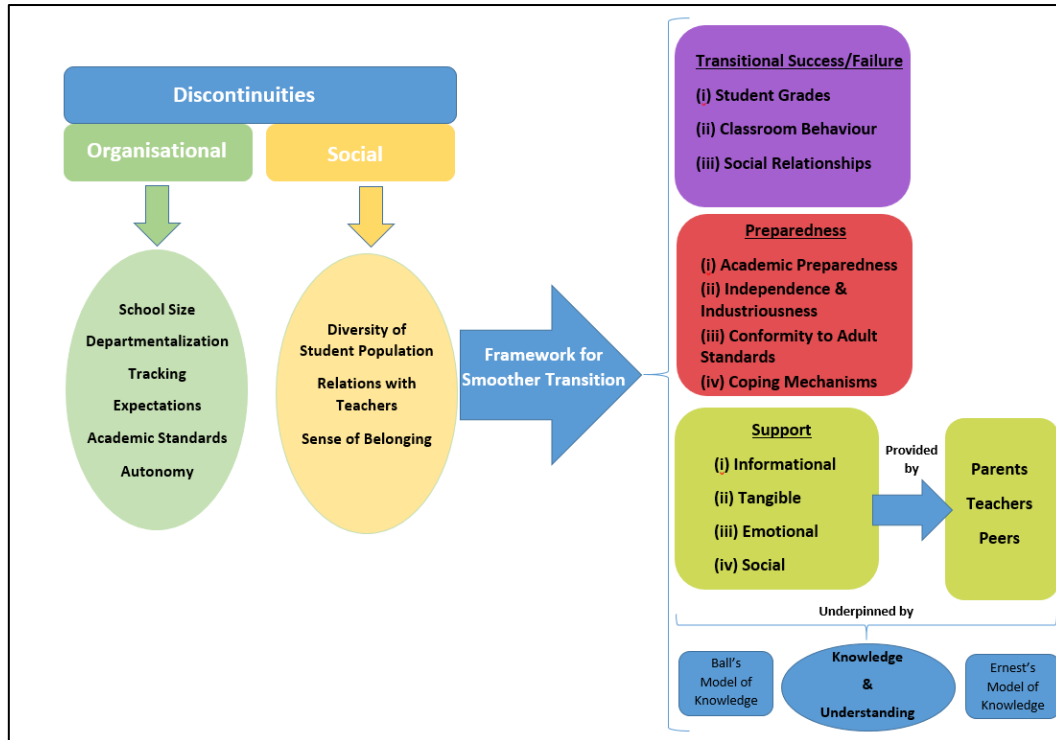

## Methodology

The research design for this quantitative study involved the distribution of questionnaires to a representative sample of two groups of stakeholders involved in the transition process; namely sixth class teachers in primary schools and first year mathematics teachers in second level schools<sup>1</sup>. For the purpose of the study two advisory groups, one involving primary teachers and another involving second level mathematics teachers, were established. Their role was to help with the development

---

<sup>1</sup> In Ireland 6<sup>th</sup> class is the final year of primary education which 1<sup>st</sup> year is the name given to the first year of second level education.

and piloting of the questionnaires and to help the authors in relation to sampling issues. To allow for comparison of responses from primary and second level teachers the questionnaires were of a similar nature and both were based on the framework for transition developed by the authors from the work of Anderson, Jacobs, Schramm and Splittgerber (2000) and the models of knowledge proposed for primary teachers by Ball, Thames & Phelps (2008) and for second level teachers by Ernest (1989). This theoretical framework is outlined in Figure 1.

**Figure 1: Theoretical framework**

This study was unique in that it looked solely at the issue from the perspective of teachers. As such, only some dimensions of this model were relevant to this study namely the discontinuity pillar, the support pillar and the teacher knowledge pillar. This particular paper has an even narrower focus and looks solely at the pillar of teacher knowledge.

The sampling frame for this study was a list of all 3,300 primary schools and 723 second level schools in Ireland (DES website February 2016). The targeted sample was 700 sixth class teachers and 400 first year mathematics teachers. By consulting the primary school advisory groups, the authors established that on average, there is one sixth class teacher in each primary school in Ireland. As a result, a simple random sample of 700 primary schools was selected. Overall, the sample included 21.2% of all primary schools. Having consulted with the second level advisory group it was established that on average, there are two mathematics teachers teaching first year mathematics in each school in Ireland. Hence using this estimate, a stratified random sample of 200 second level schools around Ireland was selected. This sampling technique ensured that an accurate representation of each type of school (secondary, vocational, community and comprehensive) in Ireland was included in the sample. Overall, the sample included 27.7% of all second level schools in Ireland.

The questionnaires were distributed to the 700 primary schools and 200 second level schools in April 2015. The primary school questionnaires were sent to the principal of each school and they were

asked to distribute these questionnaires to the sixth class teacher. The pack sent to each of the 700 principals included an information sheet for the principal, a teacher information sheet along with the questionnaire and a stamped address enveloped for the questionnaire to be returned in. The second level questionnaires were sent to the Head of Mathematics in each of the 200 second level schools and they were asked to distribute the questionnaires to the first year mathematics teachers in their school. The pack sent to each department head included an information sheet for their perusal, an information sheet for first year mathematics teachers along with two questionnaires and two stamped address envelopes in which the questionnaires could be returned. At both primary and second level, each stamped addressed envelope included was given a number corresponding to the school selected so the researchers could identify the schools that had not returned the completed questionnaires. Two weeks after sending the questionnaires, follow-up telephone calls to each of these schools were undertaken with the aim to increase the response rate.

Upon receipt of the completed questionnaires the quantitative data was inputted and saved into the computer programme SPSS. Descriptive analysis examined primary teachers' knowledge of the mathematics curriculum and teaching strategies employed in secondary school and second level mathematics teachers' knowledge of the mathematics curriculum and teaching strategies employed at primary level. Descriptive analysis also allowed the authors to determine how these levels of knowledge affected the approach adopted by second level teachers when teaching first year students and also to determine if the transition from primary to secondary was educationally successful from the teachers' perspective. The authors will now present the results of this analysis in an attempt to address the aforementioned research questions.

## Findings

Based on the population size it was determined that, to allow for a 5% margin of error, the study would require 263 responses from sixth class teachers and 133 responses from first year mathematics teachers. The actual response rate was 296 primary school teachers (approx. 42%) and 171 second level teachers (approx. 43%). The primary teachers who responded were distributed across 271 schools (38.7% of schools surveyed) while the second level teachers who responded were distributed across 101 schools (50.5% of schools surveyed).

The first research question sought to ascertain sixth class teachers' knowledge of the first year mathematics curricula and the teaching strategies employed by first year mathematics teachers as well as first year teachers' knowledge of the sixth class curriculum and the teaching strategies adopted by sixth class teachers. The findings related to this research question are presented in Figure 2 and Figure 3.

**Figure 2: Primary teachers' responses when asked (a) *How familiar are you with the first year mathematics syllabus?* and (b) *How familiar are you with the recommended teaching methods for first year mathematics?***

**Figure 3: Second Level teachers' responses when asked (a) *How familiar are you with the sixth class mathematics syllabus?* and (b) *How familiar are you with the recommended teaching methods for sixth class mathematics?***

These findings demonstrate that teachers, at both levels, have a deficient understanding of the syllabus and teaching strategies that their students were/will be exposed to in their previous/next year of schooling. Over half of sixth class teachers (56%) reported that the first year mathematics syllabus was either highly unfamiliar or slightly unfamiliar to them. The corresponding figure for second level teachers was 49%. The responses in relation to knowledge of teaching strategies were even more pronounced. Almost three-quarters of sixth class teachers (73%) stated that they were highly unfamiliar or slightly unfamiliar with the teaching approaches used in mathematics classrooms at second level. Likewise, 77% of first year mathematics teachers stated that they were highly unfamiliar or slightly unfamiliar with the pedagogical approaches employed by sixth class teachers. Furthermore, only 13% of sixth class teachers claimed to be in any way familiar with the teaching approaches used by first year mathematics teachers while the corresponding figure for the first year teachers who responded was 15%.

The second research question was two-folded and sought to analyse the knock on effect of the gaps in teacher knowledge discussed previously. In order to address this research question both groups of teachers were first asked to rate their agreement with the statement “*There is a fluid transition*

between primary and secondary mathematics”. The second level teachers were then further probed on these knock on effects when they were asked to describe the approach they adopt when teaching first year mathematics students upon their entry to second level. For this, they were asked to pick from a pre-determined list of four options, which included “Other”. The responses received are provided in Figure 4 and Figure 5.

**Figure 4: Teachers’ responses when asked their level of agreement with the statement “There is a fluid transition between the primary and secondary school mathematics curricula.”**

**Figure 5: Second level teachers’ responses when asked which of the 4 strategies outlined best describe their approach to teaching first year mathematics**

Figure 4 shows that a large proportion of both groups of teachers believe that the transition from primary school mathematics to second level mathematics is not smooth. For example, 44.6% of sixth class teachers believe this to be the case compared with 44.4% of first year mathematics teachers. Only one teacher in both groups strongly agreed that there was a fluid transition between primary school mathematics and second level mathematics with a further 34 in each group agreeing with the sentiment. The lack of fluidity or continuity is elaborated upon further when secondary teachers were

asked to describe the approach that they adopt when teaching first year mathematics students. Of the 168 teachers who responded to this question 67.9% stated that they “See it as an opportunity for a fresh start and initially assume as little as possible about student knowledge or ability”. Despite mechanisms, such as the Education Passport<sup>2</sup> being introduced in recent years, this study shows that teachers, most probably due to their own lack of knowledge of the primary school curriculum, continue to adopt a “fresh start” approach. This will undoubtedly lead to a disjointed and fractured transition from primary to secondary mathematics education.

## Discussion and conclusion

“If a teacher is largely ignorant or uninformed he can do much harm” (Conant, 1963: 93)

This research study has demonstrated that sixth class teachers have gaps in their knowledge in relation to the syllabus and pedagogical approaches being adopted at second level while the same can also be said about second level mathematics teachers in relation to the primary school mathematics syllabus and favoured pedagogical approaches. Teachers in both of these sectors do not have the full repertoire of knowledge prescribed by Ball, Thames & Phelps (2008) and Ernest (1989). As Conant (1963) points out, such gaps can be detrimental to students’ progress and prove a hindrance in their academic progression. This gap in teacher knowledge can prevent teachers from adequately preparing students for the transition process or providing them with a sense of continuity when they make the transition. For example, in a study carried out by Bicknell et al. (2009) teachers expressed concerns that gaps in their own knowledge meant that they were not equipped to prepare students for the mathematics they would face at second level. Likewise, students in a study carried out by Green (1997) reported that the lack of continuity between primary and second level mathematics education, which stemmed from the lack of understanding of the mathematics syllabi and teaching strategies being employed in the years either side of the transition on the part of teachers, meant that they did not face new challenges on entry to second level and as a result their motivation and attitudes declined. Hence, internationally it has been shown that these gaps in teacher knowledge can play a role in the declining attainment levels and attitudes of students during the transition. As a result, it is critical that steps are taken to improve teachers’ knowledge in this regard in order to improve students’ experience of transition.

In addition to the ramifications already discussed in international literature, this study found that the knowledge levels reported by teachers had other consequences, namely the lack of fluidity in transition and the approach adopted by teachers when students enter first year. The lack of fluidity in transition reported by teachers in this study is unsurprising, as without an in-depth understanding of the previous or subsequent syllabi and teaching approaches it is difficult for teachers to ensure curriculum or pedagogical continuity. Such continuity is critical in order to allow for a educationally successful or fluid transition from primary to second level mathematics education (Evangelou et al., 2008). Teachers who do not possess the knowledge domains outlined in the work of Ball, Thames & Phelps (2008) and Ernest (1989) struggle to provide curriculum and pedagogical continuity and are

---

<sup>2</sup> The Education Passport was an initiative introduced in 2014. It requires primary schools to pass documentation onto second level schools which details a rounded picture of the child’s progress and achievement at primary school as well as signalling to second level schools what support a child may need. The overall purpose of the Education Passport is to help the child progress and experience continuity as they move from primary education to second level education.

forced to adopt a “fresh approach” with their first year students. This is the only option available to teachers who are not informed about the syllabus and/or pedagogical practices that students were exposed to in their previous year of schooling. It is not surprising that this deficiency in the area of MKT among teachers has resulted in pedagogical approaches that are not well received by students, and thus lead to boredom, lack of motivation and a consequential decline in students’ attainment levels (Bicknell et al, 2009). Due to such concerns, the authors believe it is of paramount importance that teachers are given the opportunity to develop knowledge of the sixth class and first year mathematics syllabi; of students in both these years; and of the teaching strategies in place across both levels. Only when such opportunities are available will teachers be in a position to develop the range of knowledge domains required for teaching and the hurdle of discontinuity will be overcome.

*This paper discusses a primary prospective teacher analysis of practice from a video episode she selected from her own practice – aimed at exploring the use of non-standard length measurement units. The analysis focuses on the revealed knowledge (MKT) while in practice, on the reflection when justifying the choice of the episode, and on her analysis of such episode. The results reveal aspects of PT knowledge associated with anticipating students' difficulties, but also her difficulties in interpreting and give meaning to student use of non-standard measurement units in a non-standard way. From the analysis, the need for an improvement in the use of video-based tasks in teachers' education is discussed, as well as the importance and impact of analyzing and discussing the analysis made by PT in and for educators' professional development.*

*Keywords: Mathematic teachers' knowledge, measurement, video analysis.*

## Introduction

Mathematics teachers' knowledge and professional development has acquired an important relevance for research, enhancing its complexity. Particularly, the research focusing on mathematics prospective teachers' (PTs) education brings to the fore the role and importance of the relationships between teachers' mathematical knowledge and their knowledge of the content and students (e.g., Ball, Thames, & Phelps, 2008). Following such focuses, new trends (conceptualization and implementation of interventions) for accessing, understanding, and developing teachers' and PTs knowledge are being developed (e.g., Ribeiro, Mellone, & Jakobsen, 2013; Santagata & Bray, 2015; Sherin, Linsenmeier, & van Es, 2009).

More recently, analyzing video episodes has been both a focus of attention and a source for teacher education (e.g., Llinares & Valls, 2010; Sherin & van Es, 2002). In that sense, the reflection and discussion upon one's own practice through video analysis is perceived as a powerful path for the development of a teacher's knowledge and awareness—focusing essentially on the mathematically critical features, both for teachers and students (e.g., mathematical content, competencies, interactions). One such critical aspect for students concerns measurement (e.g., Sarama, Clements, Barrett, Van Dine, & McDonel, 2011), particularly with regard to length. Considering the core role of teacher knowledge in student learning a focus on such knowledge is essential to better understand students' difficulties.

This paper aims at contributing to a broader and deeper understanding of the hows and whys sustaining the intertwining of teachers' knowledge (in the sense of Mathematical Knowledge for Teaching—MKT; Ball et al., 2008) and professional competency of noticing (in Mason's 2002 sense). Therefore, the research question in this study is what kind of knowledge is mobilized by the teacher when analyzing students' interactions with the mathematical content in a videotaped episode

of measurement. For doing so, a video clip of a primary PT practice on length measurement is discussed, as well as her analysis of such video. The results reveal powerful trends concerning both the video analysis process as well as PT knowledge concerning length measurement.

### **Theoretical framework**

As in other mathematical topics (e.g., adding or dividing fractions), the understanding of the mathematical whys of the measurement process is not straightforward, the understanding of such process being much more complex than the process itself. Piaget (1972) mentions that acquiring the notion of magnitude requires going through different stages, from the use of words to express the magnitude (correctly) until one has the knowledge about the measurement of such magnitude. Going through such stages is not a straightforward path, and developing a broader and deeper understanding of the concept image and definition involved (in the sense of Tall, 1988) is a core aspect of such development.

Two aspects in measuring a length are crucial: the dimension and the distance. The dimension is connected with the use of physical resources, and the distance concerns the space between two points/objects. Although both notions are perceived in an intertwined and inseparable way, due to its nature, one can't approach them in a single identical manner with students (Clements & Stephan, 2004). Such a measuring process requires the choice of the unit to use and perceive the quantity of units (or unit parts) are needed (how many) to go from one point to the other. Ultimately, one would need to combine both processes in order to get a more approximated value for the considered magnitude. In that sense, measuring is linked with two core ideas: the inverse relationship between the size of the unit used/number of units needed and the need for using the same unit in the same process of measuring (e.g., Clements & Stephan, 2004), applying it using a certain algorithm. Measuring the length thus requires knowing the standard measure(s) used, as well as the differences from using different measurement units (e.g., hands, foot, fingers) and the possibility of using these non-standard measurement units in a non-standard way.

Teachers' MKT on measurement is essential for developing students' knowledge and awareness of the topic. Among the MKT subdomains, and due to the aim and context of the work reported here, we consider for discussion the Common and Specialized Content Knowledge (CCK and SCK) and the Knowledge of Content and Students (KCS) subdomains. For doing so, examples linked with length measurement are used. The Common Content Knowledge (CCK) is associated with the mathematical knowledge required by teachers, including being able to use the instruments to correctly perform a certain measurement, knowing that no empty space must be left, as well as that there shouldn't also exist any overlays (instrumental knowledge). In doing so, knowing what instruments to use (in the sense of standard instruments/measurement) for measuring different entities and the differences between the entities they measure is involved. It corresponds to knowledge of how to perform, assuming a user's perspective (knowing how to measure). Complementary to this CCK, following the MKT conceptualization, teachers are required to be in possession of mathematical knowledge specifically linked with the tasks of teaching (Ball et al., 2008). Such Specialized Content Knowledge (SCK) includes knowing the mathematical whys justifying the different measuring processes (considering all the stages mentioned by Piaget, 1972). In addition to requiring knowledge of the different ways of measuring different entities, from one side, teachers' knowledge should also include knowing the whys of using such different forms of measuring (and the associated units).

Complementarily, it should include knowing possible different units for measuring the same entity and the ways of doing so (e.g., length), as well as the whys associated with the use of (non)standard units. In that sense, such knowledge does not include only knowing the whys associated with the procedures, but also includes the concepts (both image and definition in Tall's 1988 sense) and the whys associated with such concepts (e.g., the inverse relationship between the size of the unit and the number of iterations needed). Thus, it corresponds to a core aspect of the knowledge that allows teachers to give meaning and interpret students' solutions and comments (part of the interpretative knowledge, e.g., Ribeiro et al., 2013) while in practice.

Both CCK and SCK (and HCK, although it is not discussed here) give support for teachers' developing their practice—conceptualizing and implementing the tasks, hearing students' comments, and interpreting them in order to decide the path to follow at each moment. Those decisions are also informed by the knowledge teachers have of their students' difficulties or what they consider easier.

Intertwining knowledge of the content and knowledge of the students' learning processes concerns the KCS. It includes knowing that one of students' difficulties concern the measuring process (e.g., the need for using units with different natures), which is related to the complexity of understanding the measuring process (e.g., Clement & Stephan, 2004). In such subdomain of knowledge, one can also include the knowledge allowing teachers to anticipate students difficulties in differentiating the measurement instrument (non-standard unit, e.g., the hand) and the measuring unit, or on ways of using non-standard measuring units (e.g., using the finger length or width).

Recent research has shown the need for designing instruments/resources for teacher education allowing them (and the researcher) to characterize the knowledge in action when analyzing their own practice (e.g., Kersting, Givvin, Sotelo, & Stigler, 2010). One such resource is video analysis (of classroom episodes), which allows a focus on how and which knowledge (prospective) teachers bring to front when interpreting, analyzing, and reflecting upon the recorded interactions (e.g., Kersting et al., 2010; Van Es & Sherin 2002). When focusing on selecting and characterizing a video episode, Sherin et al. (2009) consider three dimensions: (i) window, (ii) depth and (iii) clarity. In the particular case we address here, focusing on length, windows dimension is related to evidences of students' different levels of comprehension of the measurement of length; depth dimension is related to evidences of interactions in which students participate in the decision making process about choosing the measuring unit, the instruments and the measurement procedure and clarity is related to evidence of student's arguments that transparently show their comprehension of measurement of length.

Reflecting upon what seems to be happening, and discussing grounded on the analysis elaborated, is perceived as a pathway for developing teachers' knowledge and professional noticing (Sherin et al. 2009). Such professional noticing includes identifying what is important in a teaching situation, using what one knows about the context to reason about a situation, and making connections between specific events and broader principles of teaching and learning (Van Es & Sherin, 2002). Such noticing is thus linked with the ability for examining practice pinpointing the significant aspects in order to be better informed at the time of making their pedagogical decisions.

### **The context of the study**

Aiming at identifying and deepening the understanding of the content of teacher knowledge and how it intertwines with teacher actions and beliefs several case studies have been developed – in different

contexts and involving different school levels, mathematical topics, and competencies, contributing also to conceptualizing tasks of different natures focusing on developing teachers' knowledge (e.g., Ribeiro et al., 2013).

## Method

We first present the participant of this study, and afterward, the specific context and analysis stages and process. Here we focus on the knowledge and awareness about the topic of length measurement of a primary PT (Carla), who was part of a bigger research project in which her professional development through video analysis and reflection was the aim. Carla was in the last year of the teachers' training program at University Autònoma of Barcelona, and she was teaching the field practice to grade 2. Previously, she had some training concerning classroom analysis, identifying and interpreting relevant events in a video from a novice teacher. As part of the field practice, PTs have to record the 10 classes they teach (one hour each) and choose one episode to analyze and reflect upon – which has to be transcribed. The selection of the episode needs to be justified, mentioning the whys associated with its mathematical richness and referring explicitly to the mathematical goal pursued. For selecting and analyzing such an episode, Sherin et al.'s (2009) criteria (windows, depth and clarity) should be used (which have been previously explored with the PTs). Therefore, the analysis should focus on the mathematical content approached, student-teacher interaction, and students' understanding.

For selecting the episodes, PTs' were advised to look for situations they perceived as involving a "high level" of students mathematical knowledge and discussions/argumentations. Carla's choice was an episode aimed at introducing "the measurement of the length and width of objects using non-standard units" (e.g., the length of the classroom using the foot; the length of a glue package using the finger). An example of the proposed tasks is: using an unconventional length measure (finger), determine the length of the glue package. Although Carla chose a 15 minutes long video associated with the goal "review the content," she only considered it important to analyze and reflect upon the last six minutes – sustaining such choice on her perceived richness, in terms of Sherin et al.'s criteria (2009). In the video, one can perceive how the students assign the corresponding number (amount of units) to the length or width of the objects as a result of comparing such amount with the unitary measurement they consider as a reference. In the discussion, the inverse relationship between the length to be measured and the unit used is also explored. Complementary to the video and Carla's analysis, Carla (as all the other PT) were also asked to justify (in a written form) their actions in the video they selected.

The analyses were made in different stages and each of them followed the same structure. First, each researcher focused on the divergent aspects, then there was a joint discussion focusing on them. Such joint discussions contributed to a refinement of the analysis and increased the researchers' own mathematical awareness and "interpretative knowledge." Here we expand the notion attributed to this expression by Ribeiro et al. (2013) by including the researcher's ability to read, hear, and understand the interactions and knowledge in action. The first stage focused on analyzing Carla's revealed knowledge in the part of the video she considered important to analyze and reflect upon—the last six minutes. In the second stage, the focus of attention was Carla's analysis of her own practice using the same criteria PTs use for doing the analysis (Sherin et al.'s 2009 criteria). The third stage focused on the mathematical aspects associated with what happened in the first part of the video—which Carla

chose not to include in her analysis—and the possible whys concerning her knowledge and awareness leading to such choice.

### Analysis and discussion

When analyzing Carla's practice (the 15' video) with a focus on the CCK, SCK, and KCS, different aspects of her revealed knowledge are identified that sustain her awareness and professional competency of noticing. She reveals knowing the importance of measuring with different non-standard units (CCK), leading to the inverse relationship between the number of units and the size of such units (CCK):

Carla: *I gave an example, showing to the students that is not the same measuring with bigger or smaller hands, so I put my hand in the sheet they had to measure and asked a student to put his hand next to mine, to compare the different measures of both hands, telling them: "Do you see that his hand is smaller? Then my measure will be smaller than his".*

Also, the students' difficulties in measuring without leaving empty spaces between units is anticipated (KCS) when interacting with students:

Carla: *Of course, another thing is how we put our hands. If some of you put them like this (partially opened) and some of you put them as Isaac did (completely opened), Isaac will get less . . . But it doesn't mean that it is wrong; it simply indicates that we have different hands and we have measured differently.*

However, we can see a potential conflict identifying the unit of measurement, arising at least four different possible unit combinations: kin's and teacher's hand, both in a close or open position. In spite of Carla's ability to identify the previous situation as an interesting topic to be discussed in the class (noticing), it is noteworthy that there is a lack of awareness of the necessity of exhaustiveness when re-covering the measurable object (Clements & Stephan, 2004).

While teaching, Carla indistinctly uses dimension and distance—the two aspects of length (Dickson, Brown, & Gibson, 1991)—revealing aspects of the content of teachers' knowledge that need to be a specific focus of attention in training. Such knowledge would sustain the conceptualization and implementation of tasks aimed explicitly at exploring both concepts and their complexity. Not overcoming such difficulties, and thereby enriching teachers' SCK on measurement, would contribute to a low level of professional competence of noticing, particularly concerning the students' difficulties in distinguishing perimeter and area (and volume)—KCS.

Focusing on her analysis of the students' reasoning (only the last six minutes of the video), the fact that she can differentiate various aspects of understanding from different students reveals Carla's (advanced) level of professional competency of noticing according to Sherin et al.'s (2009) criteria. Such can be linked with her KCS as well as her interpretative knowledge (Ribeiro et al., 2013). In that sense, she takes into consideration (CCK and SCK) the dimension, the absence of empty spaces between the use of the measurement units, the use of anthropomorphic units, and the inverse relationship between the size of the unit and the number of iterations – on the written justification Carla wrote: *Hugo and Daniel notice that the different results of the measurement depends on the size of the hands; Miguel, on the other hand, concludes that the result depends on the ways the hands are placed).*

When justifying the choice of the episode to analyze, Carla's reflection reveals an awareness of the relationship between the SCK on the content, her decisions, and her ability to anticipate the students' difficulties and understanding of the topic (KCS).

*Carla: I chose this particular part of the class because it reveals the moment when the pupils become aware that when measuring with non-standard instruments and units, they get different results... Through the students' reflection and reasoning, they get that the size of the hands matter when measuring the length (thus getting different results) and that not only the size of the hand matters, but also the ways one uses it. I also have to note that after the mentioned reasoning emerged from students, I registered the different values on the blackboard, and I could then use it to explain to the whole class. During this period, I also use different teaching strategies, including the registration on the board (with the number and the unit used), giving time for students to present their results, and promoting reflection concerning the measurement technique used, supported by visual examples, as they could have difficulties in the content concerning both the measuring process and finding the relationship between length and units used.*

However, in the remainder time of the episode Carla didn't chose to analyze (the first nine minutes), something curious and mathematically important happened. Analyzing it can shed some light on teacher decisions and associated specialized knowledge as well as concerning the need for a change in Sherin et al.'s (2009) criteria for selecting and analyzing the video episodes.

During the first part of the episode, one student (Miguel) provides a completely different answer to the posed questions (e.g., length of the class in steps, when the rest of the class provided answers around 30, his answer was 14). Carla interpreted it as a misunderstanding of the measurement process, showing him in each case "how to do it correctly." But the consistency of Miguel's answers reveals a high level of understanding (concept image and definition, Tall, 1988) of measurement (Clements & Stephan, 2004), using non-standard units. When Carla discussed the question "How many fingers are needed to measure the glue package?" Miguel again disagrees with the other students and with Carla's validation of a length of eight fingers. With the glue package on the top of the table, on the vertical, the following dialogue occurs:

Teacher: *No? How many fingers did you get?*

Miguel (putting the finger vertically along the glue package): *One!*

Teacher: *One? Like this? (The teacher repeats the measurement process using the indicator finger horizontally)*

Miguel: *No, two...*

Teacher: *Two? With two you can cover all the distance?*

Miguel: *No...ah...four...*

Teacher: *Don't know what you are measuring...*

Miguel: *Ah, four, four...*

Teacher: *No! It can't be...you should get eight, you are doing it wrong.*

Although the goal of the class was “*to use non-standard length measures,*” such measures have been used and explored by Carla only in a standard way (the one with which she was used to – taking into consideration the cultural aspects). Such exclusive use, linked with the content of SCK, makes it difficult to anticipate and understand (KCS) Miguel’s answers—use of non-standard measurement units in a non-standard way. The fact that when reflecting upon her practice and analyzing the video she did not point to this aspect as problematic sustains the need for a change in the way the video analysis task has been conceptualized. And, in an intertwined way, makes us wonder about Sherin et al.’s (2009) criteria for professional competency, as when focusing only on her own analysis (of the last six minutes), Carla could have been considered to have an advanced level of such competence; when looking at the part of the video she did not analyze, a different conclusion could be drawn. In that sense, there is also evidence of the interdependent nature of such competence and teachers’ knowledge.

Carla seems to not be aware of the inexplicit use of a one-dimensional measurement unit on a three-dimensional object, leading thus to some contingency moments. To overcome such moments, she opted (grounded in her own revealed knowledge of measurement) to tell the student “how to do it”. Although aspects of professional awareness and competencies of noticing are present both in her practice and in her analysis of the video, her knowledge shaped such aspect, leading to a partial view of the students’ understanding of the measurement length and units. This supports the need for a complementary discussion and reflection upon the video analyses PTs make in order to focus also on the mathematically critical aspects they are not aware of, and which are a barrier to completely achieving the advanced level of professional competency of noticing expected when using Sherin et al.’s (2009) criteria.

## Final comments

From the work focusing on the video analysis, three aspects can be enhanced: teachers’ knowledge and professional noticing abilities; reflection and awareness capabilities; video-based task design and its potentialities. Although of different natures, these aspects have in common the educator’s responsibility in changing the training process. Through this case study, one can better understand aspects of the content of the different subdomains of MKT, both revealed in practice as well as expressed when reflecting upon such practice when analyzing the video. Other aspects concern the impact of the interactions and the prevalence of non-standard length measurements in standard ways, and that revisiting the practice didn’t become a prompt for awareness and noticing development, obviously linked with previous experiences and MKT. This calls our attention to the need for an exterior element to pinpoint these critical features, leading them to become a starting point for developing such knowledge and awareness.

Although the video analysis performed by Carla with the provided instrument did not accomplish completely the defined aim, our analysis of her practice and of her own analysis of the video was a prompt for inquiring our own practice as educators in terms of interpretative knowledge (Ribeiro et al., 2013) and of awareness of the educators professional noticing abilities. One future research path concerns thus the develop of a complementary instrument for video analysis that would allow trainees

to dig deeper into their awareness of the mathematical whys sustaining what happens and to focus also on the educators specialized knowledge, awareness and noticing abilities.

# Investigating Lesson Study as a practice-based approach to study the development of mathematics teachers' professional practice

Anita Tyskerud, Janne Fauskanger, Reidar Mosvold, & Raymond Bjuland

University of Stavanger, Faculty of Arts and Education, Norway; [anita.tyskerud@uis.no](mailto:anita.tyskerud@uis.no)

*The study, whose methodological approach is the focus of attention in this paper, is a qualitative, single longitudinal case study. The object of study is Lesson Study (LS), and the unit of analysis is two LS cycles. What teachers learn about teaching practice and student learning in mathematics from participating in the two cycles is investigated. LS and teaching practice are in the study regarded as object-oriented activities. It is claimed that indications of what the teachers learn during LS processes can be uncovered by the use of discourse analysis because learning is considered as a change in discourse.*

*Keywords: Lesson Study, mathematics teachers, professional development, teaching practice.*

## Introduction

Recent studies have focused on the potential of practice-based approaches for developing mathematics teachers' knowledge and practice. In this paper, we investigate a methodological approach to study how Lesson Study (hereafter LS) as a particular practice-based approach to professional development can contribute to teachers' development (Thames & Van Zoest, 2013). In Japan, LS has been used for professional development of teachers for more than a century (Ronda, 2013). Since Stigler and Hiebert (1999) wrote "The Teaching Gap", researchers from other countries have become interested in LS as a structured approach to teachers' professional development (e.g., Fernandez, 2002). In Norway, the Ministry of Education and Research calls for more school-development projects, and LS is mentioned specifically in a recent strategy document (KD, 2014).

Cohen, Raudenbush and Ball (2003) suggest that teaching can be regarded as instructional interactions among teachers and students around a certain content. Increased student learning thereby requires a change in these instructional interactions. Thames and Van Zoest (2013) call for research to focus more directly on these instructional dynamics. We suggest that LS provides a great venue for studying the development of teachers' interactions about teaching practice and student learning.

We focus on issues related to research design and methods in a project where LS is used to study indications of what the teachers learn during LS processes. To frame this discussion, the paper presents an ongoing research project in a Norwegian lower secondary school, where teachers learn and develop their professional practice from participating in two LS cycles. The aim is to highlight and discuss some methodological issues that occur when coordinating two sociocultural theories in a study of teachers' learning about their own practice and student learning. Although this is a theoretical rather than an empirical paper – some would suggest that it sits at the border in between – we provide a brief empirical example from the study to illuminate our approach.

## Context of the study

A group of mathematics teachers is observed in two LS cycles with an overall focus on what the teachers learn about their own teaching practice and student learning from participating in these two cycles. A sociocultural stance is used to investigate teachers' learning and to understand the

participants' perspectives and interactions in the LS group. Knowledge is regarded as shared and collective rather than individual and develops through social negotiation (Radford, 2008). The role of verbal interaction in the learning process is essential, because new knowledge is considered to develop through talk in social interaction (Dudley, 2013). The theoretical and analytical frameworks used in this study coordinate two sociocultural theories: activity theory (Leontiev, 1978) and the commognitive theory (Sfard, 2008). Research on human development and learning thus becomes the study of development of discourse.

Tabach and Nachlieli (2016) propose a combination of activity theory with communicational theories to study mathematics teaching, and our coordinated theoretical framework adheres to this proposal. Activity theory is used as a grand theory, and LS and teaching practice are seen as activities in the way Leontiev (1978) thought of activity. To Leontiev, all human activities are oriented towards an object with a certain motive. The activities consist of three components at dynamic levels: object-motive, actions-goals and operations. In coordination with this theoretical perspective, and to identify what the teachers have learned on a discourse level, the commognitive theory (Sfard, 2008) is used as a local theory. This theory defines learning in terms of discourse, and it presents certain characteristics of a mathematical discourse: word use, visual mediators, routines and endorsed narratives. In this study, the development of teachers' mathematical discourse about teaching practice and student learning in the goal-oriented actions and operations in the LS activity is studied.

The main data sources for the ongoing research project are video-recorded observations from two LS cycles and focus group interviews (FGI). One LS cycle lasts about three months. The two cycles took place in spring (first cycle) and autumn (second cycle) 2016. The school implemented LS as their school-development project in January 2016, and this was the teachers' first experience with LS. The LS group consists of four mathematics teachers, one participant from the school administration (the group leader) and one external expert (the first author of this paper). All the teachers' meetings are video- and audio-recorded. In addition, all documents produced by the teachers during the whole process, and some of the students' written works, are collected. Since conversation and communication are crucial in the study, FGIs before and after each LS cycle are conducted. The purpose of a FGI is to get a variety of perspectives on a given subject (Kvale, 2007). In the first FGI, a discussion about the current teachers' teaching practice, including making plans, teaching, evaluation and the teachers' thoughts about student learning is facilitated. In the second FGI, it is important to let the participants reflect on what they have learned about their own teaching practice and student learning. In the third FGI, the focus is on the LS process and what can be done differently in the next cycle. In the last FGI, the most crucial topic relates to teaching practice and student learning, and contains the same focus as the second FGI.

### **A coordinated theoretical framework to investigate teacher development**

Describing the landscape of using more than one theory, Birkner-Ahsbahr and Prediger (2014) refer to networking strategies or connecting strategies. They distinguish these strategies by the degree of integration, from *ignoring other theories* on the one hand, to *global unification* on the other. Figure 1 gives an overview of the approaches in between. Networking strategies are useful to analyse the same empirical phenomena using different approaches (Birkner-Ahsbahr & Prediger, 2014).

**Figure 1. Networking strategies (Bikner-Ahsbahr & Prediger, 2014, p. 119).**

The strategies of coordinating and combining are mostly used for a networked understanding of an empirical phenomenon or a piece of data (Bikner-Ahsbahr & Prediger, 2014, pp. 119–120). The difference between coordinating and combining theories depends on how elements from the two theories are well fitting or not. While coordinating can only be possible if the theories have compatible cores, theories with conflicting basic assumptions can be combined. In this study, activity theory and the commognitive theory are coordinated, because they have similar ontological and epistemological perspectives. LS and teaching practice are seen as object-oriented activities. Tables 1 and 2 give an overview of these activities. LS and teaching practice as object-oriented activities have a common motive: to promote student learning. They have however, different objects and goal-oriented actions. Another main difference is the teaching in LS (the research lesson). Because of the participating observers and the teachers' research question(s) – they are researching their own teaching practice – the teaching is planned in order to promote teachers' learning and development as well as students' learning. The focus on instructional interactions between teacher and students around content (cf. Cohen et al., 2003; Thames & Van Zoest, 2013) is naturally embedded in LS. In order to study your own teaching practice to increase student learning, teachers are conducting goal-oriented actions. These actions represent each step of the LS cycle; formulate goals and plan the lesson, teach the lesson, observe students and reflect on/evaluate the research lesson. Each action has its own goal – prepare teaching, facilitate students' learning, gather data to answer research questions and learn from the lesson. To constitute the goal-oriented actions, there are different operations, listed in Table 1.

To describe the meaning of teachers' professional teaching practice, we draw upon the work of Ball and Forzani (2009). They consider mathematics teaching as professional work and this work of teaching mathematics does not come natural. It has to be learned through deliberate training. Teaching practice is all about designing activities that increase student learning, but the work of teaching mathematics can also be decomposed into several core components. For instance, a teacher must present mathematical ideas, respond to students' mathematical questions, find examples that illustrate certain mathematical points and so on – all examples of what Ball and colleagues refer to as “the mathematical tasks of teaching” (Ball & Forzani, 2009; Ball, Thames, & Phelps, 2008). This is another aspect of what they mean by referring to teaching as professional practice. In order to carry out the tasks of teaching mathematics, a specific knowledge is required that is connected with the work of teaching. This constitutes a particular knowledge base that is shared within the teaching profession.

Activity	Lesson Study															
Objects/ motive	Investigate own teaching (object) to improve students' learning (motive)															
Actions	Plan the lesson				Teach the lesson			Observe the lesson			Evaluate the lesson					
Goals	Prepare teaching				Facilitate students' learning			Gather data to answer research questions			Improve the lesson					
Operations	Study other textbooks, curriculum materials, teacher journals, and previous research  Formulate lessons goals, research question  Select artefacts, design worksheets, group work, differentiation  Prediction on students responses and plan observation				Introduce and exemplify			Support students' problem solving			Observe students			Discuss achievement  Discuss the strengths and weaknesses of teaching		
Present problems					Observe case students											
Documenting learning indicators					Interview case students											
Reflect on improvement and make a new plan					Document and present results											

**Table 1: LS and Activity Theory (translated from Mosvold & Bjuland, 2016, p. 188)**

Considering teaching or “the work of teaching” as an object-oriented activity, the object/motive is teaching in a way that leads to student learning. The goal-oriented actions are the tasks of teaching, and the operations are when the teachers actually conduct the tasks of teaching (see Table 2). These operations require mathematical knowledge for teaching (Ball et al., 2008). Developing teaching practice also includes developing teachers’ knowledge for teaching (Lerman, 2013). In this study, Ball et al.’s (2008) knowledge component: “Knowledge of content and students” is used when studying what teachers learn about student learning.

Activity	The work of teaching mathematics
Objects/motive	Help students learn
Actions	Mathematical tasks of teaching
Goals	Student learning of specific mathematical content
Operations	Conduct the mathematical tasks of teaching, depending on teachers’ knowledge for teaching

**Table 2. Teaching practice and Activity Theory**

The following example illustrates how the local theory is applied in coordination with the grand theory. In the activity of LS, one of the goal-oriented actions is evaluation. Within this action, an

operation is to “discuss observations” (see Table 1). In the discussions of observations from the second research lesson, the teachers discuss how the students had worked on a task of finding the shape of a sandpit that can fit 500 litres of sand. They recall how one boy responded when challenged by the teacher to try another figure than a rectangle – like a triangle. The boy responded, “Yes, then we just double, because that is half, then...” Another teacher comments that the boy found another solution. Although the example is limited, it displays some characteristics of a mathematical discourse. In this action of discussing their observations, the teachers use mathematical words like shape, rectangle and triangle. Their restatement of a student’s response illustrates a mathematical routine that appears to involve the area of a triangle. When analysing the teachers’ discourse in the actions of LS over time, the local theory may help us identify changes in discourse – which is how Sfard (2008) defines learning – on an object level or meta level. Introduction of new words are examples of object level learning, whereas changes in the metarules of the discourse constitute learning or development on meta level.

### **Considering the role of the researcher**

In the described study – like in numerous similar LS research projects – the researcher acts as participant observer. Being a participant observer in research – as the first author of this paper – might lead to both advantages and challenges. Connelly and Clandinin (1990) underline one advantage when they focus on the relationship between the researcher and the participants in the context of research in education. They stress the importance of all parties’ equality, which gives rise to better collaboration. The first author is a participant observer in the way Bryman (2012) defines as being an “overt full member” (p. 441). This means that the researcher is completely involved in the group’s work. Bryman distinguishes between “covert full member” and “overt full member”. The differences being if the members of the group are aware of the researcher’s status as a researcher or not. In the present study, the participants are aware of the first author’s role as a researcher. Bryman (2012) claims that there are some challenges associated with the “overt full member” role. As an active participant, you may forget your role as a researcher. He refers to this as “going native” (Bryman, 2012, p. 445). To avoid this, it is important to be aware of the different roles you have as a participating observer. In the group meetings, the researcher switches between a conversation role and a member role. In the research lesson, the researcher does not teach the lesson, but participates in activities as an observer. Wadel (1991) refers to this role as the role of the apprentice. In addition, another essential aspect of the researcher role in this study is “the knowledgeable other” in the LS group, the role of observer-spectator (Wadel, 1991). The most important part of this role is to guide the group through the LS cycle and help the teachers to keep focus on their own research. Previous research has shown that without an external expert, teachers easily forget the research question (e.g., Takahashi, 2013) and collaborate without actually doing LS.

Staying long in the field increases the stability of observations and dependability in a qualitative project (Cohen, Manion, & Morrison, 2007). In this project, data collection spans over a calendar year. The time span is particularly important when the researcher acts as participant observer in a LS group, in order to reduce potential reactivity effects (Cohen et al., 2007). Another element that supports the dependability in the study is the teachers’ reflections on the outcomes of their own learning. This is useful for the analysis, because we can then compare findings (related to observed change in discourse) with the teachers’ own reflections. The participants’ opportunity to agree with

the descriptions and interpretations the researcher makes during the LS cycles underpin the confirmability in this research. Since one researcher is participating in all the conversations when the teachers talk about their own reflections on a meta-level, this researcher's voice – repeating their different opinions – enables the participants to confirm or disconfirm. This can only happen because one researcher is a participant observer.

In the final step of a LS cycle, the teachers have to think through what they have learned during the whole process. Based on interpretations of the data material, the researcher attempts to make thick description of teachers' learning through LS. In the process of creating such thick descriptions, we follow Stake (2010) who emphasizes the connection to theory in addition to providing rich descriptions and interpretations of data – thus supporting the transferability of the research.

## Concluding discussion

In this paper, we have referred to a study of teacher learning in LS as a starting point for discussing some theoretical and methodological issues that can be involved when studying what teachers learn about teaching practice and student learning. In their call for more practice-based approaches to study the development of mathematics teachers' knowledge and professional practice, Thames and Van Zoest (2013) argued that such efforts required “work on conceptualizing practice, formulating questions about practice, and developing methods for studying it” (pp. 592–593). We suggest that LS provides a useful venue for such studies, but we agree with these researchers that further work – conceptual and methodological – is necessary. A possible approach is to use our proposed coordination (Bikner-Ahsbahr & Prediger, 2014) of activity theory and the commognitive theory to study mathematics teachers' learning in the context of LS. This might be useful in multiple ways. In the following, we highlight two potential benefits of such a coordinated theoretical framework.

First, the application of Leontiev's (1978) activity theory provides a useful framing for a reconceptualization of the work of teaching mathematics. Ball and Forzani (2009) propose that the work of teaching mathematics is constituted by the recurrent tasks of teaching that teachers encounter when carrying out this work. Their conceptualization fits within the idea of teaching as professional practice. In the TeachingWorks (2015) project, they develop these ideas further and identify a number of core practices that are particularly important in the work of teaching. A challenge with these and other efforts to conceptualize the work of teaching is that the components of practice – for instance the mathematical tasks of teaching – sometimes appear to be on different levels, and the issue of purpose often appears absent. Using Leontiev's (1978) idea of distinguishing between object-oriented activity, goal-oriented actions and operations in a reconceptualization of the work of teaching mathematics, may solve both of these potential challenges while at the same time preserving the obvious strengths of previous conceptualizations. Such a theory-based reconceptualization enables new questions to be posed and may support the development of a theory of mathematics teaching that communicates with existing theories of learning and development.

Second, the application of Sfard's (2008) commognitive theory enables the development of more operational definitions of teaching and teacher learning about teaching practice and student learning. When applying a definition of teaching that coordinates perspectives from activity theory with Sfard's theory, the issues of motives and purpose are embedded. The proposed definition of Tabach and Nachlieli (2016, p. 303) is a good candidate: “teaching can be defined as the communicational activity

the motive of which is to bring the learner's discourse closer to a canonical discourse." This definition draws upon Sfard's (2008) definition of learning as an observable change in discourse, and the application of such a theory makes teaching and learning more easily observable.

In interpretative research, the goal is to understand and interpret the meanings of human behaviour such as teachers' talk, and it is important for the researcher to understand motives, meanings, reasons and other subjective experiences rather than to predict causes and effects (Hudson & Ozanne, 1988). This paper highlights and discusses some methodological issues that may arise when investigating development of mathematical knowledge for teaching in LS from a participationist (rather than acquisitionist) perspective (Sfard, 2008), focusing on teachers' participation in object-oriented LS activities and analysing their learning in terms of discourse as two different grain sizes. The two levels occur because the theories look at learning differently; activity theory is focusing on acting humans, whereas discourse theory is focusing on humans who communicate. Both perspectives are arguably embedded when mathematics teachers' professional practice is developed through LS, and an application of such a coordinated theoretical perspective might represent another step towards the efforts to understand what teachers learn about teaching practice and student learning (cf. Thames & Van Zoest, 2013).

# First year student teachers dealing with non-routine questions in the context of the entrance examination to a degree in Primary Education<sup>1</sup>

Aitor Villarreal, Lluís Albarracín<sup>2</sup> and Núria Gorgorió

Universitat Autònoma de Barcelona, Facultat de Ciències de l'Educació, Spain;  
[aitor.villarreal@uab.cat](mailto:aitor.villarreal@uab.cat); [lluis.albarracin@uab.cat](mailto:lluis.albarracin@uab.cat); [nuria.gorgorio@uab.cat](mailto:nuria.gorgorio@uab.cat)

*We understand Fundamental Mathematical Knowledge (FMK) as the initial mathematical background we expect students to have at the start of their education to become Primary School teachers. In this paper, we focus on the answers given by 241 first-year student teachers to two non-routine questions that were part of an entrance examination. Non-routine questions are those for which students do not have a straightforward algorithm available to reach the answer and/or the result obtained by using it needs to be interpreted within the problem's context. The results show that non-routine questions are a powerful tool to assess the solidity and stability of their initial mathematical knowledge but also a powerful tool to find out whether the students have appropriated the essential ways of thinking and working in mathematics. Our findings also suggest that the mathematical knowledge of first-year student teachers is far from the desired FMK.*

*Keywords: Fundamental Mathematical Knowledge, non-routine questions, teacher education.*

## Introduction

Within the framework of a program that aims to improve initial teacher training in Catalonia – *Programa per a la Millora de la Formació Inicial de Mestres, MIF* – an entrance assessment has been created. Its purpose is to regulate the access to primary teaching degrees and will be applied for the first time in June 2017. The assessment includes a mathematics test intended to ensure the mathematical knowledge of future students of teaching degrees. In this context, in an attempt to find evidence of the distance between the student candidates' initial mathematical knowledge and the desirable mathematical knowledge, our study focuses on characterizing the knowledge demonstrated by a group of 241 students in their first year of training as primary teachers. In this paper we focus on the analysis of their responses to 2 non-routine questions.

## Fundamental Mathematical Knowledge (FMK)

In Castro, Mengual, Prat, Albarracín and Gorgorió (2014) we introduced Fundamental Mathematical Knowledge (FMK) as the disciplinary mathematical knowledge that students need to benefit from courses in mathematics and mathematics teaching during their education to become teachers, considering the requirements of the professional practice and the competences to be developed by children in primary education. FMK is the disciplinary knowledge on which to build throughout teacher training to attain the mathematical and pedagogical content knowledge required

---

<sup>1</sup> The study presented here has been developed within the the research project *Caracterización del conocimiento disciplinar en matemáticas para el Grado en Educación primaria: matemáticas para maestros*, supported by the *Dirección General de Investigación* in the framework of I+D, RETOS, (ref. EDU2013-4683-R).

<sup>2</sup> Lluís Albarracín is a Serra Húnter Fellow at the Universitat Autònoma de Barcelona.

for professional practice. As teacher educators, we regard FMK as the mathematical knowledge starting point for our courses, which should be based on a thorough knowledge of elementary mathematics, being the foundation that would support a structurally robust training.

As we have defined FMK, it is not explicitly part of the different models that characterize teacher knowledge. However, it relates to them. Ma (1999) develops Shulmans' proposal (1986) and brings up the notion of profound understanding of emergent mathematics. Our idea of FMK is related to Ma's proposal, but focuses on the initial knowledge required for teacher training, as opposed to this author who is interested in the educated teacher. Ball, Thames and Phelps (2008) propose a characterization of mathematical knowledge for teaching from what teachers do when they teach mathematics and from the knowledge and skills they need to achieve for students to learn.

Considering that we are focusing on young adults that want to become teachers, FMK is close to their notion of Common Content Knowledge (CCK), understood as the subject-specific knowledge needed to recognize and solve mathematical problems that any educated adult should have. However, since FMK is defined in terms of requirements to enter a teaching degree, FMK would be mathematical knowledge essentially linked to the school-subject "mathematics". FMK would be the knowledge upon which our students would construct their Specialized Content Knowledge (SCK) and Horizon Content Knowledge (HCK) during their education to become teachers. Rowland (2008), based on observation in the classroom to characterize situations in which the teachers' mathematical content knowledge is visible, proposes the reference framework called Knowledge Quartet Framework. The Knowledge Quartet has 4 dimensions: foundation, transformation, connection and contingency. Again, the idea of FMK can be related to the Foundation dimension, even though the latter refers to expert knowledge

There is extensive research aimed at developing theoretical models of different types of knowledge required to teach mathematics. However, much less attention has been paid to research focused on establishing what students' mathematical knowledge is (or should be) when entering teacher training programs (Linsell and Anakin, 2012). According to Linsell and Anakin (2013), the theory developed so far around knowledge for mathematics teaching shows limitations when analysing students' knowledge on entrance to the faculties, since it is based on what teachers do in practice.

FMK focuses on the knowledge of core concepts and on the ability to solve exercises, problems and situations applied to different fields – numbering and arithmetic, relations and change, space and shape, measurement, statistics, and randomness – together with the ability to assess the adequacy and reasonableness of the response in each case. We understand mathematical competence as the ability to use mathematical knowledge encompassing both mathematical and non-mathematical situations. Mathematical competence is based on factual knowledge and concrete skills to carry out mathematical activities and it includes the ability to ask and answer questions in and with mathematics, and the ability to deal with mathematical language and tools (Niss and Højgaard, 2011).

Mathematical competence goes beyond knowledge of procedures and it manifests itself in the use of conceptual knowledge in different situations. It requires the knowledge of rules, definitions and connections and domain structure, and knowing why certain procedures work for certain problems, what the purpose of each step of a procedure is, and making the connections between these steps

and their conceptual foundations. Non-routine questions cannot be approached in an automated way and solving them requires a deep understanding of the concepts and procedures involved in them. This is why we want to know whether or not non-routine questions are a suitable tool to evaluate the initial mathematical knowledge of student candidates in relation to FMK in terms of competences.

## Method

In the process of construction and refinement of the mathematics test of the entrance assessment, we examined different groups of students who had just started their training as teachers but had not yet had any courses related to mathematics or didactics of mathematics. The main data used in this study comes from the test answers of the 241 first-year students of the Primary Education Degree at the Universitat Autònoma de Barcelona during the school year 2015-16. For this cohort of students, the test was not yet a requirement for admission. The test students had to pass had 4 different versions around the same mathematical ideas, and was made up of 25 questions. Students were given 90 minutes to complete the test not being allowed to use any type of calculator. They were randomly handed out one of the four versions, and we afterwards verified that the four groups of students were statistically equivalent in terms of their entrance characteristics.

The questions in the test were related to the core content of the curriculum for compulsory education. At least half of them were non-routine questions in the sense that there was no straightforward algorithm available to the student to reach the answer. In the cases in which such an algorithm was available, the result obtained by using it had to be interpreted within the problem's context. When there was a simple approach to solve a question, its application would however be a cumbersome and time-consuming task. Therefore, given the limited time, these questions called for the development of efficient approaches to solve them.

## Results

### *Ruler question*

Questions 1 and 2, given in Figure 1, were question 15 in versions 1 and 4, and versions 2 and 3 of the test respectively. In the students' test, the centimetre in the images corresponded to exactly one centimetre.

This question involves the measurement of a length with a tool, which is part of the content of compulsory education and is similar to questions that can be found in tools aimed to test primary children's mathematics. It's a non-routine question, since it cannot be answered by a direct reading of the image because the segment to be measured does not start at point 0 and the subdivisions of the ruler do not correspond to decimal units. The question requires knowledge of the number line and representing fractions on it.

Figure 1: Question 15 of versions 1 and 2

The students' answers are summarized in Table 1. Since all the students answered this question, both in version 1 and 2, we interpret that they believed to know the correct answer. For the question in version 2, where the fraction involved is  $\frac{1}{2}$ , 78.22% of the students gave a correct answer, while in version 1, which additionally requires a measurement using the  $\frac{3}{4}$  fraction, the percentage of success is 38.46%.

Version	Correct Answers	Errors	Blank	Total
1	45 (38.46%)	72	0	117
2	97 (78.22%)	27	0	124
Total	142 (58.92%)	99	0	241

**Table 1: Answers to the *Ruler question***

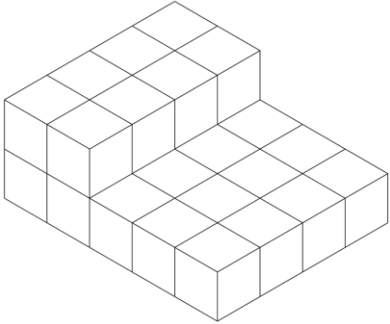

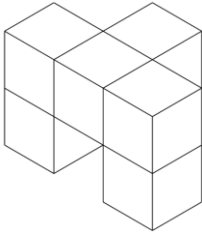

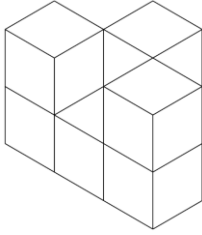

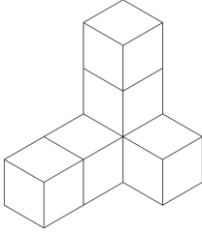

We generally observe a tendency to induct, i.e. the students answer the question from what they would do to approach a similar routine question. The correct answer is 4.75 cm, and little more than a third of the students answered correctly, and the answer 4.3 arises from considering that each subdivision of the unit corresponds to 0.1 cm and calculating the total length counting subdivisions. This answer contains an additional error, since units are ignored when expressing the measurement.

Similarly, the answers 4.7 cm, 5.3 cm and 5.7 cm stem from automatically considering that each subdivision equals 0.1 cm. The three answers consider a reading of the graphical information contained in whole units. Thus,  $4.7 = 5 - 3 \times 0.1$ . In the 5.3 answer, there is an additional error since subtraction would be required  $5.3 = 5 + 3 \times 0.1$ . The 5.7 answer implies an incorrect reading of the graphical information when supposing that the segment contains 6 whole units  $5.7 = 6 - 3 \times 0.1$ .

The error of 19 cm also answers to an automated process, since it stems from considering each subdivision as 0.1 cm. The incorrect answer 9.5 cm arises from considering that every two divisions equals 1 cm and then acting routinely. In addition, those who make this mistake do not stop to think whether the segment may be longer than the ruler being used to measure. We also noted another type of errors resulting of applying a routine process. Here the students gave the result of the measurement by rounding amounts, such as in 4.8 cm or 5.8 cm, from rounding 4.75 and 5.75, respectively. In version 2, the correct answer is 5.5 and the errors detected similarly stem from applying automated processes – such as acting inductively or rounding – without questioning the meaning of the procedure they are using or the answer obtained.

### ***Cubes question***

Question number 16 – shown in Figure 2 – was slightly different in the four versions of the test, but was always related to the concept of volume. It approached the idea of measuring the volume of a solid directly by counting units, again a concept present in compulsory education. However, all these were non-routine questions in the sense that they differed from typical textbook exercises that require the calculation of a volume by applying a formula. This question additionally required the interpretation of figural information, even though the figures were rather simple.

<p>If the edge of each cube measures 4 cm, what is the volume of this object?</p>  <p>Version 1</p>	<p>If the edge of each cube measures 4 cm, what is the volume of this object knowing that we can see all the cubes that integrate the object?</p>  <p>Version 2</p>
<p>If the edge of each cube measures 4 cm and the volume of the object is <math>512 \text{ cm}^3</math>, how many hidden cubes are there?</p>  <p>Version 3</p>	<p>The volume of the object is <math>384 \text{ cm}^3</math>. All the cubes that integrate it are identical. What is the length of the edge of the cubes?</p>  <p>Version 4</p>

**Figure 2: Versions 1, 2, 3 and 4 of the Cubes question**

In versions 1 and 2, the question required interpreting figural information, mastering the notion of unit of measurement, being able to calculate the volume of a cube with a 4 cm edge and, particularly, having a way to quickly figure out how much  $4 \times 4 \times 4$  is. In both cases, students should be able to express their answers using the appropriate units. Version 2 was more complex than version 1, since it explicitly brought up the idea of hidden cubes. The questions in versions 3 and 4 also required interpreting figural information in a representation that also included the idea of hidden cubes, but this time providing the volume of the global object.

The question in version 3 required determining the number of hidden cubes, therefore calculating the volume of a cube with an edge of 4 cm, using the multiplication algorithm or having a way to quickly calculate  $4 \times 4 \times 4$ . Then it required being able to find how many times  $512 \text{ cm}^3$  could contain  $64 \text{ cm}^3$ , by either using the traditional division algorithm or any other efficient procedure. The question in version 4 was more complex, since once the number of small cubes was determined, the students had to find the volume of each of them, and after that finding the length of the edge. With a given length, finding the volume is certainly a routine question; however, the opposite is clearly non-routine.

Table 2 shows the number of correct, erroneous and blank answers for each version of question 16. In contrast to what happened with the *Ruler question*, in all versions of question 16 there was a

significant percentage of blank answers, which indicates how the students perceived the difficulty of the different versions.

Version	Correct	Erroneous	Blank	Total students
1	23.21%	46,43%	30,36%	56
2	20.69%	43,10%	36,21%	58
3	9.09%	59,09%	31,81%	66
4	8.20%)	39,34%	52,46%	61
				241

**Table 2: Answers to the Cubes question**

If we pay attention to the percentage of corrects answers, we see that the success in versions 1 and 2 is similar and much higher than that of versions 3 and 4, which also have a similar success rate. We interpret this difference as due to the fact that questions in versions 3 and 4 are much further away from textbook questions than the questions in versions 1 and 2, and all of them are far from how they have dealt with volume in their previous schooling.

In version 1, the correct answer is  $1792 \text{ cm}^3$ , since there are 28 cubes with a volume of  $64 \text{ cm}^3$  each. Among the 56 students, only 13 reached the correct answer and 18 gave no answer at all. Among those that gave a wrong answer, the most common errors lie in not knowing how to find the volume of the small cube or in mixing the idea of volume with that of surface area. Another common error lies in not identifying the right number of cubes in the figure: only 8 of the wrong answers are attained using the correct number of cubes, the others that make sense deal with the question considering there are 20 cubes.

In version 2, the correct answer is  $384 \text{ cm}^3$ , since there are 6 cubes with a volume of  $64 \text{ cm}^3$  each. Among the 58 students dealing with these questions, only 12 reached the correct answer and 21 gave no answer at all. The percentage of blank answers being higher than in version 1 would confirm the idea that students considered this task to be more difficult than task 1, most likely because it brings up the idea of hidden cubes. Calculations are simpler than in version 1, since the number of cubes is a one digit number. However, students also have problems in knowing how to find the volume of the small cube or mix the idea of volume with surface area.

In version 3, the correct answer is 2 hidden cubes, since the object is made up of 8 cubes and 6 of them are visible. The total number of cubes in the object can be found by dividing 512 by 64, since the volume of each cube is  $64 \text{ cm}^3$ . Among the 66 students, only 6 students reached the correct answer and 21 gave no answer at all. The percentage of blank answers being close to the one in versions 1 and 2 would suggest that students do not consider this question to be more difficult than the others. As in version 2, calculations are simple, since the number of cubes is a one digit number. One common error is to not answer to the number of hidden cubes, but to answer the number of cubes that make up the object. Among the incorrect answers, 7 of them clearly show that the students knew they had to divide the volume of the object by the volume of the small cube, but again encountered problems in relating the length of the side of the cube to the volume of the cube, and directly used the side length or the surface area of one the sides of the cube. It is interesting to

note that, among the wrong answers, there is at least one that suggests that the student attempted to directly read the figural information given.

To solve the question in version 4 the student had to divide the volume of the object,  $384 \text{ cm}^3$ , by 6 which is the number of the cubes, obtaining  $64 \text{ cm}^3$ . Version 4 was given to 61 students, 5 of them solved it properly, 24 obtained wrong answers and 32 gave no answers, a much higher percentage than in version 3. Among the 24 wrong answers, we found three where the student divided 384 by 6 but went no further, giving as a result  $64 \text{ cm}^3$ ,  $64 \text{ cm}$  or 64. Among the wrong answers, we also find those of 11 students that divided the volume by 3 to calculate the length of the side and, in some cases, there are added errors like using the wrong units or rounding off the result.

We wish to note that, in all versions, miscalculations were often present. Once again, as in the *Ruler question*, what is most striking about the students' answers is that, too often, it seems that they did not try to make sense of what they were doing. We might think that the students would be content with providing a numerical answer without paying attention to the meaning of either the question or the answer they are giving.

## Discussion and conclusions

In this paper, we have analysed how a group of 241 first year student teachers deal with two non-routine questions in the context of a test intended, in a near future, to select those students that will be allowed to access a degree in Primary Education. Our results show that the percentage of correct answers relates to how far apart the questions posed are from the type of questions the students may have encountered in their previous schooling. The difficulties encountered by the students show that their initial mathematical knowledge is not solid enough to be considered a sufficient basis on which to build up their mathematical content knowledge and didactical knowledge. The results also show a significant offset between the initial mathematical knowledge of the student tested and the FMK understood as the desirable starting-point knowledge even though they may consider they have the knowledge required to address these questions, given that the number of blank questions is generally small. Moreover, we have little evidence that they master mathematical modes of thought or that they have problem tackling competence. Even to find a reasonable answer – one that makes sense – does not seem to be part of their way of doing mathematics.

Non-routine questions in the examination were designed to assess the students' understanding of basic algorithms and core concepts and their ability to move from specific to general thinking. Therefore, even if the questions essentially dealt with ideas taught in compulsory education, they challenged the student to reason and to use mathematical structures, and required that the student thoroughly understood the knowledge, skills and problem approaches he was using.

Non-routine questions seem to be a powerful tool not only to test basic concepts, but also to check the existence of the relationships among them, and to verify whether the students grasp the essence of doing mathematics and the thought processes involved. It is in this way that we consider that non-routine questions were useful to assess the students' initial mathematical knowledge. Our results also seem to suggest that when non-routine questions are simple, as in the *Ruler question*, students tend to solve them by using a procedure that would solve a similar standard question, without critically analysing what they are doing or how they are doing it. In the same way, when the question is non-routine due to its complexity, the evidences we obtained show gaps in their

knowledge of concepts and relationships between concepts. However, these are hypotheses that would need further research to be tested.

<sup>2</sup>Middle East Technical University, Faculty of Education, Ankara, Turkey; [bcetinka@metu.edu.tr](mailto:bcetinka@metu.edu.tr)

*This study aimed to examine prospective teachers' anticipations of students' thinking on the measure of the arc and measure of the central angle, circumference, and area of the circle and to explore the changes in their anticipations as they conduct three lesson study. For this purpose, case study method was used. Three prospective middle school mathematics teachers participated in the study and completed three lesson study. The data were analyzed in terms of three components: the prospective teachers' anticipations of (1) how students' would think; (2) what difficulties they would have; and (3) what powerful ideas they would have. The results showed that lesson study cycles with real classroom experience provided opportunities for the prospective teachers to develop anticipations of students' thinking.*

**Keywords:** Lesson Study, prospective teacher knowledge, anticipating student thinking, middle school mathematics.

## Introduction

Recently, teachers' knowledge of mathematics has become an object of concern. Ball and colleagues have expanded teacher knowledge proposed by Shulman (1986) by defining "the mathematical knowledge for teaching" (Ball, Thames, & Phelps, 2008). Pedagogical content knowledge (PCK) is part of the mathematical knowledge for teaching, and it focuses not only on content knowledge and pedagogical knowledge, but also on integration and transformation of content and pedagogy (Ball et al., 2008). According to Ball and others (2008), the components of PCK are knowledge of content and teaching (KCT), knowledge of content and students (KCS), and knowledge of content and curriculum (KCC). This study focuses on knowledge of content and students (KCS). Hill and others (2008) defined "KCS as content knowledge intertwined with knowledge of how students think about, know, or learn this particular content" (p. 375). Ni Shuilleabhain (2015) added that KCS includes students' understanding of content, student developmental sequences, typical student errors, anticipation of what students are likely to think or find confusing and common student computational strategies. Teachers should consider students' needs and interests when they plan for lessons. They must anticipate students' typical thoughts, ideas, and difficulties when selecting teaching materials and making decisions about the implementation of the lessons. Teachers must also attend to and interpret students' emerging and incomplete ideas during the instruction. Each of these tasks requires knowledge and skills developed through the interaction between mathematical understanding and knowledge of student thinking (Ball et al., 2008). Prospective teachers who can recognize and appreciate students' thinking and cognitive development could design and implement learning activities to meet students' needs and interest (Ball et Al., 2008; Llinares, Fernandez, & Sanchez-Matamoros, 2016).

However, their experiences and knowledge of students' thinking are very limited (Peterson & Leatham, 2009). Hence, teacher education programs should be designed to help prospective teachers improve students' mathematical knowledge and skills related to KCS by anticipating student thinking, among other abilities.

Lesson study is one of the models that helps teacher candidates develop their knowledge related to student thinking. It is a professional development program in which teachers collaboratively work on teaching. In this program, teachers first determine learning goals of the lesson and plan the lesson. Subsequently, one of the teachers in the group teaches a lesson and other group members observe the teaching process. Finally, they evaluate and revise the lesson plan so that it can be implemented second time (Lewis, Perry, & Hurd, 2009; Murata, Boffering, Pothen, Taylor, & Wischnia, 2012). In planning a lesson, the teachers are usually guided to focus on expected learning activities, expected student reactions or answers, teacher's responses to student reactions, and possible evaluation activities. This professional development model may provide prospective teachers with opportunities to plan, implement, criticize, and reflect on lessons collaboratively (Carrier, 2011).

Although research studies emphasize the importance of teachers' knowledge of student thinking, we know little about the development of prospective teachers' knowledge and skills in anticipating student thinking (Webb, 2006). Lesson study practices are found helpful in developing teachers' competence to anticipate students' mathematical thinking (Lewis et al., 2009; Tepylo & Moss, 2011). In this regard, the present study aimed to investigate prospective teachers' knowledge of student thinking of the concept of circle as a two-dimensional figure (disk) and as a one dimensional curve and to explore any changes in their anticipations as they work on three lesson study cycle.

## **Conceptual framework**

The theoretical basis of the lesson study model acknowledges that cognition is social and that learning takes place in enriched learning environments in a cooperative way (Fernandez, 2005). In this regard, lesson study is a professional development program that encompasses constructive learning and creates learning opportunities (Lieberman, 2009). As lesson study is based on planning before the practice, observations during the practice, and cooperation and reflection throughout the practice, it contributes to making 'learning' a cultural activity, which ultimately makes this model more significant (Dudley, 2013). According to Davies and Dunnill (2008), this model differs from other cooperative models in that the cooperation adopted in lesson study continues before, during, and after the practice. All these characteristics of lesson study model give teachers different perspectives and show them how an effective mathematics education should be offered (Erarslan, 2008). Researchers emphasize that integrating lesson study model into teacher education programs can help prospective teachers develop knowledge and competence by learning from practice (Rasmussen 2016; Sims & Walsh 2009). Lesson study enables prospective teachers to work on lesson plans collaboratively and to conduct careful observations of learning and teaching activities. The model also allows prospective teachers to discuss and reflect on their own practice (Fernandez 2010). It mainly helps prospective teachers gain curriculum knowledge and pedagogical content knowledge, including knowledge of common student mistakes. Observing lessons gives prospective teachers the opportunity to notice things about the classroom environment, and most importantly, to see the situation from the perspective of students (Lewis, 2002). Thus, they can become familiar

with what students actually know, how they think, and what they can do as well as with areas in which they may have difficulty (National Research Council, 2001, Takahashi, 2005).

## Methodology

This study focuses on investigating the prospective teachers' anticipations of students' thinking of the measure of the arc and angle and circumference and area of the circle. Furthermore, it explores how such anticipations change during the lesson study. For this purpose, case study design was adopted. This design provides an in-depth analysis of single or multiple cases by means of various data collection tools (Creswell, Hanson, Clark, & Morales, 2007).

## Participants and context

The participants of this study were three prospective middle school mathematics teachers enrolled in a state university in Ankara. They were in their last year of the program and were willing and motivated to participate in the study. They were 22 years old, and their GPAs were between 3.29-3.47 out of 4.00. The teacher education program generally focuses on content knowledge (i.e., mathematics) in the first and second years. On the other hand, during the third and fourth years, most of the courses are related to mathematics education. Prospective teachers who graduate from the program can work as mathematics teachers in middle schools (grades 5 to 8).

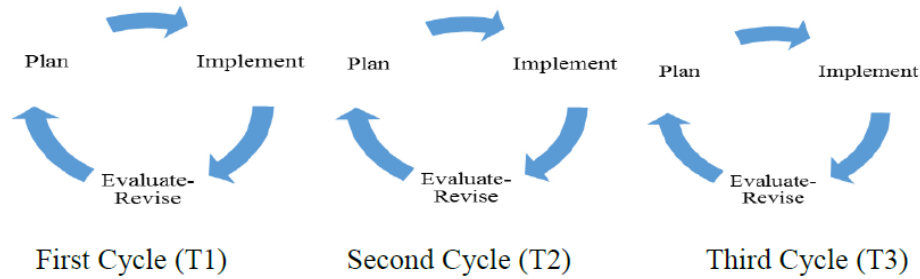

## Data collection

Within the scope of the three-week study, the prospective teachers worked as a group and planned, implemented, and revised three lessons (each of which lasted about 80-120 mins) for each learning objective on the topic of circle that is a part of the 7<sup>th</sup> grade math curriculum (MoNE, 2013). The prospective teachers used a lesson plan template to design the lessons. It consisted of four columns listing the (1) learning activities and key questions (and time allocation), (2) expected student reactions or responses, (3) teachers' responses to student reactions, and (4) goals and method(s) of evaluation (see column 2 of Table I).

Steps of the lesson: learning activities and key questions (and time allocation)	Student activities/ expected student reactions or responses	Teacher's response to student reactions / Things to remember	Goals and Method(s) of evaluation
---	---	--	--------------------------------------

**Table 1: Lesson plan template**

Afterwards, one of the group members implemented each lesson plan in real classrooms. The implementation process was video recorded. Regarding the last stage, the first author and mentor teacher evaluated and provided feedback to group members. Subsequently, the group revised the lesson plan (see Figure 1). Moreover, prospective teachers were expected to write a diary about this process.

**Figure 1: Lesson study cycles**

The same cycle was repeated for each lesson plan. Prospective teacher 1 (T1) focused on the following learning objective: “Identifying central angles, their intercepted arcs, and the relationship between the measure of the arc and measure of the angle.” T2 focused on “Calculating the circumference of a circle and a segment of a circle.” T3 focused on “Calculating the area of a circle and a segment of a circle” (MoNE, 2013). The initial and revised lesson plans designed by the prospective teachers, the video recordings of the lesson study meetings, the video recordings of the lessons conducted, debriefing meetings after each lesson, and the observation notes and diaries taken by the prospective teachers, researchers, and training teacher during the implementation of the lesson provided the data for this study.

### Data analysis

The data were coded based on the themes from the relevant literature (Ball, et. al., 2008; Fernandez & Chokshi, 2002; Hill, et. al, 2008; Schoenfeld, 1994) as well as from the participants’ responses. For this purpose, researchers examined the prospective teachers’ articulations and behaviors during study lessons and searched for the incidents showing their anticipations of (a) student thinking, (b) difficulties that students would have, and (c) students’ powerful ideas. Anticipations of how students would think involve predicting how students think in general, what deductions they can make, and what types of connections they can make. Anticipations of students’ difficulties involve predicting the challenges, mistakes, and misconceptions of students regarding the concept of circle. Lastly, anticipations of the powerful ideas that students might have involve expecting the key ideas about the relevant concepts. The data were examined based on this analytical framework for each lesson study cycle, and the findings were compared across three lesson study to examine any changes observed throughout the study.

### Findings

This section presents the prospective teachers’ anticipations of (1) how students would think, (2) the difficulties that students would have, and (3) the powerful ideas that students would have, as teachers design and implement three study lessons on the concepts of the measure of the arc, measure of the angle, and circumference and area of the circle. In Table 2, frequencies represent prospective teachers’ anticipations related to each component of student thinking observed for each study lesson.

Table 2 shows that the prospective teachers pointed out that 26 different thoughts could be considered as typical for students (i.e., component 1) in the study lesson. For instance, they expected

that students could explain central angles as the midpoint angle of the circle, or they anticipated that students would know how to draw a circle using different tools, such as a coin or a compass.

	Types of plan	How students' would think typically	What difficulties they would have	What powerful ideas they would have
First	Lesson plan	10	2	3
Cycle	Revised lesson plan	10 (0 new anticipation)	3 (2+ 1 new anticipation)	3 (3+ 0 new anticipation)
Second	Lesson plan	8	-	5
Cycle	Revised lesson plan	9(8+ 1 new anticipation)	1 (0+ 1 new anticipation)	6 (5+ 1 new anticipation)
Third	Lesson plan	7	5	6
Cycle	Revised lesson plan	7 (7+0 new anticipation)	5 (5+ 0 new anticipation)	8 (6 + 2 new anticipation)

**Table 2: Frequency of prospective teachers' thoughts related to the components of anticipating student thinking**

Among these 26 different anticipations, only one new anticipation was included in the revised plan after its implementation in a real classroom. More specifically, in the second study lesson, they thought that the students would quickly give the correct answer when they were asked to spot the circumference of the circle. However, since the students pointed the region inside the circle as the circumference of the circle, the prospective teachers included such typical student thinking in the revised lesson plan and made some revisions, as illustrated in the following dialogue:

T2: Some students conceived the circumference of the circle as inside of the circle. We had never considered this.

T1: Yes, I didn't know what to say when they gave this answer.

T3: So, we need to include some questions in the lesson plan. For example, shall we say 'What do you think of when we say 'circumference of the school ground?' Then we can tell them to walk around the school ground.

T2: Let's decide a starting point and tell them to start walking from there and walk around the school ground until they reach the same point.

T1: Yes, then students would realize that circumference is not actually the same as inside [of the circle]. Then we can ask them to think about the circumference of a circle.

According to Table 2, the prospective teachers reported 9 different student thoughts could be considered difficult (i.e., component 2) in the study lesson. For example, they thought that students might confuse the concepts of circle and sphere. They also anticipated that students might consider meter as a unit of arc. Among these 9 different anticipations, two were included in the revised plans after its implementation in real classroom. In the first cycle, during the implementation of the lesson, the prospective teachers realized that students would confuse the central angle with inscribed angle. Thus, in the revised lesson, they decided to remind the students about the difference between these two types of angles. The following dialogue shows how they considered this idea as they were revising the lesson plan:

T1: Did you see that students confused central angle with inscribed angle?

T2: Yes, it seems that they didn't know the difference. We never thought about it. So, what shall we do? Let's draw a figure and ask them if it's a central angle. If they say 'yes', we'll use a material that shows an angle as a combination of two rays (half lines). Here, we can make a straight angle and ask the students what type of an angle it is.

T1: Then, students would say it's a straight angle based on what they learnt it in the previous lesson. Let's make it a 360-degree angle and draw a circle taking the origin of the angle as the center and ask what type of an angle it is.

T2: The students would say "It's a central angle because the origin is at the center of the circle."

T3: Yes, then we can show the example with an inscribed angle and ask if it is a central angle. I think students will say it's not because the origin does not cross the center.

T1: This way, they can differentiate between a central angle and an inscribed angle.

As seen in Table 2, the prospective teachers pointed out 17 different student thoughts could be considered as powerful ideas (i.e., component 3) in the study lessons. For instance, they expected that students could explain differences between circle and disk, and they anticipated that students would know what pi is. Among these 17 different anticipations, three new anticipations were included in the revised plans after their implementations in real classroom. In the third cycle, the prospective teachers asked students to find the area of a circle by using the area of a parallelogram. However, following the lesson, they realized that the instructions in the activity sheet were not clear enough to guide the students. This experience led them to contemplate about their expectations concerning students' powerful ideas (i.e., making connections between the area of a circle and of a parallelogram) based on which they made some changes to the instructions. The following dialogue illustrates how their expectations changed:

T1: The activity sheet was not very clear, so students did not understand the relationship between the area of a disk and the area of a parallelogram. We wanted to make it easier using what they learnt in quadrilaterals, but it didn't work. What shall we do?

T3: I think we should say that circle doesn't look like a quadrilateral. Then they can notice it. Later, we can ask what part of a disk and the height of a parallelogram look similar. They might say 'the radius of disk'. But, what's important here is whether they can tell, which part of a disk has a relationship with the base length of a parallelogram.

T2: Yes, so let's include this in the lesson plan.

To sum up, the data analysis showed that the prospective teachers identified various anticipations related to the three aspects of student thinking. They thought about how students develop ideas related to the fundamental elements of a circle as well as the circumference and area of a circle. They also recognized the importance of designing the lesson in the light of powerful ideas. In addition, they successfully anticipated different student difficulties and mistakes. The study lesson also help the prospective teachers produce new anticipations of student thinking after implementing and reflecting on the lessons. The prospective teachers might not have thought about these issues if they had not had a chance to implement and revise study lessons.

## Conclusion and results

The findings showed that prospective teachers' anticipations of student thinking for each study lesson varied. The study lesson provided the prospective teachers an opportunity to consider student thinking as an essential part of the planning. They were expected to work collaboratively and think deeply about students' thinking (typical student responses, misconception, powerful ideas, prior knowledge, and understandings, etc.) as they plan their lessons. The lesson plan template guided prospective teachers to document their ideas about student thinking, making them explicit and the object of discussion. In this way, study lessons created a context for discussion about student thinking.

Furthermore, the lesson study allowed them to develop knowledge and skills related to student thinking through powerful experiences in real classrooms. Such opportunities allowed them to get to know students well and analyze the learning process from students' perspective. Some previous studies reported similar results (e.g., Ni Shuilleabhain, 2015; Webb, 2006). In this regard, lesson study could be used as a model in undergraduate programs to help the prospective teachers develop knowledge and skills related to student learning.

Even though prospective teachers' anticipations of student thinking were observed for each study lesson, a clear development through the three cycle was not observed. In this study, each cycle focused on learning objectives involving different concepts and skills (e.g., identifying central angles and calculating circumference and area of a circle). Such differences might have influenced prospective teachers' anticipations. Another reason for not being able to detect a clear development through three cycles might be related to the analytical framework used in the study. To reveal different aspects of development of teachers' anticipations, a more structured and detailed analytical framework could be used.

# Mathematics teachers' knowledge and professional development in a Lesson Study context

Vanessa Crecci, Miguel Ribeiro, Dario Fiorentini, UNICAMP, Brazil; [vancrecci@gmail.com](mailto:vancrecci@gmail.com),  
[cmribas78@gmail.com](mailto:cmribas78@gmail.com), [dariofiore@terra.com.br](mailto:dariofiore@terra.com.br)

*Keywords: Teachers' professional development, interpretative knowledge, mathematics teachers' specialized knowledge, Lesson Study.*

## Some preliminary words

The Saturday Group [Grupo de Sábado] (GdS), which emerged in 1999, is a collaborative group that brings together teachers from schools and academics (prospective teachers, master and PhD students, teacher educators) interested in researching the teaching of mathematics in a collaborative environment. Although gatherings are held on the university landscape, there are no formal academic regulations controlling participation. Recently the participants have focused their interest in improving their practices by deepening their mathematical and pedagogical knowledge. In that context, in order to frame the work to be developed, a Lesson Study (LS) has been devised, involving teachers from primary, lower and upper secondary, prospective teachers and researchers. For the implementation of LS, a structure with three subgroups has been established (one for each school level – primary, lower secondary and upper secondary). Complementary to the subgroups meetings (discussion and reflection upon tasks conceptualization and implementation), there will be meetings involving all the GdS elements. In those large group meetings (following the work already being done) the work goes around discussing and reflecting upon the situations emerged from teachers' practice the participants consider problematic. In particular, such discussions are aimed at contributing for developing teachers' knowledge, professional competency of noticing (in Mason's 2002 sense) and professional awareness. For the development of this project we consider what we call a hybrid methodology, where goals of two different natures are pursued. On the one hand, there is an interest in studying the development of a Lesson Study as teacher education strategy in the Brazilian context. On the other hand, the research goal concerns the teachers' professional development process, considering such development addressed through the lens of the Mathematics Teachers' Specialized Knowledge – MTSK (Carrillo et al., 2013) conceptualization, intertwined with what we term of interpretative knowledge (Jakobsen, Ribeiro, & Mellone, 2014). When discussing teachers' knowledge, besides the analysis of teachers' classroom practices and interviews, also a focus on the dynamics emerged in the subgroups and on the GdS will be analysed, as well as teachers' narratives grounded on their own experience (Connelly & Clandinin, 1988).

## Lesson Study as a teacher education strategy

Considering the GdS context and the goals of the project in which this hybrid Lesson Study will be developed, six steps are considered. We have to recall that these steps have been emerged from the work with participants – by the nature of the GdS (a collaborative working group). The environment in which these steps are going to be developed are perceived as the context in which data for the research dimension will be gathered.

- 1) Teachers identify a critical aspect from their own mathematical practice which they aim to discuss, reflect upon and improve. Such critical feature will be firstly discussed in each of the

subgroups, taking into consideration the specificities of the contexts, and afterwards socialized and discussed in the large group (GdS) with all the participants;

- 2) After the identification of the critical features, all the subgroup elements will discuss their own previous experiences, also grounded on some readings on documents (e.g., papers, books) where such problematic (or similar) is discussed. Such discussion aims at allowing deepening the participants MTSK, understanding and awareness on the problem at hand;
- 3) Grounded on the discussions and reflections focusing on the problematic, teachers will conceptualize a task or sequence of tasks aimed at contributing for minimize the identified problem. Such tasks will be firstly prepared and discussed in each of the subgroups;
- 4) The following considered stage concerns the implementation of each task prepared on the subgroups in the GdS, in order to deepen the levels of discussion both on the nature of the tasks, its mathematical goals and ways of implementation. We have to recall that in such discussion are involved teachers from different school levels which is perceived as an opportunity to intertwine different aspects of the MTSK and teachers' awareness;
- 5) The next stage concerns the participants analysis of the implementation (all the participants will analyse the task, the implementation process and the teachers knowledge involved and required). Such analysis will occur firstly on the subgroups and afterwards some episodes will be discussed in the GdS;
- 6) The last stage (of each cycle), concerns the writing and discussion of narratives focusing on the lived experiences.

### **The development of LS as a research project**

Understanding LS as a proficient way to engage mathematics teachers in a professional development landscape, we focus on discussing the MTSK mobilized, involved and recognized by teachers when preparing, implementing and discussing mathematical tasks. In an intertwined manner the dimensions of the interpretative knowledge will be focus of attention at all the previously considered moments. Data collection will be taken from the video recordings of the subgroups meetings and the GdS meetings; classroom practices; interviews to teachers; interviews to students after the implementation of the tasks and teachers narratives. With the analysis we intend to contribute for a broader understanding of teachers' professional development and on the MTSK and interpretative knowledge developmental processes.

# Combining two frameworks: A new perspective on mathematics teacher knowledge

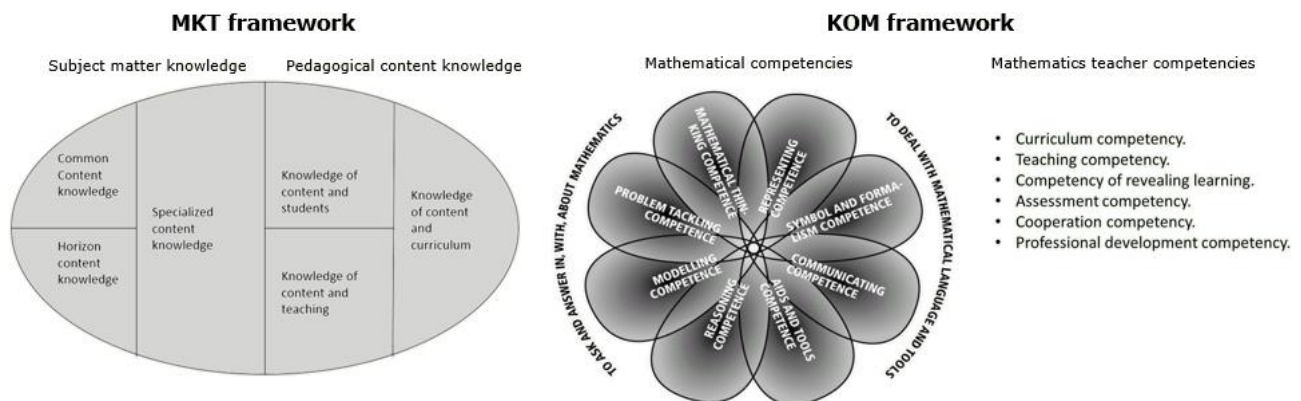

Knud Thorbjørn Sloth<sup>1</sup> and Ingi Heinesen Højsted<sup>2</sup>

<sup>1</sup>University College Capital, Denmark; [thorbjrn@yandex.com](mailto:thorbjrn@yandex.com)

<sup>2</sup>University College Capital, Denmark; [ingi.heinesen.hoejsted@skulin.fo](mailto:ingi.heinesen.hoejsted@skulin.fo)

**Keywords:** *Mathematical knowledge for teaching (MKT), competencies and mathematical learning (KOM), combining frameworks.*

For many years, there has been an interest in the role of the teacher in mathematics education research. During this time, efforts have been made to conceptualize the professional knowledge required to be a mathematics teacher. However, yet no consensus has been reached on how to describe the knowledge and ability, which is special to mathematics teachers. One framework, “Mathematical Knowledge for Teaching” (MKT) (Ball, Thames & Phelps, 2008), developed in Michigan includes subject matter knowledge, pedagogical content knowledge and tasks of teaching, and is widely used, in praxis and theory. The Danish competency-based framework “Competencies and Mathematical Learning” (KOM) (Niss & Jensen, 2011), which is described in terms of possessing eight fields of mathematical competency and six competencies related to the teaching of mathematics, is less used. The frameworks have not yet been used together. This is what we propose to do using the framework for networking of theories as formulated by Bikner-Ahsbabs and Prediger (2010), which describes strategies for connecting theoretical frameworks.

**Figure 1: The MKT and KOM frameworks**

## Method

Based on a case study of the development of mathematics teacher knowledge among students in the Danish preservice mathematics teacher education program (Sloth & Højsted, 2016), which aims to qualify prospective teachers for work in primary and lower secondary schools, we investigate how and to what extent MKT and KOM can capture what the preservice teachers learn. Finally, referring to the model for networking of theories proposed by Bikner-Ahsbabs & Prediger (2010) we compare the two frameworks.

## Results

We find that MKT and KOM can be used to describe most of our findings regarding the development of mathematical teacher knowledge in our case study, but the manner they describe them is different and do not always overlap. For example, when preservice teachers learn about different subtraction algorithms, which pupils might employ, we find the MKT framework can give a nuanced description of the unique mathematical knowledge and skills involved in teaching through its description of “Specialized content knowledge”. The KOM framework does not address the issues of teaching at this level of detail, but one could say that the teaching of subtraction algorithms requires different mathematical competencies, like representation competency and symbol and formalism competency as well as teaching competency. Another example is when preservice teachers learn how to perform mathematical modelling and how to analyze the mathematical models of others. We find that KOM can capture this with modelling competency, whereas MKT lacks a way to describe mathematical processes like modelling, problem solving and reasoning skills. Meanwhile the details of the didactical aspects of the development of modelling competency are not elaborated in KOM. For example, typical difficulties pupils encounter when working with modelling are not described. This could call for the development of what corresponds to knowledge of content and students and specialized content knowledge, but with regards to competencies.

## Conclusion

We conclude that MKT and KOM give different perspectives on mathematics teacher knowledge, that there are overlaps and differences when applied to practical situations, but also that the frameworks themselves may benefit from the perspective of each other. Using both frameworks on our case, we find that they can complement each other and describe a greater range of mathematics teacher knowledge. Furthermore, we suggest that using or combining concepts from both frameworks can result in a new understanding of the knowledge and ability needed by mathematics teachers.

*Keywords: Mathematics teaching, teachable moments, phenomenology.*

## Introduction and purpose of the study

Teaching is a complex phenomenon that encompasses ever-changing situations, where teachers are challenged to positively deal with unanticipated circumstances such as teachable moments. This poster draws from an ongoing doctoral research study, a hermeneutic phenomenological study, which seeks to identify and explore teachable moments corresponding to intermediate mathematics teachers' lived experiences. The research is guided by the following questions: What does it mean to teach intermediate mathematics? What does it mean to recognize and utilize teachable moments at an intermediate mathematics level? At this stage in the research, the term *teachable moment* is generally defined as an opportunity that arises when connections have been made to advance learning by a learner and/or an educator. More specifically, the term *moment* is distinctly defined as an expected or unexpected occurrence that allows learners and/or educators to deepen their understanding. The poster focuses on the background and context of the study, by highlighting the rationale, framework and methodology of the study.

## Background and context

Teachers often question the underlying purpose of teaching and its subjective meaning across three general categories: teaching subject content; teaching based on certain pedagogical tools; or teaching the child. Researchers in mathematics education have asked: What does it mean to teach mathematics? How can one become an effective mathematics teacher? On one hand, researchers tend to focus on teachers' content knowledge and/or pedagogical knowledge, or an integration of the two. However, having in-depth context knowledge in mathematics does not necessarily equate to teaching it effectively (Muri, 2008). Also other researchers question how the two categories of knowledge—mathematics (subject matter) and teaching (pedagogy)—can be integrated. On the other hand, mathematics researchers such as Doxiadis (2003) suggest that teaching mathematics effectively means humanizing mathematics for learners, and that “education is—should be, at its best—a process involving the complete human being” (p. 2). In this sense, humanizing mathematics means teaching it in a way that involves students as participants in mathematics, which is beyond mere content delivery or teaching certain skill sets. This poster draws from a study that aligns with this second view.

## Theoretical framework

The epistemology of phenomenology centers on didactic meaning as opposed to arguing or developing abstract theory. In their discussion of the theoretical and conceptual framework for a phenomenological study, Savin-Baden and Howell Major (2012) stated that “the essence experience

is so central and is to be uncovered before it is categorized, researchers do not tend to use a theoretical or conceptual framework... [because] doing so could impose presuppositions on the meaning of the experiences” (p. 221). The objective of this study is not to make broad generalizations about experiences of all mathematics teachers, but instead to examine individual teachers’ personal experiences associated with a very specific phenomenon of teachable moments.

## Methodology

In order to understand what teachable moments means to mathematics teachers, and how teachers use them in their day-to-day, moment-to-moment teaching, it is necessary to first gain insight into teachers’ lived experiences by exploring their reasoning, beliefs, and intentions for teachable moments. As a consequence, to this underpinning, the study employs a hermeneutic phenomenological research design founded on an epistemology of interpretivism. The study uses qualitative methods to collect data. These include semi-structured interviews, field notes and researcher journal. Participants comprise a purposeful sample of intermediate teachers with experience of teaching mathematics in Ontario, who have had lived experiences related to the phenomenon of teachable moments.

## Conclusion

The “teachable moment” is viewed as a somewhat intangible pedagogical prize; a teacher might know what it feels like, yet may not identify its characteristics. Educators such as math teachers seek moments of openness and creativity with their students so they can personally experience “the psychic rewards” of teaching (Lortie, 1975). Too often, such moments happen suddenly and slip away just as quickly, leading some teachers to conclude that such occurrences are a matter of chance. This study therefore seeks to shed some light on the characteristics of teachable moments in mathematics education to deepen teachers’ understanding and use of such teachable moments in their respective practices.

### Introduction

Given the prominence that the general education research ascribes to the impact of assessment on teaching and learning it is surprising that there had been so far no TWG dedicated to assessment of mathematics at CERME. TWG21, which met for the first time at CERME10 in Dublin, aimed to fill this gap. Given that this was a new group we decided to focus on assessment of mathematics considered broadly in order to gauge where the interest of the mathematics education community lies in this field, which encompasses very many different aspects. Although traditionally assessment has been discussed across many TWGs at CERME, TWG21 aimed to bring researchers together who have an interest in this topic and can, for the lack of a common forum, at times feel isolated. To reflect the landscape in the general literature we called for papers investigating the nature of assessment and its effects on student learning making use of a wide range of methodologies, from large quantitative and mixed methods study to small investigative qualitative studies. We were delighted to have 24 papers and one poster discussed at the conference. In what follows, we have grouped the papers in thematic clusters to reflect the variety of submissions regarding both focus and methodology. We conclude with some reflections on the working of the group and some suggestions for the directions this group can take in future CERME conferences.

### Thematic clusters

We identified six overarching themes that could serve as an organizing tool for the papers submitted to TWG21. Below, we describe each of these themes in turn.

**Different approaches to assessment:** Papers in this theme considered the affordances, drawbacks and validity of innovative assessment, both for students and for teachers. Davies proposes comparative judgment at university level as a new way of assessing students. In his paper, he investigates issues connected to the validity of this method for assessing conceptual understanding in mathematics. Lemmo and Mariotti investigate the issues connected with transitions of tasks from a paper and pencil form to an electronic form. They challenge the view that students employ similar solving strategies in both environments and find that indeed students solve the task differently in the two modalities. Teledhal investigates the validity of narrative accounts as an assessment tool for problem solving and concludes that those accounts do not offer enough details of the problem-solving process to be a valid tool for assessment. Dahl describes the perceptions of a group of science students (engineers, mathematicians, and other sciences) for group oral assessment. She finds that students

across disciplines agreed that a group exam gives less differentiation of grades compared to an individual exam. Finally, Reit discusses whether the validity of teachers' intuitive assessment practices is supported by empirical findings and shows that a sequential consideration of thought structures in a solution approach leads to reasonable results and may justify its application in school due to its straightforward implementation, especially when assessing modelling tasks.

**In service and pre-service teachers' views:** A second important theme that emerged from the submissions to TWG21 was related to teachers' views, beliefs, and use of assessment methods, both during their training and in their professional practice. Hofmann and Roth report on a study aimed at fostering preservice teachers' diagnostic skills with a focus on students' abilities, problems and misconceptions with graphs of functions. They explore the affordances of two tools for promoting diagnostic skills: video analysis and task analysis. Pratt and Alderton analyse English mathematics teachers' assessment approaches in the context of the current changes in assessment policy in the UK. To this end they use a Foucauldian analysis of teachers' discourse to sketch the power structures involved. They find that the official removal of the levels only superficially affected teachers' practices and teachers still relate these to the 'old' language of attainment levels. Kaplan and Haser investigate 27 preservice middle school mathematics teachers' purposes in planning the assessment and their views and suggestions about the assessment part of a lesson plan. Findings of the study indicate that purposes underlined by preservice teachers in preparing the assessment part of the lesson are similar across the sample and they all related to the teacher actions.

**Professional development:** Papers in this cluster addressed the role of professional development in fostering teachers' (both in service and pre-service) competences in assessing student understanding. Grapin and Sayac investigate the use of external (e.g. researcher-created) assessment tasks by primary school mathematics teachers and teachers' practice by using an activity theory perspective. They find that teachers design tests with low levels of complexity and did not invest much in assessment as a professional activity. Pilet and Horoks present analytical tools to characterize assessment activities as part of teachers' practice in algebra. The authors exemplify why high school teachers came to consider assessment as a potential lever to enhance both the students' learning in mathematics and the teachers' development. Initial results indicate that the teachers developed better indicators to select the students' productions that they will use for the discussion after a task, but that they use they make of these products hasn't improved. In her theoretical paper, Andersson argues that the addition of the dimension Teacher Instruction (ATI) as a key strategy to the five key strategies proposed in Wiliam and Thompson's (2007) framework of formative assessment could facilitate the analysis of teachers' use of formative assessment activities and improve the guidance and support of teachers' implementation of high quality formative assessment practice. Finally, in this group Santos and Domingos investigate portfolio assessment in geometry for pre-service teachers through the lenses of activity theory and procepts. They find students engage in qualitative different pathways when solving these problems.

**Formative assessment/feedback:** We received many papers discussing formative feedback and the submissions in this group spanned from primary to upper secondary school with focuses both on teachers' use of formative assessment and students' engagement with such assessment. Chanudet investigates the assessment of problem solving by using a grid of criteria. The paper focuses on the use that teachers make of such tool to facilitate formative assessment and offers the example of the

practice of one teacher where she analyses instances of formative feedback occurring in this classroom. Zhao, Van den Heuvel-Panhuizen, and Veldhuis investigated the effects on student achievement of supporting Chinese primary mathematics teachers' use of classroom assessment techniques. In this experimental study, the intervention consisted of teachers participating in workshops on the use of these techniques and using them in their classrooms. Results indicate that the students of teachers that gained more insight about their students from using the techniques, improved their mathematics achievement scores more than other students. Gurhy focuses on Irish students' perspectives on the use of assessment for learning in primary school. Findings indicated that students were positive about the feedback in, and practices of, assessment for learning, became more confident and expressed a feeling of enjoyment related to this. Two related papers reported findings from FaSMEd, a European project on the use of technology for formative assessment. In the first paper, Cusi, Morselli and Sabena analyse a teacher's strategies to provide feedback during class discussion. They identify five strategies: revoicing, rephrasing, rephrasing with scaffolding, relaunching, and contrasting. In the second paper, the authors describe how materials were designed to facilitate technology-enhanced formative assessment practices. They then show how the design framework can be used to analyse the implementation of technology-enhanced materials. They argue that materials designed in this way, combined with the functionality of technology, enhance a teacher's capacity to activate Wiliam & Thompson (2007) formative assessment strategies.

**Task design:** Three papers were dedicated to this theme. O'Brien and Ní Ríordáin describe the development, design, and theoretical underpinning of a diagnostic test for algebra. The test is aimed at lower secondary students in Ireland and is intended to help teachers identify the causes of students' errors. The authors discuss their reasons for adopting this approach. Beck investigates students' written solutions from CAS-allowed exams. Based on the analysis of students' solutions a descriptive model for assessing these solutions is set up. The paper also discusses how formative assessment could help students develop their competencies in communicating mathematics. Moomaw investigates the validation of a constructivist game- and story-based measure (Teddy Bear Picnic) for pre-school mathematics. In this measure, pre-school pupils are assessed while playing several interactive games. Psychometric tests show that the test appears to be a valid and reliable measure of pupils' level of mathematical development.

**Large-scale/standardized tests:** Finally, we received several papers addressing issues related to the use and design of large nationwide standardized tests. Garuti, Lasorsa, and Pozio describe the development of items for national assessment in Italy. They show how both quantitative and qualitative analysis can be used to improve the psychometric properties of items, whilst also improving their validity in terms of appropriate and relevant mathematical content. Ferretti and Gambini investigate the persistence of certain misconceptions in the transition between school and university. They focus on properties of powers and analyse two Italian nationwide databases to find that indeed certain misconceptions persist across this transition. Drücke-Noe and Kühn analyse characteristics of statewide exams in eight countries through task analysis and find that the cognitive demands of most competences needed to solve these tasks are rather low with the only the competence 'working technically' being often assessed. Cunningham, Shiel, and Close investigate the relation between the current Junior Certificate mathematics examination in Ireland for Grade 9 to the PISA and TIMSS frameworks. Their findings show that the Junior Certificate examination is moving closer in the direction of the PISA approach, but this is also motivated by the comprehensive

reform in mathematics in this country. Finally, Olande investigates how Grade 9 students solve an item involving the interpretation of graphs. Using student responses to an item from the national test in Sweden, his analysis shows that only a very small proportion of students use graphical reasoning in their solutions.

## Conclusions

In the process of preparing for this new group at CERME10 we were impressed not only by the variety of work we received but also by the methodological variety of the papers that spread from small qualitative case studies to large statistical surveys. The theoretical frameworks employed were also varied, from Activity Theory to Foucauldian analysis. We believe this variety to be sign of a growing interest in mathematics education for assessment; not only in the sense of validation of large scale tests, but also in terms of the effect that assessment has on teachers' actions in the classroom and as such on student learning. This variety, however, can also be sign of a field which has yet to find its unifying themes: the presence of a forum for discussion like TWG21 can therefore help define these emerging unifying themes. Validity of assessment for example – although ubiquitous in many papers – was hardly explicitly addressed. Indeed, in the final session of our group which was dedicated to reflecting on the group experience with an eye to future meetings, we observed some issues which at times have hindered communication. One of those was the lack of uniformity in definitions of recurring terms or sometimes the lack of clear definitions at all. It was felt that agreement on definitions of basic terms is important for communication and collaboration, and the lack of this clarity of definitions can be again a manifestation of a developing and growing field. We also noticed the absence of papers discussing the impact of assessment methods on student learning, a theme which is very much present in the assessment literature. The final reflection of the group concerned the presence of *mathematics* in the research presented. The group felt that in a topic such as assessment it may be easy to lose the focus on the mathematics assessed and instead discuss generic assessment research. While assessment research in general education is obviously very important to the work of this group, all participants felt that the focus should be on the mathematics assessed, and that indeed it may be a difficult balancing act not to replicate research and constructs that are already used in the general assessment literature and keep the focus on the fact that we aim to use these findings and constructs to investigate the assessment of mathematics. Although this balancing act might make for a difficult enterprise, we are confident that in the coming CERMEs we will be able to continue discussing general assessment issues such as validity, but always with a clear focus on the mathematics to be assessed and its didactics.

# Formative assessment - and the component of adjusted teacher instruction

Catarina Andersson

Department of Science and Mathematics Education, Umeå University, Sweden;

[catarina.andersson@umu.se](mailto:catarina.andersson@umu.se)

*This theoretical paper is based on an empirical study where the framework of formative assessment by Wiliam and Thompson was used to analyze teachers' use of formative assessment in their mathematics classroom practice. The paper argues for treating a component named Adjusted Teacher Instruction (ATI) as a key strategy in complement to the five key strategies in the original framework. ATI is a significant component in formative assessment, but also particularly challenging for teachers to implement in their classroom practice. Treating ATI as a key strategy could facilitate the analysis of teachers' use of formative assessment activities and enhance the understandings about what kind of ATIs are most useful for whom under what conditions. Extended understandings about effective formative assessment activities are important in decisions about what formative assessment to include in teacher education and in-service training for teachers.*

*Keywords: Formative assessment, assessment for learning, mathematics, instruction.*

## Introduction

The encouraging potential noticed in formative assessment has motivated scholars to further engage in both empirical studies and theoretical work in the research area of formative assessment. The theoretical understandings of formative assessment have evolved during a long time, often affected by empirical studies in which researchers has been responsive to teacher practice. This paper focuses on a component of formative assessment that is regarded particularly significant, but also difficult in carrying out formative assessment. In this paper this component is called Adjusted Teacher Instruction (ATI) and it is argued for treating ATI as a key strategy in parallel to teacher feedback.

Black and Wiliam (1998) in their research review demonstrated that large student achievement gains are possible when formative assessment is employed in classroom practice. This review received widespread attention and caused a discussion about the need for and role of an extended assessment culture and practice. Since then, implementation of formative assessment has been on school policy agendas in many countries (Tierney, 2006), but this implementation has often proven to be challenging (Birenbaum et al., 2015). Several attempts have been unsuccessful in accomplishing a substantially developed formative assessment practice (James & McCormick, 2009; Schneider & Randel, 2010) and misunderstandings and distortions of essential features of formative assessment are detected in policy and practice (Swaffield, 2011). Some factors facilitating and hindering the implementation regarding the teacher, student, assessment and context are identified (Heitink, Van der Kleij, Veldkamp, Schildkamp & Kippers, 2016), but still a strong research base supporting how to effectively help regular teachers to implement a high quality formative assessment practice is lacking (Schneider & Randel, 2010; Wiliam, 2010). Such a research base needs to include both how to design effective professional development programs for teachers and what kind of formative assessment to include in such programs.

This paper is related to the latter issue. The discussion in the paper is theoretical, but originates from an intervention study in which a group of mathematics teachers learned about formative assessment

(see Andersson, 2015). In this study, formative assessment was conceptualized as one big idea and five key strategies (see Wiliam & Thompson, 2008) in a framework that was used in the professional development program and for structuring the data collection and data analysis.

## Background

Black and Wiliam defined formative assessment as “encompassing all those activities undertaken by teachers, and/or by their students, which provide information to be used as feedback to modify the teaching and learning activities in which they are engaged” (Black & Wiliam, 1998, pp. 7–8); a definition that provide several possible focus in carrying out formative assessment. Consequently, Black and Wiliam’s review included studies investigating different strategies for carrying out formative assessment, using the term formative assessment in different meanings or using alternative terms such as feedback, self-regulated learning or peer-assisted learning. As Bennett (2011) points out, without a consensus about the term formative assessment, the effects will be unclear. A common and clear terminology and definition of formative assessment is also desired to eliminate misunderstandings and distortions in policy and practice.

To maximize instructional benefits, we need to know more about what constitutes effective formative assessment (Wiliam & Thompson, 2008; Wiliam, 2007). To gain valuable insights about best practices it is important to be clear about the way formative assessment is conceptualized in for example studies of implementations of formative assessment that are empirically linked to student achievement. The formative assessment practice needs to be carefully analyzed and described to provide information about specifics of such practices as well as how these specific characteristics may have functioned as part of an enhanced learning process.

Black and Wiliam’s review included studies showing the potential instructional benefits of different strategies for carrying out formative assessment. It can be expected that a classroom practice that integrate such key strategies to a unity would open up extended opportunities for learning and thus offer higher potential for improving student achievement. The empirical study motivating this paper is one of few studies investigating the impact of such an integrated practice on students’ achievement. Following sections of the text outline Wiliam and colleagues’ conceptualization of such a practice, followed by a description of the operationalization of that framework.

## One big idea and five key strategies

A more recent definition of formative assessment by Black and Wiliam is more detailed:

Practice in a classroom is formative to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about next steps in instruction that are likely to be better, or be better founded, than the decisions they would have taken in the absence of evidence that was elicited. (Black & Wiliam, 2009, p. 9)

This definition clearly demands every formative strategy to fulfill the big idea of using evidence of student learning to adjust instruction to better meet students’ learning needs. The conceptualization of formative assessment as one big idea and five key strategies (Wiliam & Thompson, 2008; Black & Wiliam, 2009) is visualized in Figure 1. The matrix visualizes how three processes (horizontally) and three agents in the classroom (vertically) construct five key strategies (KS) in formative assessment. The three processes constitute the defining characteristics of formative assessment

inherent in the definition above and are central for the big idea of using evidence of student learning in decisions about how to proceed in the instruction. The three agents who are responsible for the learning in the classroom are defined as the teacher, the learner and the peers.

	Where the learner is going	Where the learner is right now	How to get there
Teacher	KS 1 Clarifying learning intentions and criteria for success	KS 2 Engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding	KS 3 Providing feedback that moves learners forward
Peer	Understanding and sharing learning intentions and criteria for success	KS 4 Activating students as instructional resources for one another	
Learner	Understanding learning intentions and criteria for success	KS 5 Activating students as the owners of their own learning	

**Figure 1: The relationship between key strategies (KS), instructional processes and agents in the classroom (After a figure in Black & Wiliam, 2009, p. 8)**

The different key strategies in formative assessment are connected and sometimes dependent on each other's existence and performance. For example, clear learning intentions guide the teacher to chose questions/tasks that elicit relevant information about students' learning and help the teacher to provide goal directed feedback. In addition, learning intentions clear to the students enhance their opportunities to be engaged and involved in the learning process (their own or their peers').

### **Using the big idea and five key strategies to analyze classroom practice**

The author of this paper participated in a research group responsible for a study about professional development in formative assessment for a group of randomly selected mathematics teachers. The framework above was used in the professional development program, in the data collection and in analysis of formative assessment used in the teachers' mathematics classroom practices.

Two rounds of data collection and analysis were made, before and one year after the professional development program. Both times, observations were completed in each teacher's mathematics classroom practice and all teachers were interviewed. The big idea and the five key strategies structured observation schemes and interview guides, with a focus on what formative assessment activities the teachers used in their mathematics classroom practice.

Each formative assessment activity was supposed to be classified in relation to one of the five key strategies or the big idea. From a teacher perspective the big idea pertains to Key strategies 1–3. Accordingly, activities aimed at clarifying where the learner is going could be classified as belonging to KS 1 and activities aimed at eliciting where the learner is right now as belonging to KS 2. Teacher

feedback aiming at moving student learning forward was classified as belonging to KS 3. This process led to one remaining group of teacher activities concerning teachers' use of information about learning needs (the big idea) that did not fit to any of the other key strategies. Therefore, to clarify our data and for consistency reasons, we decided to include the new category Adjusted Teacher Instruction (ATI) as a new 'strategy' in parallel to feedback. Both strategies (ATI and feedback) aim at taking learning forward. Consequently, no activities were classified as belonging to the big idea. The formative activities classified as ATI were the activities aiming at taking learning forward that did not concern teachers' oral or written feedback.

Before the professional development program (PDP) the most common ATI activity was to use results from a diagnosis in the textbook to choose a group of tasks (regular or advanced) for each student's individual work with the chapter in the textbook. Other ATI activities used by a smaller group of teachers were, for example: individualized tasks for a student; adapted materials for example work sheets, homework or tactile materials; extra or modified lecture for the class, a group of students or for individual students; and adaption of time set aside for a chapter in the textbook. After the PDP individual teachers extended their repertoire of ATI activities (from the same type of activities as identified before the PDP), for example lectures for group of students became more common. The teachers' use of ATI activities was also affected by new activities connected to Key strategy 2. Many teachers had started to make use of students' misunderstandings, which were often identified by using mini-whiteboards as an all-response system. In general, the teachers received information about student learning more often and in various ways and could consequently make adjustments of instruction more often and with more precision.

In our analysis of formative assessment activities in teacher's mathematics classroom we decided that teacher activities connected to the use of evidence of learning needs could either be classified as a feedback activity or as an Adjusted Teacher Instruction activity. Thus, feedback and Adjusted Teacher Instruction would have a shared position within the third teaching and learning process (How to get there) for the teacher's actions (see Figure 1). This proposed shared position will be discussed below.

## Discussion

In this paper, Adjusted Teacher Instruction (ATI) is suggested as a component of particular significance in formative assessment to be treated as a key strategy, a proposal that could improve the use of the formative assessment framework by Wiliam and Thompson (2008) in research, policy and practice. The advantage is twofold: (1) the ATI component will get a more prominent place and (2) the framework will be more coherent. These advantages, but also some concerns, will be discussed below.

One advantage of treating ATI as a key strategy would be that teacher activities within this strategy could be defined and further studied in the same way as for activities belonging to other strategies. The few studies using frameworks unifying several formative assessment strategies in analysis of teacher classroom practices do not always provide specifics about teachers' adjustment of instruction (e.g. Wylie & Lyon, 2015; Randel et al., 2011). Such specifics are desirable because the instructional decisions and actions taken to better meet student needs are crucial for students' continued learning opportunities (Wiliam, 2007) and because using evidence of learning to inform next instructional

steps has been experienced as a challenging aspect of formative assessment (Cowie & Bell, 1999; Heritage, Kim, Vendlinski, & Herman, 2009; Oláh, Lawrence, & Riggan, 2010).

Research addressing this crucial and difficult component in formative assessment is desirable to enhance the understandings about what ATIs are effective under different circumstances, but this area of research needs improvement in terms of becoming more prominent, the definition of the area and the number of empirical studies conducted (Bellert, 2015). Research about feedback has resulted in guiding models for what type feedback is more or less effective, for different students and under different conditions (e.g. Hattie & Timperley, 2007; Shute, 2008). Similar knowledge about ATI is important because a main aspect of formative assessment is that planning of instruction is decision driven. To secure that the information from the assessment will be useful, a feasible way is to plan instruction backwards with a clear decision in mind and searching for relevant evidence to make decisions in a smarter way (Wiliam, 2007). Skilled teachers can design teachable moments into their lesson because they have already thought of alternative instructional decisions before the information was collected (ibid., p. 1089).

If we know more about what instructional adjustments are likely to be most effective in different situations this would be helpful guidance for policy and practice, for example in teacher education and in-service training for teachers. The knowledge base can be extended from conducting studies that empirically link different types of ATI to student achievement and by careful analysis, descriptions and conclusions about ATI characteristics and their function as part of an enhanced learning process. One example of a study contributing to this knowledgebase is a study by Ruiz-Primo, Kroog and Sands (2015). This study of science and mathematics teachers was restricted to *informal* formative assessment, in which the interaction between teacher and students is central. Studied within this interaction, the characteristics of the teacher's response were classified according to type of oral feedback or type of *instructional move*. Additionally, the type of teachers' actions observed in more and less expert teachers was studied. The results were separated for individual student work and whole class work. Using a two step cluster analysis, there were five variables included for teachers' instructional moves: (1) re-teaching (e.g., going over content again in the same or similar way as before); (2) solving problems with students (e.g., asking students for their input along the way while solving a problem); (3) solving problems without students (e.g., solving or modeling the solution to a problem without student input); (4) re-clarifying the task (e.g., reminding students of what they need to do); and (5) providing the correct answer (e.g., giving the answer without explanation) (Ruiz-Primo et al., 2015, p.17). This study does not only tell us that instructional adjustment were implemented, but also specifies these adjustments and compare the use of them in two kinds of work conditions and by two groups of teachers.

Another advantage of treating ATI as a key strategy in parallel with feedback is that the framework would be more coherent. In fact, also Wiliam includes instructional adjustment as a second aspect of feedback in the meaning that feedback is provided to the teacher so he or she can modify the instruction to be more effective (Wiliam, 2010, p. 33). However, the feedback *to* the teacher is comparable to elicited evidence of student learning in Key strategy 2, and this might generate confusion. The suggested shared position for feedback and Adjusted Teacher Instruction might clarify the framework to avoid misunderstandings and distortions in policy and practice and thus provide a better guidance. Such guidance might have affected the design of the professional development

program in the study behind this paper (see Andersson, 2015). In the program ATI was not treated as a key strategy and did not get the same focus and time set aside as the other key strategies did. This might have affected the limited extension of types of ATIs at group level in the results.

A concern about treating ATI as a key strategy regards the need and meaning of the big idea. Elaborating the big idea from a teacher perspective, Key strategy 1 is not indispensable for teachers' eliciting and using information of students' learning needs, only critical for ending up with evidence useful for formative assessment. Wiliam distinguishes between diagnostic assessment and assessment that is instructionally tractable, where the latter form not only indicates what needs attention but also what needs to be done to address the issue (Wiliam, 2007, p. 1063). Wiliam points to the need of the teacher to have a range of instructional alternatives beyond just repetition:

For formative assessment to be instructionally tractable, the teacher must be clear about the range of alternative instructional moves that are possible, should then decide what kinds of evidence would be useful in choosing among the relevant alternatives, and only then elicit the evidence needed to make that decision. (Wiliam, 2010, p. 33)

While Key strategy 1 is ultimate, Key strategy 2 is a prerequisite for the implementation of the big idea. Key strategy 3 concerns the very foundation of the big idea about formative assessment. The big idea is important in the evaluation of the function of the implementation because it reflects the whole assessment cycle, which Wiliam suggests should be performed backwards (see above).

Another concern regards the distinction between feedback and Adjusted Teacher Instruction. The distinction we made (see Andersson, 2015) do not match the distinction made by Ruiz-Primo et al. (2015), probably caused by the different conceptualization of formative assessment. Even when using the same conceptualization of formative assessment, some activities will be a definite feedback *or* ATI activity, but other activities will have a more uncertain belonging. In our case, when teachers used the “thumb of role” giving feedback as *two stars and a wish* (showing the student two excellent aspect of their work and an idea for improvement), this is categorized as feedback. When a teacher decides on finishing work on algebra a week earlier than planned, this is ATI. A more uncertain activity would be when the teacher together with the student decides what tasks are most appropriate for the student to work with. We would classify this as an ATI activity, from the rationale of not being restricted to oral or written feedback from the teacher.

## Conclusion

The advantage of treating ATI as a key strategy put forward in this paper is ultimately about improving the guidance and support of teachers' implementation of high quality formative assessment practice. ATI is experienced as difficult to implement by teachers. At the same time, the ATI component does not always receive much focus in analysis of teacher classroom practices. A more specified analysis and communication of research results about ATI could provide teachers with better guidance. In addition, a more coherent framework could be easier for teachers to understand. The big idea is an important guiding idea and the key strategies concretize this idea. The quality of any formative assessment activity is dependent on the extent the activity meet the aim of the key strategy as well as the big idea.

This paper argues for more studies conceptualizing formative assessment as a unity of different strategies of which ATI is one. Ultimately such studies examine the effect of implementation of

formative assessment on both teacher classroom practice and student achievement. The formative assessment practice needs to be carefully analyzed and described to provide information about specific characteristics and their function as part of an enhanced learning process. Such research might end up in models similar to those of feedback (Hattie & Timperley, 2007; Shute, 2008), showing more and less effective ATI, for different students and under different conditions.

# Written documentations in final exams with CAS

Johannes Beck

Julius-Maximilians-Universität Würzburg, Germany; [beck@dmuw.de](mailto:beck@dmuw.de)

*This article focuses on students' written solutions from CAS-allowed exams. Based on the analysis of students' solutions a descriptive model is set up. It can be used for assessing students' solution as well as creating exemplary documentations. The purpose of these documentations is to help teachers reflect about their practise of writing down solutions and the norms they set by this for exams. This paper also shows how formative assessment could be a means to help students develop their competencies in communicating mathematics.*

*Keywords: Upper secondary education, exams, written solutions, Computer Algebra Systems, formative assessment.*

## Introduction: Challenges in exams with computer algebra systems

Digital technologies like graphical calculators and computer-algebra-systems (CAS) influence various aspects of mathematics education in general and the classroom-practise in particular (cf. Barzel ea. 2005). Most prominently, the way tasks can be solved changes drastically: where once it was necessary to differentiate a function with pen and paper, now every student can use a CAS and by pressing a short series of buttons the result appears on the screen. The new possibilities fuelled the hope that “[t]he new tool provided the chance to concentrate more on central competencies in mathematics education, concept formation, problem solving and modelling competencies, and to outsource algorithmic operations to the machine” (Drijvers & Weigand, 2010). While the shortcutting of the work of calculating with pen and paper enables classes to have more time for the central competencies, it also forces teachers and students to think about how to document the process of “working” on a task. This article focuses on the aspect of how communication in a CAS-environment could be shaped.

In this context, the study aims at identifying problems, difficulties and possibilities concerning students' solutions, categorize elements in those according to their function within the solving process and suggest a possible standard for written solutions with CAS. Against this background, the suggestions can also be interpreted as assessment criteria and, thus, a given students' solution can be assessed. Furthermore, it is a goal to provide a theoretical model that describes the development of students' documenting competency. The following research questions are

1. How do students write down their solutions in final exams? Which different forms of documentations do they use? What kinds of problems or difficulties (if any) are connected with these forms?
2. How can students' written solutions be described by means of a category system?
3. How could a developmental model look like that
  - a. describes how students' competencies in documenting the solving process with CAS can be developed?
  - b. offers learning strategies and exemplary solutions for shape this development?
  - c. encompasses criteria for assessment in final exams?

The major motivation for this study is to create a sound set of suggestions for teachers, for application in the classroom and for preparing students for the final exams. Formative assessment plays a crucial role in developing an adequate documentation competence. This article gives an answer to the second question and presents an outline of ideas to research question (3).

## Theoretical framework

The theoretical framework to tackle the questions above encompasses two important fields: written documentations as communicative texts, and formative assessment, which will be the basis for creating didactical material for teachers.

In exams the purpose of documentations is to enable others to understand how the solution has been gained and to evaluate to which degree the solution is correct or incorrect (cf. Ball & Stacey 2003). Thus, the communication of mathematical knowledge is the primary aspect. In terms of the communication model by Jakobson (1960) the communication situation can be described as follows: the learner is the ADDRESSER, the teacher is the ADDRESSEE and the written-down solution is the CONTACT (or channel) for the MESSAGE (1960, p. 353). The CODE in this communication situation can be considered as coming from three different areas: (1) the natural language, (2) the mathematical language, encompassing the symbolic language as well as the mathematical register (cf. Pimm 1987), and (3) the computer world with CAS-commands and also its own register (cf. Siller & Greefrath, 2010).

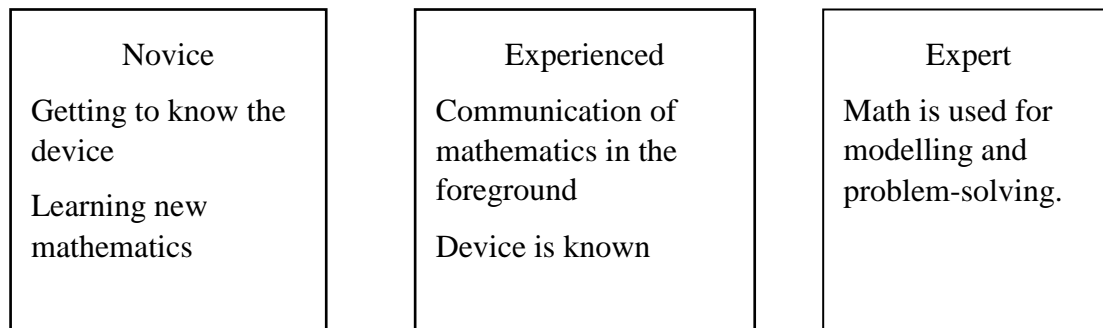

In exams the written documentation is – according to the communication model above – the only channel by which the message is sent from the addresser to the addressee. Naturally, in such a situation it is neither possible nor allowed for the corrector to inquire in case he or she does not understand a part of the solution. Busse speaks of all written communication as “reduced communication situation[s]” (2015, p 320, translation by the author), arguing that only the text itself and the recipient of the text are present in the situation. As a result, the understanding of texts can be reduced to the allocation of the recipient’s knowledge to elements of the text.

The second part of the theoretical background is about formative assessment and how it might be used to develop the documentation competence of students over a longer period. “Assessment for learning”, as formative assessment is sometimes called, can be outlined as “the process of seeking and interpreting evidence for use by learners and their teachers to decide where the learners are in their learning, where they need to go and how best to get there” ( ARG 2002, p. 2). Black & Wiliam (2009) describe how five key strategies constitute formative assessment:

1. Clarifying and sharing learning intentions and criteria for success;
2. Engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding;
3. Providing feedback that moves learners forward;
4. Activating students as instructional resources for one another; and
5. Activating students as the owners of their own learning (Black & Wiliam 2009).

The crucial and most difficult point here is to have criteria for good written solutions. As Weigand

points out “there are no algorithmic rules or norms how to document a solution on paper” (Weigand 2013, p. 2772). He reports from a long-term project in Bavaria (a part of Germany) that students have “difficulties in using SC [scientific calculator] and (problem-)adequate representations especially, as well as the documentation of the solution with paper and pencil” (Weigand 2013, p. 2763). Therefore, teachers need to focus on the development of the competence to document adequately over a longer time. Students have to reflect about documentations and grow into the communication practices of the mathematics community. In Germany, the most important framework of mathematical competencies is the one by the KMK (cf. KMK 2012). The KMK distinguishes three requirement-levels to describe the requirements that can be addressed in tasks in relation to six central mathematical competencies and five central mathematical guiding ideas. This framework is not made for the development of the competence to document (which I see as only a part of the competence of communicating mathematically) but for describing and testing the competencies. Thus, a model was created that focuses more on the development and tries to reflect the difficulties of handling the CAS, too. The competence model by Dreyfus & Dreyfus (1991) is insofar an important reference work that it describes how the development of competencies from a novice stage to an expert stage happens in five steps. According to Dreyfus & Dreyfus, novices act according to rules very explicitly while experts have internalized the rules so much that the behaviour has become part of them. The model for the development of the documentation competence distinguishes only three stages. For teachers it is thus easier to think of the stages as of the three consecutive years (10th to 12th grade) when CAS-classes can be allowed permanently in special classes. The model tries to reflect some difficulties teachers reported in CAS-classes (cf. Beck 2015, Weigand 2013) by shifting the focus of each of the three stages:

**Figure 1 – Development model**

1. Novice: Focus on technology-use: Learning to deal with already known and new mathematical content *with the new tool*, in order to get accustomed to it.
2. Experienced: Focus on communication: Reflecting about the use of the tool and the communication of mathematical content.
3. Expert: Focus on modelling and problem-solving: Applying the mathematics to modelling problems with the help of the CAS.

Although high-school CAS-classes only use one device (like the TI-nspire or the CASIO Class Pad II) it is not the aim to restrict the mathematical competence to just this one device. Therefore, also the competence to document should not be chained to the tool that is used but be applicable to all kinds

of tasks and problems. To achieve such a flexible competence teachers could use formative assessment as shown below.

It is the teacher's task to initiate a discussion about how the digital tool changes the nature of the solving process and, as a consequence, the written solution (strategy 2, see above). This is also a reflection of the benefits of a CAS. As already mentioned, it is not necessary anymore to write down every step in the solving process in order to perform it. A lot of algorithmic procedures can be outsourced to the CAS. This reflection might help students to progress further on their way from novices to experts.

Furthermore, as Black & Wiliam state "peer- and self-assessment are activities that might be used to pursue the fourth and fifth [key strategy] respectively" (p. 8). As a useful activity students (and teachers as well) could check and discuss whether their own documentation and the documentation of classmates meet the criteria. Students can discuss problems regarding the understandability of solutions amongst themselves and with their teacher. From a theoretical perspective, it seems to be most promising to apply these activities with experienced students (Fig. 1), after the students are used to work with the CAS but before complex (modelling-)problems are treated. Yet, this assumption has not been tested empirically. Regarding the documentation of solutions one aim is a high level of language use (most prominently: mathematical terminology). This is part of the competences communicating mathematically and mathematical reasoning (cf. KMK-Bildungsstandards, K6 and K1; Blum 2010).

## Methodology

As a first step, a descriptive model has been developed from students' authentic solutions from high-stake final exams. These exams are the last time in the students' life and therefore these reflect (to a certain degree) the knowledge and the practise of the students. From a linguistic perspective, it is one aim to identify which elements students use in their documentations and which function is connected with each form. This is a typical pragmatic approach (cf. Meibauer 2008). The underlying question of this form-function-analysis can be formulated as follows: With which forms of representation do students document each step of the solving process? From a mathematical perspective, it is the aim to identify difficulties and problems in the students' solution. One problem is that traditional mathematical notation is mixed with computer language with the result that the created expressions do not fit the requirements of "the community of mathematicians".

Bavarian teachers of CAS-classes have been asked to send in nine written solutions each from the final exams. The students have three groups of tasks to solve (calculus, geometry, data & statistics) and have 180 minutes time. Three solutions came from students who have been average, three from students who have been above average, and three from students who have been below average in the preceding semester. Similar data has been collected every year (starting with 2014) for further evaluation and research. Four to five teachers answer this request every year.

The first research question is how students document their solving process in exams. So far, in Bavaria (Germany) only little official advice about documentations of solving processes is given. Normally, the Institute for School Quality and Educational Research (ISB) provides such material and official notes in addition to the curriculum. In order to develop such advice, it is a very valuable first step for researchers to analyse authentic documentations and to develop a descriptive model with which

problems and difficulties can be identified and categorized.

The representational dimension describes with which forms of representation students document. There might be expressions, which use some kind of formulaic symbols (traditional mathematical, computer-syntax, mixed-forms), verbalisations (both natural language and the special mathematical vernacular) and graphic representations. In the latter category, mixed forms (such as graphs, tables, sketches, etc.) are also counted.

representational dimension				activity dimension
CAS-related notes				
explanations				
mathematical idea				
results				
structuring elements				
	formulaic expressions	verbalisations	graphic representations	

**Figure 2 – Category system for description of students' solutions**

The second, *activity dimension* describes which purpose an element has, that is what actually is documented with it and which step, or activity, in the solving process it is related to. Central categories are:

- *CAS-related notes* make the use of CAS explicit, either by stating the CAS command (input), by writing down the output (e.g. “false”, which is odd in a German text), or by unspecifically writing – in short form – that the CAS was used (e.g. “CAS: ...”).
- According to Wagner and Wörn (2011) *explanations* comprise three different facets: concepts and ideas (what-explanation), algorithms and procedures (how-explanation), argumentations and logical connections (why-explanation). They often focus on:
  - *mathematizations*, which show that information given in the task-description is translated into mathematical notation or terminology;
  - *interpretations*, which are translations of computer-output and the construction of meaning in relation to the task.

The terms mathematizations and interpretations are related to the respective activities in the extended modelling cycle by Siller & Greefrath (2010).

- Furthermore, there are elements which refer to the underlying *mathematical idea*, e.g. in order to find the maximum of a function  $f$  it is necessary to solve the equation  $f'(x)=0$ . From this element, the mathematical idea can be reconstructed.

- Every mathematical activity leads to some *result*. This might be the answer to a posed question or a step that takes one closer to the final result.
- *Structuring elements* are used to structure the text on the surface (the layout) and the way the information is presented. They can also be used to set up links between pieces of information such as single steps in the solving process and the chronological order in which they were performed.

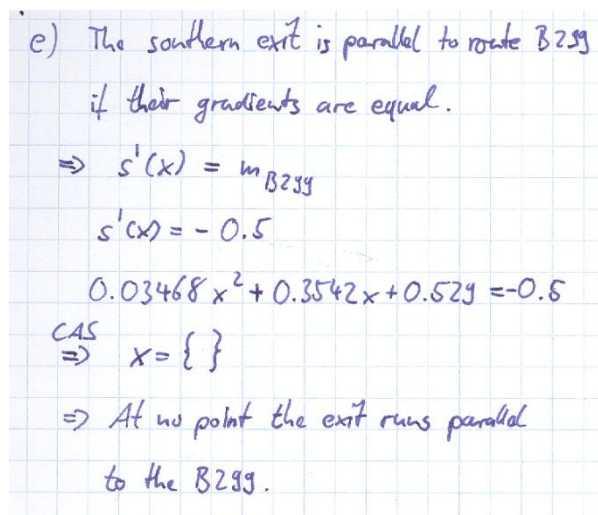

## Results

The first result is that the category system above (Fig. 2) is suitable to describe students' solutions. It can be observed that in regard to the documentation of CAS-commands the style was very homogenous throughout each class. In one of the classes, CAS-commands have been documented. In the second class, the CAS-use was indicated by writing "CAS" either over an equation or at the beginning of a line. In the third and fourth class there were no CAS-commands at all. This phenomenon can be explained by the normative standards that the respective teacher had set in the preceding year. Secondly, students who had a correct solution always showed the necessary mathematical ideas. Fig. 3 shows two different ways how mathematical ideas can be presented: either in verbalized form (line 1) or encapsulated in a formulaic expression (line 3).

A further result of the analysis of the students' documents is that written solutions *without* verbalised explanations were often harder to understand and that the solving process could not be reconstructed that easily.

### Authentic and exemplary solutions

As shown above, elements of written solutions can have different functions. Among them explanations can contribute a lot to make students' documents easily understandable. According to Jörissen and Schmidt-Thieme explanations can be characterised as "primarily verbal statements" with the goal that the reader can understand connections (2015, p. 401, translation by the author).

c) The southern exit is parallel to route B239 if their gradients are equal.

$$\Rightarrow s'(x) = m_{B239}$$

$$s'(x) = -0.5$$

$$0.03468x^2 + 0.3542x + 0.529 = -0.5$$

CAS  
 $\Rightarrow x = \{ \}$

$\Rightarrow$  At no point the exit runs parallel to the B239.

Figure 3 – Student's solution: original and translation

Furthermore, additional explanations extend the transmitted information with the possible consequence of redundancy. However, misunderstandings can possibly be prevented. As already mentioned Wagner & Wörn distinguish three different types of explanations: explain-what, explain-how and explain-why (2011). These sub-categories can be found – rudimentarily – in the students'

solutions, too. It is most important to notice here that students often explained verbally although it was not explicitly asked to do so in the formulation of the task.

The task of the example (Fig. 3) is to check whether there is a point at which the exit of a highway – modelled by a polynomic function  $s$  – runs parallel to another road – the route B299.

In the example (Fig. 3) we see that the student explains the mathematical idea of his solution verbally at the beginning. It is a rudimentary how-explanation. The verbal inaccuracy at this point is not that important because the information given in the text is supported by the mathematical formulaic expression, which is the equation. The output (“{ }”) follows a CAS-use which is documented *unspecifically* (see above). The student confuses proper mathematical syntax with device-specific CAS-output and mixes both into an incorrect expression. As a concluding answer to the task a verbal interpretation of this output is written down.

The categories from Fig. 1 can be used to describe and explain students’ solutions. But they can also be used to help teachers to reflect written solutions and their own practise of writing mathematical texts. Furthermore, on the basis of the categories exemplary solutions can be created, as shown below (Fig. 4).

Category	Exemplary solution
Explanation	The roads run parallel to each other when there is a point at which $\varnothing$ has the same gradient as $\varnothing(\varnothing) = -0.5\varnothing$ .
Mathematical idea	$\varnothing'(\varnothing) = -0.5$
Result	This equation has no solution, therefore,
Expanation	the roads do not run parallel to each other.

Figure 4 – Exemplary solution for teachers

It cannot be expected of students’ solution to show such a degree of verbalisation. It is not the purpose of exemplary solutions to set minimal standards for students but to show teachers how solutions can be documented. The categories help to structure the text and to make the function of single elements more apparent.

## Discussion of results and conclusion

Teachers may apply the categories in two ways: firstly, the categories can provide guidelines for documentations in a constructive way. For example, every documentation should make clear what the *mathematical idea* was that lead to the solution. Furthermore, students and teacher could agree in classroom discussions that verbalized *explanations* help to make clear the connections of different (symbolic) elements and, thus, allow the reader(s) to follow the solving process more easily. The notation of *CAS-commands* (if and how) could also be agreed upon in the class or amongst teacher even on a school level. Secondly, they then might be used for assessing students’ solutions for formative purposes as well as summative purposes. The categories might help teachers and researches alike to see documentations more clearly as a set of elements with different functions that make up the whole text. The exemplary solutions illustrate different possibilities of documentations. They can

be used for reflection in pre-service professional development courses as well as in in-service professional development courses.

In conclusion, it is important that students develop the competence to assess by themselves if a solution is acceptable and to create good solutions on their own (formative assessment key strategies 4 and 5). The main determining factors are the purpose of the documentation and the intended addressee, both of which may make an additional verbal explanation necessary. To provide support for this development is a major challenge for modern mathematics education. The combination of “learning to document” with some elements of formative assessment is a promising way to meet this challenge.

# Teachers' formative assessment practices: The case of an IBME-centered course

Maud Chanudet

University of Geneva, Switzerland; [maud.chanudet@unige.ch](mailto:maud.chanudet@unige.ch)

*In Geneva canton (Switzerland), a special course has been designed to deal with problem solving. Within one 45-minute period per week, teachers have to improve students' problem solving competencies and to assess them frequently. In order to assess students' problem solving competencies, most teachers use grids of criteria with a summative purpose. The global objective of our research is to find out if and how using such a tool can also foster formative assessment processes. In this paper, we present an exploratory study focused on teachers' formative assessment practices. In order to do so, we study the practices of a teacher giving this IBME-centered course and show how she uses formative assessment in her teaching practices.*

*Keywords: Formative assessment, summative assessment, problem solving, IBME, teachers' practices.*

## A course dealing with problem solving

In French-speaking Switzerland, the shared curriculum for compulsory education insists on the importance of problem solving in mathematics education in order to make students familiar with inquiry based mathematics education (IBME). The aim is to promote students' scientific processes of thought. But as Dorier and Maass say "inquiry based mathematics education remains quite marginal in day-to-day mathematics teaching" (2014, p. 303). That is why in Geneva canton, a special course called *mathematics development* has been created to focus on and develop students' problem solving competencies. Students aged 13-14 years old (grade 8) with a scientific profile are involved. Within one 45-minute period per week, teachers have to improve the students' problem solving competencies and at the same time, assess them frequently.

This course is subject to many constraints and raises two fundamental questions in mathematics education: how to foster and how to assess students' problem solving competencies? Thus it is necessary to identify what problem-solving competencies are and consequently what students are expected to learn and to know.

## IBME and problem-solving competencies

In the French mathematics teaching tradition, problem solving has been seen for many years as a means to develop specific mathematical content and knowledge (Brousseau, 1998). For the past couple of years, however, many countries, and especially European countries, have been emphasizing problem solving in mathematics and inquiry-based mathematics and science education (IBMSE) as a learning goal for its sake. The European Rocard's report (Rocard et al., 2007) promotes a wider implementation of IBMSE in classrooms as a tool to make sciences and mathematics more attractive to students. Nevertheless, this increasing interest in IBMSE has not been followed by a concise and commonly shared definition (Dorier & Garcia, 2013). If we are to summarize, it

refers to a student-centered paradigm of teaching mathematics and science, in which students are invited to work in ways similar to how mathematicians and scientists work. This means they have to observe phenomena, ask questions, look for mathematical and scientific ways of how to answer these questions (like carrying out experiments, systematically controlling variables, drawing diagrams, calculating, looking for patterns and relationships, making conjectures and generalizations), interpret and evaluate their solutions and communicate and discuss their solutions effectively. (Dorier & Maass, 2014, p. 300)

### **Intended learning outcomes of IBME**

The goal of IBME is to make students work in a way similar to the one of mathematicians and to make students familiar with a scientific approach to solve problems. For Hersant (2012), a scientific approach cannot be considered as a relevant learning goal, especially because it is unclear, non-unique and too ambitious. Thus the intended learning outcomes of IBME are not so easy to interpret and implementing IBME in classrooms remains a crucial issue. If we look at institutional instructions of the *mathematics development* class, teachers are invited to propose *open-ended problems* (Arsac, Germain, & Mante, 1991) to students, which is, in France and in French speaking Switzerland, a traditional way of introducing students to IBME. An *open-ended problem* is a problem which has a short text, has no obvious solution and method, deals with students' familiar conceptual domain and enables students to make the problem their own. Facing such a problem, students should learn different strategies. It aims more generally at both establishing scientific debate rules and developing a scientific approach following the pattern of *try - conjecture - test and prove*. But according to Hersant (2010), what gives this approach a scientific dimension is not only the existence of trials, conjecture and proof but the articulation among these. She also emphasizes that there is no unique scientific approach. The first goal is not so clear, neither is the second. Debate rules can indeed refer to logical rules (several examples don't prove a proposition, a counter example is sufficient to disprove a conjecture, etc.) or to social rules (listen to the others, etc.). Consequently, curriculum and instructions about *open-ended problems* do not seem to be sufficient to help teachers to define what is institutionally expected about students' problem solving competencies.

Identifying what we want students to learn and to know about problem solving is still a problematic issue. The identification of the intended learning outcomes from IBME is by no means obvious even for teachers, and the danger is that students might not be aware of what they are supposed to learn and to know. That is why IBME learning goals should be at the midst of specific discussions with students in class. Even though such discussions should also be encouraged when acquiring a more classical mathematical knowledge, it is all the more important in the case of IBME.

### **Problem solving narration activity**

To assess students' problem solving competencies, teachers have to be able to access what students did in order to solve the problem and especially what solving strategies they used. That is why the *problem solving narration activity* (Bonafé et al., 2002) has been institutionally chosen as a means to assess students. It can be defined as a new contract between students and teachers in which students have to explain the best they can, how they solved, or tried to solve, the problem (including mistakes, wrong ways, dead-ends, help they received...) and teachers have to assess students on these and only these points and especially not take into account the fact whether students found the right answer or

not. With this activity, the fact that students have to explain all the strategies they tried and all the ideas they had to someone else, presupposes that they are capable to do so firstly to themselves. They have to reconstruct their reflection and make a synthesis of which strategies were effective, which one were wrong ways or led to dead-ends, etc. In that sense, it can emphasize students' reflection about what solving problems in mathematics means, about their own problem solving competencies and it can encourage the development of para and proto-mathematical knowledge. *Problem solving narration activity* as a scheme used principally for summative assessment can also foster students' problem solving competencies and assume a formative function. This last observation leads us to consider the assessment of problem solving competencies, not only with summative purpose, but also with a formative purpose.

### **Assessing students' problem-solving competencies**

According to Allal (2008) assessment is summative as soon as a synthesis of the competencies and knowledge learnt by the student at the end of his curriculum is established. Thanks to the distinction made by Scriven (1967) and then by Bloom (1968) between summative and formative assessment, Black and Wiliam give the following definition:

Practice in a classroom is formative to the extent that evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited (Black & Wiliam, 2009, p. 9).

The notion of feedback is a key component of formative assessment. Formative assessment contains "all those activities undertaken by teachers, and/or by their students, which provide information to be used as feedback to modify the teaching and learning activities" (Black & William, 1998, pp. 7-8). Another key component of formative assessment is that students understand the target of their work and that they grasp what is expected (Harlen, 2013). But it means that "students need to have some understanding of the criteria to apply in assessing their work" (Harlen, 2013, p. 17). Once again, the necessity of specific discussions with students about assessment criteria and about what they are expected to learn is emphasized.

To classify classroom formative assessment, Shavelson et al. (2008) are using a continuum, that ranges from formal embedded assessment to informal, on the fly formative assessment. It means that formative assessment does not take a unique form but that it can be planned or not, it can refer to formal tools to collection of data or not, etc. Adopting this point of view, formative assessment can be considered as a practice integrated within the learning process (Lepareur, 2016). Referring to formative assessment about IBME is all the more relevant that

the practice of formative assessment, through teachers and students collecting data about learning as it takes place and feeding back information to regulate the teaching and learning process, is clearly aligned with the goals and practice of inquiry-based learning. (Harlen, 2013, p. 20)

These definitions of summative and formative assessment enhance that identifying assessment according to *when* it occurs (after a phase of teaching *vs* within a teaching activity for instance) or *how* it occurs (paper-pencil test *vs* worksheet for instance) seems less relevant than distinguishing assessment according to its function. But it does not mean that these two principal functions of assessment (summative and formative) cannot coexist. Thus some researchers (Allal, 2011; Harlen,

2012; Shavelson et al., 2008) argue that they can coexist in what Earl (2003) calls *assessment for learning*. The same assessment activity can serve to summative and formative purpose. It means that data collected by the teacher can be used to give students a mark but also to improve learning and teaching. On the other hand, for Shavelson et al. “formative assessment could serve summative needs” (2008, p. 298). In our research, we deal with teachers’ practices in the *mathematics development* class. Our objective is to find out if and how using an assessment tool as a grid of criteria, firstly with summative purpose, can also foster formative assessment processes. In this paper, we focus only on teacher’s formative assessment practices. For that, we study the practices of a teacher giving this IBME-centered course.

## Teachers’ formative assessment practices

### Context of the research

The teacher whose practice we are going to analyze, was a member of a one year commission, created in September 2015, and gathering another teacher and ourselves. The purpose of this commission was to give teachers of *mathematics development* classes a common tool to assess students’ problem solving competencies with both summative and formative purpose, and consequently to ensure common expectations about IBME (from teachers, and more globally from schools). To do so, we have been working for one year to elaborate a grid of criteria aiming to assess students’ *problem solving narration activity*. This development of the tool was mainly based on teachers’ expertise. Indeed, teachers have implemented the grid in their class, and according to their experiences, we adjusted, removed and added some criteria. Nevertheless, we dealt with an existing tool elaborated by the Geneva team in the wake of the PRIMAS<sup>1</sup> project and were careful to take into account some research results (as those of Hersant (2010)). The grid in its final version summarizes criteria related to five dimensions of such an activity: presentation, narration, research, technique and modelling. These dimensions induce ways to look at the students’ production according to expected qualities. For instance, the modelling dimension is characterized by two criteria: “Appropriation of the problem: rephrase the problem in French and/or express it with drawings, diagrams, tables” and “Use of pertinent mathematical tools and theories, strategies”.

So, this teacher whose practice we are going to analyze has been reflecting on the intended learning outcomes of this IBME-centered course and on the summative assessment of problem solving competencies, for one year, thanks to the meetings with the other members of the commission. She used the grid elaborated by the commission, in her class, principally with a summative purpose. However, thanks to our hypothesis that summative and formative assessment can co-exist, we would like to see if she also referred to formative assessment, thanks to specific discussions with students about criteria, and feedback related to their production. That is why we analyzed her formative assessment practices.

---

<sup>1</sup> Available at <http://www.primas-project.eu/fr/index.do>

## Theoretical framework

To characterize teachers' formative assessment practices, we referred to criteria elaborated by Lepareur (2016). She defined five strategies<sup>2</sup> : eliciting goals and criteria (S1); managing discussions and activities which can produce some evidence of effective learning (S2); giving feedback to students which make them progress (S3); helping students to be responsible for their learning (S4); helping students to be a resource for their peers (S5). Even though her research dealt with science and mathematics teachers' formative assessment practice, in our case, we only study mathematics teachers' practices. In that sense, we made some adaptations about key words and sub-strategies she defined. The table 1 is the grid we used to characterize the mathematics teacher's formative assessment practices. The T is used for the teacher, S for the students.

## Methodology

We video recorded two consecutive periods of *mathematics development* given by this teacher, member of the commission, at the end of the school year. The nine students of the class were working in four groups (3 groups of 2 students, 1 group of 3). They were working on two problems related to the introduction of algebra. At the end of the second period, students had to give a narration about the problem they were working on to the teacher. Consequently half of the second period was devoted to the narration and students were invited to use office software to write their research down. To interpret data and make it relevant with our theoretical framework, we transcribed all interactions occurred in class for both lessons (about 67 minutes) and classified interactions according to strategies and sub-strategies defined in the table 1.

Strategy	Key words	Code	Description
S1	Goals	S11	T explains the goals of the activity.
	Criteria	S12	T explains the intended learning outcomes, what will be assessed.
S2	Progress in activity	S21	T collects information about students' progress in the activity.
	Strategies	S22	T collects information about strategies used by S.
	Understanding	S23	T questionnes S about their understanding of the goals.
	Knowledge	S24	T takes information about previous S' knowledge.
	Self assessment	S25	T helps S to situate themselves in relation to assessment and success criteria.
S3	Feedback (what students have to do)	S31	T gives an information to make explicit what S have to do left.
	Feedback (how students can do it)	S32	T provides explicit information about how S have to do it, to move on.
S4	Responsabilisation	S4	T emphasizes S' ideas, gives them independancy to access resources.
S5	Interactions (group)	S51	T encourages S to discuss with others members of their group. Peers are seen as a resource.
	Interactions (class)	S52	T integrates S' propositions and encourages others to react on.

<sup>2</sup> Translated from Lepareur (2016).

**Table 1: Grid of analysis of formative assessment practices, adapted from Lepareur (2016)**

For instance, during the following interaction between the teacher and a student, we can see that the teacher tries to make the student explains his strategy.

Teacher: Yes but how did you find this?  
 Student: I made a lot of stuff.  
 Teacher: But try... what did you do? It's interesting to know how you were thinking.  
 Student: I made all of this but like everything in reverse.  
 Teacher: Yes so the first step. What did you do at the first step?  
 Student: 24 minus 7.  
 Teacher: Yes, you went backwards in your calculations. Yes. It's a good idea. Doing backward calculation is in fact a lead.

In that case, we identify a formative assessment practice, according to the strategy S2 “managing discussions and activity which can produce some evidence of effective learning” and more specially the strategy S22 “collecting information about strategies used by students”.

### Results and analysis

We found out 44 episodes when formative assessment strategies occurred thus we can say that this mathematics teacher refers frequently to formative assessment in her practice. We identified 4 times the strategy S1; 25 times strategy S2; 10 times strategy S3; 3 times strategy S4 and 2 times strategy S5. The figure 1 illustrates the percentage of apparition of each strategy. To summarize, we can notice that the teacher refers to every strategy (S1, S2, S3, S4 and S5).

**Figure 1: Strategies of formative assessment**

On top of that, she uses principally the strategy S2: “managing discussions and activities which can produce some evidence of effective learning”. It represents more than half of the strategies of formative assessment used by this teacher. The strategy S3 which refers to “give feedback to students which makes them progress” is also used frequently, about one time out of four.

But if we look deeper, we can see that each sub-strategy is not used with the same frequency (figure 2). We can see that for the strategy S1 related to the goals and criteria, the teacher only explains the goals of the activity (S11) but not the criteria of assessment or the intended learning outcomes (S12). This lesson occurred at the end of the year so we can make the hypothesis that by then students knew well what they were expected to do.

**Figure 2: Strategies of formative assessment according to key words**

Then, for strategy S3 about feedback, the two ways; “provides information to make it explicit what is left for the students to be done” (S31) or “how they have to move on” (S32) are represented, but the second one more than the first one. The idea is that this teacher helps students both knowing what they have to do but even more how they can continue. For the last strategy (S5) dealing with interactions, the teacher focuses on discussions within the groups. The absence of strategy S52 about “the integration of students” can easily be explained by the fact that during these two lessons, students only worked in group, without any collective classroom discussion.

## Conclusion

We can say that this mathematics teacher refers frequently to formative assessment in her practices (44 times during a 67 minute-lesson). She uses a very large set of formative assessment tactics; eliciting goals and criteria; managing discussions and activities which can produce some evidence of effective learning; giving feedback to students which make them progressing; helping students to be responsible for their learning; helping students to be a resource for their peers. But she uses principally formative assessment to manage discussions and activities which can produce some evidence of effective learning, and especially, she collects information about strategies students use. The feedback she provided to students is mainly about how they can continue, how they can do what they have to do to solve the problem. The only strategy which does not appear is this related to explanation of criteria and expected learning outcomes. We can make the hypothesis that it has been at the core of a discussion in the first part of the schoolyear. In that sense, it should be interesting to focus on what happens at the beginning of the schoolyear and to study how teachers explain and negotiate the intended learning outcomes with students.

To conclude this paper, we can say that this exploratory study shows that formative assessment seems to be relevant for this teacher in order to foster her teaching practices in the case of an IBME-centered course. It is, nevertheless, necessary to enlarge the study, in order to compare and expend or not the results, and to have more information about how teachers refer to formative assessment. On top of that, we can imagine that working with teachers about these strategies could foster their formative assessment practices.

The most represented sub-strategy related to “discussions and activities which can produce some evidence of effective learning which is used frequently” (S2) is “collecting information about strategies used by students” (S22). It appears 19 times. It is also the strategy that occurs the most, all categories taken into account. The only other significant strategy dealing with S2 used by the teacher is “taking information about students’ progress in the activity” (S21). So the teacher focuses on where students are in the activity and what they have done to get there.

<sup>3</sup>Educational Research Centre, Drumcondra, Dublin 9, Ireland; [gerry.shiel@erc.ie](mailto:gerry.shiel@erc.ie)

*It has been argued that the PISA assessment has had a disproportionate impact on Project Maths, the new mathematics curriculum recently implemented in post-primary schools in Ireland, which seeks to emphasise deep conceptual understanding and problem solving in real-life contexts. This paper describes an analysis of the content, cognitive processes and contexts underpinning Junior Certificate mathematics examination questions set for students in Grade 9 in 2003 and 2015, using the frameworks underpinning the PISA and TIMSS studies. Despite a significantly increased reading load for students, the Junior Certificate mathematics examination continues to emphasise lower-order processes, at the expense of higher-level thinking, as defined by PISA and TIMSS, while there has been a small increase in the proportion of items presented in practical contexts. The need to examine the effects of Project Maths in classroom settings is highlighted.*

*Keywords: Mathematics, assessment, Project Maths, Junior Certificate.*

## Introduction

Since 2010, all students entering post-primary school (Grade 7) in Ireland have studied under Project Maths, an innovative mathematics curriculum introduced in an effort to increase the relevance of mathematics for students, and to improve teaching and learning. Since 2015, all aspects of Project Maths have been assessed in the Junior Certificate (JC) mathematics examination, a state examination taken by almost all students at the end of Grade 9 (Third Year). The purpose of this paper is to examine changes in how and what mathematics is assessed in the JC, and how these changes relate to the frameworks and approaches to assessment of mathematics underpinning the OECD Programme for International Student Assessment (PISA) (OECD, 2016), and the Trends in International Mathematics and Science Study (TIMSS) (Grønmo, Lindquist, Arora, & Mullis, 2013).

Ireland has participated in PISA since its inception in 2000. Although Ireland has been consistently among the highest-performing countries on reading literacy in PISA, performance on mathematical literacy has generally been at the OECD average, and, on one occasion (2009), significantly below it. Although average performance on mathematics in Ireland was above the OECD average for the first time in 2012, this reflected a decline in the OECD average rather than an increase in the performance of students in Ireland, compared with, for example, 2003 and 2006.<sup>1</sup> Students in Grade 8 in Ireland

---

<sup>1</sup> It should be noted that over three-quarters of students in PISA 2012 in Ireland had not studied under Project Maths, with students in Grades 9 and 10 studying the preceding curriculum, except those in a small number of Project Maths pilot schools.

did not participate in TIMSS between 2003 and 2011, but did take part in the most recent cycle, in 2015.

Concerns about standards in mathematics have increased in recent years and outcomes in PISA are just one factor contributing to this. There have also been concerns about declining performance among entrants to university mathematics courses (Gill, O'Donoghue, Faulkner & Hannigan, 2010).

In 2005, the National Council for Curriculum and Assessment began a process leading to the implementation of a revised mathematics curriculum for post-primary schools. This involved the commissioning of a research paper looking at international trends in mathematics education (see Conway & Sloane, 2006), and a consultation process involving interested parties (NCCA, 2005). Following two years of development work, the Project Maths curriculum was introduced into 24 pilot schools in 2008, and implementation began in all post-primary schools in 2010, with a phased introduction that was completed by 2015. The aims of Project Maths at Junior Cycle level (Grades 7-9) include developing mathematical knowledge, skills and understanding needed for continuing education, for life and for work; fostering a positive attitude to mathematics; and developing the skills of dealing with mathematical concepts in context and in applications, and in problem solving (DES, 2013). There are five inter-related strands in the curriculum: Statistics and Probability; Geometry and Trigonometry; Number; Algebra; and Functions. Learning outcomes are identified for students intending to take the JC mathematics examination at Higher and Ordinary levels, with no separate course for Foundation level.

Project Maths has received a mixed reception. The Irish Mathematics Teachers Association (IMTA) (2012) noted that insufficient detail was provided on aspects of course content, giving rise to uncertainty as to whether certain topics were included or not. Drawing on a survey of teachers in Project Maths pilot and non-pilot schools conducted as part of PISA 2012 in Ireland, Cosgrove et al. (2012) reported more frequent use of ICT in pilot schools, and more positive changes in learning and assessment, though teachers in pilot schools were less confident in their teaching. Concerns about readability were raised in the same study, with teachers in pilot schools arguing that the problems presented to students in classroom and assessment contexts contained more text and greater linguistic complexity than was the case prior to Project Maths, when teaching and learning mathematics were more formal and less contextualised. Similar concerns have been raised about the effects of readability on performance in the PISA mathematics assessment as a result of the complexity of contexts that are presented to students (Eivers, 2010).

A small number of studies have looked at the initial effects of Project Maths on students' performance. A study by the National Foundation for Educational Research in the UK (Jeffes et al., 2013) found no achievement differences between students in schools implementing Project Maths for longer or shorter time periods, or between those that had implemented more, compared with fewer, content areas. Although students in pilot schools in the PISA 2012 sample in Ireland achieved higher mean scores on each PISA mathematics content area, and on overall performance, differences were not statistically significant (Merriman, Shiel, Cosgrove & Perkins, 2014). Worryingly, students in pilot schools had significantly higher levels of anxiety about mathematics than their counterparts in non-pilot schools.

The lack of evidence for a significant change in mathematics performance since the implementation of Project Maths, as well as claims that PISA has had a disproportionate impact on the Project Maths curriculum (e.g., Kirwan, 2015; Grannell, Barry, Cronin, Holland & Hurley, 2011) points to the need for a critical look at changes to the JC mathematics examination. This paper looks at whether the contexts, content and processes underpinning the examination differed in 2003 and 2015 (when analysed through the lens of PISA and TIMSS) and whether examination papers have become more or less readable between the same two time points. The research questions addressed are as follows:

- (i) What changes in mathematical content, cognitive processes, and item contexts can be identified from a comparison of the pre-Project Maths 2003 Junior Certificate examination with the post-Project Maths 2015 examination with reference to the TIMSS and PISA mathematical frameworks and tests?
- (ii) What changes in readability can be identified from a comparison of the pre-Project Maths 2003 Junior Certificate examination with the post-Project Maths 2015 examination?

## Methodology

### Examination paper analysis – Context, content and process

This study focuses on the JC state examination papers in 2003 and 2015 as examples of papers before and after the introduction of the revised curriculum. The 2003 papers were chosen because a similar classification exercise was previously carried out on these papers by Close and Oldham (2005). The 2015 papers were chosen as a comparison as they were the first to include all Project Maths content areas for all JC students.

Junior Certificate mathematics is examined at three levels: Higher Level (HL), Ordinary Level (OL) and Foundation Level (FL). There are two papers each for HL and OL and one for FL. Consequently, the study included ten papers in total (five for each year). The aim was to classify the questions in each examination paper in terms of the main components of the TIMSS 2015 Grade 8 mathematics framework (Grønmo et al., 2013) and the PISA 2003 and 2015 frameworks (OECD, 2003; 2016). The relevant characteristics of these frameworks are outlined below. The PISA framework was chosen as it reflects recent trends internationally towards realistic mathematics and problem-based learning in rich contexts. The TIMSS framework was also used in this study as it reflects a more traditional, curriculum-based approach, with a focus on the mathematical concepts, skills and applications seen as necessary for further study of mathematics and for life. Using both frameworks allowed the analysis to capture more fully any changes in the JC examination between the selected time points.

TIMSS mathematics has four content domains: Number, Algebra, Geometry and Data and Chance. There are three cognitive domains: Knowing, Applying and Reasoning. The PISA mathematics framework has three dimensions: Context, Content and Competency<sup>2</sup>. PISA classifies each mathematics item in terms of its context – Personal, Occupational, Societal or Scientific. The PISA

---

<sup>2</sup> For the purposes of this study, the 2015 framework was used to classify items by Content and Context. However, the 2003 Competency Clusters were used as they are more suited to the JC examinations and are more consistent with the TIMSS Cognitive Domains. In addition, the 2003 Competencies were used in Close and Oldham (2005).

content categories are Change and Relationships, Space and Shape, Quantity, and Uncertainty and Data. The PISA 2003 framework also classifies items by groups of cognitive processes or ‘Competency Clusters’. The three clusters are Reproduction, Connections, and Reflection.

The Reproduction cluster in PISA can be summarised as the ‘reproduction of practised knowledge’ (OECD, 2003), which covers the category of Knowing in TIMSS but also some of Applying. The Reflection cluster involves ‘advanced’ reasoning, abstraction and generalisation in novel contexts, which often requires a higher cognitive demand than some Reasoning items in TIMSS.

Within each JC paper, each part of a question (a i), ii), etc.) was treated as a separate item. Each item was classified by two of the authors (RC and SC) according to the dimensions outlined above. Classifications were carried out independently and all disagreements were recorded and discussed until a consensus was reached. Very few disagreements arose in relation to the content or context of the items. By comparison, more disagreements occurred where judgements were made about the processes involved in answering the items i.e. in identifying TIMSS Cognitive Domains and PISA Competency Clusters. This is not surprising, as determining the primary process required to answer a test item is, by nature, a more subjective exercise. Initial agreement rates for cognitive processes per examination ranged from 74 percent (TIMSS classifications for FL 2015) to 97 percent (PISA classifications for FL 2003). Most examinations had an agreement level above 80 per cent.

### **Reading load and readability analysis**

An analysis of the reading load and readability of JC mathematics examination papers administered in 2003 and 2015 was also conducted. Reading load here refers only to the number of words to be read, while measures of readability aim to assess the overall difficulty of the text. Data were generated for word count, number of sentences, average number of words per sentence, and average number of complex words (words with three or more syllables). An overall measure of readability for each paper was obtained by taking the average results (in Grade level units) of eight readability measures including the Flesch-Kincaid Grade Level. Prior to applying these formulae, title information, general instructions and item numbers were removed. In addition, diagrams were deleted (though labels and numbers were retained), and functions were replaced with a placeholder, as readability formulae are not designed to assess the complexity of these elements.

## **Results**

### **Classification of items by content, cognitive process and context<sup>3</sup>**

The data in Table 1 show that, between 2003 and 2015, there was an increase in the number of JC examination items in Data and Chance (+10 percentage points), as defined by TIMSS, with a corresponding increase in Uncertainty and Data (+9 percentage points), as defined by PISA. The change in these content domains can be ascribed to the increased emphasis on Statistics and Probability in the revised curriculum. These increases were more or less counter-balanced by decreases in Number (-5 percentage points) and Geometry (-4 percentage points) on the TIMSS content dimension and in Quantity (-8 percentage points) in PISA.

---

<sup>3</sup> For brevity, the results of the item categorisation are collapsed across HL, OL and FL for each year.

TIMSS Content Domain	TIMSS % Items	JC 2003 % Items N = 187	JC 2015 % Items N = 208	PISA Content Domain	PISA % Items	JC 2003 % Items N = 187	JC 2015 % Items N = 208
Number	30 (30) <sup>4</sup>	21	16	Quantity	25	27	19
Algebra	30 (25)	24	27	Change & Relations	25	31	34
Geometry	20 (30)	30	26	Space & Shape	25	25	24
Data & Chance	20 (15)	11	21	Uncertainty	25	11	20
Not covered <sup>5</sup>		13	10	Not covered		6	3

**Table 1: Percentages of items in each TIMSS and PISA content domain, and percentages of total JC 2003 and 2015 items, by TIMSS and PISA content domains**

Table 2 presents the results for the cognitive process dimensions. Relatively few of the JC examination items for either 2003 or 2015 fell into the TIMSS Reasoning category, although there was an increase between 2003 and 2015 (+6 percentage points). Only two items in 2015 (1%) were categorised as PISA Reflection, with none in 2003. However, the proportion of Connections items was higher in 2015 than in 2003 (+8 percentage points), with a corresponding decrease in Reproduction items. Despite this, most of the JC items for both years were classified as TIMSS Knowing and Applying and PISA Reproduction.

TIMSS Cognitive Domain	TIMSS % Items	JC 2003 % Items N = 187	JC 2015 % Items N = 208	PISA Cognitive Domain	PISA % Items	JC 2003 % Items N = 187	JC 2015 % Items N = 208
Knowing	35	35	45	Reproduction	25	88	79
Applying	40	57	42	Connections	50	12	20
Reasoning	25	7	13	Reflection	25	0	1

**Table 2: Percentages of items in each TIMSS and PISA cognitive (process) domain, and percentages of total JC 2003 and 2015 items, by TIMSS and PISA cognitive domains**

Part of the intention of Project Maths reform was to place more emphasis on using mathematics to solve problems set in practical realistic contexts. Table 3 shows the results of classifying the items in the 2003 and 2015 JC exams into items with some sort of practical context and items which are purely mathematical or intra-mathematical. The results show that around half of the items in the 2015 examination papers had a practical context reflecting a small change since 2003 (up from 40%). These figures are similar to the TIMSS percentages for mathematical and practical contexts, whereas all PISA items are placed in a practical context. It is important to note that the practical contexts of

<sup>4</sup> TIMSS 2003 Content Domain weightings in parentheses.

<sup>5</sup> Some JC topics are not included in the TIMSS and/or PISA frameworks e.g. sets, trigonometry and proofs of geometric theorems.

TIMSS items and JC 2003 and 2015 exam items are generally minimal compared with the more substantial and often realistic contexts of PISA items.

Context Category	TIMSS approx.% Items	PISA % Items	JC 2003 % Items, N = 187	JC 2015 % Items, N = 208
Mathematical	50	0	60	49
Practical	50	100	40	51

**Table 3: Comparison of TIMSS and PISA test items and JC exam item percentages by context category**

### Reading Load and Readability<sup>6</sup>

Table 4 shows that, at JC HL, the number of words students were expected to read on Paper 1 increased from 765 in 2003 to 1335 in 2015 (a 75% increase). At OL, the word count increased from 662 to 1240 (an 87% increase), and at FL, the increase was from 530 to 1027 words (a 94% increase). However, the average difficulty of the text that students were expected to read remained about the same at HL (Grade 4) and OL (Grade 2). There was an increase at FL (from Grade 0 to Grade 2). The average number of words per sentence remained more or less the same (and even decreased by 3 on HL Paper 1 in 2015), while the proportions of complex words also remained about the same.

Examination Paper	No. of Item Parts	No. of words	No. of sentences	Avg. no. words per sentence	No. of complex words (Percent)	Flesch-Kincaid grade level	Average readability grade
2003 HL Paper 1	32	765	58	13	61 (8)	5.0	4
2015 HL Paper 1	45	1335	135	10	123 (9)	4.1	4
2003 OL Paper 1	40	662	76	8	35 (5)	2.6	2
2015 OL Paper 1	41	1240	181	7	64 (5)	2.2	2
2003 FL	32	530	73	7	23 (4)	1.6	0
2015 FL	43	1027	140	7	57 (6)	2.3	2

**Table 4: Readability measures for JC examination papers in 2003 and 2015**

### Conclusion

The impetus for the Project Maths curricular reform arose, in part, from Ireland's performance in PISA mathematics (NCCA, 2012). However, the current analysis does not indicate that the assessment of JC mathematics has been unduly influenced by the PISA approach. The distribution of items by content area on the JC examination in 2015 was similar to its predecessor in 2003, when viewed through the lens of TIMSS and PISA, though more Data and Chance items were included in

<sup>6</sup> Again, for brevity, results for this section are reported for Paper 1 only for HL and OL. There is only one paper for FL for each year.

2015. This is in line with the increased emphasis on Statistics and Probability in the new JC curriculum. While there were proportionally more Reasoning items (as defined by TIMSS) in the JC examination in 2015 than 2013, there were no Reflection items (as defined by PISA) in 2003 and only 2 in 2015. However, there was an increase in the proportion of PISA Connections items in the JC examination, and a reduction in the proportion of Reproduction items. One objective of Project Maths is to place more emphasis on higher-order cognitive processes, such as problem solving and reasoning in the mathematics curriculum and examinations. The analysis above suggests some movement in this direction in JC state examinations, but not to the extent that might be expected from such a comprehensive reform. The analysis also indicates that the 2015 JC examination is more similar to TIMSS than to PISA in terms of content and processes. This is reinforced by the finding that the proportions of items described as being presented in practical (rather than purely mathematical) contexts were similar in the JC 2003 and 2015 exams, despite large increases in the amount of text that students had to read. Remarkably, however, the readability (overall difficulty) of the text in the JC examinations was broadly similar in 2003 and 2015. A study by King and Burge (2015) found that readability levels for clusters of PISA 2012 items ranged from US grade levels 7.5 to 10.9 (UK reading ages 12.3 to 15.5 years). Hence, the linguistic complexity of PISA items is greater than that required for JC mathematics. The analysis here focuses only on state examinations of JC mathematics, and not on the implementation of Project Maths in the classroom. Given that Project Maths has now been fully rolled out, it would seem timely for an exploration of the extent to which teaching and learning has changed.

*In this paper we present the design of specific digital resources and related methodology, conceived with the aim of exploiting connected classroom technology to carry out formative assessment processes in the mathematics classroom. The digital resources have been created and experimented within the European Project FaSMEd. By using a multi-dimensional theoretical frame developed within FaSMEd, we offer elements of validation for the design, focusing in particular on the activation of formative assessment strategies through the use of “helping worksheets”. The elements of validation will be illustrated through an example from a case study.*

*Keywords: Formative assessment, technology, digital resources, task design.*

## Introduction

This contribution stems from the European Project FaSMEd (“Improving progress for lower achievers through Formative Assessment in Science and Mathematics Education”), aimed at investigating the role of technologically enhanced formative assessment (FA) methods in raising students’ attainment levels.

Within FaSMEd, FA is conceived as a method of teaching where evidence from learning is used to adapt both teaching and learning. Wiliam and Thompson (2007, in Black & Wiliam, 2009) focus on *three central processes* in learning and teaching, which represent the aims related to the collection, interpretation and exploitation of these learning evidence: (a) *Establishing where learners are in their learning*; (b) *Establishing where learners are going*; (c) *Establishing how to get there*.

In the model developed by Wiliam and Thompson these three *central processes* are connected to the *three main agents* that intervene (the teacher, the student, the peers) and to the *FA key-strategies* that could be activated: (A) Clarifying and sharing learning intentions and criteria for success; (B) Engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; (C) Providing feedback that moves learners forward; (D) Activating students as instructional resources for one another; (E) Activating students as the owners of their own learning.

A theoretical model to analyse the use of technology in FA practices has been elaborated within FaSMEd (Aldon et al., in print, and Cusi, Morselli & Sabena, 2016). The model extends Wiliam and Thompson’s model, taking into account three main dimensions: (1) *the five FA key-strategies* described by Wiliam and Thompson (ibid.); (2) *the three main agents* that intervene; (3) *the functionalities of technology*. The third dimension - the *functionalities* of technology – was added within FaSMEd to focus on the ways in which technology can support the three agents in developing the FA strategies: (a) *Sending and sharing*, that is the ways in which technology

supports the communication among the agents of FA processes; (b) *Processing and analysing*, that is the ways in which technology supports the processing and the analysis of the data collected during the lessons; (c) *Providing an interactive environment*, that is when technology enables to create environments in which students can interact to work individually/in group on a task or to explore mathematical/scientific contents.

We argue that the FaSMEd three-dimensional framework may represent a useful tool for:

- *designing* digital materials for technology-enhanced FA practices and the corresponding methodology, and
- *analysing* how these materials are implemented in the classroom.

In this paper we will refer to the study carried out in Italy, where we added the fundamental assumption that, in order to raise students' achievement, FA has to focus not only on cognitive, but also on metacognitive factors (Schoenfeld, 1992). For this reason, our design is aimed at i) fostering students' ongoing reflections on the teaching-learning processes, and ii) focusing on making thinking visible (Collins, Brown & Newmann, 1989) through students' sharing of their reasoning with the teacher and the classmates, by means of argumentative processes.

In the following we present the design of digital materials and of the methodology for their implementation in the classroom. We will then focus on the specific case of "helping worksheets" and analyse its implementation in a case study. The analysis will be based on the FaSMEd three-dimensional framework. The analysis of FA strategy C (Providing feedback that moves learners forward) will be deepened with reference to the four major levels of feedback introduced by Hattie and Temperley (2007): (1) *feedback about the task*; (2) *feedback about the processing of the task*; (3) *feedback about self-regulation*; (4) *feedback about the self as a person*.

## **Design of the digital materials and of the methodology for their implementation**

The research developed within FaSMEd has been built on the model of design-based research (Cobb et al, 2003), so it is based on successive cycles of design, observation, analysis and redesign of classroom sequences. The design experiments we carried out in Italy were characterised by three subsequent cycles of design. The first two cycles were carried out in March-May 2015 and in September-December 2015. The third cycle started in May 2016 and has not been completed yet. The results we present in this paper refer to the first two cycles of the design.

In tune with the theoretical assumptions presented in the previous paragraph, we chose to use a technology that supports the students in sharing, discussing and comparing both their written productions and the strategies developed to carry out the different tasks. Specifically, we explored the use of a connected classroom technology (CCT), which creates a network between the students' tablets and the teachers' laptop, allowing the students to share their productions, and the teacher to easily collect the students' opinions and reflections: IDM-TCClass.

The design experiments involved 25 classes (from grade 4 to grade 7) from three different clusters of schools located in the North-West of Italy. Each school was provided with tablets for the students and computers for the teachers, linked to IWB or data projector. In order to foster collaboration and sharing of ideas, students were asked to work in pairs or in small groups on the same tablet.

During the first two cycles of design, we carried out about 450 hours of lessons. The researcher was in the class as both an observer and a participant (to support the teacher in the use of the technology and in the implementation of the digital resources). In some cases, also Master students were present as observers. The corpus of data is constituted by video-recordings of the lessons, written transcripts, field notes taken by the observers, teachers' interviews after sequences of lessons, students' written questionnaires and groups of students' interviews during a Q-sorting activity (questionnaires and Q-sorting data were collected at the end of the design experiments).

The use of IDM-TClass was integrated within a set of activities on relations and functions, and their different representations (symbolic representations, tables, graphs). These activities, in line with the aims of the FaSMEd Project, were adapted starting from existing research-informed materials.

For each activity, we have prepared a sequence of different worksheets, to be sent to the students' tablets or to be displayed on the IWB (or through the data projector). The worksheets were designed according to *four main categories*: (1) worksheets introducing a problem and asking one or more questions (*problem worksheets*); (2) *helping worksheets*, aimed at supporting students, who meet difficulties with the problem worksheets, through specific suggestions (e.g. guiding questions); (3) worksheets prompting a poll between proposed options (*poll worksheets*); (4) worksheets prompting a focused discussion (*discussion worksheets*).

Usually the activity starts with a problem worksheet, sent from the teacher's laptop to the students' tablets. Students work in pairs or small groups of three. After facing the task and answering the questions, the pairs/groups send back to the teacher their written productions. The teacher can decide to send helping worksheets to some groups, or the groups can ask for them.

After all groups have sent back their answers, the teacher sets up a classroom discussion in which the students' written productions are shown and feedbacks are given by the teacher and by classmates. The discussion is engineered starting from the teacher's selection of some of the received written answers, to be shown on the IWB, and aims at highlighting: (a) typical mistakes; (b) effective ways of processing the tasks; (c) the comparison between the different ways of justifying. During the part of the discussion focused on these aspects, therefore, the criteria for success could be clarified through the analysis and comparison of the different written productions.

The teacher can also display the discussion worksheets or poll worksheets, if she realises that some specific aspects were neglected, to support the class discussion during different parts of the lessons. It is also possible to create polls on the spot to check students' understanding, or their awareness about what has been developed during the activity, or their attitudes toward the activity.

In the next paragraph we illustrate the design of the helping worksheets and the corresponding implementation, and present the analysis of an example from a case study. The example has been chosen because it is a paradigmatic one, which enables to highlight how the implementation of helping worksheets, through the support of CCT, fosters the activation of FA strategies and the dynamics between them.

## The design and implementation of the *helping worksheets*: Analysis of an episode

Helping worksheets are conceived to support students in facing the tasks posed through the problem worksheets and are sent to selected students during the problem-solving phase, when: (a) they ask to receive a help; (b) the teacher realises that they are stuck; (b) the answers they send to the teacher highlight mistakes or difficulties. Moreover, helping worksheets may be sent to all groups, after they sent their answers to the teacher, as a checking tool for their work.

Usually we design sets of differentiated worksheets, according to the possible difficulties students could meet when facing a problem worksheet. Since our activities are adaptations of existing research-informed materials, the hypothesis about students' difficulties and the corresponding feedback that could be provided are drawn also from these materials.

We focus on helping worksheet 1A (see figure 1), which is matched to problem worksheet 1 within an articulated activity on time-distance graphs. The activity, which is our adaptation of some materials from the Mathematics Assessment Program, developed at the University of Nottingham (<http://map.mathshell.org/materials/lessons.php>), starts with the interpretation of a given time-distance graph and develops through the matching between graphs and stories and the construction of graphs associated to specific stories. We adapted the tasks in order to propose them to students from grade 5 to 7. To ground the time-distance graph on a meaningful activity, we designed an introductory activity on the use of a motion sensor (a device connected to a graphic calculator, showing, in real time, the Cartesian representation of a produced motion).

Worksheet 1 introduces a task on the interpretation of a time-distance graph representing the journey of a student, Tommaso, from home to the bus-stop. The worksheets' sequence connected to this task was conceived to gradually lead students in the interpretation of the graph, focusing their attention on the meaning of ascending, descending and horizontal traits of the graphs. Students are also asked to focus on the reasons supporting the correct interpretation of a time-distance graph, with the aim of making them, on one side, reflect on their thinking processes and share these processes with their classmates and, on the other side, consolidate their competencies in justifying and analysing their answers. The question on worksheet 1 (within the white box, see fig.1) requires students to interpret the meaning of a descending line within the graph. Students have to highlight that in the period of time from 50s to 70s the distance from home decreases, so Tommaso is going back for a while. Helping worksheet 1A (fig. 1) first of all makes students focus on the word "straight" to help them to abandon the idea that the graph could represent the drawing of the road. Moreover, it aims at fostering a correct interpretation of the descending line in the graph, making students look at two specific points within the graphs, that is (50, 100) and (70,40), to highlight that the distance from home is decreasing.

Sending a helping worksheet to a specific group of students is a way to activate FA strategy C, because students are provided with feedback about the task (if they receive this kind of worksheets, they realise that their answers should be completed and/or corrected) and feedback about the processing of the task (the suggestions and the guiding questions on the helping worksheets are aimed at supporting the students in facing the problem). Moreover, giving feedback represents a way of making students activate themselves as owners of their learning (FA strategy E).

Fig. 1: The helping worksheet

During our design experiments, some students (in particular, low-achieving students) face difficulties also in interpreting the *purpose* of the provided helping worksheets, as supports to face the tasks. This is a manifestation of their lack of metacognitive control. For this reason, after the first cycle of design experiments, we introduced the displaying and collective meta-level analysis of helping worksheets as a fundamental characteristic of the methodology for their implementation.

As an example of this specific implementation of helping worksheets, we present and analyse an excerpt from a discussion on helping worksheet 1A, which was carried out in a 5th grade class. The discussion was aimed at making students aware of the goal of the helping worksheet and at pointing out specific mathematical aspects related to the task, namely to make them: (1) look at points within time-distance graphs as bearers of two linked information (the distance from home and the time spent); (2) interpret the variation of the distance in terms of moving away/approaching home; (3) avoid the typical mistake of interpreting the graph as a drawing. We remind that the researcher takes part in the discussion as both an observer and a participant.

220 Researcher: The first ones who are going to speak are those who did *not* receive this helping worksheet. Let's read the help that is given and try to say why, in your opinion, it is an help...what it helps you to do... The main question to be answered is still this one (*she indicates question 1, presented in Worksheet 1*). The help says (*reading*) "Remember that Tommaso is walking on a straight road. What is his distance from home after 50s? What is his distance from home after 70s?"

221 Teacher: Why do the suggestions focus on this?

222 Researcher: What do these questions help to do?

*Several students raise their hands.*

223 Carlo: Because they help you to understand the distance in the period between 50s and 70s. Because, at 70s, he is nearer...

224 Researcher: So you are saying that it enables to look at the distance, aren't you?

This discussion was planned with the objective, on one side, of eliciting evidence of students' understanding at a metacognitive level (strategy B), and, on the other side, of activating some students as resources for their classmates (strategy D). In fact, the researcher (lines 220, 222) and the teacher (line 221) are fostering a meta-reflection, involving the students that did not receive the help in clarifying the reasons why the questions posed on helping worksheet 1A could provide help in answering questions 1. Their aim is, therefore, to activate FA strategy C at the peer's level. Specifically, Carlo's intervention (line 223) represents a feedback about self-regulation because he highlights that the questions in worksheet 1A enable to focus on the change in Tommaso's distance from home, during that period of time. Through this comparison with their classmates, students can therefore become aware of the kind of support that helping worksheets could give and can also develop new tools to face similar activities in an effective way.

Then, the teacher focuses students' attention on a part of the helping worksheet that was *not* mentioned by Carlo:

225 Teacher: And why does it [the help] suggest that Tommaso is moving on a straight road?

226 Carlo: Because it wants to make us reason on the fact that he is going back.

227 Researcher: What mistake couldn't be done if I remember that the road is straight? ...  
(*Silence*) If I don't know that the road is straight, what could I think?

*Anna mimes a curvy road with her hands.*

228 Arturo: I could think that the sensor initially indicates a direction, then he goes on the right... (*Arturo is referring to the introductory activity with the motion sensor*)

229 Teacher: So a change in the direction.

230 Researcher: That we are zigzagging, in a strange way.

231 Teacher: It is the reason why it remembers us that the road is straight. You recalled, with your memory, what we experimented last time. If we hadn't worked with the sensor, you, maybe, would have proposed different answers.

Again the teacher and the researcher focus students' attention on the suggestions contained in helping worksheet 1A to make them become aware of its role in supporting the resolution of the task (strategy C). The teacher (line 225) focuses on the first suggestion given in worksheet 1A (*Remember that Tommaso is walking on a straight road*) and the researcher (lines 227) aims at making students reflect on the possible misinterpretations that this suggestion wants to prevent. Students are, in this way, provided with both feedback about the processing of the task and feedback about self-regulation, because they can become aware of the possible mistakes that could be done in the interpretation of this kind of graphs, learning how to monitor their work. Also the teacher (line 231) provides a feedback about self-regulation because she is making the students notice how the previous experience has influenced their answer to the current question. Carlo (line 226) and Arturo (line 228) are activated as instructional resources for their classmates (strategy D).

## Discussion

In this paper we referred to the theoretical lenses provided by the FaSMEd framework to present and discuss the design of digital resources and the corresponding method of implementation, with a special focus on the helping worksheets. The analysis we developed, on one side, shows that the

FaSMEd three-dimensional framework represents a useful tool for both designing digital materials for technology-enhanced FA practices and the corresponding methodology, and analysing how these materials are implemented in the classroom. On the other side, this analysis provides a validation of the design and implementation because the FaSMEd framework offers some important criteria according to which the digital worksheets and the methodology for their implementation can be evaluated as effective tools to foster FA processes: (1) the activation of different FA strategies; (2) the involvement of all the agents; (3) the evolution of the FA strategies (in particular toward strategy E, which should constitute a constant objective of the activities); (4) the different levels of feedback provided; (5) the support provided to the three fundamental FA processes.

At the same time, the analysis of the design and implementation of the helping worksheets in the chosen episode enabled us to highlight a pattern that characterises the evolution of FA strategies when helping worksheets are implemented. In fact, the use of the helping worksheet, combined with the sending and displaying functionality of technology, turned into the activation of several FA processes, with the involvement of all the agents. During the group-work phase, by sending the helping worksheet to the students, the teacher is activating FA strategy C with the aim of activating also strategy E. After the group-work phase, a meta-level discussion devoted to the sharing and analysis of helping worksheet is planned by the teacher (strategy B). As a result of the design based process, two different ways of fostering students' meta-level reflections have been identified: initially, the students who did *not* receive the worksheets are asked to reflect on the possible role played by the provided help (becoming instructional resources for their classmates, strategy D); then, the students who *did* receive the help (mostly low achieving students) are asked to discuss on the ways in which they used it, making their reasoning explicit and being activated as the owners of their own learning (strategy E). During the discussion, all the students receive feedback from the teacher and their classmates (strategy C) and are provided with the opportunity to clarify the learning intentions associated to the worksheet (strategy A).

We think that this pattern, since it is recurring throughout our corpus of data, represents an important validation of the design of helping worksheets, because it highlights the effectiveness of these resources and their implementation in fostering the development of FA strategies and the fruitful involvement of all the agents.

Other elements of validation can be highlighted if we interpret the results of the activities carried out through the helping worksheets in terms of the three fundamental FA processes that are supported: (a) the students are supported in establishing *where they are in their learning* when they use the help as a feedback to assess their own answer; (b) the teacher is supported in helping students clarify *where they are asked to go* when, during the class discussion, the characteristics of given answers are analysed and discussed; and (c) the teacher and the students are supported in establishing *what needs to be done to get there* when, during the class discussion, the helping worksheets are analysed to highlight in what ways they could help and what kind of suggestions they give.

We are now developing a similar analysis to highlight, referring to these criteria, how the other categories of worksheets are used to foster the activation of FA strategies through the support provided by technology. This will enable us to identify the connections and mutual support between

the different worksheets and the methodologies through which they are implemented during the lessons.

*This contribution is framed in a European project on the use of technology to foster formative assessment strategies (FaSMEd project) and addresses the crucial issue of feedback therein. The theoretical framework refers to formative assessment, with specific focus on different levels of feedback. By analyzing data from teaching experiments in grades 5 and 7, we identify strategies employed by the teacher to provide feedback during class discussion and investigate the effect of such strategies on the enactment of formative assessment.*

*Keywords: formative assessment, technology, feedback, teacher, peers.*

## Introduction and theoretical background

### Formative assessment and feedback

This contribution is framed within the European Project FaSMEd (“Improving progress for lower achievers through Formative Assessment in Science and Mathematics Education”), aimed at investigating the use of technology to promote formative assessment (FA) practices in the mathematics and science classroom. FA is conceived as a method of teaching where

“[...] evidence about student achievement is elicited, interpreted, and used by teachers, learners, or their peers, to make decisions about the next steps in instruction that are likely to be better, or better founded, than the decisions they would have taken in the absence of the evidence that was elicited” (Black & Wiliam, 2009, p. 7).

Wiliam and Thompson (2007) describe five key FA strategies: (A) Clarifying and sharing learning intentions and criteria for success; (B) Engineering effective classroom discussions and other learning tasks that elicit evidence of student understanding; (C) Providing feedback that moves learners forward; (D) Activating students as instructional resources for one another; (E) Activating students as the owners of their own learning.

Feedback is a crucial issue in FA. Hattie and Temperley (2007) define feedback as “*information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one’s performance or understanding*” (p.81) and identify four major levels of feedback: (1) feedback *about the task* (concerning how well a task is being accomplished or performed); (2) feedback *about the processing of the task* (concerning the processes underlying tasks or relating and extending tasks); (3) feedback *about self-regulation* (concerning the way students monitor, direct, and regulate actions toward the learning goal); (4) feedback *about the self as a person* (consisting in positive (and sometimes negative) evaluations and affect about the student). Hattie and Temperley also point

out that feedback is a consequence of specific actions and that *can also be sought by students, peers, and so on, and detected by a learner without it being intentionally sought.*” (p.82).

### **Enhancing formative assessment: technology and tasks**

Specific theoretical and methodological assumptions of the Italian team (the three authors) within FaSMEd concern the importance of fostering students’ development of ongoing reflections on the teaching-learning processes, and helping students to make their thinking visible (Collins, Brown and Newmann, 1989), sharing their ideas with the teacher and the classmates. These basic assumptions entail specific choices concerning the technology and the tasks.

Concerning technology, each class is equipped with a Connected Classroom Technology (CCT) through which the students’ tablets and the teacher’s laptop are connected. In order to foster collaboration and sharing of ideas, students are asked to work in pairs or in small groups on the same tablet. By means of the CCT equipment, students are able to receive worksheets from the teacher, send back their written answers, and answer to instant polls proposed by the teacher; the teacher can easily collect the students’ opinions and reflections during or at the end of an activity, as well as the written answers, and receive the statistics concerning the answers to the polls. The teacher’s computer is connected to an Interactive White Board (IWB) or a projector, so that it is possible to select and display written productions and the results of polls.

Concerning the tasks, students are asked to work on sequences of activities with a strong argumentative component: they are required to provide their answer and explain it in a written text. In this way, they are encouraged to make their thinking visible and to provide the teacher and the peers with a written text that will be shared and analysed during mathematical discussions (Bartolini Bussi, 1998). The mathematical content at issue is relationships and functions, and their different representations (symbolic, tabular, graphic). Activities are adapted from the ArAl project (Cusi, Malara & Navarra 2011) and The Mathematics Assessment Program (<http://map.mathshell.org>).

Summing up, the typical lesson starts with a peer activity on one worksheet. After having collected all the students’ written answers, the teacher promotes a class discussion, starting from the analysis of some written answers (selected and displayed on the IWB). The discussion concerns the task level (correct answers and typical mistakes), the task processing level (effective ways of approaching the task) and the communicative level (effective ways of communicating the answer and the explanation). Comparison between different solutions is especially promoted. For further details on the organization of the lessons, see (Cusi, Morselli and Sabena, 2016).

### **Previous results and the current research questions**

In former studies (Cusi, Morselli and Sabena, 2016) we analysed classroom discussions performed within the FaSMEd teaching experiments, and highlighted that CCT may support the activation of FA strategies by the teacher, by the peers (peer assessment), and by the student himself (self-assessment). In this contribution we focus on *strategy C (providing feedback that moves learners forward)* and we investigate: what are teacher’s strategies that may foster FA strategy C; which level of feedback is provided; what are the effects of this strategy (in terms of activation of other strategies such as D and E).

## The context

In Italy the FaSMEd project involved 20 teachers, from three different clusters of schools located in the North-West of Italy (from grade 4 to grade 7). During all the teaching experiments, one of the authors was present in the classes with the teachers, acting as a participant observer. The analysis is based on video-recordings of the classroom discussions, with the help of written transcripts and field notes by the participant observer (one of the authors).

## Analysis

By analysing several episodes from the teaching experiments, we came to a first characterization of teacher's feedback strategies, that is the ways in which she gives feedback to students. In the subsequent part, we provide a short example for each kind of feedback strategy, highlighting the level of feedback provided. Moreover, we will discuss the effects of each feedback strategy in terms of activation of FA strategies. All the examples come from the third lesson on time-distance graphs, performed in grade 7. The lesson sequence on time-distance graphs (about 20 hours, 8 worksheets) was adapted from the Mathematics Assessment Program (<http://map.mathshell.org>) and was introduced by an experience with a motion sensor, which provided instantaneous graphical representation of a linear motion performed by the students. This lesson was chosen because it contains all the typical teacher's feedback strategies that recurred in different classes and grades in our teaching experiments. Here we refer to worksheet 6, where a graph and three possible stories are presented:

The students are asked to answer to the following question: “What is the story that this graph represents? Justify your answer.” Students work in pairs and send their written answers to the teacher's computer, as soon as they feel ready. The teacher, together with the participant observer, reads the answers as they arrive at her laptop and selects some of them for the discussion. The first selected answer is the one by the group of Mil and Pon:

“For us the answer is B for two reasons:

1. You cannot do 1600 meters by foot in half an hour

2. The graph represents precisely the information given by the story. Then Tommaso climbs the hills, the first trait is the climb, the second is still a climb but less steep. When he comes to the top, then Tommaso climbs down and goes back home”.

We may observe that Mil and Pon highlight two reasons for the choice of story B: the first one is based on *everyday life experience* (they draw from the graph the information that 800+800 meters are walked, and they point out that it is not possible to walk for 1600 meters in half an hour; since it is actually possible to walk 1600 meters in half an hour, this argument is wrong), the second one is based on a *wrong interpretation of the graph*: they interpret the graph as a picture of the hill, that Tommaso first climbs up and then descends down. For the teacher, the discussion of students' production is the occasion for *giving feedback on two levels*: *about the task* (clarifying that the graph *represents* the relation between distance from home and time, and is not a picture of the hill, so it does not share with it any resemblance, in principle) and *about the way of processing the task* (pointing out that the justification must be based on a careful analysis of the information provided by the text and the graph). To this aim, the teacher promotes a discussion (*strategy B*). Mario is asked to read the production of Mil and Pon, then the discussion starts.

Transcript	Analysis
217. Teacher: Then, answer B for two reasons. Ok, Lollo?	The teacher encourages the students to activate themselves as resources for Mil and Pon (strategy D).
218. Lollo: We did, because... we did the experience with the motion sensor... that if the line was more oblique the... the line, if it was more oblique, it meant that he (Tommaso) went faster, it did not mean that the road was steeper, because if the road is steeper you go slower...	Lollo gives a feedback about the task (strategy C), suggesting that the different inclination of the segments should be interpreted in terms of different speed. To warrant his statement, he refers to the experience with the sensors. He activates himself as resource for Mil and Pon (strategy D). He also adds that, when the road is steeper, usually one goes slower, and not faster, referring to everyday experience.
219. Teacher: Rob?	
220. Rob: This is a graph, it is not the drawing of the hill.	Rob makes explicit that the graph does not represent the drawing of the hill, giving a feedback about the task to Mil and Pon. He activates himself as instructional resource for his classmates (strategy D), providing feedback about the task (strategy C).
221. Teacher: It is not the drawing of the hill, it is the graph that represents what?	The teacher encourages Rob to make explicit his comment to Mil and Pon's answer. This intervention is a <b>relaunching</b> : she poses another question, linked to Rob's intervention, with the aim of deepening the analysis. Relaunching Rob's intervention the teacher implicitly gives a feedback (strategy C) to Rob himself, suggesting that his intervention is worthwhile.

222. Rob: The... the journey of one boy, and anyway they told that it is not possible to do 1600 meters in half an hour, we already said it last time [ <i>he refers to the lesson with motion sensors</i> ], it is a graph, it doesn't have to be really real... really near to reality.	Rob gives a feedback (strategy C) about the processing of the task, pointing out that the justification must not rely on empirical arguments but on the interpretation of the task. The teacher's <b>relaunching</b> is efficient in turning Rob's former intervention, which provided a feedback about the task, into a meaningful feedback about the processing of the task.
223. Observer: Do you understand what he is saying?	
224. Mario: For me you can do it easily, you can even do 2 or 3 kilometers...	Mario challenges Mil and Pon's justification A, on the basis of empirical experience. Mario is giving a feedback on the task (strategy C): the first answer relies on a wrong argument.
225. Rob: For me yes...	
226. Teacher: Then, the fact of 1600 meters in half an hour, your classmate says that actually you can do it in half an hour, then that is not a good motivation. Somebody else was talking about the second motivation, motivation B, the fact that the graph explains us that Tommaso climbs the hill and so on. Lollo said: "No, because when we did the experience with the sensor we went on a oblique line, but the path we were doing was not on a hill, it was not steep".	The teacher synthesizes the interventions of Lollo, Mario and Rob, stressing that the justification 1 is not correct. Then she shifts the focus on justification 2, focusing on the correct interpretation of oblique lines within a time-distance graph. In this way, she activates strategy C, giving Mil and Pon a feedback about the task (it is a mistake to interpret the task as the picture of a hill) and the processing of the task (focusing on the ways in which the time-distance graphs should be interpreted). Here we may see instances of both <b>rephrasing</b> (the teacher reformulates some arguments so as to make them more intelligible to the mates) and <b>revoicing</b> (the teacher revoices some of the students' interventions, so as to draw the attention on specific effective parts of the given arguments).
227. Ur: Teacher, but I agree with what Lollo said. I thought that if it is steep you walk slowly, while after, when it becomes less steep, Tommaso goes faster.	Ur intervenes, referring to Lollo's first intervention (218). Ur activates herself as owner of her own learning (strategy E). This intervention confirms that Lollo became a resource for his mates.
228. Teacher: But the fact that... you say: "the fact that the road is more or less steep can give us information on the reasons why he goes faster or slower"...	The teacher gives a quick feedback to Ur, reformulating her sentence, so that other students can intervene. This is again an example of <b>rephrasing</b> .
229. Mark: Teacher, moreover we told that with the sensor if we went faster... the segment went more	Mark intervenes making reference to the experience with sensors (thus linking the inclination to the speed)

<p>vertically, but here ... they say that he is climbing and he goes too much... he goes fast, and then when it [the segment] becomes less steep he goes less fast. I don't know, in the descent he goes really faster than on the other two traits, but if they say that he climbs up in the first trait, he goes fast, and then when it starts being plane he goes less fast.</p> <p>[...]</p>	<p>and pointing out that something doesn't work in what Mil and Pon wrote: in their interpretation of the graph as a picture the first trait is the steeper part of the hill, but in the interpretation of the graph in terms of speed (as in the previous experience with the motion sensors) the segment is steeper when the speed increases. Mark expresses his own doubts about the two contrasting interpretations: in reference to everyday experience, it is not so common to walk faster in the steeper trait of a hill. Mark's intervention is an instance of strategy E, but his intervention could also act as feedback for Mil and Pon (strategies C, D).</p>
<p>234. Teacher: But I... this answer really tells that the first segment, the first two parts of segment that go up describe the hill, the steep climb, the less steep climb, the top and after the descent...</p>	<p>The teacher goes back to Mil and Pon's written answer, so as to foster the comparison between their answer and the intervention of Mark. By <b>contrasting</b> in this way the two answers, the teacher is implicitly giving a feedback to Mil and Pon (strategy C) and turning Mark as instructional resource for them (strategy D).</p>
<p>235. Student: That is wrong.</p>	<p>This intervention confirms that the contrasting was efficient in fostering the comparison between the different positions of Mark and Mil and Pon.</p>
<p>236. Teacher: Then the idea that the segments, as Rob said... "the graph is different from the drawing of a hill", or Lollo said "when we did it with the sensors we saw this kind of segments but we were not climbing, it meant that we changed the speed"... Let's remember always that the y axis describes what? The distance from home in meters.</p>	<p>The teacher intervenes with a <b>rephrasing</b>: she teacher reformulates and synthetizes the interventions of the students, so as to give a feedback to Mil and Pon. The activated strategy is C (providing feedback). In this way she is efficient in turning the feedback about the task into a feedback about the processing of the task (she draws the attention on the meaning of the two axes). We call this kind of intervention a <b>rephrasing with scaffolding</b>, since the teacher, besides rephrasing, adds some elements to guide the work on the graph.</p>

## Results and discussion

Within the FaSMEd project, we performed several teaching experiments in grades 5 to 7, setting up task sequences and proposing them in a CCT environment. As a first result (Cusi, Morselli and Sabena, 2016), we showed how technology may support the activation of several FA strategies. In the current paper we focused on FA strategy C (providing feedback) and explored the ways in which the teachers may intentionally provide feedback during class discussions, the kind of feedback that is provided and the possible links with FA strategies.

The analysis of several class discussions performed during the teaching experiments led us to identify typical strategies employed by the teacher to provide feedback. Such strategies are exemplified in this paper through the analysis of a class discussion in grade 7. Here we summarize the strategies and discuss further developments of our study. The first strategy is **revoicing**, that occurs when the teacher mirrors one student's intervention so as to draw the attention on it. Often, during the revoicing, the teacher, stresses with voice intonation some crucial words of the sentence she is mirroring. **Rephrasing** takes place when the teacher reformulates the intervention of one student, with the double aim of drawing the attention of the class and making the intervention more intelligible to everybody. Rephrasing is applied when the teacher feels that the intervention could be useful but needs to be communicated in a better way so as to become a resource for the others. We also found special instances of rephrasing, when the teacher, besides rephrasing, adds some elements to guide the students' work. Drawing from Wood, Bruner & Ross (1976) the term "scaffolding", we call this special strategy a **rephrasing with scaffolding**. The revoicing and rephrasing strategies are used to activate strategy D, since they turn one student (the author of the intervention) into a resource for the class. Moreover, we observed that often revoicing and rephrasing (and rephrasing with scaffolding) are efficient in promoting the evolution of the kind of feedback, for instance (as in the reported example) from a feedback on the task to a feedback on the processing of the task. **Relaunching** occurs when the teacher reacts to a student's intervention, which (s)he considers interesting for the class, not giving a direct feedback, but posing a connected question. In this way, by relaunching the teacher provides an implicit feedback (strategy C) on the student's intervention, suggesting that the issue is interesting and worth to be deepened or, conversely, has some problematic points and should be reworked on. **Contrasting** takes place when the teacher draws the attention on two or more interventions, representing two different positions, so as to promote a comparison. By contrasting, FA strategy D and E are activated (the authors of the two positions may be resource for the class as well as responsible of their own learning).

The aforementioned strategies, besides being efficient ways to boost the discussion, are powerful formative assessment tools, since they foster the activation of formative assessment strategies. When addressing one student's statement, the teacher gives an implicit feedback on it (strategy C), suggesting the intervention deserves further attention. Moreover, in this way strategies D and E are activated and the feedback may evolve from feedback on the task to feedback on the processing of the task. We deem that this kind of classification may shed light into the crucial role of the teacher in enhancing FA within class discussions. All the documented strategies seem to be intentionally applied by the teacher. Anyway, the given feedback is implicit, since the teacher does not address directly the correctness of the student's intervention. As a consequence, the feedback is not always sought by the students. We are aware of the fact that we were able to single out and discuss only some effects of a given feedback, namely when a student explicitly refers to a previous intervention or changes his mind immediately after an intervention by a peer or by the teacher. Other effects of a given feedback are less visible during a class discussion: in order to study them, it will be necessary to analyse further activities of the students or collect a-posteriori interviews.

For the moment we focused on class discussions around the analysis and comparison of students' written productions. In the future we plan to go on with our analysis, focusing on other crucial

moments of the teaching experiments, such as the discussion after a poll, or the discussion on specific helping worksheets. As a further development, we plan to compare the strategies we outlined with Bartolini Bussi (1998)'s classification of teacher's interventions during a mathematical discussion. Moreover, we aim at complementing the present study, concerning the way feedback is given (feedback strategies), with a study on the *content* of feedback. To this aim, we plan to deepen the categorization of levels of feedback provided by Hattie & Temperley (2007), so as to take into account the specific features of the proposed mathematical tasks.

# Mathematics students' attitudes to group-based project exams compared to students in science and engineering

Bettina Dahl<sup>1</sup>

<sup>1</sup> Aalborg University, Denmark; [bdahls@plan.aau.dk](mailto:bdahls@plan.aau.dk)

*At Aalborg University, science, engineering, and mathematics students spent half the time each semester working in groups on projects within a problem based learning (PBL) curriculum. They are assessed through group exams. A survey showed that overall, the students are positive towards the group exam but there are significant differences between engineering, science, and mathematics students. Within this collectivistic student culture, some engineering students are very positive towards group exams, while mathematics, science, and other engineering students are less positive. In terms of the opportunity to obtain a fair grade in a group exam, the mathematics students are moderate positive, with different engineering students being more or less positive. All students agree that a group exam gives less differentiation of grades compared to an individual exam.*

*Keywords: attitudes; project exam; group exam*

## Introduction

At Aalborg University (AAU) in Denmark, science, engineering, and mathematics students work half the time each semester in groups of four to eight students on a project in a problem based learning (PBL) curriculum. PBL is student-centred and self-directed learning in teams with problem analysis and problem solving (Barge, 2010). The project is documented as a joint written report with an oral group exam lasting around four hours. This exam has traditionally consisted of two phases: First the group presents the project, then the external examiner and the supervisor examine the group. Each student is awarded a grade that may not be the same as the others. From 2006–2012 the Danish government banned group exams, but during this time AAU students still worked in PBL groups but the exam became an individual oral exam of around half an hour per student. This situation led to research on assessment methods in PBL, and Kolmos and Holgaard (2007) concluded that the students, the academic staff, and the external examiners preferred the group exam. One argument was that the students were not able to interact with each other during an individual exam, hence it was not possible to test PBL process competencies such as collaboration and teamwork. Since Danish law states that a grade solely depends on the student's performance at the exam (they cannot earn partial credits during the semester), this created a misalignment between PBL teaching and the assessment methods. In 2013 the group exam was reintroduced in Denmark and at AAU. The Faculty of Engineering and Science (FES) now added an individual phase into the previous group exam, where each student is questioned without interference from the group. Dahl and Kolmos (2015) found that the students overall were in favour of the reintroduction of the group-based project exam, but that students from two different engineering programmes were not equally positive, partly owing to their previous experience with the individual project exam and partly owing to professional cultures of individualism or collaboration influencing their attitudes. Maull and Berry (2000) and Bingolbali et al. (2007) showed that mathematics and engineering students are different in terms of their learning of mathematics, so one might ask whether a similar division

between engineering and mathematics students is seen in relation to which type of exam is perceived appropriate. This paper therefore compares students from eight programmes in science, engineering, and mathematics in relation to how they perceive the new group exam, the new individual phase as well as the opportunity to obtain a fair grade.

## **Theoretical background**

### **Alignment and exams**

Biggs and Tang (2011) argue that in order for students to learn the intended learning outcomes (ILOs), teaching should be constructively aligned with the ILOs and the exam. This theory fits other studies stating that an upcoming exam is a key factor for students' motivation and learning (Boud & Falchikov, 2006); i.e. the 'backwash effect' of exams. Hence, one can argue that in a PBL curriculum, the exam method should be aligned with the team-based and collaborative teaching method and the ILOs on PBL process competencies. Romberg (1995) argues that a group exam is able to test "reflection on one's own thinking, reasoning and reflection, communication, production, cooperation, arguing, negotiating" (p. 165). One can thus argue that a group exam assesses PBL competencies of communication and cooperation. However, each programme also prepares the students for a professional life after the university so the problems that the students address vary and AAU's PBL model is developed "on the basis of both professional and educational argumentation" (Kolmos et al., 2004, p. 9). One might anticipate that professional culture influences the students' views of the group exam, particularly master students.

### **Cultural differences in engineering, science, and mathematics**

Murzi et al. (2015) studied how students perceived their discipline culture using Hofstede's dimensions. One dimension measures individualism versus collectivism. Overall, students had a high individualistic score. Mathematics, computer engineering, and electronic engineering students were among the *less individualist* students. This fits the study by Burton (2004) where a majority of professional mathematicians worked co-operatively. Murzi et al. (2015) further argued that they had expected industrial design students to be more collectivistic as they rely on collective work in team projects but the results were opposite. Architect students' scores fell between mathematics and industrial design. Dahl and Kolmos (2015) also found significant differences between the engineering programmes Architecture and Design (AD) and Software Engineering (SE) at AAU. SE students were significantly more positive toward the group exam than those of AD. AD combines architecture with civil engineering and students here expect a more individual-oriented programme whereas SE is a system-oriented approach and a collaborative profession.

### **Research questions**

How do the students from the eight programmes view the group-based project exam compared to the individual project exam and the individual phase of the new group exam? How do they experience the grading? What does this tell us about mathematics assessment in PBL?

## Methodology

The questionnaire was piloted after the January 2013 exams and the revised questionnaire consisted of 20 questions of which most had several sub-questions. After the June 2013 exams, all 4,588 FES students received a link to this questionnaire and 1,136 responded. The response rate was relatively low (25%), which unfortunately is not uncommon for online surveys, but the level is still reasonable (Nulty, 2008). The response rate for each study programme cannot be determined separately but the number of student responses were as follows: Computer Science (CS: 40), Energy (EnE: 50), Mechanics and Production (MP: 39), Physics and Nano science (PN: 27), Architecture and Design (AD: 79), Mathematics (M: 28), Software (SE: 51), and Electronic (EIE: 48). In this paper, all questions are translated from Danish by the author. The programmes compared all had a relative large number of students who responded. The engineering programmes are civil engineering.

## Results

### Views of individual versus group-based project exam

Of all FES students, 34% preferred the individual exam and 57% the group exam, but students in different programmes were not equally positive towards the group exam (see Figure 1).

**Figure 1: "I would prefer an individual project exam"**

EnE students were the least positive towards the group exam while SE students were the most positive. Table 1 shows the programmes that were significantly different.

	EnE	AD	PN	M
CS	.047	.037		
EIE	.043			
SE	.002	.004	.041	.031

**Table 1: Significant differences in answers to the question if they preferred the individual exam**

SE and EnE are at opposite ends of the group-individual preference and they are each significantly different from many programmes. SE, CS and EIE are the most collective while EnE, AD, PN, M are the more individualistic, although M appears to be more moderately individual. MP are not significantly different from any. Master students are significantly more positive towards the individual exam than bachelor students ( $p = .001$ ). Almost half the master students preferred the individual exam while only a third of the bachelor students did. Comparing bachelor and master students in each programme, there is only a significant difference for EIE ( $p = .002$ ).

The survey asked a related question: “The time spent on the individual part is better spent on a longer joint part?” Of all FES students, 34% agreed, 50% disagreed, and 15% did not know. The students do not differ except MP, which is significantly different from AD ( $p = .005$ ) and M ( $p = .030$ ) (see Figure 2). Overall the students are positive towards the individual phase, particularly M. There is not significant difference ( $p = .114$ ) between bachelor and master students for all FES. When comparing students in each programme, MP bachelor and master students are significantly different ( $p = .024$ ) but here the master students are the more positive toward the group exam.

**Figure 2: “The time spent on the individual part is better spent on a longer joint part”**

### **How did the students experience the opportunity to obtain a fair grade?**

A question asked if the students were satisfied with their own grade. Overall, 83% agreed and there was not a significant difference between the eight programmes. Another question asked whether they found that all their group members had received a fair grade. Here only 66% agreed. In all groups, a majority of students had agreed but EnE (61%) and AD (59%) agreed significantly less than SE (76%) and PN (85%). EnE was different from SE ( $p = .046$ ) and PN ( $p = .037$ ) while AD was ( $p = .019$ ) different from SE and PN. When comparing each programme, most had given significantly different answers to the two questions except EIE ( $p = .064$ ), PN ( $p = .324$ ), and SE ( $p = .760$ ).

The survey also asked the students who had tried the individual exam whether the new group exam gave a better or a worse opportunity to obtain a fair grade. The views differ greatly (see Figure 3).

**Figure 3: “Does the group exam provide a better or worse opportunity to obtain a fair grade...?”**

When comparing the programmes, one sees that only M is not significantly different from any of the others while students from several of the engineering programmes answer significantly differently from each other (see Table 2). M therefore appears to be quite moderate in their views of whether or not the group exam gives a better or worse opportunity to obtain a fair grade. CS, EIE, SE, MP and to some extent PN are more positive towards the group exam as giving them a fair grade, while AD and EnE in general state that it provides them a worse opportunity to obtain a fair grade, compared with the individual exam. The students answering this question were all from the second **year** or older, as these were the only ones who had experienced both types of exams.

	CS	EIE	SE	MP	PN
EnE	.001	.004	< .001	< .001	.015
AD	.030	.039	< .001	.005	

**Table 2: Significant differences in answers to the question if the group exam provided a better or worse opportunity to obtain a fair grade**

The survey also asked the students whether there was a larger differentiation of grades in the group exam compared to the individual exam. The Danish grade scale has five passing grades (2, 4, 7, 10, 12) and two failing grades (-3, 0). This question relates to an internal discussion at both AAU and in Denmark debating if the group exam uses less of the grade scale as it is harder to give a precise individual grade and weaker students can hide and good students are not rewarded. Only a minority of the students confirmed that the group exam resulted in more differentiated grades. The lowest was EIE, where 7% said that the group exam resulted in more differentiated grades to some or to a higher extent, while the highest was M with 29%. This difference was not significant ( $p = .069$ ).

## Conclusions

### Individual versus group exam and the individual part of a group exam

The students were in general very positive towards the group exam but there are significant differences. Murzi et al. (2015) found that mathematics, computer engineering, and electronic engineering were among the *least* individualistic within a very individualistic student culture. One might argue that in general the AAU students are used to working in PBL and thus have a more collectivistic culture since, overall, the majority of students were in favour of the group exam when asked to compare it to an individual exam. This study of AAU students shows that in agreement with Murzi et al. (2015), CS and EIE were among the most collectivistic students as they were among the most positive towards the group exams. However, this is stated within the frames of a collectivistic AAU culture. Murzi et al. (2015) found mathematics students to also be among the least individualist, however at AAU, M appeared to be among the more individualistic students, even though AD and EnE appeared to be even more individualistic. Architect students in Murzi et al. (2015) were not among the individualist groups. In relation to their attitudes to the time spent on the individual part of the group exam, M were the most positive toward the individual part. M was again close to AD but quite different from MP. PN students were closer to the M students.

Master students were generally more positive toward an individual exam than bachelor students, especially EIE. However MP master students appeared very positive toward having a longer joint part in the new group exam. One might argue that this is related to the fact that the master students have been used to the individual exam prior to 2013, or perhaps to how they perceive their future professional life (wrongly or rightly) might have an impact.

### Fairness of grades

The students were overall satisfied with their own grade but relatively less satisfied with the grades given to their peers. Given the relatively low response rate, it could make sense that students answer this question significantly differently. The question in the questionnaire did not explicitly ask if their peers were over/under-graded, but it appears that seeing how their peers behave at the exam, perhaps with reference to their work during the semester and then experiencing what grade they received, often left the other students feeling some degree of unfairness. More research is needed here in order to determine why. The students also differed when they compared the group and the individual exam in relation to the opportunity to receive a fair grade. Here, M was more or less in the middle, not being significantly different from any of the other programmes. In general one sees that the same programmes as above show ‘collectivist’ preferences (CS, EIE, SE, MP) and ‘individualistic’ preferences (AD, EnE), which to some extent validate the results shown above and show that the students are consistent in their answers. However, one also needs to discuss to what extent their experience of receiving a fair grade is correct. Do students always know which grade they deserve? Furthermore, the perception – rightly or wrongly – of not being awarded a fair grade, might negatively influence their view of the exam. Students are occupied by fairness in grading and their perception of justice is significantly affected by the assessment method (Burger, 2016).

Students appear to obtain more similar grades when they are assessed as a group than if they are assessed individually. The question is then – which is the right grade? One might argue that in a group exam of up to eight students, it might be difficult to make a distinction between each group member, which to some extent might explain the different opinions about own grade and the grade of the group members, and the same question can only be asked once. On the other hand, one might also argue that since a group exam to some extent is able to test PBL process competencies, which an individual exam cannot, the grades given in a group exam are the more accurate.

### **Summing up and impact for mathematics assessment**

It appears that mathematics students are not distinct from engineering or science students on the issue of preference for individual or group exams. The eight groups were mixed; ergo mathematics students were more similar to some engineering students but different from others. This is different from what is known from how the learning of mathematics takes place when comparing mathematics and engineering students. For instance Bingolbali et al. (2007) found that engineering students see mathematics as a tool and therefore wish to see the application side. In science, engineering, and mathematics PBL projects, mathematics is applied to solve problems, but in a mathematics project, the body of mathematical theorems used to solve a problem usually takes up a considerable part of the project work and the report. Thus, the role of mathematics is different in the PBL projects in each programme. Assuming that the group exam is the best fit to PBL, it is unexpected that the students are not more in agreement with each other about the group exam. An obvious answer is that the group exam does not fit each programme equally well. The more moderate views of the mathematics students could indicate that it is a reasonably good fit when there is an individual phase as this is a way to serve both the individual and collaborative aspects of mathematics.

The question of individualistic or collective attitudes may also depend on the overall student culture. Murzi et al. (2015) found that mathematics students were among the *least individualistic* within an individualistic culture, while this study found the mathematics students to be among the *most individualist* students within a collectivist culture. With caution, one might argue that the most individual student cultures were AD and EnE, with M and PN also being individualistic but not as much. The most collectivist student cultures were SE and CS, with EIE and MP also being collectivistic but not as much.

However, the above conclusions should be treated with caution as the students base their attitudes about the group exam on the ‘learnt’ curriculum (Bauersfeld, 1979), which is not necessarily the same as the intended curriculum. The group exams were intended to be the same throughout the FES and prior to the reimplementation, workshops had prepared the supervisors for this type of exam. It is, however, unlikely that all group exams were identical as students, supervisors, and external examiners were different. One should therefore hesitate to draw too strong conclusions, particularly also taking into account the relatively small response rate. The results are *indications* of how students in different programmes at a Danish PBL university perceive a group exam and therefore which attitudes curriculum planners might expect from students if other universities wish to implement a type of project work or group exams. Curriculum planners need to consider what is the general ‘culture’ of collaboration both at the university and in the future profession, they need to

consider how the exam has a backwash effect on how the students work, and that bachelor and master students might not perceive such an exam in the same way. The group exam might also be a better fit for some groups than others, but in terms of mathematics, it neither appears to be an obvious fit, since mathematics students might lean more towards the individualistic culture, nor does it appear to be a bad choice since the students in general are positive. This might reflect the mathematics culture as being both individual and collectivistic. In terms of grading, curriculum planners need to consider that group exams might result in a smaller distribution of grades.

# A case for a new approach to establishing the validity of comparative judgement as an assessment tool for mathematics

Ben Davies

Loughborough University, United Kingdom; [b.m.j.davies@lboro.ac.uk](mailto:b.m.j.davies@lboro.ac.uk)

*Traditional, criterion-based assessments have recently been criticised for rewarding the procedural over the conceptual, limiting exam writers' ability to focus on authentic mathematics and necessitating complex mark schemes that are difficult and time consuming to implement (Jones, Swan & Pollitt, 2015; Bisson, Gilmore, Inglis & Jones, 2016). This paper discusses an assessment innovation, comparative judgement, that avoids the above criticisms by using the innate human capacity for comparative, over criterion-based, judgement. After a review of the reliability and validity literature in this area, a theoretical examination of validity research on comparative judgement results in the proposition that a new approach is necessary. The final section of the paper suggests that investigation of predictive validity, as defined by Trochim (2006), may address the concerns raised regarding previous research on the validity of comparative judgement.*

**Keywords:** *Assessment, comparative judgement, conceptual understanding, reliability, validity.*

If presented with two large bags of gold and invited to keep one, most people would have a strong preference. While unlikely to know the exact quantity in either bag, it is usually not difficult to identify which is heavier by comparison. *Comparative judgement* is an assessment tool that exploits this innate capacity for comparison (Thurstone, 1927, "The Law of Comparative Judgment") rather than isolated evaluation against specified criteria. This well-established principle of psychology forms the basis for an innovative assessment that offers an alternative to the criterion-based status quo. This paper is a theoretical discussion of investigations into the reliability and validity of this approach to mathematics assessment. This is followed by a detailed theoretical examination of validity, resulting in the suggestion that further work and a new approach is necessary to establish validity in a more substantive manner. While making few definitive claims regarding the nature of the new approach, a case study in assessing conceptual understanding is used to illustrate the potential of two approaches based on what Trochim (2006) refers to as predictive validity.

## What is comparative judgement?

Comparative judgement relies on expert judges making a series of comparisons between two responses to a given question. Without any specific criteria, judges are simply asked to 'choose the better response'. Using an automated system to generate pairs of students' responses for comparison, comparative judgement generates a ranked order from 'best' to 'worst'. This ranked order, produced after each response has been compared to others several times, is based on the Terry Bradley model (Pollitt, 2012) that generates a standardised parameter estimate (z-score) representative of the relative quality of each response. In the absence of specific marking criteria, the rankings produced are "instead grounded in the collective expertise of the judges" (Bisson et al., 2016, p. 143), avoiding the necessity to explicitly define the target of the assessment.

## A summary of the literature on Comparative Judgement

Before examining the literature on reliability and validity, this section begins with a discussion of two key benefits claimed in the comparative judgement literature.

### Benefits, motivations and intentions

Comparative judgement facilitates the targeting of specific aspects of mathematics without having to embed a precise definition into a marking schedule (Pollitt, 2012). For example, Bisson et al. (2016) used comparative judgement to investigate *conceptual understanding* in undergraduate mathematics. This “important but nebulous construct” (Bisson et al. 2016, p. 143) has been the topic of much debate. Bisson et al. (2016) claim experts are capable of recognising examples of conceptual understanding, but find it difficult to generate comprehensive, reliable scoring rubrics. As suggested by Bisson et al. (2016), by grounding the definition of an area of assessment solely in the collective understanding of judges, this problem is at least partially avoided. Assessment of conceptual understanding will be returned to in a later section of this work.

Jones, Swan and Pollitt (2015) also argue for the need to “free assessment designers from restricting tasks to those that may be easily scored by conventional means” (Jones et al. p. 170). They claim this would allow for the introduction of components that more adequately reflect the assessments purported purpose. A study involving four experienced GCSE (General Certificate of Secondary Education for England, Wales and Northern Ireland) exam writers producing an exam explicitly for comparative judgement marking found that exam writers experienced greater freedom to write more open-ended questions providing students with the freedom to experience more genuine problem solving situations (Jones & Inglis, 2015). Moreover, this freedom was successfully used, as evidenced by the survey responses of 23 teachers who evaluated the suitability of this exam script. Examinations of this type have been long sought-after but have seldom materialised due to the need for a demonstrably reliable and valid tool for assessment (Jones & Inglis, 2015).

These benefits, particularly that of eliminating assessment criteria, raise questions of reliability and validity. An assessment based on such apparently subjective foundations might initially attract substantial skepticism. These questions are the focus of the following two sections.

### Reliability

In the context of comparative judgement, reliability has universally been used to refer to the notion of repeatability across different judges and judging communities. This is often referred to as *inter-rater reliability*.

There is a growing collection of case studies demonstrating high inter-rater reliability in the use of comparative judgement. Bisson et al. (2016) demonstrated high inter-rater reliability in the contexts of conceptual understanding of entry-level undergraduate statistics ( $p$ -values), undergraduate pure mathematics (derivatives) and elementary school-level algebra (using letters in mathematics). Using a split-half technique in each of the three studies, judges were divided into two groups of equal size. As a result of the computerised method by which judges make comparisons, this split-half comparison was repeated 20 times in each study without requiring any additional comparisons from the judges. Pearson’s correlation coefficients were computed for each iteration of each study, the results of which are summarised in Table 1.

	Participants	Range in $r$ over 20 trials	Mean $r$	Median $r$	Standard Deviation
<b><i>P</i>-values</b>	10 judges, 20 students	.664 - .855	.749	.762	.06
<b>Derivatives</b>	30 judges, 42 students	.826 - .907	.869	.872	.02
<b>School Algebra</b>	10 judges, 46 students	.678 - .837	.745	.742	.04

**Table 1: Summary of comparative judgement reliability results from Bisson et al. (2016).**

Jones, Swan and Pollitt (2015) produced results consistent with the above in a problem solving context. When applied to both traditional GCSE examination scripts and purpose-written open-ended examination scripts, comparative judgement performed well when implemented by a diverse group of 23 judges, consisting of ten GCSE examiners, one non-GCSE examiner, seven mathematics education lecturers, two researchers, one research student and two advisors. When separated into two groups (of 12 and 13), the Rasch sample separation reliabilities, often considered similar to Cronbach's  $\alpha$  (e.g. Wright & Masters, 1982) were .80 and .93, indicating acceptably high internal inter-rater reliability for each group. Jones et al. (2015) also report a Pearson product-moment correlation coefficient of .87, providing further evidence for the inter-rater reliability of comparative judgement when assessing problem solving.

In every reviewed study on the reliability of comparative judgement to-date, the results have positively indicated that comparative judgement performed reliably across judging communities.

### Validity

Consistent with the majority of studies in the comparative judgement literature this paper adopts the broad definition that a valid assessment measures that which it purports to measure (Koretz, 2008). Most investigations of the validity of comparative judgement have focused on what Trochim (2006) refer to as convergent validity, based on comparison with traditional measures of mathematical achievement. Bisson et al. (2016) has taken a different approach, by investigating content validity, based on comparisons with other psychometrically validated instruments.

A measure is said to have *convergent validity* if it produces results similar to others that should theoretically be similar (Trochim, 2006). On investigating assessment of problem solving, McMahon and Jones (2015) reported “comparative judgement outcomes correlated as expected both with test marks and with existing student achievement data, supporting the [convergent] validity of the [comparative judgement] approach” (p. 368). Jones and Inglis (2015) reported a correlation of .86 between students' GCSE marks and their parameter estimated  $z$ -score based on a comparative judgement assessment, providing further evidence in this direction.

Finally, Bisson et al. (2016) investigated both convergent validity and content validity across all three studies on which they report; see Table 2. The former was evaluated with methods similar to those

above, analysing correlations between traditional student achievement data and comparative judgement results. Content validity, a comparison of the measure against the relevant content domain (Trochim, 2006), was based on correlation analysis between comparative judgement results and other psychometrically validated measures of conceptual understanding; see column two of Table 2. It should be noted that the choice of topics ( $p$ -values, derivatives and algebra) in Bisson et al. (2016) were “driven by the existence of validated instruments to measure conceptual understanding of those topics” (p. 144). As is discussed later, the absence of such instruments for most topics in mathematics appears to serve as a significant barrier for this line of research. For the list of topics available Bisson et al. (2016) conclude that comparative judgement is a valid measure of conceptual understanding.

	<b>Traditional measure</b>	<b>Instruments</b>
<b><i>P</i>-values</b>	.555	.457
<b>Derivatives</b>	.365	.093
<b>School algebra</b>	.349	.428

**Table 2: Summary of comparative judgement validity results from Bisson et al. (2016). The ‘traditional measure’ line refers to the correlation between achievement data and comparative judgement  $z$ -scores. The ‘instruments’ column refers to the correlation between comparative judgement  $z$ -scores and scores on an existing psychometrically validated measure (RPASS-7, CCI and ‘Concepts in Algebra’, respectively).**

Jones and Inglis (2015) also investigated content validity of exam scripts. They asked experienced experts to analyse the content of the exam scripts produced when writers were freed from the constraints of traditional assessment criteria. Their qualitative analysis resulted in the assertion, consistent with their hypothesis, that these exam scripts placed more emphasis on conceptual thinking than their GCSE counterparts. It should be noted that this aspect of the study was focused on the exam scripts themselves, not on students’ responses.

The evidence in this section suggests that comparative judgement is likely to perform at least as well as established tools for mathematics assessment in many or even most contexts. Moreover, Bisson et al. (2016) provide evidence of content validity in three specific mathematical domains. As discussed in the final section, the scope for expansion of the argument for content validity is limited, given the absence of other psychometrically validated measures. The following section focuses on the necessity for a complementary approach to establishing the validity of comparative judgement.

### **The necessity for a different approach to validity**

This section has two aims. First, this section establishes the necessity for an approach other than the convergent validity-based studies discussed above. Second, this section discusses the limitations of the content validity approach proposed by Jones et al. (2015) as a suitable answer to the shortcomings of convergent validity discussed above.

Assessing the validity of comparative judgement only by comparison with traditional assessment appears to significantly limit the argument for comparative judgement. While arguments regarding

efficiency (Bisson et al. 2016) and the freedom to write examinations with a different mathematical focus (McMahon & Jones, 2015) still stand, proponents of comparative judgement claim it to have the potential to assess something fundamentally different from that assessed by traditional approaches. Bisson et al. (2016), for example, argue that comparative judgement can be used to assess ‘conceptual understanding’, an aspect of mathematics known to be difficult to assess using traditional assessment. However, in establishing the validity of comparative judgement in this area, they refer to comparisons with traditional assessment data. This approach to validity appears problematic from the outset as it limits a successful measure of validity to something not worse than traditional assessment; an approach claimed to be ineffective in assessing their domain of interest. Jones et al. (2015) note similar reservations pointing out that traditional student achievement data, often compared with comparative judgement, can be criticised for its overly-procedural focus. Jones et al. (2015) go on to assert the need for a different approach, pointing to comparisons with ‘other psychometrically validated measures’ as a satisfactory solution.

### **A further analysis of the limitations of convergent validity**

A key aspect of the argument for comparative judgement is that it facilitates reliable assessment of areas previously difficult to assess. Thus it seems logical to believe that comparative judgement, when explicitly focused on assessing those areas (e.g. conceptual understanding) should reward different abilities/strengths than those rewarded by traditional assessment.

Taking this reasoning to its logical conclusion results in the assumption that some students should perform better under comparative judgement than under traditional assessment. Thus it seems at best limited to evaluate a new assessment tool by its ability to reproduce the results of traditional assessment. Consider a hypothetical student with a particular aptitude for memorising procedures but difficulty with the conceptual understanding underlying and drawing together important ideas. Based on previous critiques of traditional criterion-based approaches, one might assume this student would perform well on such an assessment. However, one might hope that this student would score poorly on comparative judgement assessment given the claims of Bisson et al. (2016). Hence, arguing for the validity of comparative judgement by pointing to its comparability with traditional assessment seems inherently limited.

Establishing convergent validity has made a significant progress toward gaining legitimacy and the credibility to justify further, more detailed work. However, it seems that a complementary direction is necessary in establishing other aspects of validity, thereby further developing the argument for the adoption of comparative judgement.

### **The limitations of content validity**

As noted by Jones et al. (2015), making comparisons with alternative psychometrically-validated instruments appears to be an obvious and fruitful way forward in establishing the validity of comparative judgement. However, the absence of such instruments in most domains serves as a substantial barrier to progress. Returning to conceptual understanding, the absence of such instruments in this realm is well-documented and is a significant reason Bisson et al. limited their study to just three content domains.

It is theoretically possible to develop more such instruments. However, the number of instruments will always be far fewer than the number of mathematical domains in need of assessment. At present,

the content validity approach relies on inherently inductive reasoning. Evidence supporting comparative judgement in a small number of domains has little relevance for the new and previously untested. If comparative judgement is to be established as a viable assessment tool for a greater range of domains, I further claim that yet another approach is necessary.

The final section below seeks to identify a way forward that is cognizant of the issues raised above.

### **Predictive validity through the case of conceptual understanding**

Having argued the necessity for something new, this final section offers a plausible approach attempting to avoid at least some of the above criticisms. This new approach, *predictive validity*, is illustrated here by further considering the case of conceptual understanding. It should be noted that this is just one such possible solution that, like previous sections, is intended to raise more questions than it answers. It too is not without its flaws.

As defined by Trochim (2006), *predictive validity* refers to a measure's ability to predict something it should theoretically be able to predict. If one is to accept conceptual understanding as fundamental to mathematical development (NCTM, 2000; Ofsted, 2008; Rittle-Johnson, Siegler, & Alibali, 2001), a valid measure of conceptual understanding should serve as a predictor of other mathematical success. In the absence of suitable comparative measures for evaluating content or convergent validity, predictive validity appears a logical alternative. This section addresses two possible such approaches that may aid in establishing the validity of comparative judgement.

First, comparative judgement could be evaluated as a predictor of performance on traditional assessment. Allowing for the passage of time, moving away from an immediate comparison with traditional assessment (see convergent validity) creates the opportunity for a student's general mathematical maturity and understanding to progress. This argument hinges on the assumption that conceptual understanding is so fundamental to mathematical development that it should act as a future predictor of mathematical performance in general, even on assessment for which conceptual understanding is not an explicit focus. If one is to accept this assumption regarding conceptual understanding then those that perform well on a comparative judgement assessment of conceptual understanding at time 1, should perform well on any assessment at time 2.

This approach may be criticised by those who argue that if an attempt to avoid immediate comparison with traditional assessment results in a delayed comparison with the same traditional assessment, then nothing has been gained by analysing predictive over convergent validity.

Another approach to predictive validity is to seek other measures of mathematics success not beholden to traditional, criterion-based assessment. Such measures of mathematical success may appear hard to come by. However, metrics such as success at postgraduate level, or success on relevant career pathways may provide an interesting solution. While arguably somewhat crude, these measures may provide useful sources of comparison. Using such measures, one could compare comparative judgement *z*-scores from prior years with success on these future measures to evaluate the predictive validity of comparative judgement here. For example, in an attempt to evaluate validity in the tertiary context, it would be possible to consider success in tertiary mathematics. By using comparative judgement to assess a series of tertiary exam scripts, it may be possible to evaluate predictive validity by comparison with future success in postgraduate studies or related mathematical

careers. A significant correlation between comparative judgement rankings and future success would stand as strong evidence for the predictive validity of comparative judgement.

This second approach to predictive validity benefits from avoiding any comparison with traditional assessment. However, unsurprisingly raises many questions of its own, particularly regarding the quality and availability of data related to such future measures of success. Moreover, predictive validity still does not grapple with the ways that scores and interpretation of scores are used. Kane (2013) offers yet another approach, drawing on the general principles of construct validity (i.e., how well an assessment reflects the true theoretical measurement of a concept) to grapple with the assumptions underpinning the interpretation and use (IUA) of assessment scores, rather than the scores themselves. The implications of this ‘argument-based approach’ approach to validation of comparative judgment are unclear, but his detailed discussion of IUAs draws attention beyond the process of assessment in of itself to the use and interpretation of the assessment findings in the real world. For example, the evaluation of comparative judgment results could usefully require an evaluation of the consequences of the assessments’ use, and negative consequences in some could render the use of the results unacceptable in some circumstances.

I do not claim to have covered the full range of criticisms that may be levied at the new approaches. Nor do I claim predictive validity is the only response to the limitations of existing research discussed earlier. The intention of this section is to initiate a discussion regarding a new approach to validation of comparative judgement that might facilitate an extension of the argument for comparative judgement beyond the mathematical domains for which we have other tests.

## Conclusions

This paper has been a discussion of an exciting and relatively new approach to assessment. In particular, the focus has been on the necessity for a new approach to evaluating the validity of comparative judgement. It should be noted this work does not advocate for the abandonment of one approach in favour of another. Rather, it advocates for a wider range of complementary approaches that together will form a comprehensive body of research.

This paper has argued that by moving beyond convergent validity, researchers will have the ability to investigate the validity of comparative judgement in a manner less limited by comparisons with the status quo. Moreover, it has been argued that the recent content validity solution, suggested by Jones et al. (2015) is insufficient in scope and is inevitably limited by the non-existence of psychometrically validated measures for the vast majority of mathematical content.

Finally, this paper proposed two new approaches, based on predictive validity, that avoid some of the discussed limitations. A research programme including investigation of predictive validity and the interpretation and use of assessments has the potential to extend the discussion about comparative judgement, and ensure that further uptake of this exciting new development in mathematics assessment is evidence-based and beneficial to the students for whom it is designed.

# Cognitive demand of mathematics tasks set in European statewide exit exams – are some competences more demanding than others?

Christina Drücke-Noe<sup>1</sup> and Svenja Mareike Kühn<sup>2</sup>

<sup>1</sup>Pädagogische Hochschule Weingarten, Weingarten, Germany, [druekenoe@ph-weingarten.de](mailto:druekenoe@ph-weingarten.de)

<sup>2</sup>Universität Koblenz-Landau, Koblenz, Germany, [kuehn@uni-koblenz.de](mailto:kuehn@uni-koblenz.de)

*Statewide exit exams play an important role in education as they tend to define what is considered important in a subject. This paper examines characteristics of Mathematics tasks set in such exams in eight European countries at the end of lower secondary education. The main result of this descriptive study is that the cognitive demand of most competences needed to solve these tasks is rather low. The only exception is ‘working technically’. So far, these results can neither be explained with the public impact these exams have nor with relevant exam regulations.*

*Keywords: Exit exams, mathematics, competences, routines and facts, cognitive demand.*

## Introduction

### Key competences and statewide exit exams

A changing need for competences in a knowledge-based society has caused literally all European countries to agree to equip all learners in compulsory schooling with certain ‘key competences’ “which represent a combination of knowledge, skills and attitudes that are considered necessary for personal fulfilment and development; active citizenship; social inclusion; and employment” (Eurydice 2012, p. 7). ‘Mathematical competence and basic competences in science and technology’ is one of the eight key competences defined. As these are promoted either by a national strategy or by applying large-scales initiatives instead (Eurydice, 2012), competences are relevant in different forms of assessment, too.

Central written exams at the end of a particular educational stage are one form of assessment in the majority of European countries. In secondary education such exams are frequently taken at the end of upper secondary education (ISCED level 3) and in some countries additionally at the end of lower secondary education (ISCED level 2), which marks the end of compulsory schooling. Subjects tested are usually at least Mathematics and the language of instruction.

Exit exams are mostly compulsory either for all students, regardless of the type of school attended, or just for those in public-sector schools (Eurydice, 2009). Even if these exams are “optional, as in the case of the ‘national qualifications examination’ in the United Kingdom (Scotland), or the Dutch CITO test, nearly all pupils take them in practice” (Eurydice, 2009, p. 23) which hints at the relevance of these exams. However, despite having the same name and sharing the purpose of summarizing the achievement of individual students at the end of an educational stage, statewide exit exams of any two countries differ in several respects such as the time awarded or the institutions which set them (cf. Klein, Kühn, van Ackeren & Block, 2009) or the ways the results are used or published (cf. Eurydice, 2009).

## Research on statewide exit exams

International research on statewide exit exams reveals various perspectives. Considering governance and accountability Klein & van Ackeren (2011) identify considerable national differences, e.g. as regards the role of the governing bodies, the degree of standardization of these exams, the use of the results or varying intentions ranging from control to support of schools. Other research focuses on setting standards and promoting innovation by means of such exams (e.g. Bishop, 1998) but also draws attention to contrary positions. Wößmann (2008) even gives evidence that such exams enhance students' achievement. Further research addresses the impact of such exams on the selection of tasks for teaching (e.g. Cheng & Curtis, 2012; Neill, 2003). In this context a backwash-effect of exams on teaching and learning is also frequently discussed (e.g. Biggs & Tang, 2011; Boud & Falchikov, 2006). Especially such summative forms of assessment have this effect and exert a considerable influence on both teachers and students because exit exams set standards as to what is to be achieved or considered important. As a consequence, exams ought to be carefully designed, even more so if governing bodies use them as a strategic instrument to influence teaching. However, there is only scant research on characteristics of tasks set in exit exams, and some of these studies are somewhat dated (see overview by Krüger (2015) for various subjects).

With respect to tasks particularly set at the end of lower secondary education in Europe, this lack of research might be due to the fact that only few countries like Northern Ireland and Scotland have a longstanding tradition of such exams, whereas most other countries only introduced them in the last one or two decades (Eurydice, 2009). However, given the broadly conceded relevance of tasks in Mathematics (e.g. Arbaugh & Brown, 2005; Neubrand, Jordan, Krauss, Blum & Löwen, 2013), it is astounding that only very few studies examine tasks set in exit exams in this subject. One study by Kühn and Drüke-Noe (2013) identifies a low level of cognitive demand of the tasks set in the 15 German states (*Länder*), and it reveals that applying routines and using facts (working technically) is a dominant competence when solving the tasks, whereas more complex competences, such as problem solving or argumentation, are far less needed. Another study by Vos (2013) focusses on specific modeling aspects of tasks set in the Netherlands and reveals that concerns about test reliability seem to limit the range of modeling aspects tested.

## Methodology

Based on the discussion in the section above, the following four research questions are addressed: Which mathematical competences are needed to solve the tasks set in statewide exit exams and which level of cognitive demand is realized? Are the competences of similar importance? Which national exam characteristics can be identified which might be related to their public impact in each country? Can national exam characteristics be explained on basis of national exam regulations?

To address these questions a classification scheme by Kühn (2011) is used, which was developed in a German comparative study on mathematics tasks. The scheme's subject specific categories, which are based on educational standards in mathematics, are used to identify and understand the structure as well as content- and process-related characteristics of tasks (cf. Kühn & Drüke-Noe, 2013). In the scheme the various categories and their subcategories are described in detail and illustrated by examples. Some of these categories are: mathematical content (subcategories: arithmetic, algebra, geometry, stochastics), types of mathematical activities and mathematical competences. In the

course of developing this classification scheme, country-specific requirements for the design of exam tasks (e.g. *Specifications* in England, *Notes des Service* in France, or *Examen Programma* and *Constructie opdracht* in the Netherlands) have been examined if they were publicly available. Thus, the classification scheme includes general (instead of country-specific) categories for task analysis so that it can be used for a transnational comparison of task characteristics.

Based on this classification scheme, various task characteristics, such as competences necessary to solve a task and the level of cognitive demand of each competence, can clearly be identified. Each task is assigned to one or more of six mathematical competences (argumentation, problem solving, modeling, use of representations, working technically, communication), and for each competence one of four levels of cognitive demand is marked by a score (0: not needed, 1: low level, 2: intermediate level, 3: high level).

Analyses of the impact of these exams rely on documents published by the Eurydice network.

The sample comprises 655 tasks set in eight European countries (Ireland (IE), France (FR), Italy (IT), the Netherlands (NL), Norway (NO), Portugal (PT), England (UK-ENG) and Scotland (UK-SCT)). In both years 2008 and 2011, only these countries set written statewide exit exams in Mathematics at the end of lower secondary education (ISCED level 2), i.e. when students are aged 16. All tasks were translated into German and then categorized by a student who was excellent in mathematics and its didactics. The student was trained in several steps: tasks were classified and reasons for classifications had to be articulated. By means of this communicative validation agreement was gradually achieved. Additionally, the student could query classifications at any time.

## Results

### Quantitative findings

The descriptive results presented here are aggregated for both years 2008 and 2011. For each of the eight countries the findings provide insight into mathematical competences needed to solve the exam tasks. Table 1 informs on the number of tasks (N) set in each country and it provides information on the level of cognitive demand realized by giving mean scores (M) and standard deviations (SD) for each of the six competences.

		argumentation		problem solving		modeling		use of representations		working technically		communication	
Country	N	M	SD	M	SD	M	SD	M	SD	M	SD	M	SD
IE	96	.01	.102	.28	.452	.46	.501	.15	.355	1.41	.535	.02	.144
FR	60	.40	.807	.77	.647	.67	.629	.63	.712	1.13	.724	.28	.585
IT	63	.17	.423	.37	.485	.79	.652	.67	.762	.90	.560	.37	.517
NL	50	.32	.713	.72	.497	.78	.648	1.22	.932	1.32	.768	.74	.527
NO	124	.10	.400	.40	.582	.52	.618	.54	.562	.94	.621	.29	.522
PT	39	.26	.637	.54	.643	.51	.506	.82	.885	1.18	.756	.77	.742
UK-ENG	152	.26	.581	.37	.512	.50	.575	.67	.726	1.16	.656	.45	.639
UK-SCT	71	.08	.327	1.00	.378	.65	.657	.56	.626	1.39	.547	.59	.523

**Table 1: Mean scores of cognitive demand of the six competences**

Table 2 reveals if exam results are used to award certificates and if and how exam results are published. These categories are used to judge the exams' impact (cf. Eurydice 2009, 2012).

Country	IE	FR	IT	NL	NO	PT	UK-ENG	UK-SCT
Award of certificates	x		x			x		x
No impact on students' progression		x		x	x		x	
Publication of results organized or required of schools, by central/local government				x			x	x
Publication of results at the discretion of schools			x					
No publication of results	x	x			x	x		

**Table 2: Ways in which results of statewide exit exams are used and published**

With respect to the first two research questions, the results in table 1 indicate an overall very low level of cognitive demand of all six competences for all countries. Since a maximum score of 3 can be reached, which stands for a high level of cognitive demand of a competence, the means realized indicate that most competences are only rarely needed to solve the tasks. This means that if a specific competence is needed at all its cognitive demand is mostly low. As mean scores of about 1.00 or more are almost exclusively limited to 'working technically', it can be concluded that this competence considerably determines the overall cognitive demand of the tasks set. This shows the relative importance of this competence, as more complex ones, such as argumentation, problem solving or modeling, are only rarely needed in any of these countries. This fact, however, is not fully in accordance with national exam regulations, such as those of France, England and the Netherlands, which explicitly require that these competences are tested, too. All in all, these results hint at the relative importance of applying routines and using facts to solve the tasks set.

Finally, based on the results given in both tables, for none of these countries a systematic relation can be identified between the overall mean levels of cognitive demand realized and the impact of the exams. For example in Scotland the impact can be considered high (certificates awarded, results published) and the mean levels of cognitive demand of all competences are relatively high, too. On the contrary, in France the impact can be considered low (no impact on students' progression, no results published) and the mean levels of cognitive demand are fairly high, too.

### Examples of tasks

The following two examples of tasks and their analyses are to illustrate the quantitative findings given in table 1. The first example serves to illustrate the relative importance of working technically. In many tasks this is either the only competence needed or it is the only one which is cognitively more demanding. The task shown in figure 1 is typical in the sense that it only requires to work technically. To factorize the given sum of products, several steps need to be carried out (working technically, intermediate level). In all countries, however, most tasks which require this competence are of an even lower cognitive demand.

Factorise:  $x^2 + 7x + 12$

**Figure 1: Working technically at an intermediate level (source: Ireland, 2011)**

Sounds are vibrations in the air. A sound spreads through the air. We then speak about sound waves. Sound can be visualized using a device that turns sound vibration into an electric vibration. Below you see what this device shows for two different sounds. Both figures show a number of vibrations within a certain period of time (for example, 1 millisecond).

The number of vibrations per second is called the sound frequency.

◇ Which figure shows a higher frequency? Explain how you get to your answer.

**Figure 2: Relatively high cognitive demand of a task (source: the Netherlands, 2011)**

The second example given in figure 2 shows one of the few tasks in the entire sample which are not only relatively long and complex but also require a number of rather complex competences.

To understand both diagrams (figures A and B) the introductory text needs to be read first (communication, intermediate level). Then a given model needs to be applied to the context (modeling, low level). The comparison of both complex diagrams (use of representations, high level) is supported by problem solving strategies (intermediate level). The final decision on the appropriate diagram requires an argumentation that needs to be written down (communication and argumentation, both intermediate level). In contrast to the majority of tasks in the sample this one does not require to work technically.

### **Influence of national exam regulations on task characteristics**

To explain the different levels of cognitive demand of tasks set in different countries (cf. table 1) national exam regulations are considered, too. As not all regulations are publicly accessible, the following analyses are only based on the ones applicable in England, in France and in the Netherlands. The document analyses are to show if and in which way individual competences are mentioned. Furthermore, the analyses are to reveal if the relevance of any of the competences is stressed in relation to other ones.

The analyses of these documents firstly reveal that exam regulations in these three countries demand explicitly that competences such as argumentation, modeling and communication are tested. While in France and in England these competences are merely mentioned, in the Netherlands the cognitive demand of individual competences is described in some more detail. For example with respect to argumentation and communication regulations in the Netherlands explicitly ask for “reasoning strategies” and “communication by means of adequate mathematical language” (cf. CEVO, 2009). In addition, the requirements concerning modeling are even more specific as the entire modeling cycle including its individual steps is mentioned.

Contrary to expectation, though, the way competences are specified does not directly correspond with realized mean levels of cognitive demand. One example is the level of cognitive demand of modeling in France (brief specifications) which is similar to the one in the Netherlands (more detailed specifications). A second example is the considerably different mean levels of cognitive demand of argumentation in France and in England despite the fact that both countries have rather brief and similar specifications of competences.

The document analyses secondly reveal that none of the exam regulations studied state in any way how intensively individual competences are to be considered in the exams. There is also no statement as to the relative importance of working technically. Thus, on the basis of the exam regulations it is not possible either to explain the relatively high mean levels of cognitive demand of this competence in all countries.

All in all, the findings show that exam regulations do not correspond systematically with task characteristics. Furthermore, the more detailed analysis of only three countries shows that further research is necessary to explain how exam regulations are put into practice. Considering theories of educational governance, it must be assumed that such regulations do exert an influence on the selection or the development of exam tasks but so far it is not entirely clear in which way this impact works in practice. As a consequence and with special regard to competences, more needs to be found out on the application of exam regulations by those who either select and develop exam tasks or design entire exam papers by assembling tasks. For these reasons it is necessary to find out which other elements directly influence characteristics of exam tasks in different countries.

## **Conclusion and implications**

Although all eight countries examined supposedly promote key competences including mathematical ones, the task characteristics raise the question how thoroughly these competences have been implemented, since cognitive demand is primarily determined by working with routines. As exam tasks influence the selection of tasks for teaching and as the task characteristics identified in this descriptive study can neither yet be explained by the use of the exams' results nor be explained by exam regulations, further research is necessary that addresses both the influence of national curricula and that of existing exam design regulations as well as their application. Beyond this, further research should also address reforms actually taken to promote competences in these European countries to explain the results.

More detailed research of the tasks set in two different years is of interest, too. This also has to do with the influence such tasks have on teaching (cf. Black & Wiliam, 1998). More detailed research of this kind could possibly better help to understand the so far unsystematic relation of the exams' impact (see table 2) and the characteristics of the tasks set.

The results presented in this study also raise further interest in more recent developments on exam design regulations and the ways in which they influence actual exams. Especially with respect to exams taken at the end of lower secondary education not much is known about this relation yet. Research on further development in the direction of a broader and more explicit notion of competences which includes explicit research on the cognitive demand of individual competences in these exams is desirable, too.

From a process-oriented perspective, a number of interesting research questions arise that focus on factors which influence the development of tasks set in central exams. There are two important factors of interest: One of them is longstanding traditions of tasks in these countries which might help to understand the task characteristics presented in this study. A second factor is the professional knowledge of those people who design the exam tasks. As the findings presented cannot fully be explained by exam regulations, attention is shifted towards the role of those people who develop tasks set in the statewide exit exams. It is well worth finding out if these people are aware of the different competences and – even more and on a more detailed level – of the various facets which these competences have. Modeling can be taken as an example here, as this competence comprises more than just mathematising (cf. exam regulations in the Netherlands). Furthermore, it is of interest to see if people who design the tasks are aware of different levels of cognitive approach of individual competences.

Finally, more recent theories on educational governance as well as findings from research on implementation support the assumption that the design of exam tasks is not exclusively influenced by relevant exam regulations. There is evidence for a considerable and multi-factorial influence of any people who are involved in the design of exams. More traditional attempts of research, which explain directions of influence, are based on a model of governance which is hierarchically structured and works in a linear way. More recent approaches, however, that try to explain these directions of influence, even identify a systematic discrepancy between formal exam regulations set by both political and administrative bodies and the way they are applied in practice. There is evidence that this seems to be caused by a necessary re-contextualization and transformation of existing regulations by the individuals involved (cf. Altrichter & Maag Merki, 2010). Research both on innovation and implementation shows similar findings and reveals that administrative regulations and their implementation in practice can even differ widely (cf. Gräsel & Parchmann, 2004). To sum up, far more research is necessary to understand how exam design regulations are put into practice and how task characteristics can be explained.

# A vertical analysis of difficulties in mathematics by secondary school to level: Some evidence stems from standardized assessment

Federica Ferretti<sup>1</sup> and Alessandro Gambini<sup>2</sup>

<sup>1</sup>Alma Mater Studiorum, University of Bologna, Department of Mathematics, Bologna, Italy;

[federica.ferretti5@gmail.com](mailto:federica.ferretti5@gmail.com)

<sup>2</sup>INVALSI, Italy; [a.gambini@unibo.it](mailto:a.gambini@unibo.it)

*A longitudinal analysis of the recurring mistakes at different school levels in national standardized assessment tests is presented. The analysis of the outcomes highlights some difficulties common across different school grades. Subsequently, we extend our research to university students: we investigate the results of tasks solved by students at the end of high school and at the beginning of university in an e-learning environment called AlmaMathematica. We examine whether there are commonalities between errors that lead to wrong answers at school level and university level. Results show that university students share the same difficulties of high school students when faced with similar tasks.*

*Keywords: Mathematics test, summative evaluation, semiotics.*

## Introduction

Our research is carried out selecting a set of tasks sharing common features among the national standardized assessment tests INVALSI (National Assessment Institute for the School System) and the results of the AlmaMathematica tests administered to students at the end of high secondary school and at the beginning of university. As we can see in the next section, the INVALSI gives back the results at national level to each item of each test. Thus, we have, each year, results for grade 2 and 5 (in Italy, second and fifth years of Primary School), grade 8 (third year of low secondary school) and grade 10 (second year of high secondary school). Most of the research based on these data concerns vertical and common features arising at different test level outcomes (Branchetti et al, 2015). In this research perspective, we investigate common difficulties that emerged from the vertical analysis of INVALSI secondary schools test results. In the second phase of the project we further develop the research expanding to university level students. In order to do this, we analyzed the results of mathematics tests in the AlmaMathematica project, an e-learning environment in which many students of the fifth (and last) year of high secondary school and university freshmen perform mathematics tasks. Hence, we asked the following research question: Is it possible to identify some common student behavior when facing mathematics tests from secondary school to university? For this we analyse two tasks of INVALSI mathematics tests of grade 8 and grade 10 giving an example of analysis of linked tasks in which different approaches are implemented. The comparison between the two tasks allows us to interpret some difficulties encountered by the students. The analysis of a related task in AlmaMathematica suggests some possible ways to interpret students' behaviors at university level. All three tasks have the same structure and the same mathematical content, but the likely difficulty is represented by the switch from a representation register to another one. The same skills are required for all three tasks and the purpose of our research is to investigate if there are common aspects in the task solutions.

## National Evaluation Service and AlmaMathematica Project

INVALSI is the Italian national institute for the educational assessment of instruction and every year, through National Evaluation Service (SNV), it carries out periodic and systematic national assessment to check student knowledge and skills in Mathematics and Italian language. Every year, INVALSI performs assessment tests in a census to school grades 2 and 5 (Primary School), 8 (low secondary school), and 10 (high secondary school) and it returns the results of the sample for each item of all tests administered. As part of our research we consider in detail the results of two tasks in mathematics standardized tests carried out by grade 8 students in a.y. 2010/11 and by grade 10 students in a.y. 2011/12. To conduct this research, it has been crucial the use of a research tool of INVALSI tests, the *GestInv Database* that we will describe in detail later. To investigate difficulties at university level, we examine the results of the performance of students using AlmaMathematica. AlmaMathematica ([almamathematica.unibo.it](http://almamathematica.unibo.it)) is a project of the University of Bologna designed specifically to create links between Secondary School and University. It is aimed at students who wish to enroll in undergraduate courses at the University of Bologna and it provides basic courses in mathematics, statistics and probability. The environment that has been created refers to the tasks of the Entrance Tests to a restricted number of Curriculum courses (TOLC), and to the evaluation of basic knowledge tests. Access to the statistical data allows us to investigate the percentage of correct answers for each question.

## Theoretical lenses

Our main hypothesis is that a longitudinal analysis involving a large number of students can give relevant information about difficulties existing at secondary school level and can allow us to infer whether these difficulties remain at the beginning of university and in what fashion. Our research stems from evidence arising from the analysis of Large Scale Assessment (LSA) tests. We do not consider LSA merely as a way to provide a ranking or scores for benchmarks or as a search for correlations between variables of context, but we assume that its results can provide information on the teaching/learning process. In accordance with many researches (i.e. Looney, 2006) we consider the analysis of the results of standardized assessment through the lens of formative assessment. The information given back by LSA contains not only global scores (measured by statistical models), but it also highlights the specific phenomenon observed individually. Among the results of standardized assessments many significant macro-phenomena are visible that can be explored and interpreted through some of the lenses of mathematics education as the most frequent difficulties described in literature are also reflected in the students' responses. We conjecture that this kind of longitudinal analysis carried out through the comparison between the data sets from different years and levels could be useful to better interpret the difficulties that arise in secondary school and remain until university. For this reason, we need some criteria to link tasks from different grades: we have chosen the tasks that had the lowest correct response rate in the standardized tests and for which the topic is present both at secondary school and university. In particular, our research focuses on powers and manipulation of exponents and the difficulties with these topics have been widely reported in the literature (Pitta-Pantazi et al., 2007, Cangelosi et al., 2013). Indeed some studies have already reported common difficulties with management of exponentials between university students and high school students (Cangelosi et al., 2013). This led us to think that some misconceptions regarding exponential expressions are persistent over time. The students' mental

constructions and the way in which they develop a meaningful understanding of exponentials has been the subject of other studies (i.e. Pitta-Pattanzi et al., 2007). In this is a vertical analysis made among secondary school students the authors found that, independently from the age of the students, there is an issue in the treatment of the exponentials that led them to provide wrong arguments in comparing powers with the same base or with the same exponents. Starting from these evidence, we conducted our research concerning expressions with exponentials, in particular the manipulation of different representations of exponentials. We are interested in understanding if the phenomenon showed from the quantitative analysis also implies that the difficulties encountered by students at different school levels are the same. To investigate this phenomenon, we need a further qualitative analysis, which is on-going, and its results will not be included in this paper. As we can see below, we detect that the main common difficulties are related to the semiotic representations management and, in order to interpret it, we use the semiotic approach proposed by Duval (1993, 2006). According to Duval, for each object there is more than one possible semiotic representation and one of the highest processes of mathematics is precisely the management of different representations of the same object. Our analysis will show that recurrent errors made by students, in all investigated levels, can be reduced to the difficulties concerning the management of different semiotic representation of the same object and the transformation of representations within different registers. We can then identify the main difficulties in the conversion (Duval, 1993). Duval (2006) suggests that the switch from natural language (verbal register) to algebra (symbolic register) requires a high level of complexity. Furthermore, according to Duval, it is possible to classify the different representations of a mathematical object in different registers, which are a set of signs and rules that can be manipulated. Such registers may themselves be classified as discursive (natural language written or spoken, mathematical symbols) or non-discursive (diagrams and figures). Still, it is possible to distinguish within each category those that are multifunctional registers, i.e. suitable to explain processes that cannot be put in algorithmic form, from those mono-functional, i.e. especially dedicated to algorithmic processes. In the first category there is natural language, in the second arithmetic and algebraic symbols. In the mono-functional register treatments can take the form of an algorithm, while in multi-functional ones, this is not possible. This fact will be crucial in the analysis of the behaviour of the students in our research.

## Methodology and data analysis

Our research is a mixed method sequential research (Johnson & Onwuegbuzie, 2004), with design QUAN → QUAL → QUAN. The first quantitative phase consists in an analysis of statistical results of the standardized items. Then, among the selected standardized items, we search for the ones with a topic common between secondary school and university levels. Subsequently, we look for the ones that highlight the same educational phenomena. Finally, we search on AlmaMathematica for the ones with the same features. We conduct a research looking at tasks at low secondary school level, high secondary school level and the initial stage of university undergraduate level. We needed a common topic to start with and we chose powers. In Italy, this is a topic used in the final national examination at the end of low secondary school, which is then elaborated in the second year of high secondary school and it is considered an “entry requirement” (and therefore investigated) for all university courses that require mathematics knowledge and skills. To search for tasks concerning powers among all the ones of the standardized assessment INVALSI test from 2008, which has had a low rate of correct answers, the INVALSI Database Gestinv is used. This database is an online

tool of research ([www.gestinv.it](http://www.gestinv.it)) that contains more than 1,400 items administered in the Italian national standardized tests and it is used in professional development programs implemented by schools and in research in mathematics education. Inside the database, there is a PDF of all tests administered in Italy from 2008, in which each item of these tests is accompanied by detailed results, statistical classifications, and data split into different categories. In respect of each item there is the image of the question, the goal of the content, the process, the reference to the National Guidelines for Curricula, some keywords characterizing the content, the text of the question, the correct answer or the image of the correct answer, the percentage of national response, the characteristic curves, and the item information. The Gestinv database can be used in many ways: when entering the section of Mathematics it is possible to search by National Guidelines for Curricula, Keywords, Full Text, and to do a Guided Search: a cross-search - with connectors and/or - of all parameters in respect of each item and all its features, such as the percentage of national response. Through the tool Guided Search we searched for all of the secondary school tasks of INVALSI Tests of Mathematics, referring to the keyword “powers” which had percentages of correct national responses below 50%. The research displayed about ten tasks with these features, and we looked for those whose analyses represent the same didactic phenomenon. As we see in the next section, we studied two tasks that had “common errors” displayed at national level: one by low secondary student (13 years old) and one by high secondary school students (15 years old).

Once such tasks are identified, we check if the analysis of the tasks about powers in AlmaMathematica Project shows the same type of errors. Students who performed exercises and problems in this e-learning environment are 18-20 years old; this allows us to investigate whether the same phenomenon persists with students of different age and how it occurs in various levels.

## The analysis of tasks

The following task was administered in a census at grade 8 Italian students in a.y. 2010/11.

**E11. A tenth of  $10^{20}$  is:**

- A. ☐  $10^{10}$
- B. ☐  $1^{20}$
- C. ☐ 100
- D. ☐  $10^{19}$

**Figure 1: Question D11, Grade 08, INVALSI Test, a.y. 2010/11**

Figure 2 shows the national percentage of correct, mistaken, missed, and invalid answers and the percentage of choice for each option.

**Figure 2: Data of Question D10, Grade 08, INVALSI Test a.y. 2010/11**

The question was administered in a.y. 2010/11 to a population of approximately 600,000 grade 8 students, the sample (from which the statistical data are calculated) was composed by about 27,000 students. To give the correct answer a correct management from natural language to algebra is necessary. As we notice, the percentage of correct answers is low (the correct answer is option D, and it has been chosen by 26.2% of students). Option A and B have been chosen almost by the same percentage of students. Students that answered A worked incorrectly on the exponents (they probably halved the exponents or subtracted ten from the exponents). Students who choose option B had divided the base by ten. A similar situation appears also in the following question, administered at grade 10 students in the INVALSI N of the a.y. 2011/12.

**Figure 3: Question D10, Grade 10, INVALSI Test, a.y. 2011/12**

**Figure 4: Data of Question D10, Grade 10, INVALSI Test, a.y. 2011/12**

As shown in Figure 4 the correct answer was chosen only by 12.1% of students. This question was administered in a census to 530,000 grade 10 students, and about 42,000 students composed the sample. The most common option is B: students who have chosen this option have halved the

exponents. This situation has some features in common with the previous one: the task structure is the same and the construction of the distractor is similar. In the 8<sup>th</sup> grade task, the numbers involved are integers and in the 10<sup>th</sup> grade task are fractions, but the solution of both tasks require the manipulation of powers, and the conversion from different registers. Another similar situation occurred in the analysis of the results of the exercise referring to powers in the AlmaMathematica Project. Entering the e-learning environment AlmaMathematica there are 5 sections and one of them is about algebra. Inside this section there are 7 subsections including “Powers and Roots”. Students enter the online environment and perform the exercises; each student can perform the exercises more than once. When a student makes a mistake, it is only reported that the given answer is incorrect but the display does not show the right one. The percentages of answers, shown in Table 1, are related to the first attempts given by students. When we extrapolated the data, there were 1625 registered and 773 students attempted the exercise. By analysing the data we can see that one of the tasks has some characteristics in common with the previous ones; the task is the following one (Figure 5).

**Q.3** Which is one third of the number  $\left(\frac{1}{3}\right)^{30}$  ?

☐ A.  $\left(\frac{1}{9}\right)^{10}$

☐ B.  $\left(\frac{1}{3}\right)^{31}$

☐ C.  $\left(\frac{1}{9}\right)^{30}$

☐ D.  $\left(\frac{1}{3}\right)^{10}$

**Figure 5: Question Q.3, Section “Powers and Roots”, AlmaMathematica Project**

Answer A	Answer B	Answer C	Answer D
13.7%	25.9%	12.3 %	48.1%

**Table 1: Data of Question Q.3, Section “Powers and Roots”, AlmaMathematica Project**

Also in this case we notice that the structure of the task has several elements in common with the previous two. Indeed, the situation is similar to the situations that occurred in the INVALSI tests: the solution of the task requires interpreting a verbal delivery and employing working with powers. Also the distractors are similar to the distractors in the INVALSI task grade 10<sup>th</sup>. Specifically, the number presented in option C, in which the exponent is divided by a third, is obtained by an incorrect manipulation of the exponent exactly as the number present in option B in the previous task. As we can see in Table 1, the percentage of correct answer is slightly higher and almost half of the students chose option D, just like the majority of students of grade 10 chose option B. The exercises in AlmaMathematica were performed by students at the end of the secondary school and at the beginning of university but almost all users are university students. Thus, we can observe that among all analysed levels (from low secondary school to university) the conversion from natural language to symbolic representation about power manipulation is an issue. Specifically, observing the results obtained in high secondary school and university tests, we show that the students who

made the same mistake: they manipulated in the wrong way the exponent of the powers leading back to the exponent the “verbal indication” provided in the stimulus. Indeed, in both tasks they chose the option in which there is an incorrect manipulation of the exponent.

## Conclusions and further directions

Our main hypothesis is that a longitudinal analysis, performed with many students, can give relevant information on the directions to link (and, then interpret) longitudinal shared difficulties from low and high secondary school to university. We study students’ behaviour when solving mathematics exercises in which the management of representation of powers in different registers is required. As shown by Cangelosi et al. (2013) certain errors when working with exponential expressions persist as the students progress through their mathematical studies. Many students memorize algebraic rules with little or no conceptual understanding of their meaning because the rules of algebra and its terminology seem distant from their way of thinking. It follows that these students have trouble keeping track and applying the rules appropriately (Kieran, 2007). The description of the difficulties of students in algebra, particularly in the interpretation of mathematical symbols, was also addressed by Carraher and Schliemann (2007). Kieran (2007) noted furthermore that a main issue is the ways in which students work with variables and algebraic expressions, discussing in depth the development of algebraic thinking in middle and high school. In our case the problem is the management of verbal representation of power and algebraic representation. The processes put in place to manage these different representations are well framed in Duval (2006). In all tasks analysed, a switch from natural language (verbal register) to the algebra (symbolic register) is necessary to give the correct answer, and this presents a high level of complexity (Duval, 2006). Indeed, we studied the difficulties of students in conversion from two different registers, from natural language to symbolic representation. Particularly, we analysed the difficulties to convert from one multi-functional register to one mono-functional register, and despite this represents a difficulty, it is impossible to avoid this situation in the teaching/learning processes. Results show that students make common errors in managing different representations of an object. For a better interpretation of the phenomena that we observed, we shall need a further qualitative analysis and for this reason we are conducting some interviews with school and university students. Research in mathematics education regarding the transition from secondary to tertiary education highlights that students’ difficulties are related to a multiplicity of factors – cognitive and meta-cognitive – and it is still more problematic when accessing university education (Gueudet, 2008). These difficulties highlight that one of the causes is the gap in the prerequisite knowledge, specifically in the manipulation of different objects representations. In conclusion, information acquired by LSA and by the e-learning environment has brought to light some recurrent mistakes. The analysis of this data allows us to interpret a didactic phenomenon, and it is also in this perspective that we consider standardized assessment as a tool for formative assessment.

<sup>1</sup>INVALSI, Rome, Italy, [stefania.pozio@INVALSI.it](mailto:stefania.pozio@INVALSI.it)

*In this paper we describe how mathematical items are constructed for the Italian National Education Assessment System (SNV). After a brief description of the structure of the Italian SNV, we describe – through an example – how mathematical items are analyzed and finalized before being submitted to Italian students of different school grades. Each item is analyzed from two different perspectives: first the mathematical content and its relevance in the teaching and learning of mathematics is considered and then the statistical analysis of the field trial results are examined. The challenge we face is to maintain an appropriate balance between these two different aspects.*

**Keywords:** Assessment, mathematics tests.

## Introduction

Italian National Assessment System (SNV<sup>1</sup>) started its work in 2008 through annual surveys conducted by the National Institute for the Evaluation of the Education System (INVALSI) at different school levels. The INVALSI develops standardized national tests to assess students' reading comprehension, grammatical knowledge and mathematical competence, and administers them to the whole population of primary school students (Grades 2 and 5), middle school students (Grades 6 and 8), and high school students (Grade 10), see Figure 1. From 2008, the SNV test on reading and mathematical competence is part of the 8<sup>th</sup> Grade national final examination. Therefore it contributes to the final evaluation of the students (Garuti & Martignone, 2016).

Grade 8									
Grade 10									

**Figure 1: The design of INVALSI surveys from 2008 to present**

SNV surveys aim at taking a snapshot of schooling as a whole: in other words, it is an evaluation of the effectiveness of education provided by Italian schools. The results of a national sample are

<sup>1</sup> <https://INVALSI-areaprove.cineca.it/>.

annually reported<sup>2</sup> stratified by regions and disaggregated by gender, citizenship and regularity of schooling. These results are public, as well as the tests and the scoring guides. However, the results of each school are sent confidentially to the principal.

The mathematics items are connected to the National Guidelines for the Curriculum and to some teaching practices that have consolidated over the years. Another important reference is the UMI-CIIM curriculum "Mathematics for the citizen" (Anichini et al., 2004), which is based on results of mathematics education research and has deeply influenced the last formulation of the national curriculum. The SNV Framework defines what type of mathematics is assessed by the SNV tests and how it is evaluated. It identifies two dimensions along which the questions are built: the mathematical content, divided into four major areas (Numbers, Space and Figures, Relationships and Functions, Data and Forecasts); and the mathematical processes involved in solving the questions (Knowing, Problem solving, Arguing and proving). These dimensions are closely and explicitly related to the National Guidelines. The framework adopted by SNV assessment includes aspects of mathematical modelling as in PISA survey (Niss, 2015), and aspects of mathematics as a body of knowledge logically consistent and systematically structured, characterized by a strong cultural unity (Arzarello et al., 2015).

The SNV tests differ from PISA or TIMSS surveys not only for its frequency (annual vs. triennial), for the type of tested population (census vs. sample), and for the target population (grade-based vs. age-based students for PISA), but mainly for its goals: as a matter of fact the SNV tests results aim at providing to the Ministry a national benchmark for the assessment of the Italian students at different grades taking into account the national curriculum. In addition, each school and each class receives its own results according to the dimensions described above, compared with the national results and the results of 200 schools or classes with the same socio-economic background. Results are returned to the schools according to the two dimensions of the framework: content and mathematical processes as well as for each item (including the response rates for each option in the case of multiple-choice item).

### **The goals of the study**

The aim of the present study is to illustrate the two approaches used to select mathematics items: mathematical content and its relevance in the teaching and learning of mathematics and the statistical analysis of the field trial results.

### **The construction and analysis of mathematics items**

The preparation of the SNV items takes place in two steps. A first set of items is prepared by in-service teachers of all levels, subsequently, the SNV National Working Group builds the test by selecting items so that the test is balanced both from the point of view of contents and processes.

Since 2013, the item development has been carried out during a summer school held in July, involving about 200 in-service teachers. All item developers are teachers who teach at the school level for which they prepare the items. All items are classified according to the SNV framework

---

<sup>2</sup> [https://invalsi-areaprove.cineca.it/index.php?form=precedenti\\_risultati](https://invalsi-areaprove.cineca.it/index.php?form=precedenti_risultati).

(mathematical content, question intent, mathematical process involved and specific links with the National Guidelines).

Towards the end of the year in which the summer school is held, the items are revised and assembled in booklets. Five different working groups (group-level), one for each grade involved, prepare the field trial. The group's work consists of the analysis of the items and the selection of those deemed most suitable to be included in the booklets. Each group-level constructs at least two booklets, making sure that they are balanced from the point of view of both content and processes. Once the items have been tested in the field trial, the results are analyzed by the SNV National Working Group in order to prepare the final booklet for the main study. This National Working Group is formed by the coordinators of the level-groups, generally experienced teachers, researchers in mathematics education and statisticians. The revision of the booklet is supported by psychometric analysis, conducted according to CTT model (classical test theory) and the IRT model (item response theory – 1p Model) (Rasch, 1960, Hambleton, 1991).

If one item does not fit the parameters, we try to figure out what doesn't work. Sometimes the problem can be that the text is not entirely clear from a linguistic point of view, that some distractors are too attractive or not attractive enough, or the percentage of correct answers is too low, especially when the question requires an open constructed response. In this case, if the item is interesting from an educational point of view and it tests important skills, it is modified according to the analysis done and included in the next field trial. In some cases it is difficult to change the item while maintaining its significance from a mathematical point of view, so if the psychometric properties of the item are too weak we prefer to exclude the item from the final booklet.

Our research questions are:

- a. In which way item analysis, that is the statistical analysis of the psychometric properties of an item within a test, may support the progressive refinement of the item formulation?
- b. How to balance the tension between producing a test with good psychometric properties and guaranteeing at the same time that it has appropriate or relevant mathematical content?

### **Qualitative and quantitative analysis: one example**

The example below shows the analysis performed on each mathematical item. Each item is analyzed from two different perspectives: the mathematical content and its relevance in the teaching and learning of mathematics and the statistical analysis of field trial results. In fact, an item may be robust in terms of statistical analysis, but not significant from the point of view of mathematical competence to be measured and vice versa an item could be very interesting from the aspect of mathematics education, but not suited to a standardized test. The challenge that we face is how to ensure the right balance between these two aspects.

From the mathematical educational point of view, the item that we propose as an example in Figure 1, belongs to Space and Figures content. It doesn't require the calculation of the volume of a solid, which is a typical and traditional request at this educational level (8th grade), but the understanding of the relationship between a given quantity (1 litre) and the shape and dimensions of a container. The four figures have different sizes and shapes. Each response option is accompanied by a plausible justification.

One litre of water is poured in each of the container showed below. In which container will the water reach the maximum height?

- A. ☐ In container A, because the base area is smaller
- B. ☐ In container B, because its sides are all equal
- C. ☐ In container C, because its volume is smaller
- D. ☐ In container D, because its height is higher

**Figure 1: Original item (before the field trial)**

The item was administered to a random sample of 389 students, representative at the national level (see Table 1). The high number of respondents ensures the robustness of the results of the test. Analyses are conducted by considering the overall functioning of the item as well as the functioning of each option (4).

item:37 (A25-M8SF601)							
Cases for this item		389	Item-Rest Cor.	0.11	Weighted MNSQ	1.09	
Item Delta(s):		1.30					
Label	Score	Count	% of tot	Pt Bis	t (p)	PV1Avg:1	PV1 SD:1
A	1.00	38	9.77	0.11	2.08(.038)	-0.94	1.11
B	0.00	44	11.31	-0.07	-1.46(.145)	-1.39	0.81
C	0.00	136	34.96	0.14	2.77(.006)	-1.13	0.78
D	0.00	144	37.02	-0.11	-2.27(.024)	-1.40	0.86
7	0.00	1	0.26	-0.06	-1.14(.254)	-1.92	0.00
9	0.00	26	6.68	-0.06	-1.27(.206)	-1.43	1.13

**Table 1: The original item: Results from field trial**

The item has some problems from the point of view of both the overall functioning and the functioning of individual distractors. A, B, C, D labels represent the different options, the code 7 represents invalid answers and the code 9 represents missing answers. Taking into account the correlation coefficient (in table 1, Item-Rest COR.= 0.11), we notice that the value is positive, but below what we consider the reference value (0.20). This means that the item, as was proposed in the field trial phase, is not able to discriminate students with different skill levels. The correct option (A) is chosen by a small number of respondents, (9.77%). The question, therefore, seems to have a high level of difficulty but, at the same time, it is not so discriminant. In fact, if we consider the correlation coefficient for the correct answer (A) the correlation is low (Pt Bis 0.11). The three distractors have problems too: the weakest is the third (C): besides being very attractive (34.96%) it

has a positive biserial-correlation index, even slightly higher than the correct option (Pt Bis = 0.14). This means that the students who choose this option have a higher level of ability, as measured by the whole test, than the students having selected the correct answer. This is confirmed by the IRT analysis shown on the plot of characteristic curves by category (see Figure 3).

**Figure 3: Characteristic curves by category**

The item difficulty, estimated by Rasch scale, is 1.30 (Figure 3, Delta(s): 1.30). The IRT model confirms the difficulty of the item. The chart shows on the x-axis the estimated ability of respondents (in logit units) and on the y-axis the probability of answering correctly to the item. Therefore each curve represents the evolution of a response option, in terms of skill of students and chance to choose a certain option. The curves relative to observed data are then compared with theoretical trends that question should have, depending on the Rasch model (continue blue curve). This comparison reveals that observed behaviour of correct option (in legend, Item 37:1) is not fitting with the theoretical model. From the plot, we can see that the probability to choose the correct answer does not increase with the increase of the skill level. The distractors trends have some problems as well. In particular, the distractor C (Figure 3, Item 37:3) has a probability to be chosen which is higher than that to choose the correct answer, even for the highest level of ability.

The field trial item analysis results help us to make hypothesis about which mathematical aspects of this item don't work. The two more often selected options (C and D) contain both terms that probably confuse students (volume and height), and elements linked to students' cognitive difficulties related to the concept of volume, as shown by the relevant research (Vergnaud, 1983).

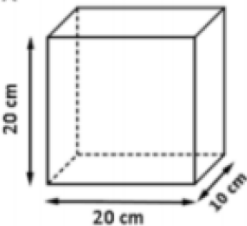

In option C, the word "volume" probably attracts high level students as they know that the item is about the volume. Probably they think that the lower the volume, the greater the height, because they do not grasp the right relationship between the measures of the base area and the supplied quantity (1 litre). Option D is attractive probably because the question is about the "maximum height" and this option is the only one in which the term "height" is mentioned. This item is interesting from the point of view of mathematical skills and it is closely related to the Mathematics

National Guidelines, but it does not seem to be clear for students. Probably its question intent is not well focused either. In fact, given the formulation of the item, we cannot understand the reason why students are unable to answer correctly: does it depend on the fact that students are not able to identify the right container or on the fact that they are not able to identify the right justification?

The question has therefore been modified for the Main Study test (2015) in order to remove its problematic elements (Figure 4).

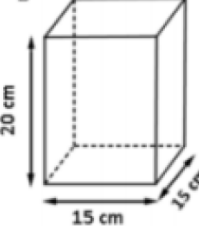

One litre of water is poured in each of the containers showed below.

**A**

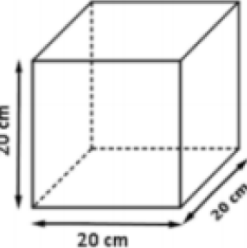

20 cm  
20 cm  
10 cm

**B**

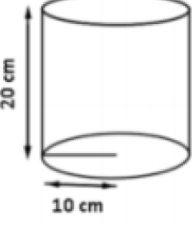

20 cm  
15 cm  
15 cm

**C**

20 cm  
20 cm  
20 cm

**D**

20 cm  
10 cm

In which case the water will reach the highest level?

A. ☐ In container A

B. ☐ In container B

C. ☐ In container C

D. ☐ In container D

**Figure 4: Modified item (after field trial)**

In the new version of the item “the maximum height” is no more mentioned, because the question is about “the highest level”. Moreover, all figures have the same height (20 cm), in order to help students to focus their attention on the shape of the containers and on the dimensions of the base.

Finally, the justification has been removed from the response options. The item question intent was partly modified, but it is more focused.

The fact that the figures have all the same height allows students to focus more on the size of the base of the containers rather than on the meaning of volume or on the relationship between volume (1 L) and the shape of the containers.

From the point of view of mathematics education the first version of the question was probably more interesting because it was more stimulating (the containers have different sizes and each option has different justifications). This type of question would be very suitable for a class discussion. For example, as part of work with the class, it would be interesting to isolate the crucial variable through a discussion in order to highlight the different ideas of the concept of volume. However, in a standardized national test, where the item is administered to all the Italian 8th grade students, it should be able to discriminate between skill levels, without losing in mathematical relevance.

Figure 5 show the characteristic curves of the modified item administered to the national sample (about 28500 students, with the presence in the classrooms of external observers).

**Figure 5: Characteristic curves by category**

The item is still rather difficult (Item Delta = 1.66, and the percentage of correct answers 19.58%), but its discrimination has improved (Item-Rest Cor. = 0.25) as well as the index of FIT (Weighted MNSQ = 1.03). Only the option B seems to have some problems: its correlation coefficient, in fact, have a positive value (Table 2, Pt Bis= 0) even if this correlation is not significant (in table, sig.  $p = 0,952$ ). The real change is observed on the curves of each response option (Figure 5). In the previous version of the item, the trend of the curves highlighted a number of issues about the different response options. Now we can see that the correct option (Label A; Item 18:1) follows the theoretical model (continuous blue curve) and the curves of the incorrect options drop with increasing student skills. Option B still remains problematic: you can notice from its curve on the graph that this option (in legend, Item 18: 2) has lower probability to be chosen, in comparison with the other distractors, by students of any skill level. Analysing the item from the mathematical content point of view you can see that option B involves an estimate of the base area which is slightly more complex ( $15 \times 15$ ) than the other options. On the other hand, the other two options C e D, (Figure 5, 18:3 e 18:4) work well: in fact they have higher probability to be chosen by students with low abilities and this probability decreases according to the increase of skill. As intended, the item so modified results to be better focused on a specific question intent.

## Discussion

In this paper, we have described how we construct mathematics items for the Italian Assessment System and which aspects are taken into account in the selection of items for the main study. The debate between statisticians and researchers in mathematics education (as well as experienced teachers) of the National Working Group for the construction of the mathematics national test is always very lively. The challenge is to be able to maintain the right balance between these aspects, with the awareness that through a standardized test many mathematical skills cannot be measured. The choice is never between pretty or ugly questions, but between suitable or unsuitable questions in a standardized test aimed at all the students of the country. In this example we showed how statistical analysis has allowed us to improve the item from the linguistic point of view and better focus on the purpose of the item. In this way the mathematical aim of the item is saved while its

psychometric properties are improved. Over the past few years, in a few cases we have submitted items that were very interesting from a mathematical point of view, but unsuitable for a test of this kind as they didn't provide information about students' ability. However some of these questions would be more appropriate to be discussed in a classroom setting, proceeding by trial and error until arriving at a shared solution, rather than being included in a standardised test.

The challenge that we try to face is to be able to build interesting questions on math skills that are important to the teaching and learning of mathematics, but that provide a solid measure of students' mathematics skill levels, with the aim of providing useful information for teachers to enrich their work in the classroom.

*A recent research (Sayac, 2016) has shown that assessments proposed by primary school teachers are mainly summative and not used to increase student knowledge. To further this work, we have decided to study teachers' assessment practices in mathematics, but also to improve them in the context of a collaborative environment. In such a project, as researchers and teacher educators, we share the same goal with the teachers involved: developing assessment for learning and helping students to learn better in mathematics. For studying this environment and for analysing the professional development of any actor, we use the Activity Theory framework (Engeström, 2001) but also the notions of "evaluative episode" and "professional judgement in assessment", developed by Sayac (in progress) for defining the didactic paradigm of assessment. In our paper, we present our methodology and focus on one aspect of this research: the use of external assessments as tools for improving assessment practices.*

*Keywords: Assessment practices, external and internal assessment, validity in assessment.*

In France, recent modifications in curricula and institutional directions encourage teachers to assess competencies (and not only knowledge), but also to develop, in their classes, "assessment for learning": teachers should consider that assessment is a part of the didactic process and use assessment information for adjusting their teaching strategies. A recent study by Sayac (2016) with some primary school teachers, has showed that assessments in mathematics are mainly summative and that teachers use the results principally for the end of term report. Moreover, assessment tasks are not complex and previously studied before taking the test.

Furthermore, few assessment tools are made available to primary teachers. Until 2012, national diagnostic assessments were organized at the beginning of Grades 3 and 6 and teachers could use them for a diagnostic purpose, but these tests do not exist anymore. In the same time, the number of large scale assessments in primary school has increased in France, but items are not free and only results are published (Brun & Pastor, 2009, Dalibard & Pastor, 2014; Lescure & Pastor, 2008,). So, teachers cannot use items or results directly for their classes and educators can only exploit general results for providing an overview of trends in students' mathematical knowledge or difficulties.

Since 2016, a bank of exercises (with scoring procedure, explanation of the difficulties and propositions of teaching strategies) has been created for helping teachers to assess students at the beginning of Grade 3. It is a commendable initiative, but it raises a lot of questions about these exercises and their use: even if each task is relevant with regard to its assessment aim, teacher must select many of them to elaborate a complete test. How is this selection done and which competencies are finally assessed? Is scoring guide used or not by teachers? How? Etc.

Like other external assessment tools, this could improve teaching and assessment practices, but merely delivering assessment tasks seems not to be sufficient: for designing tests and using results for a better regulation in classes, we think that, in addition to assessment tools, teachers must have knowledge about mathematical notions, teaching them.

Finally, these observations about the bank of exercises have led us to conduct a study to analyze and improve teachers' assessment practice; we suppose that training teachers in assessment will also impact their teaching as a whole. We have chosen to conduct our research in a specific mathematical domain (whole numbers) at the beginning of the elementary school (Grade 1 to 3), in a collaborative environment. After specifying our research and training aims, we explain our theoretical frameworks and methodology for studying this environment and the professional development of any actor and conclude with perspectives.

## **Research aims and context**

This research aims to continuing to explore the assessment practices primary school teachers in mathematics but also to improve them as part of a collaborative research-training. It is undertake in a special network "AeDeP" at FIE (standing for Associated educational Design-experiment Places at French Institute for Education); this type of project is initially based on an educational question shared by different actors (teachers, researchers, school directors, local authorities) and is built for sharing experiences and designing common tools. Our two key issues are:

1. How do primary school teachers assess their students? We focus on test content (which type of tasks do they propose? What techniques are necessary to solve them? Etc.), but also on how teachers design their assessments (what kind of resources they use? What do they do with the results? Etc.)
2. How can such a collaborative research-training improve teachers' assessment practice, and more generally mathematics teaching?

We present in this paper one part of our three-year project, called "EvalNumC2" and we focus on the development of assessment practices in mathematics at primary school. For this part of the project, regular meetings are planned (one per month) with all the actors (ten primary school teachers and us, two educators/researchers) and with different aims depending on the timing of the research. At the beginning, researchers will only collect the tests produced by teachers (without training) and information about teachers' practice; after, external assessments and didactic tools designed by researchers will be introduced.

## **Theoretical framework**

### **Activity theory for studying professional development in a collaborative environment**

We consider that the Activity Theory expanded by Engeström (2001) is a good framework to study this kind of collaborative project of research and training through the objects and the tools used by the subjects, i.e. the teachers involved and us, as mathematics teacher educators/researchers (MTE-Rs). In this framework, the activity of teachers in which we are interested is their assessment practice and the activity of MTE-Rs is to explore and develop these assessment practices within the collaborative environment. We look at the activity of the different subjects in order to produce

results concerning professional development of each one, promoted through this collaborative device (Jaworski, 2006).

Among the tools used in the AeDeP, we have chosen to focus on two specific ones: a list of criteria for studying the validity of test items and tests designed by researchers. In the following we explain why.

### **Didactic paradigm of assessment**

To study the assessment practices of teachers, we adopt the didactic paradigm of assessment developed by Sayac (in progress). In this framework, teachers' assessment practices are studied through the evaluative episodes they propose during the learning process, but also from the evaluative logic of teachers that becomes apparent in the design of the episodes (resources, method, nature of the tests provided), through their professional judgment in assessment and their grading practices.

A number of researchers draw on the notion of professional judgment when considering learning assessment by teachers (Klenowski & Gunn, 2010; Laveault, 2008; Wyatt-Smith, Morgan & Watson, 2002). For them, professional judgment includes both cognitive process and social practice (Mottier Lopez & Allal, 2008), which is not the same as a "mechanical gesture of measurement" (Wyatt-Smith et al., 2010), but must be considered as a "flexible dynamic process comprised of middle and final judgments" (Tourmen, 2009). The professional judgment of teachers could be viewed as an act of discernment and as the ability to build intelligibility of the phenomenon of assessment, while taking into account the epistemic, technical, social, ethical and paradigmatic dimensions of classroom assessment practices (Tessaro, 2013). In the didactic paradigm of assessment, the professional judgment is considered as a kind of "didactic vigilance" (Pézar, 2010) specifically applied to the assessment activity of teachers. This allows them to on the one hand give a valid verdict (Chevallard, 1989) about students' mathematical knowledge, individually and collectively, from data collected during the different evaluative episodes. On the other hand this allows them to mutually articulate the different moments of the learning process (especially to connect evaluative episodes to the other moments of the learning process), based on data collected during the different evaluative episodes. This professional judgment in assessment is related to teachers' mathematical and didactical knowledge and assessment skills. It also depends on individual factors as beliefs on learning and assessment as well as professional and personal experiences on assessment (Brady & Bowd, 2006; Di Martino & Zan, 2011; Jong & Hodges, 2015).

### **Validity of tests**

Researchers and teachers, and more generally, all assessment designers, have a same preoccupation about the test: they want to be sure that their tests assess what they should assess and only that. In previous work, we have described a methodology and listed didactic criteria for analysing the validity of an external assessment in mathematics (Grapin, 2015; 2016). We transfer and adapt these principles with two different aims: as researchers, for analyzing the content of internal tests designed by teachers (classroom assessment), and, as educators, for helping teachers to construct their own assessments.

For studying the validity of a test of a mathematical domain, we consider two levels: locally (exercise by exercise) and globally (the test as a whole). From a didactical point of view, the *a priori* analysis of each item is crucial because it gives indicators to guarantee that a task is relevant for achieving its assessment aim. For each item, we realize such an analysis specifying the tool or object aspect, the registers implicated with their possible congruence (Duval, 2006), the types of tasks involved in the resolution, the different techniques (adequate and inadequate through curricula) for solving the problem, the arithmetic problem classes (Vergnaud, 1996), the complexity levels (Sayac & Grapin, 2015). We also take into account the techniques involved in the resolution; if an item can be solved with a technique or a strategy different from the ones expected relatively to his assessment' aims, we consider the item as inconsistent.

For studying and ranking items according to their complexity, we have developed a tool (Sayac & Grapin, 2015) which takes into account three factors. In the first one, the wording and the task context are considered (what is difficult to understand the question?), in the second one, the mathematical knowledge involved in the solving process is studied, and finally in the third one, concerns the level of competency (is the task usual or not, does the student have to take initiative?). For each of these factors, we attribute a degree of complexity between 1 (simple) and 3 (complex). We also observed that discussions between teachers arise during the use of this tool because they do not have the same ideas about the complexity, depending on their teaching or their representations of mathematical notions (Sayac & Grapin 2013). So, this tool seems particularly appropriate to use with the teachers in our project.

On a global level, we study whether the items are representative for the curriculum: have all types of tasks been represented? What are the complexity levels (defined *a priori*) of the items? Are they different or similar? Which registers of representation are involved? When a same type of task is represented by different items, are the effective techniques similar? Etc.

## **Methodological elements and preliminary results**

The Engeström triangle (Engeström, 2001) allows identifying, for each subject, objects that will evolve during the collaborative project of the research and training, through the mediation proposed via the tools, the rules and the division of labor and the communities.

For the teachers involved in the project, the main object is to assess their students. It comes to study specifically, from the collaborative environment, tests designed by researcher as one of the tools used. We will study how these tests could:

- 1- Enhance assessment tasks proposed by the teachers in terms of diversity, complexity and coverage of the mathematical domain.
- 2- Develop teacher's professional judgment through the study of students' answers to these tests and the confrontation between all the teachers during the meetings.
- 3- Work on the coding of students' answers and therefore, on grading.

Studying or using external tests could foster the teachers' professional development, because they will be validly designed from the epistemological and didactical point of view (Grapin & Grugeon,

2015). The evidence of validity will allow us to show how these tests could be relevant for the three points above.

We consider as Johnson, Severance, Penuel and Leary (2016) that:

Professional development organized around the analysis of mathematical tasks has potential to prepare teachers for standards implementation by helping them develop common understandings of standards and how to help students meet ambitious new learning goals. (p. 173)

Therefore, we believe that the contribution of assessment tasks from external tests, in a collaborative context, could develop teachers' skills on assessment tasks design and contribute to enhance their professional judgment in evaluation (Gueudet, Pépin & Trouche, 2013).

## **Methodology**

At the start of the school year, we collected tests designed by teachers involved in our project in order to analyze the assessment tasks with the tool developed in previous research (Sayac & Grapin 2015). We will also collect new tests designed by the teachers at the end of the school year, after the collaborative group work in the meetings. Each assessment will be analyzed in terms of its validity with the criteria listed above; we will principally observe the change in content between the beginning and the end of the project (variety of type of tasks, complexity of tasks and the coding of students' answers).

Each teacher will also fill in a questionnaire about his or her assessment practices (How does he or she design tests? Which resources does he or she use? What are the periods of assessment in his/her classes? How does he or she use the results?). The results of these questionnaires will be used to compare teachers but also as an element for analysing the evolution of their practice.

Lastly, for relying assessment and teaching in classes, each teacher involved in the project will have to keep a "daily book" (journal) in which he or she explains briefly the aim and the content of each mathematical course (in the numerical domain). He or she will also have to identify, according to his/her own representations, the evaluative episodes and describe these more specifically. We will analyze the content of the tasks proposed in tests and during teaching to study their correlations and their evolution during the project. As observed by Grugeon and Bedja (2016), we suppose that training teachers in assessment will also improve teaching: teachers should propose a wider variety of types of tasks, but they also should be able to have a better interpretation of students' errors and propose adapted instruction to upgrade students' level of understanding.

## **Preliminary results**

At the time of writing, we cannot present full results because this project started in September 2016 and we are in the process of collecting first data; we show however two example of tasks, extracted from the same test, one of the teachers in our study used in Grade 3.

In a first task (Figure 1), the five questions are similar and aim to assess the decomposition of written numbers in canonical expressions. In all examples, the underlying structure is regular. We observe that such a task is not complex (we quote level 1 on each factor of complexity) and assesses five times the same knowledge: only the positional aspect of numeration (and not the decimal aspect).

■ Décompose comme dans l'exemple. Exemple :  $50\ 482 = 50\ 000 + 400 + 80 + 2$

$5\ 472 = 5\ 000 + 400 + 70 + 2$  ✓  
 $8\ 070 = 8\ 000 + 70$  ✓  
 $56\ 030 = 50\ 000 + 6\ 000 + 30$  ✓  
 $560\ 000 = 500\ 000 + 60\ 000$  ✓  
 $205\ 009 = 200\ 000 + 5\ 000 + 9$  ✓

**Figure 1: First exercise and students' answer extracted from a classroom assessment designed by a Grade 3 teacher.**

The second exercise of the test (Figure 2) looks like the first one and assesses the same type of knowledge.

Décompose comme dans l'exemple. Exemple :  $42\ 500 = (4 \times 10\ 000) + (2 \times 1\ 000) + (5 \times 100)$

$4\ 750 = (4 \times 1\ 000) + (7 \times 100) + (5 \times 10)$  ✓  
 $35\ 000 = (3 \times 10\ 000) + (5 \times 1\ 000)$  ✓  
 $260\ 050 = (2 \times 100\ 000) + (6 \times 10\ 000) + (5 \times 100)$  ✓  
 $304\ 008 = (3 \times 100\ 000) + (4 \times 1\ 000) + (8 \times 10)$  ✓  
 $540\ 600 = (5 \times 100\ 000) + (4 \times 10\ 000) + (6 \times 100)$  ✓

**Figure 2: Second exercise and students' answer extracted from a classroom assessment designed by a Grade 3 teachers.**

Throughout the full test, there isn't any exercise for assessing the decimal aspect of numeration. We conclude that such a test is not valid and in the project we are going to elaborate other questions with the teachers to fill this lack.

We have not yet achieved the analysis of all classroom assessments designed by teachers involved in the project, but it seems that, as we can observe in the two previous examples, tasks are repetitive, having low complexity and for the numeration, assess principally positional aspect of the numeration. Such observations led us to propose external assessments with other types of tasks: exercises designed to assess numerical aspect of the numeration but also complex situations intended to develop students' abilities.

## Conclusion and perspectives

We have focused in the paper on the original and theoretical notion of "didactic paradigm" designed recently by Sayac (in progress). What we can tell currently, from the first data collected (tests, questionnaires, interviews) is that the teachers, participating in our research, design tests with low levels of complexity and have invested very little in assessment as a professional gesture. They assess their students as they can, with very subjective practices. So, it seems that our research, with its training dimension, will make possible a real professional development concerning the assessment tasks proposed in mathematics by these teachers and their professional judgment in assessment.

So, besides studying and providing primary school assessment practice in mathematics and designing assessment tools, our research aims also to develop these theoretical elements. At the end of the project, it will be possible to show the impact on the teachers' practice and interests, and the limitations of this methodology, according to our theoretical framework. It would then be possible to extend such studies in other mathematical domains (as geometry) or in other levels, for example at secondary school.

# Using assessment for learning to enhance mathematics education in the primary school: Irish students' perspectives.

Ann Marie Gurhy

Dublin City University, Dublin, Ireland; [amgurhy@eircom.net](mailto:amgurhy@eircom.net)

*Previous research suggests that assessment for learning (AfL), when used effectively, can greatly enhance student learning and achievement. However, students' views regarding AfL are often overlooked. This paper reports on one part of a broader study that investigated the interplay between lesson study, continuing professional development in AfL and mathematics teaching and learning. The paper explores the views of students in one Irish Primary School regarding their use of AfL practices during mathematics lessons over the course of one academic year. Evidence suggests the use of AfL strategies and techniques enhanced children's mathematical confidence, and improved their engagement with, and attitudes to, mathematics. By the end of the intervention, children readily used the language of AfL, engaged in AfL practices and played a more active role in their own learning and assessment, identifying the use of self-and peer-assessment as a highlight.*

**Keywords:** Assessment for learning, mathematics, student voice, student engagement.

## Background and focus of the project

Assessment, as argued by Gardner (2012), is a “hot topic” across the entire education spectrum and rarely out of the limelight (p.103). In particular, assessment for learning, with its emphasis on learning as opposed to measurement has in recent years, according to Chappuis (2014), “garnered the lion’s share of assessment attention and established a pretty good name for itself” (p.21). This paper is about assessment for learning (AfL) in mathematics which is conceptualised using the following *second generation* definition generated by the Third International Conference on Assessment for Learning in New Zealand in 2009 which states:

Assessment for Learning is part of everyday practice by students, teachers and peers that seeks, reflects upon and responds to information from dialogue, demonstration and observation in ways that enhance ongoing learning. (Klenowski, p.264)

This definition clearly captures the key tenets of AfL, foregrounds classroom practices, highlights the notion of AfL as a bridge between teaching and learning (Wiliam, 2011), and views teachers and students as the primary agents of educational change (Lysaght & O’Leary, 2013). Research evidence suggests that focusing on the use of day-to-day AfL is one of the most powerful ways of improving learning in mathematics classrooms and can result in significant learning gains (Wiliam, 2007). Additionally, various studies have also linked AfL to increased student motivation and self-esteem (e.g., Clarke, 2008), enhanced self-regulated learning and metacognitive abilities (e.g., Andrade, 2013), and better student-teacher relationships (e.g., Clarke, 2014). In the Irish context, government policy emphasises the centrality of AfL in teaching and learning although few teachers have received assessment-related continuing professional development (CPD). The Department of Education and Skills (DES, 2011a) has highlighted that AfL is not used sufficiently widely in Irish schools and

concerns have also been raised about teacher assessment literacy. Regarding mathematics, data from the 2009 National Assessments of Mathematics and English Reading (DES, 2010b), school inspections (DES, 2010a) and international reports (PISA, 2009) have suggested Irish students are underperforming. Indeed, Hislop (2013), chief inspector with the DES, argues that it was Ireland's poor performance in PISA 2009 that precipitated publication by the Irish government of a strategy aimed at improving standards of literacy and numeracy in Ireland: *Literacy and Numeracy for Learning and Life; The National Strategy to Improve Literacy and Numeracy for Children and Young People 2011-2020* (DES, 2011a). This strategy is one of the most significant documents pertaining to education in the Irish context in recent years, and it is especially pertinent to this research since it has particular implications for numeracy, assessment and CPD. The *Literacy and Numeracy Strategy* increased the amount of time allocated to literacy and numeracy at all class levels, and set out *ambitious* improvement targets in English and mathematics as measured on standardised tests to be achieved by 2020. Compulsory standardised testing in English and mathematics changed from two to three points in the primary cycle (second, fourth and sixth classes), with mandatory annual reporting of aggregated results to the DES to facilitate collation of a national picture of achievement. Additionally, schools must use these results as part of "robust self-evaluation" (p.40) and to prepare three-year improvement plans for the promotion and improvement of numeracy and literacy. Results also have to be given to Boards of Management and parents. Nevertheless, while various scholars (e.g., Leahy & Wiliam, 2012) agree that AfL, when used effectively, is a warranted strategy that can improve student learning and achievement, and Irish government policy emphasises the importance of using AfL in teaching and learning, apart from some small-scale studies (e.g., Lysaght, 2009), research into AfL in the Irish context remains sparse, particularly in the area of mathematics. Furthermore, there has been little or no research investigating what is going on in the hearts and minds of learners while engaging in AfL practices. This study seeks to address this gap in the field by specifically investigating the following research question presented as a hypothesis:

*The use of AfL strategies and techniques, and the adoption of AfL principles, would enhance children's mathematical confidence, and improve their engagement with, and attitudes to, mathematics.*

## Methodology

This is a practitioner action research mixed methods explorative case study, which operated within the pragmatic paradigm. Over the course of one academic year, it investigated the impact of AfL practices on the teaching and learning of mathematics at fourth-class level in one primary school in the Republic of Ireland. Specifically, it explored how the use of AfL principles, strategies and techniques affected students' attainment on standardised mathematics tests and their dispositions towards mathematics. Additionally, the research investigated the potential of lesson study (LS) as a vehicle of collaborative professional learning in AfL and considered the impact engaging in LS had on teachers' skills, knowledge, and use of AfL, and their beliefs towards AfL as a form of assessment. A key part of this study was the use of peer-to-peer learning as a vehicle of continuing professional development (CPD). Meeting after school on twenty-three occasions over the course of the intervention the teachers learned about AfL strategies and techniques on a phased basis before implementing them in their mathematics lessons prior to the next meeting. The AfL strategies used were as follows: learning intentions and success criteria; questioning and classroom discussion;

feedback; self- and peer-assessment. Additionally the teachers learned about and implemented more than twenty AfL techniques, for example, rubrics, think-pair-share, two stars and a wish, fist-to-five, learning logs, ABCD cards and comment-only marking (For further details see Wiliam, 2011).

### **Site selection and research participants**

This research project took place exclusively in the school where I teach, Scoil na nAingeal (pseudonym), from September 2012 to June 2013. It is a vertical, urban, girls-only Primary School in the Republic of Ireland with an enrolment of 438 students and an all-female staff. The profile participants included all students enrolled in fourth class for the academic year 2012-2013, 51 girls, the average age of whom was ten years in September 2012. Classes were pre-formed, intact groups and so, according to Creswell (2009), random sampling was not considered appropriate. Three teachers participated in the project, the two fourth-class teachers and one member of the Special Educational Needs (SEN) team.

### **Data collection and analysis**

Both quantitative and qualitative data were collected to decide whether to accept or reject the above research hypothesis. This aided triangulation, enhanced the study's findings and enabled better understanding of the research problem. The quantitative data were collected using one scale of an instrument developed by the researcher called the Attitude to Mathematics Questionnaire (ATMQ). This scale was labeled the ATMQ-TIMSS since it used statements 8a-8h of the Trends in International Mathematics and Science Study (TIMSS) 2007 Grade Four Student questionnaire verbatim. These statements examined "students' general attitudes towards mathematics" and "their self-confidence in learning mathematics" (Mullis, Martin & Foy, 2008, p.173). Leaving the TIMSS questionnaire unchanged facilitated comparative analysis with national and international data, and ensured the reliability of this scale (median reliability coefficients across all TIMSS countries at fourth grade was 0.83, Mullis et al., 2008, p.401). Fifty children completed the ATMQ-TIMSS pre- and post-intervention. Scoring was done using a four-point Likert scale, with response options ranging from 'Agree a lot' to 'Disagree a lot'. Raw data from the ATMQ-TIMSS were coded or categorised, recorded and prepared in Microsoft Excel and then imported into the software package, SPSS 21, where dependent (paired) samples t-tests were conducted in order to compare the scores of the same participants at Time 1 and Time 2, to ascertain whether or not the intervention had an impact (Pallant, 2013).

The qualitative data comprised transcripts and video from focus groups (FG) interviews, teachers' learning logs (TLL), students' learning logs (LL), and the researcher's journal. In addition to aiding triangulation, these data supplemented the quantitative data by facilitating a more in-depth analysis of students' views about using AfL strategies and techniques in their learning of mathematics. Braun and Clarke's (2006) six-step approach to thematic analysis was used to guide analysis of each data item individually and subsequently the complete qualitative data set.

## **Results and discussion**

### **Quantitative data**

Results from analysis of the ATMQ-TIMSS indicated that there was a statistically significant difference between pre-test ( $M = 2.03$ ,  $SD = 0.73$ ) and post-test scores ( $M = 1.56$ ,  $SD = 0.42$ ;  $t(49) =$

5.09,  $p < .001$ ), i.e. post-test scores indicated more positive attitudes towards mathematics (mean values in post-test scores were closer to 1 = *Agree a lot*). The magnitude of the difference between the pre- and post-test means can be interpreted as being large (eta squared = .35). Table 1 presents combined ‘agree’ percentages for pre- and post-results for each statement in the ATMQ-TIMSS scale.

	Statement	Subscale	n	Combined % Agreeing PRE-TEST	Combined % Agreeing POST-TEST
a	I usually do well in Maths	SCM	50	76	96
b	I would like to do more Maths in school	*	50	60	70
c	<i>Maths is harder for me than for most other students in my class</i>	SCM	50	28	14
d	I enjoy learning Maths	PATM	50	80	98
e	<i>I am not good at Maths</i>	SCM	50	26	6
f	I learn things quickly in Maths	SCM	50	58	70
g	<i>Maths is boring</i>	PATM	50	26	6
h	I like Maths	PATM	50	80	100

Note. % Agreeing = Agree a lot + Agree a little

Italicised text highlights statements that were recoded.

For discussion purposes, percentage scores for the three PATM (Positive attitude towards mathematics) statements and the four SCM (Self-confidence in learning mathematics) statements were amalgamated to provide a composite percentage score for these scales which could then be compared with TIMSS data.

\*Regarding statement b, Clerkin (personal communication, April 15, 2015) suggests it was probably originally intended to be part of the PATM scale but following factor analysis was found not to represent positive affect in the same way as the other scale items and so was excluded.

**Table 1: ATMQ-TIMSS Scale**

A more detailed exploration of the eight statements from the scale revealed that following the intervention the combined ‘agree’ percentages scores for the five positively-worded statements (a, b, d, f, h) had increased by between 12 and 20 percentage points while the percentage of students agreeing with the three negatively-worded statements (c, e, g) had decreased by between 14 and 20 percentage points. This suggests that children believed the intervention had positively impacted their general attitudes towards mathematics and their self-confidence in learning mathematics. Specifically, regarding the three statements which measured students’ general affect towards mathematics (d, g, h), results indicated that following the intervention almost 100% of the participants agreed a little or a lot with these three statements (Table 1).

## Qualitative data

Five main themes were identified following the qualitative analysis but due to space limitation these are discussed only briefly here.

### Enjoying the AfL journey

When describing their experience of using AfL practices in mathematics, the children regularly used words such as ‘fun’ and ‘enjoyment’. Their enthusiasm regarding using AfL can be succinctly summarised by Maria’s comment: “I love doing AfL and I would like to continue doing it” (LL, 13/02/2013).

### Growing positivity and self-confidence in mathematics

It is clear from the data that at the end of the study students reported a growing positivity towards and increased self-confidence in mathematics that they attributed to their use of AfL. Some believed that using AfL practices made mathematics easier and increased their liking of mathematics: “It makes maths so much more fun, ‘cause like in third class I used to hate maths and then like now that there’s all these different strategies, it just makes maths so much easier” (Sophie, LL, n.d.).

### A changed classroom dynamic

Scholars suggest (e.g., Hayward, 2012), engaging in AfL practices in the *spirit* in which it is meant impacts learning and teaching and acts as a leverage for change in classroom practices, and roles and relations. Children in this study, while recognising the teacher as overall guide and arbiter in the classroom, also identified teachers as learners. Additionally, they were beginning to monitor their own learning and to evaluate their progress. For example, Chloe commented, “I think it’s helped me, that it’s not letting the teacher correct all your work, that you, you kind of have to check it, and you have to, because there’s some silly mistakes that you could make” (FG1). Others displayed an increased confidence in their ability to assess, both themselves and others: “I think that when you correct it yourself, or for your friend, you know what you’re correcting, you know why you’re correcting, what you did wrong, so you know what you’re doing” (Emma, FG1). This suggests that through the process of engaging in AfL strategies and techniques over the course of one academic year, these students were becoming more independent learners, accepting the responsibility this brought, and were moving towards self-regulated learning.

### Peer- and self-assessment: - a highlight for children

Using peer- and self-assessment was undoubtedly a highlight for children participating in this study as this comment illustrates: “I love self-assessment and peer-assessment” (Hollie, LL, n.d.). The following comment from Ruby demonstrates that by the end of the intervention the children had developed a good understanding and appreciation of peer- and self-assessment:

I thought the self-assessment was excellent because we were judging ourselves and could learn from our mistakes. Peer-assessment was brilliant for your partner or pair could judge your work and spot mistakes that you might not have spotted yourself. (Ruby, LL, 12/06/2014)

The children believed that self- and peer-assessment not only enhanced their learning but that it was also fun. Similar to research by Topping (2010), trusting your peers was mentioned by a number of participants as integral to good peer-assessment practice. For example, Hollie remarked: “I think peer-

assessment is the best because you get to like trust your friends more, so they'll be more honest with you in the future" (FG1).

### Unexpected insights

The qualitative data also revealed some unexpected insights about students' perspectives regarding AfL. The children revealed they used the learning intentions and success criteria from their mathematics lessons to help them when doing their mathematics homework. Additionally, they described how they appropriated the AfL strategies and techniques to help them learn in other subject areas. Many children reported they liked using rubrics since they scaffolded the assessment process. Maria wrote: "My favourite thing about the AfL was using the rubric" (LL, 12/06/2013) and later explained why:

I like using the rubric because when we were first going to do peer-assessment I was like 'oh God, what will I say was wrong?' and 'I don't know what to do here', but then you showed us the rubric, and I was like 'oh, it's ok', ... with the rubric, it tells you what you're supposed to assess, (FG2)

### Conclusions

While acknowledging the limitations of this study, such as the fact that it takes place in a single school and employs a case study strategy with convenience rather than non-probability sampling, it nevertheless contributes new insights regarding AfL and mathematics, especially from students' perspectives. It demonstrates that children in primary school are capable of engaging in AfL practices, including peer- and self-assessment, and want to do so. Findings suggest that using AfL practices enhanced children's mathematical confidence, and improved their engagement with, and attitudes to, mathematics.

This study is important since, to date, little empirical research has been done into the effects of AfL practices on students' mathematics learning in the Irish context at primary level. Additionally, this study can supplement research done by academics regarding AfL since it provides a practitioner researcher's perspective of the field, thus "inside-outside" (Cochran-Smith & Lytle, 1993). Notwithstanding, perhaps the most significant contribution made by this research is that it provides a unique opportunity to listen to, and contemplate, the voice of young learners as they discuss their experiences of using AfL practices in their mathematics learning.

# Assessment of students' thinking when working with graphs of functions – Promoting pre-service teachers' diagnostic competence

Rita Hofmann<sup>1</sup> and Jürgen Roth<sup>2</sup>

<sup>1</sup>University of Koblenz-Landau, Campus Landau, Germany; [hofmannr@uni-landau.de](mailto:hofmannr@uni-landau.de)

<sup>2</sup> University of Koblenz-Landau, Campus Landau, Germany; [roth@uni-landau.de](mailto:roth@uni-landau.de)

*Diagnostic competences are essential for teacher actions; however pre-service teachers often do not have the opportunity to train these skills at university. Thus, there is a need to find out the best way to promote diagnostic competences in teacher training. During the last decades, several projects introduced videos as a tool for the training of diagnostic skills, but there is no evidence that pre-service teachers really acquire diagnostic skills better by analysing videos than by analysing tasks. The present study contributes to this growing area of research by exploring which one of these two methods promotes diagnostic skills better. Video analysis and task analysis are compared as training methods in an intervention study with a pretest-posttest design. Fostering preservice teachers' diagnostic skills with focus on students' abilities, problems and misconceptions with graphs of functions, is the specific objective of our study.*

*Keywords: Pre-service teacher training, diagnostic competence, formative assessment, graphs of functions, video vignettes.*

## Theoretical background

Good lessons require a lot of competencies on the teacher's side. Diagnostic skills, in particular, are an important part of teachers' professional knowledge and competence (e.g. Baumert & Kunter, 2006). Weinert (2000) regards diagnostic competence as one out of four basic and essential competences of teachers. Having good diagnostic skills enables a teacher to differentiate and individualise amongst learners – an ability that becomes increasingly important in today's classrooms, "[...] because lessons can no longer be planned completely in advance, and teachers have to make many decisions in the midst of instruction about how to proceed" (van Es & Sherin, 2002, p. 574). Good lessons require teacher actions that are adapted to the students' needs and abilities and, therefore, are based on diagnostic information (Klug et al., 2013; Schrader & Helmke, 2001). For the adaptation of teacher actions to pupils' needs during a lesson, relevant information needs to be obtained during the students' whole learning process. Getting an insight into the students' abilities only through the results of a final exam, is often too late to work on the students' problems and misconceptions. For this reason, our focus lies on diagnostics which take place in the learning process of the students where the teacher is still able to guide and influence the learners and their learning process. In the following, an overview of different aspects concerning diagnostics and assessment will be given.

## Diagnostic competence

The term "diagnostic competence" is often used in the literature, but there is no agreement on a definition of this expression. A wide-spread definition would be that diagnostic competence involves all the abilities of an evaluator enabling him to correctly assess other people (Schrader, 2010). Artelt and Gräsel (2009) understand diagnostic competence as the teachers' competence to

evaluate the characteristic traits of their students in an adequate way and to suitably assess the demands of learning and of the tasks. Except of these two, various other definitions are used. Diagnostic competence is often described as “accuracy” in teachers’ judgements – mostly in correlation with standardized tests – and therefore concerns the students’ achievement in tests (Klug et al., 2013). Other definitions refer to the learning process of the students itself. In this regard Weinert (2000) defines diagnostic competences as:

[...] an amount of abilities to continuously asses during lesson the state of knowledge, the learning progresses and the performance issues of the individual students as well as the difficulties of different learning-tasks, so that the teaching actions can be based on diagnostic insights. (Weinert, 2000, p.16, own translation)

All of these definitions have in common that diagnostic skills are presented as the tool allowing the teachers to gain information about the learners. This information can be used for different pedagogical decisions like grading and lesson planning (makroadaptations), but also for short-termed interventions during lessons (mikroadaptations) (Schrader, 2013). As our study does not focus on achievements in tests but on the learning process of the students, we refer to the definition of Weinert. Moreover, there are different facets of diagnostic competences (e.g. Praetorius, Lipowsky, & Karst, 2012), so that we prefer to use the term diagnostic skills, as we focus on specific parts of it: the analysis of tasks and the analysis of video sequences – both with regard to abilities, problems and misconceptions of students working on tasks with the content functional relationships.

### **Formative assessment vs. summative assessment**

The terms formative and summative assessment are quite similar to the foregoing described diagnostic competence. Again, there is no common and widely accepted definition although they are widespread in the international literature (Black & Wiliam, 1998). While summative assessment corresponds to the evaluation of students’ academic achievements, formative assessment can be equated to diagnoses during learning processes. According to Bell and Cowie (2001b, p. 538), such diagnoses during learning processes “could include continuous summative assessment”, which is why the authors “explored formative assessment as classroom assessment to improve learning (and teaching) during the learning”. Bell and Cowie (ibid.) distinguish between planned formative assessment and interactive formative assessment. The former describes an assessment activity which is planned in advance, the latter includes assessments that arise out of learning activities during the lesson (Bell & Cowie, 2001a). The purpose of interactive formative assessment is to help the students by accompanying the learning process (Bell & Cowie, 2001a). According to Bell and Cowie (2001a, p. 86) this process involves three parts: noticing, recognizing and responding. Noticing in this context means to gather information about the patterns of thought and actions of the students. This information is gathered while the pupils are working or talking. Thus, this interpretation differs from the term “noticing” described by van Es and Sherin (2002). In contrast to the meaning of “noticing” characterized by van Es and Sherin, which already includes the identification of important aspects of a teaching scenario, Bell and Cowie (2001a) regard the recognition of relevant interactions and moments as a second step. “Recognising may be differentiated from noticing in that it is possible to observe and note what a student does without appreciating its significance” (Bell & Cowie, 2001a, p. 88). Consideration of “responding” as one of

the stages of interactive formative assessment shows, that the noticing or assessment should not stand alone – the following action of the teacher is indispensable.

In this sense, formative assessment involves diagnostic as well as didactical competencies - action competence, respectively. Diagnosis/ noticing and the action which follows up the diagnosis are both parts of formative assessment. To sum up, the subject of our study is diagnostic competence according to Weinert (2000) and the following teacher action. Thus, the regarded skills manifest themselves in the three stages of interactive formative assessment: noticing, recognizing, and responding (Bell and Cowie, 2001a).

### **Graphs of functions**

The focus of the diagnosis in our project is on the students' learning processes while working with graphs of functions. The interpretation and construction of graphs of functions are essential skills - not only in mathematics education. The ability to use different (external) representations is an important issue here. It is one of the six mathematical competences mentioned in the German educational standards for mathematics and also influences two of the remaining standards (KMK, 2004). Moreover, the use of graphs of functions is essential for the topic “functional relationships”, being one of five central topics of mathematics education (KMK, 2004). In addition to that, the abundance of graphs of functions in our everyday life (e.g. functional relationships or graphical representations of data) makes them indispensable in teaching and learning. Nevertheless, previous research has shown that dealing with graphs of functions can be difficult and easily leads to misconceptions. In the literature one can find a lot of those mistakes and misconceptions (e.g. Nitsch, 2015; Leinhardt et al., 1990; Clement, 1985; Bell & Janvier, 1981), like the graph-as-picture misconception, the slope-height confusion or the interval-point confusion. Moreover, what the students think a function is or how a graph of a function should look like (concept image) does not always correspond to the definition of a function, the students have in mind (concept definition) (Tall & Vinner, 1981).

However, not all of these mistakes and misconceptions are visible on the surface but they need to be uncovered in time. Otherwise, there is the danger of a consolidation of wrong thinking making it very hard to work against them (Nitsch, 2015). In this case, wrong conceptions might still be present when students leave school or even when they enrol at university. Teachers need to be able to diagnose students' misconceptions and difficulties in time in order to foster their correct use of graphs of functions.

Giving effective feedback is a crucial aspect of teacher-learner interactions (Hattie, 20120), but often there is a lack of time for reflection and decisions on necessary actions to be taken (Black & William, 2009). The perception and processing of crucial situations often takes place intuitively – “on the fly” – when the teacher is monitoring the classroom and listening to student conversations while students are working with their partners or in groups. This is a highly demanding situation for teachers (William & Thompson, 2007). Consequently, in the beginning of teaching, teachers can experience an overloading by the wealth of information. Thus, the skills to notice, recognize and respond should already be fostered during preservice teacher training. A common way to train diagnostic skills is the analysis of tasks as it can easily be embedded in university teacher training. Thereby the university students reflect the skills which are needed to solve a task as well as

problems which can occur with the task. This method focuses on skills which are primarily necessary in lesson planning. No influence of task analysis on teachers' diagnostic skills could be found yet. It could be assumed, that a good analysis of tasks helps a person to notice things – which are expected through the analysis – in reality. Nonetheless the analysis of gestures is not part of this method and can still be a difficulty for beginning teachers. Furthermore, noticing in a situation is more complex and can be cognitive overwhelming. Therefore, another approach to train such diagnostic skills is the use of videos as part of the training of diagnostic competences, as videos are very close to reality (compare Janík et al., 2009).

Up to now, several studies have shown that pre-service teachers often do not have the opportunity to train their diagnostic skills so that these competences are only poorly developed (Ostermann et al., 2015; Praetorius, Lipowsky, & Karst, 2012). For this reason, we want to foster these skills already during the university teacher training.

## Research Question

The goal of our research is to enhance pre-service teachers' diagnostic skills through experimental settings at university. As mentioned before, there are different aspects of diagnostic skills, all important for professional teaching. On the one hand, a teacher should be able to identify possible difficulties of a task and be aware of the skills needed for solving the task. On the other hand, the teacher needs to be able to identify the concrete difficulties and misconceptions an individual student has and to react appropriately. The analysing of tasks is one common way to train diagnostic skills of pre-service teachers. During the last decades videos were introduced as training tool for diagnostic skills as well. Looking at the two approaches to the training of diagnostic skills, several questions arise that need to be answered:

1. How does the training of task analysis influence the skills for analysing learning situations?
2. How does the training of analysing videos influence task-analytical skills?

Furthermore, as the diagnoses should be the basis for teacher action, the impact of both trainings with regard to this issue is another interesting part of the investigation:

3. Which intervention results in a noticeable improvement of the actions following the diagnoses?

## Method

In order to verify the effects of the different trainings on the preservice teachers' diagnostic skills we will conduct an intervention study using a pre-posttest design. Thus, it will be a setting with two experimental groups: Experimental group one (EG1) will practice diagnostic skills by analysing videos, experimental group two (EG2) by analysing the tasks the students work on (Figure 1). The preliminary study will be conducted in winter term 2016/2017. The participating pre-service mathematic teachers (approximately 60 persons) are currently attending the same lecture in mathematics education (didactic of algebra) and will be randomly distributed into the two experimental groups. The participants of both groups receive the same content input during the lecture. The information given in the lecture will be on functional relationships and particularly focus on the representation graph of functions. Furthermore, the skills which the learners shall

acquire as well as possible student mistakes and misconceptions which can occur during learning, are of special interest.

In the intervention the participants of EG1 are asked to analyse video-vignettes. The participants of EG2 have to analyse tasks which contain the construction or the interpretation of graphs of functions. The focus of both analyses lies on diagnosis of errors regarding problems and misconceptions as well as the skills the students already have or need. The video-sequences used for the intervention can be watched multiple times, stopped at any point and the participant can jump to any point in the video that is of interest to him. This circumstance is meant to help the pre-service teachers as well as possible while they are analysing the learning process of the pupils. The tasks which are given to the participants of EG2 are the same tasks used for the video vignettes. Therefore, differences between experimental groups are limited to the characteristics of the learning resources. The analysis – both of the videos-vignettes and the tasks – happens at each individuals' home, not during the university lecture. In contrast to the test situations, there will be no time constraint during the intervention in order to foster the development of diagnostic skills.

During the pretest, additional data will be collected: teaching experience, attended university lectures in education (other subjects included), differentiating between those already attended, and those happening in the meantime of the intervention. Knowing these influences gives us the opportunity to consider them as covariates for the computation and the results.

The pre- and posttest will be conducted to measure the diagnostic skills of the pre-service teachers at the beginning and the end to be able to see the changes of these skills between before and after the intervention. The tests inquire diagnostic skills which are important for the preparation of lessons as well as those needed to be able to notice situations relevant for successful learning in class. Furthermore reactions based on the participants' diagnoses will be part of the inquiry. The test for diagnostic competencies asks participants to first analyse tasks. Then, a three-minute video will be presented, showing pupils working on the tasks previously analysed. The video can only be watched once and doesn't provide the possibility to pause. This way, we are trying to create a test-situation which is as close to reality as possible. The test includes both open and closed questions asking the participant to communicate what they have noticed and to reason about their findings.

By testing both types of analysis, we want to investigate whether different diagnostic skills have influences on each other. Moreover we expect the test to resolve, whether one method is superior to the other one. This would be the case if for one training method superior gains in both types of diagnostic skills could be observed.

Both settings of the intervention and the tests for diagnostic competence are embedded in the learning environment *ViviAn* (see Figure 2) developed by Bartel and Roth (2015). This learning environment provides a combination of video vignettes and further material and thereby further approximates the information available in real-life teaching situations. Hence, the user gets information about the students (type of school, grade, sex), the content and the learning goals of the entire lesson, and the materials the students use such as the given task and the materials (for example a big sheet of paper with a graph of a function on it). The students' protocols (products) are only available to the participants of EG1 who are analysing videos. As the participants of EG2 analyse the task in more general they shall not be influenced by the solution of the pupils.

**Figure 2: The learning environment ViviAn (Bartel & Roth, 2015)**

The data will be analysed with mixed methods. The approach of qualitative content analysis (Mayring, 2008) will be applied to create a coding guideline. Thereby the answers of the participants will be compared to experts' diagnoses. As experts serve mathematics teachers and academic staff working in the field of didactics of mathematics. These experts' diagnoses will be used as a criterion norm for the measurement of diagnostic skills by using the resulting criteria to rate the participants' answers. To resolve group differences descriptive statistics as well as inferential statistics with variance analysis will be considered.

## Expected results

The preliminary study was conducted in winter term 2016/2017. It will reveal potential problems concerning our approach, the used material and tasks. Based on these findings we will be able to improve our approach and the used material. Moreover, the preliminary study contributes to the investigation of differences between the diagnoses of tasks and videos. Prospectively, with the results of the main study, we will then be able to point out, whether trainee teachers better acquire diagnostic skills by analysing videos than by analysing tasks. Furthermore it will provide insight into whether different aspects of diagnostic skills have an influence on each other.

# Preservice mathematics teachers' views about planning the assessment

Gözde Kaplan<sup>1</sup> and Çiğdem Haser<sup>2</sup>

<sup>1</sup>Middle East Technical University, Ankara, Turkey, [gkaplan@metu.edu.tr](mailto:gkaplan@metu.edu.tr)

<sup>2</sup>Middle East Technical University, Ankara, Turkey, [chaser@metu.edu.tr](mailto:chaser@metu.edu.tr)

*The study attempted to investigate senior preservice middle school mathematics teachers' purposes in preparing the assessment, and their views and suggestions about the assessment part of a lesson plan through employing basic qualitative method. First, the "Incomplete and Improper Lesson Plan Task" prepared by the researchers was administered to the participants (N=27). Then, one-to-one interviews were conducted (N=11). Findings of the study indicated that preservice teachers underlined similar purposes in preparing the assessment part of the lesson plan, all of which related to the teacher actions. They mainly emphasized the kind of feedback gathered by the teachers rather than the students. They also considered the assessment part in the task weak since there were insufficient number and diversity of the questions.*

*Keywords: Formative assessment, feedback, preservice mathematics teachers.*

## Introduction

Formative assessment or *assessment for learning* is utilized deliberately *for learning* (Laud & Patel, 2013). It includes all activities that provide feedback for adjusting teaching activities and instruction (Black & Wiliam, 1998). Any assessment is formative if it is utilized to collect evidence about students' learning progress and current level of understanding the concept (Heritage, 2007), and to make instructional adjustments in line with their needs (Wiliam, 2007).

Feedback plays a crucial role in formative assessment (Sadler, 1989). Ramaprasad (1983, p.4) defined feedback as "the information about the gap between the actual level and the reference level of a system parameter which is used to alter the gap in some way." Feedback cannot be differentiated from the instruction and it is formative when the information provided is utilized to enhance learners' performance (Wiliam, 2007). Information gathered from feedback can be used by both teacher and students (Sadler, 1989). Teachers use it to specify students' needs and give decisions about the adjustments for further instructions (Wiliam, 2007). Students use it to realize their strengths and weaknesses (Moss & Brookhart, 2009) and to learn how to modify and improve their performances to reach the reference level. Therefore, it affects students' learning positively.

Wiliam and Thompson (2008) focused on three instructional processes; *where students are in their learning, where they are going, and how to get there* which are emphasized in Ramaprasad's (1983) definition of feedback and they suggested a formative assessment framework shown in Table 1. According to the framework, formative assessment is composed of five key strategies and one *big idea* that the outcome of students' learning processes can be utilized to make necessary changes in the instruction with respect to students' needs (Wiliam & Thompson, 2008).

	Where the Learner Is Going	Where the Learner Is Right Now	How to Get There
Teacher	(1) Clarifying and sharing learning intentions and criteria for success	(2) Engineering effective classroom discussions and tasks that elicit evidence of learning	(3) Providing feedback that moves learners forward
Peer	Understanding and sharing learning intentions and criteria for success	(4) Activating students as instructional resources for one another	
Learner	Understanding learning intentions and criteria for success	(5) Activating students as the owners of their own learning	

**Table 1: Framework relating strategies of formative assessment to instructional processes (Wiliam & Thompson, 2008, p.63)**

The five strategies can be explained in the following way: Teachers are responsible for “engineering” effective learning environment since their role is only to scaffold learning. They provide this environment by generating productive discussion setting, asking deep questions and monitoring the learning process (O'Connor, 2002). Learners’ active participation is associated with challenging tasks and providing feedback for these tasks which assist students’ learning (Black & Wiliam, 1998). Since students need to understand the learning intentions and standards for which they will be assessed, clarifying and sharing learning intentions and success criteria with the students is also very important (Wiliam, 2007). Additionally, activating learners as instructional resources for one another and for themselves is essential for any assessment approach. In this way, learners can improve the ability to judge and decide about what to do next (Berry, 2005).

Formative assessment is a significant process that can be followed in order to have information about students’ progress. Hence, each step of the assessment needs to be decided and planned continuously (Heritage, 2007). Since, as future teachers, preservice teachers need to be qualified in planning and implementing formative assessment practices, teacher education programs play a crucial role in raising the awareness of preservice teachers about the significance of formative assessment and in teaching them how to plan and use it in their classes effectively.

The current study aimed to investigate preservice mathematics teachers’ (PST) purposes in preparing the assessment part, and their views and suggestions about the assessment part of the lesson plan. Aforementioned framework guided the researchers in the process of both preparation of the task used for as the data collection instrument and analysis the participants’ responses.

### **Methodology**

In this study, basic qualitative research method was employed in order to reveal PSTs’ views about planning the assessment part of the given lesson plan.

### **Context and participants**

The study was conducted in a four-year middle grades mathematics teacher education program (MTE). The program offers mainly mathematics and introductory education courses in the first two years and mathematics teaching courses in third and fourth years. A total of 27 senior PSTs who were

enrolled in MTE program participated in the study. They were selected among PSTs who completed the Methods of Mathematics Teaching and Measurement and Assessment courses, and who were taking the Practice Teaching course. The first data collection instrument, Incomplete and Improper Lesson Plan Task (LPT) was implemented to 27 PSTs. Then, 11 PSTs were selected for the interviews with respect to their diverse answers to the questions in the given task.

### Instruments and data collection

Data were collected by LPT and a semi-structured interview protocol. LPT consisted of incomplete and improper lesson plan with three 6<sup>th</sup> grade objectives on equivalent fractions and a case where PSTs assumed to be in-service mathematics teachers implementing this lesson plan. A basic lesson plan template which addressed the lesson in beginning, middle, end, and assessment parts was used because participants were familiar with the template in the MTE program courses. The plan was incomplete because there were not any expression implying any formative assessment strategy. PSTs were expected to realize the nonexistence of these strategies and integrate one or more strategies in the given lesson plan. The plan was improper also because the first objective was unmeasurable and unobservable, there were inconsistencies between objectives and questions in the assessment part, there was no rubric for fair scoring, and questions had a weak structure in the assessment part. Certain multiple choice questions were selected because PSTs were expected to realize that feedback gathered through these questions about students' learning was limited. PSTs were anticipated to notice and eliminate these reasons of improperness of the lesson plan. Figure 1 presents the lesson objectives and 4 yes-no questions in the assessment part of the lesson plan.

<p><u>Objectives:</u></p> <ul style="list-style-type: none"> <li>• Students should be able to develop a conceptual understanding of equivalent fractions.</li> <li>• Students should be able to explore the same quantity can have different fractional names.</li> <li>• Students should be able to look for patterns in equivalent fraction.</li> </ul> <p><u>Assessment:</u></p> <p>For each equivalence please write T in the given blank if it is correct; write F if it is false.</p> <div style="display: flex; justify-content: space-around; align-items: flex-end; padding-top: 10px;"> <div style="text-align: center;"> <math>\frac{3}{4} = \frac{6}{8}</math>              A) ( )           </div> <div style="text-align: center;"> <math>\frac{46}{14} = \frac{23}{6}</math>              B) ( )           </div> <div style="text-align: center;"> <math>\frac{5}{12} = \frac{20}{36}</math>              C) ( )           </div> <div style="text-align: center;"> <math>\frac{37}{74} = \frac{1}{2}</math>              D) ( )           </div> </div>			
--	--	--	--

**Figure 1: Objectives and assessment part of the incomplete and improper lesson plan**

LPT asked PSTs to write the strengths and weaknesses of the assessment part, and give suggestions about how to improve it with regard to weaknesses they found. During the interview, PSTs commented on how they would have designed the beginning, middle, end, and assessment parts if they had prepared the given lesson plan. They responded the questions by assuming to be in a hypothetical classroom environment; they did not implement the lesson plan in their teaching. The current research report, a part of a broader study which addressed all indicated features, focused only on PSTs' views about the assessment part of the given lesson plan.

LPT was implemented in a course where PSTs attended after necessary permissions were granted. PSTs were asked if they would like to volunteer to participate in the study and those who volunteered completed the task in about 50 minutes. After one-month of data analysis period, 11 PSTs were

selected to be interviewed in one-on-one setting. They all participated in the interviews voluntarily. Interviews took 30-80 minutes and were audio-recorded with the permission of the participants. PSTs' answers to the task were reminded with the purpose of eliciting whether they wrote the responses for formative assessment purpose or not when they did not advert to the same issues during the interview. Data were analysed through content analysis. PSTs' expressions which imply the action of gathering evidence about students' current knowledge and their own competence in teaching were grouped under the "providing feedback that moves learners forward" subdomain of the formative assessment framework (Wiliam & Thompson, 2008). PSTs' purposes in preparing this part were examined under the categories of "feedback for teacher" and "feedback for students" (Sadler, 1989). One researcher, other than the authors, examined the data and they agreed that the categorization was conceivable regarding to the data. Preservice teachers' intended further actions, views and suggestions about the assessment part were also reported.

## Findings

### Feedback for teacher and students

Findings of the interviews indicated that all interview participants agreed that the assessment part provided feedback for the teacher. PSTs mainly stated that they would perform this part to gather feedback about students' level of knowledge and their own competence in teaching. PST4 emphasized both aspects as in the following conversation:

Researcher (R): What is your purpose in preparing the assessment part of the lesson plan?

PST4: In order to learn about whether I could teach the concept or not. Did I have students achieve the objectives? There can be some points that the students did not get. I prepare [the assessment part] in order to determine these points [as well].

PST13 also underlined the necessity of providing feedback about students' learning as follows:

I think the [assessment] part is necessary in order to provide feedback about what the students have learnt or have not learnt... I think using exit card is very beneficial in order to understand whether the students have learnt the concept or not.

Only one participant mentioned that this part also provided feedback to the students about their learning:

PST23: Definitely I will not grade students' work. Here, grading is so ridiculous. I check whether they understood the concept or not. I think it should provide me feedback.

R: Why do you not grade their works?

PST23: We implement it in last five minutes [of the lesson]. The students have learnt the concept in that lesson. Their knowledge is so fresh. I think there is no need to grade the exit card if the students have a perception that the assessment part serves for testing themselves. The teacher will use it to learn about what the students understand (and) also the students will realize whether they understand the concept or not through the assessment part.

Remaining ten interview participants also preferred not to grade students' responses to the questions in the assessment part since they thought that this part would be used to check students' current level

of understanding of the concept or to have them comprehend the concept better.

All interview participants expressed that feedback they obtained by means of the assessment part would affect their further instructional plans. They indicated that they would make some instructional changes according to the feedback about students' needs. They mostly preferred changing the next class's activities or teach the lesson again. However, some of the participants claimed that they probably would not have time to repeat the lesson since they need to keep the pace of the national curriculum:

I would decide what to do according to the answers of the majority of the class. If the students made major errors, I would think that I was responsible for their mistakes. Maybe, I would repeat the lesson or I would probably teach another lesson in which I could emphasize the points that the students misunderstood. However, I do not know whether I have time to do it when I would be a teacher because there is a curriculum [need to follow]. These plans are only utopia. (PST15)

### **PSTs' views and suggestions about the assessment part of the lesson plan**

In both task implementation and the interview, PSTs expressed similar ideas with different frequencies. In the LPT implementation, more than half of the PSTs commented on the strength of the assessment part and mainly emphasized the consistency of the questions in the assessment part with the lesson content (n=5). PST12 expressed that "it is a good activity [since] the students can implement what they have learnt into the assessment part." Two PSTs claimed that the assessment part was strong since "it is efficient in assessing whether the students understand the second objective" (PST8) and "the indicated questions can measure easily whether the students understand the relationship between two equivalent fractions." (PST15). PST11 and PST27 reflected on different features of the questions. They indicated that this part was useful since there were questions related to both enlargement and simplification of the fractions. On the other hand, there was not any coherence within other PSTs' expressions. For instance, PST9 stated that she liked the questions in the assessment part because "they have uncontroversial and single answer" whereas according to PST23, "the questions do not have specific answer and they prompt students to think."

Only four interview participants mentioned the strength of the assessment part by commenting on only the specific options. Two participants stated that they would keep the option c since it could assist to detect some misconceptions or errors. PST17 expressed that she liked the questions in the assessment part since they included numbers such as 37 and 46 which were not much used.

Regarding to the weaknesses of assessment part, in both LPT implementation and interviews, PSTs addressed the questions in the assessment part as insufficient in number and diversity. In LPT implementation, 6 among 27 PSTs commented on and suggested ways to improve such weaknesses:

There is only one type of question. There should be (questions) which are supported by the shapes. Not only true-false questions, but also some interpretation questions and the questions that the students can write equivalence of the indicated fractions should be added. (PST21)

According to five participants, assessment part was weak since it included questions that students had fifty per cent chance to answer them correctly. They recommended to add different types of questions to reduce students' guessing. For instance, PST19 suggested to "add some open ended questions in order to see how much the students understand the concept in an easy and reliable way." Adding verbal and daily life questions, and questions with shapes was also recommended.

During the interview, PSTs mostly underlined similar weaknesses of the assessment part and proposed suggestions to deal with them as they did in the task implementation:

I think, whether the students understand the concept or not is not assessed exactly here because there is fifty per cent chance. If I write all of them true, I will answer one or two of them correctly. (PST18)

To overcome this weakness, PST18 also recommended to add different type of question as:

If I were... I would give them and want them write an equivalent fraction to this one rather than asking true-false [questions]. Even, I can ask the same questions with the one that I asked in the beginning part of the lesson. I change its numbers. "If such a number of pieces of cake were eaten, how many pieces were eaten?" and "Is there another fraction which represents the (same) amount?"

On the other hand, none of the participants mentioned the inclusion of the rubric for fair scoring which was one of the reasons for the improperness of the given lesson plan.

## Discussion and conclusion

Findings of the study showed that all PSTs planned to prepare assessment part of the lesson plan in order to gain feedback about students' current knowledge level and their own competence in teaching, all of which related to teacher actions. Only one interview participant stated that assessment part would also provide feedback to the students about their own learning. PSTs mainly emphasized the kind of feedback gathered by the teachers although they were expected to comment on that students can also obtain feedback about their own learning and needs through the assessment. This tendency towards teacher-centred assessment was the action which provided feedback only to the teacher in order to determine the problematic areas that required more emphasis and practice (Antoniou & James, 2014). It might be due to PSTs' views that the students may not benefit from the assessment part to determine their needs and take necessary actions to meet these needs.

PSTs were against grading the assessment part of the lesson plan since their purpose in the preparation of the assessment part was only to check students' learning or to have them understand the concept well. This finding was congruent with the idea that the main purpose of utilizing formative assessment was to facilitate and improve students' learning instead of simply assigning a grade (Marshall & Drummond, 2006). When it is considered that the formative assessment serves its purpose when the teacher avoids grading students' performance (Elawar & Corno, 1985), it might be deduced that the PSTs planned to use this part for formative purpose.

PSTs indicated that feedback gathered from the assessment part assisted them to adjust their further instructional plans according to students' needs. This finding might indicate that PSTs used the assessment part of the given lesson plan formatively because they would make some changes in the next class's instruction and planned further instructional steps (O'Connor, 2002). PSTs generally preferred to repeat the previous lesson or teach another lesson by changing the existing activity in case the students had difficulty in learning the content. However, some PSTs indicated that they probably would not have such time since they needed to keep track of the national curriculum. Similar types of adjustments and lack of time issues were also reported previously (Antoniou & James, 2014). Although all PSTs talked about teachers' further actions, they did not mention students' possible further actions to enhance their own learning. The reason might be PSTs' disposition towards teacher-

centred assessment. They might not consider students' further actions because they disregarded the fact that the students could also obtain feedback through assessment part to monitor their progress and enhance their learning.

In both task implementation and interview, majority of the PSTs were able to detect the improperness of the assessment part resulted from the structure of the questions. They emphasized that they could not know whether students had learned the concept or not through these questions since students had fifty per cent chance to answer them correctly. PSTs generally recommended adding open-ended questions to eliminate this weakness. Being able to detect improperness might be due to their awareness of the requirement of the alignment between objectives and the questions in the assessment part. They might have suggested adding different questions to eliminate the inconsistency between the objectives and questions. PSTs also suggested increasing the number of the questions in the assessment part. The reason for this might be attributed to the demand of introducing students with wide range of questions to prepare them for high-stake national examinations, as reported for beginning Turkish middle grades mathematics teachers (Haser, 2006).

Due to the fact that the measurement and assessment course stresses mainly the assessment tools rather than focusing on the whole picture of the lesson plan with regard to the utilization of the formative assessment strategies, PSTs might have had difficulty in examining and integrating the intended formative assessment strategies in the lesson plan. Therefore, courses on assessment can be offered with the methods of mathematics teaching courses or lesson contents of these courses can be associated with each other so that PSTs can integrate what they have learnt about assessment into the lesson plans they prepared in the methods courses. Hence, they can have a chance to look at the whole picture of the lesson plans in terms of employing the formative assessment practices.

*Comparative studies on pen-and-paper and computer-based test principally focus on statistical analysis of students' performances. In educational assessment, comparing students' performance (in terms of right or wrong results) does not imply a comparison between the solving processes followed by students. In this paper we present an example of task analysis that allows to highlight how students' solving processes could change in switching from paper to computer format and how these changes could be affected by the use of one environment rather than another. The aim of our study lies in identifying possible consequences that specific changes in task formulation have, in terms of students' solution processes.*

**Keywords:** *Computer based assessment, comparative study, task analysis.*

## Introduction

Computer-based assessment is an actual issue. The increasing use of tests administered in the digital environment allows research in mathematics education to develop new fields of study. On the one hand research in computer based tests concerns the validity of these tests, on the other it focuses on their comparability with existing paper tests. In these two perspectives, large-scale surveys were conducted; they involve students from different educational levels, from primary to secondary instruction (Dragow, 2015; Way, Davis, & Fitzpatrick, 2005).

Computer-based tests mainly involve institutions in large scale assessment (OECD-PISA, OECD-PIAAC, NAEP, ...); one of the major interests of these institutions is to anchor every new test with ones from the previous years rather the diachronic study of students' performances in the different surveys. For this reason, some studies focus on the test-mode effect comparing performances of students taking on computer and paper-based tests.

Literature on these topics shows very mixed results; there is empirical evidence that paper-based and computer-based tests will not return the same results. On the one hand, some studies show equivalence in students' performances; on the other hand, different researches highlight a significant discrepancy on scores. For example, Kim and Huynh (2007), as many other researchers (e.g. Kapoor & Welch, 2011; Lottridge et al., 2008), show that there is no statistical evidence suggesting that the administration modality changes the coherence and consistency of computer-based tests. On the contrary Clariana and Wallace (2002) point out to empirical evidence suggesting that students involved in paper-based and digital-based tests will not obtain the same results. At a more general level, in a meta-analysis of computer versus paper-based cognitive ability tests, Mead and Dragow (1993) found that on average, paper-based test scores were very slightly higher than computer-based test scores.

The main characteristic of all these studies, which involve comparative analysis of outcomes using quantitative and statistical methods, is that they show the comparability between tests administered

on paper and pencil and in a computer environment. Such comparison is developed contrasting students' performances and it is grounded in the implicit assumption that students who achieve the same performance implement the same solution processes. Threlfall et al. (2007) propose a more accurate analysis; they focus on students' solution processes and explore the effect on students' attitudes when they are involved in paper and pencil tests migrated into a digital environment. As shown by Threlfall et al., in some cases changing to a different environment seems to make little differences in the solution process. However, for some particular tasks the computer environment deeply affects how students approach the tasks. An important issue arises: task comparability cannot be measured only in terms of students' outcomes but it is also established by the comparison between the solving strategies that they use.

These diversified results suggest that task comparability needs a deeper analysis. In particular, the comparison between students implies the problem of how and when two tasks could be considered equivalent. Ripley (2009) proposes a possible solution to this question. He distinguishes two main approaches to the use of digital devices in order to enhance assessment: *migratory* and *transformative* approach. He defines the migratory approach to be the use of technological support as a tool of administration; it consists in a transition in digital format of tasks conceived for paper format. The transformative approach involves the transformation of original paper tests integrating new technological devices which support interactive tools (graphs, applets, ...) that enhance new affordances. There are no specific studies comparing these two approaches; a possible reasonable hypothesis is that migratory could be a suitable approach to construct what in the literature is called an equivalent task. By definition, the migratory approach has the aim to maintain most of the task features unvaried in the translation process but this transition to a new environment cannot be completely unbiased. The migration from an environment to another one is not neutral because it depends on intrinsic properties of the environments. The adoption of migratory approaches is undervalued; the assumption that the translation process causes few changes on the task formulation and that these changes do not cause significant alterations on the solution processes is not to be neglected.

The purpose of this study is to examine whether the migratory approach may have effects on students' solving processes. In this perspective, the issue of test validity arises; in other words, does the use of a migratory approach maintain the validity of the original test? Below, we present part of a wider study that has the aim to analyse possible changes in students' solution procedures related to the migration from a pen and paper to a digital environment. In Ripley's words, we consider tasks that could be defined migratory or other authors could call equivalent tasks. In particular, we present one example of analysis that compares a task in his migration from paper to computer, highlighting the impact that the changes could have on students' solutions.

### **Word problem in a migration process**

In many tests, especially in large scale assessment, knowledge and skills are assessed through units consisting of a stimulus (e.g. text, table, chart, figures, etc.) followed by a certain number of tasks associated with this common stimulus. These particular features connect these kinds of tasks with word problems. In a wide perspective, the term *mathematical word problem* refers to any mathematical task where significant background information is presented through a verbal text rather

than in mathematical notation. As word problems often involve a narrative of some sort, they are occasionally also referred to as *story problems* (Verschaffel, Greer, & De Corte, 2000).

Mathematical word problems have an important role in teaching; for many decades researchers in mathematics education have focused on the possible difficulties that students encounter when they solve them. Verschaffel et al. (2000) highlight the fact that many of the difficulties met by students lie in the preliminary phase of understanding the problem situation. Interpreting students' attitudes in solving word problems is complex because it involves multiple interacting factors, both cognitive and metacognitive: stereotypes of standard problems, implicit and explicit rules that regulate mathematical activity, students' beliefs, etc. (Verschaffel, Greer, & De Corte, 2000).

Considering word problem texts (in particular, its formulation features) introduces the important issue of *representation*. Goldin and Kaput (1996) describe two distinct meanings of the term *representation*. On the one hand, the *external representations* refer to "physically embodied, observable configurations such as words, graphs, pictures, equations, or computer microworlds" (ibid., 400); on the other hand, the *internal representations* concern "possible mental configurations of individuals, such as learners or problem solvers" (ibid., 399). In the case of word problems, the solver interacts with the *external representation* presented and produces a personal *internal representation* linked with the one that she already has. Obviously, being internal, such configurations are not directly observable but they could be inferred through the solution process that the solver employs. For this reason it is possible to confirm that a change in the *external representation* could influence the construction of the internal representation and so the adoption of the solving process. Therefore, it is possible to suppose that the formulation of mathematical word problem influences both cognitive and metacognitive factors that are involved in word problem solution. Goldin (1982) highlights that small differences in some features of word problems can deeply affect the process of solution. In particular, Mayer (1982) and later De Corte & Verschaffel (1985) observe that the difficulties noticed within problem solving activities may come from an inadequate interpretation of the text.

Thus, in the perspective of comparison, it is necessary to analyse the differences between tasks to determine the possible differences that occur in students' solution processes. Identifying possible changes in a mathematical word problem requires to consider many text features. For this reason, the task is simplified by dividing the word problem into simpler elements. Gerofsky (1996) describes word problems in terms of three main components: the *set-up component* which establishes the characters and location of the story; the *information component* which encompasses the information needed to solve the problem; and finally, the *question component* which expresses the request and focuses on goal and aim.

Our purpose is to analyse tasks through specific variables that might influence the behaviour of students in the solving process. Obviously, checking these differences is a general issue that could be presented whether or not there is a migration process in a new environment; possible changes could happen even just in the paper environment.

### **Analyses of a migrated word problem**

We present the analysis of one of the items presented in the Draft 2015 PISA Mathematics framework (OECD, 2013). Figures 1 and 2 show the two versions of the famous task: "Walking", administered

in PISA 2003 survey. The text of the item has not changed; therefore, narrative or linguistic differences are not recognized in the *set-up* component.

**WALKING**

The picture shows the footprints of a man walking. The pacelength  $P$  is the distance between the rear of two consecutive footprints.

For men, the formula  $\frac{n}{P} = 140$  gives an approximate relationship between  $n$  and  $P$  where  
 $n$  = number of steps per minute, and  
 $P$  = pacelength in metres.

**Question 1:**  
 If the formula applies to Heiko's walking and Heiko takes 70 steps per minute, what is Heiko's pacelength? Show your work.

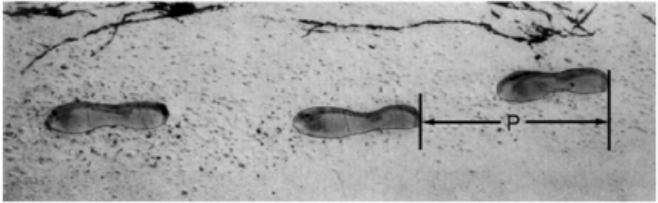

Figure 1: "Walking" paper version, administered in PISA 2003 survey

**PISA 2015**

**Walking**  
 Question 1/2

Refer to the information about measuring a person's walking pacelength. Type your answer to the question below.

If the formula applies to Heiko's walking and Heiko takes 70 steps per minute, what is Heiko's pacelength? Show your work.

The picture shows the footprints of a man walking. The pacelength  $P$  is the distance between the rear of two consecutive footprints.

For men, the formula,  $\frac{n}{P} = 140$ , gives an approximate relationship between  $n$  and  $P$  where,  
 $n$  = number of steps per minute, and  
 $P$  = pacelength in metres.

Figure 2: "Walking" computer version, shown in PISA 2015 Framework Draft

First of all, there is a difference in the editing of the text. In the paper version the task is presented in a compact way: *set-up* and *information* components are given in the same text and the *question* is presented under this text. In the digital format, the task is divided into two main sections. On the right there are the *set-up* and *information* components: they consist of an image and a description of the situation, both in words and algebraic formulas. On the left there is the question. The difference in editing seems to complicate the task; in the digital format, the text is presented in two separate columns. Therefore, the change of the question position could create variances in solution processes: the solver has to coordinate the interpretations of the different parts in which the text is divided. In other cases this change could affect the solver's comprehension. For instance, Thevenot et al. (2007) show that putting the question before a word problem (rather than classically presenting it at the end) conditions problem solution in young students and in particular it facilitates students in engaging a correct solution process. In Fig 2, the question is presented in the bottom-left of the screen; in this case the solver probably reads the question before reading the *set-up* and *information* components.

According to Thevenot et al, this fact suggests that in the digital format the interpretation of *set-up* and *information* components could be affected by the previous reading of the question.

Concerning the component *question*, there is another notable difference. In the digital format (Fig. 2), the first part of the *question* text shows the instructions for answering to the task ("Type ... below") and how to coordinate the information presented in the context ("Refer to ... pancelength"). This aspect enriches the *question* and the length of the text that students have to comprehend and interpret (in the paper version there is not any kind of instruction).

The test item format is changed; a text box in the digital version replaces the free space presented in the paper. The test item format has a strong impact on students' solution process. Kazemi (2001) investigates children's mathematical performance on test items focussing on the typology of the questions. In his study, Kazemi uses multiple-choice questions and juxtaposes them to other open-ended problems. He highlights that the typology of questions affects students' thinking in designing and interpreting problems. This impact is emphasized when there is a change of environment and so a change of tools available to the solver. Concerning computer and paper and pencil based tests, Russell and Haney (1997) describe a comparative study in terms of students' performances. They show that there are differences in performance related to the type of test item formats; substantial changes are not found in the case of tasks with multiple choice questions but there are relevant differences in the case of open response items. Moreover, assuming that the student is familiar with the writing tools available (for example the keyboard) it is reasonable to suppose that this change would not result in significant differences in the solution process. However, in using the free space in paper format, the solver has a different freedom of expression with respect to the case of the text box: in paper and pencil, the solver can produce sketches, calculate and write text both in natural and in symbolic language. These actions are not allowed in a simple text box in which one can only enter the characters on the keyboard or otherwise perform the actions allowed by the available writing tool, depending on the software used.

Finally, in both tasks the same picture is presented; nevertheless, it is possible to notice that in the digital version the picture is presented on the screen with all the strengths and limitations of the software that supports it. For example, it might be difficult (or impossible) to analyse the image through common and simple manipulation action such as turning the paper, complete the picture by drawing lines, highlight points, etc.; these actions are possible only in paper and pencil environment.

## Conclusion

In the previous example, the migration process could at first appear accurate but a deep analysis shows the opposite. At a first glance, the highlighted little differences might appear superfluous; however they are crucial to analyse and interpret students' behaviour in the solving process. The literature described in the first part of the paper indicates that each difference observed in the example may affect the solver. For instance, the change in the task editing could simplify the text comprehension if it is presented in a linear way; on the contrary, the reading could be difficult if the verbal description is fragmented in several parts. Furthermore, the position of the *question* may encourage the solver to develop a correct solution process or it could complicate the *set-up* comprehension because the solver has to coordinate its interpretation with the information presented in the text components. These little differences hide important consequences for assessment, especially if the purpose of the migration process is to ensure continuity between the paper and the

computer administration. The comparison studies presented in the literature assume that the tasks administered in the two environments are equivalent. However, our analysis shows that this starting assumption should be changed. The equivalence between performances (in terms of right or wrong results) does not imply an equivalence between the processes adopted by the students. Therefore, the analysis of the results collected in the two environments probably is not equivalent in terms of educational assessment. The answers produced by students in the digital environment seem hardly comparable with what they do on paper. Thus, there is a substantial difference in terms of the assessment; it cannot be ignored especially by national or international large scale assessment.

In addition, the change in type of test item format is crucial because it strictly depends on the intrinsic feature of the environment and on the familiarity that the solver has with the tool available. We recall also that there are cases where it is impossible to translate a task from paper to digital format through the migratory approach; for example, the tasks that require the use of physical tools and measuring instruments as ruler, compass, or other. A special case is the one of items that have the goal of assessing students' drawing abilities. In this case, the item may request to draw a figure starting from a given one, or from given measurement, or from written verbal instructions. In these cases, it is possible to introduce an ad hoc software or applet that simulates the use of drawing tools. Moreover, the issue of students' familiarity with these software or applets arises (Bennett, Persky, Weiss, & Jenkins, 2010). In the case of lack of familiarity with the use of the instrument, the digital device could be largely useless; students that use digital tools may be disadvantaged comparing them to students that use paper and pencil and physical tools. This example highlights a very serious and complex issue. Further research is needed to define criteria of control that allow to check and to compare all the little differences that occur in the migration process.

In our wider study we define a specific instrument to monitor such differences. In particular, we identify specific variables that might influence the students' behaviour in solving a certain task. We organize such variables into a table that we call *comparison tool*. Such tool is constituted by a system of indices related to the structure of word problems described before. In particular, we identify five different indices that represent possible changes that may occur in the migration process:

- **Story** refers to the *narrative dimension* (Zan, 2011) of the task (for example: characters, background, narration, etc);
- **Linguistic form** that indicates also the number and the length of sentences (for example: syntactic, organization of the sentence, lexical, etc);
- **Type of item formats** concerns the types of possible responses (for example: the question has constructed-response, selected-response, etc);
- **Format and editing** refers to layout features and position of the different components (for example: paragraphs, font, underlines, spaces, etc);
- **Data representation** is related to semiotic register used for representing information (Duval, 1993) (for example: verbal register, iconic register, math register, etc).

Each index is related with studies concerning word problem formulation and its impact on students' solution process. For example, many authors show that the narrative dimension attached to mathematical tasks is relevant to students in terms of the their availability to solve the task (Sowder, 1989). Other studies draw attention to the importance of language in student performance on

assessments (Abedi, Lord, & Plummer, 1995). Moreover, many authors pay attention to the role of representation in the teaching and learning process (Duval, 1993).

Considering the example above, the comparison tool highlights differences related to three of the five indices. In particular, tasks are different in terms of *linguistic form*, *type of item format* and *format and editing*. In fact, in the digital version there are more sentences than in the paper task. Furthermore, even if both questions are open-ended, in the computer task there is the restriction caused by the text box where type. Finally, there is a strong difference in editing: in the two task versions, the components are presented in different parts of the page/screen. The comparison tool highlights a certain number of differences; such differences could confirm our hypothesis in terms of possible differences in students' behaviour.

# **Teddy Bear Preschool Mathematics Assessment: Validation of a constructivist game- and story-based measure**

Sally Moomaw<sup>1</sup>

<sup>1</sup>University of Cincinnati, Cincinnati, Ohio, USA; [sally.moomaw@uc.edu](mailto:sally.moomaw@uc.edu)

*This research evaluated an interactive story- and game-based measure of the level of mathematical development in preschool children. Nine measurable learning trajectories identified by previous researchers—quantification, counting, set comparison, numerals, number line, positional terms, shapes, addition/subtraction, and patterning—were assessed through a series of games played by assessor and child to re-enact the story of teddy bears on a picnic. This format was selected because it engages young children, connects to constructivist curriculum and materials, and extends previous research by the author. Confirmatory factor analysis indicated that the nine developmental trajectories were strong and significant contributors to the latent construct of level of mathematical development. Results from test-retest and criterion comparisons indicated that the assessment tool was a valid and reliable measure of mathematical development for this sample.*

*Keywords: Curriculum based assessment, number concepts, preschool tests, child development, developmentally appropriate practices.*

## **Purpose**

The purpose of this research was to create and validate the Teddy Bear Preschool Mathematics Assessment (TBPMA), a play-based, constructivist measure, as a novel alternative to traditional quantitative assessments. The story- and game-based framework, in which the assessor participates with the child, was selected because it engages young children, connects to constructivist curriculum and materials frequently used in preschool classrooms (Moomaw & Hieronymus, 2011), and provides both formative and summative assessments. The hypothesis was that nine measurable variables based on seminal research—(1) quantification level, (2) counting, (3) set comparison, (4) numeral recognition and understanding, (5) movement along a number line, (6) emergent addition/subtraction, (7) understanding positional terms, (8) shape recognition, and (9) patterning—would make a significant contribution to the latent construct of mathematical development.

## **Theoretical framework**

Assessment of preschool children has grown rapidly during the 21st century (Wortham, 2012). Assessment is used to monitor children's development, make educational decisions, and evaluate programs. However, valid and reliable assessment of young children is often difficult. If children are not interested in the assessment, they quickly lose attention and refuse to participate. Also, many standardized assessments do not provide information that directly relates to the curriculum. This is frustrating for teachers, who need formative assessments in order to guide their planning and interactions with children. Therefore, assessments that are aligned to curriculum and can inform planning and instructional decisions (Stecker, Fuchs, & Fuchs, 2005) are of particular interest.

Assessment of early math development is important; research has shown that children develop substantial math knowledge prior to first grade (Clements & Sarama, 2007). Early number sense

development is a strong predictor of later mathematics achievement (Duncan et al., 2007); however, a substantial achievement gap exists between low- and middle-income children that persists as they advance in school (Jordan, Kaplan, Olah, & Lucuniak, 2006).

The theoretical framework of this research is constructivist; children are active creators of knowledge rather than passive recipients (Piaget, 1952). An instructional corollary is that students require a context that allows them to formulate or discover important relationships (Geary, 2003). For young children, play is an important mode for learning that is considered essential for cognitive development (Frost, Wortham, & Reifel, 2008).

### **Learning trajectories in early mathematical development**

Formation of content knowledge follows a developmental progression that reflects progressively higher levels of thinking (Piaget, 1952). Understanding of developmental progressions in the mathematical thinking of young children is essential for effective teaching because it guides teachers in the selection of appropriate curriculum and in effective modeling and dialogue with children. These documented developmental progressions are now referred to as learning trajectories, which serve as a bridge between theory and practice (Sarama & Clements, 2007).

The learning trajectory for quantification (Kamii, 1982; Piaget, 1952) shows a progression in young children from visual perception to more logical forms of reasoning when determining quantity and comparing sets of objects. The earliest level is referred to as *global*, in which children make a visual or tactile approximation of quantity, perhaps by taking a small or large handful of objects to represent a given amount. At the *one-to-one correspondence* level, children realize they can accurately represent a given quantity by taking one object for each item in the original group and aligning them. This important development indicates that children are now able to focus on the units in a set rather than just the global parameters. Eventually, children realize that they can *count* to determine the number of objects in a group or to create an equivalent set. Rather than simply counting because an adult tells them to, children at this level select a counting strategy because they understand that the last number they count represents the total.

Counting is an important mathematical tool for children. In their seminal research, Gelman and Gallistel (1978) developed five principles that children must understand in order to successfully use counting to quantify. Of these principles, the first three are designated as “how to count” and are likely to be developed by children in the 3- to 5-year age range. The *stable order* principle indicates that children understand that they must say the counting words in the correct order. Application of the *one-to-one* principle shows that children know they should count each object one and only one time. In practice, many (if not most) young children tend to recount objects or count some more than once, particularly as the number of objects increases. The *cardinality* principle means that children understand that when they count objects, the last number word they use refers to the total amount, not just one item. These principles do not necessarily develop in a prescribed order, and accuracy is variable throughout the early years. It is the ability to apply the principles with growing accuracy when counting increasingly large sets that constitutes a learning trajectory.

Both researchers and educators have documented that children can name numerals before they can use them to represent a specific quantity. In particular, Kato, Kamii, Ozaki, and Nagahiro (2002)

have shown a disconnect between children's ability to name numerals and their ability to use them to represent quantities.

Research by Ramani and Siegler (2008) suggests that linear number board games enhance young children's understanding of number. However, research by Moomaw (2015) indicates that there is a developmental trajectory in which children are first able to represent quantities on a grid, or bingo-type board, followed by moving a specific amount along a straight path, or incipient number line. Representing quantities by moving along a longer, curved path is more advanced.

Spatial reasoning is an important component of geometry. Bowerman (1996) has demonstrated that the order in which children learn spatial terms is consistent across languages, thus forming a learning trajectory. Terms that relate to an object that is in direct contact with another ("in," "on," and "under") are the first to develop, along with the movement terms "up" and "down." Words of proximity, such as "beside" and "next to," develop next. These are followed by terms related to position but not necessarily close proximity ("in front of," "in back of," or "behind"). Directional words, such as "right" and "left," are often not learned until first or second grade.

Seminal work by van Hiele (1999) suggests a progression, or learning trajectory, of four levels of geometric understanding, of which the first two relate directly to young children. At the first level, *visual*, children judge a figure according to its appearance. They often have a prototype in mind, so they may identify only equilateral triangles as "triangles." At the second level, *descriptive* or *analytic*, children begin to use language to describe properties of shapes. For example, they may indicate that a figure is a triangle because it has three sides.

Research has established a trajectory for early addition (Baroody & Tiilikainen, 2003). Children start by counting individual sets of objects. Next, they realize that they can count the objects in both sets all together. Eventually, children begin to count forward from the cardinal value of one of the sets; they also begin to remember particular combinations, such as doubles.

Patterning is considered a foundational component of early mathematical thinking by the National Council of Teachers of Mathematics (USA). However, there is insufficient research in this area to establish a developmental learning trajectory.

### **Development of the Teddy Bear Preschool Mathematics Assessment**

Conception of the TBPMA evolved from the author's 25 years of experience teaching preschool and kindergarten children. During this time, considerable contributions to the understanding of how children develop mathematical reasoning were made by theorists and researchers. That information was shared with interested teachers by Professor Anne Dorsey, then Director of the Arlitt Child Development Center at the University of Cincinnati. With her input, teachers began to redesign their preschool math curriculum to focus, in part, on teacher-created math games. Children's responses to these games were carefully observed, and changes to the curriculum were made accordingly. Eventually, this game- and play-based curriculum, which extended to all areas of the classroom, was published in a series of books for teachers (Moomaw & Hieronymus, 2011).

For her doctoral research, the author developed and validated an assessment of number sense in preschool children that was essentially a quantification game played between assessor and child. It

showed that this interactive form of assessment could be reliably quantified. The TBPMA extends that research to more completely measure number and operations as well as geometry.

## Methods

The TBPMA consists of a series of games that allow children to re-enact the story of teddy bears on a picnic. The game board depicts a park, including picnic blanket, wading pool, path, small climber, and merry-go-round (Figure 1). Assessor and child take turns drawing cards arranged in a prescribed order. Teddy bear counters are used throughout the game. Although the assessor participates in the game, assessor role and comments are clearly scripted to ensure procedural reliability.

**Figure 1: Game Board for the Teddy Bear Preschool Math Assessment**

The scales quantification, counting, and set comparison are measured as assessor and child draw cards with 1–8 dots to determine how many bears to place on their picnic blankets. One point is awarded for a global strategy, 2 points for one-to-one correspondence, 3 points for counting, and 4 points for counting with accuracy. Following each turn, the assessor asks how many teddy bears are on the child's blanket and scores 1 point for application of each counting principle (stable order, one-to-one correspondence, and cardinality). Next, the assessor asks who has more bears, which elicits set comparison and is scored similarly to quantification. Set sizes increase over subsequent turns.

Recognition and understanding of numerals is assessed when the bears go swimming. Children are scored on whether they recognize numerals 1–8 and can put the corresponding number of bears in the pool. Movement along a number line is measured when children draw cards with dots and attempt to move a corresponding number of spaces along a path. Understanding of spatial terms is assessed as children draw cards that tell them where to place their teddy bear in relation to the climber, as in “Your bear wants to play under the climber.” For assessment of shapes, the bears play on a merry-go-round, which has prototypical and non-prototypical shapes for seats. Scoring is based on shape recognition and the explanation the child gives for determining shape.

The addition/subtraction trajectory is assessed as children draw two cards with dots to determine how many bears to move to the picnic table. They then draw a card that indicates how many bears leave and asks how many are left. Finally, the assessor arranges the bears in an AB and an ABC color pattern for a dance and asks the child to complete the pattern.

## Data sources

A total of 146 children, ages 3 to 5 years, enrolled in childcare centers in a Midwestern USA city, were assessed. Of the sample, 60 (41.1%) were poverty level (determined by voucher participation); 37 (25.3%) were African American or mixed race; 73 (50%) were female; 65 (44.5%) were 3 years old; 63 (43.2%) were age 4; and 18 (12.3%) were age 5. For test-retest comparison, 50 (34.2%) received a second assessment; 38 (26.0%) were administered a criterion measure. Assessors were required to demonstrate reliability by independently scoring assessments conducted by the lead researcher and achieving an inter-scorer reliability of 90% over three successive tests.

## Results

The maximum possible total score on the TBPMA is 118. Among the 146 initial tests, scores ranged from 5 to 112 ( $M=62.44$ ,  $SD=28.01$ ). Assumption checks indicated the total scores were normally distributed. The correlation between child's age in months and total score was  $r=.572$  ( $p=.000$ ).

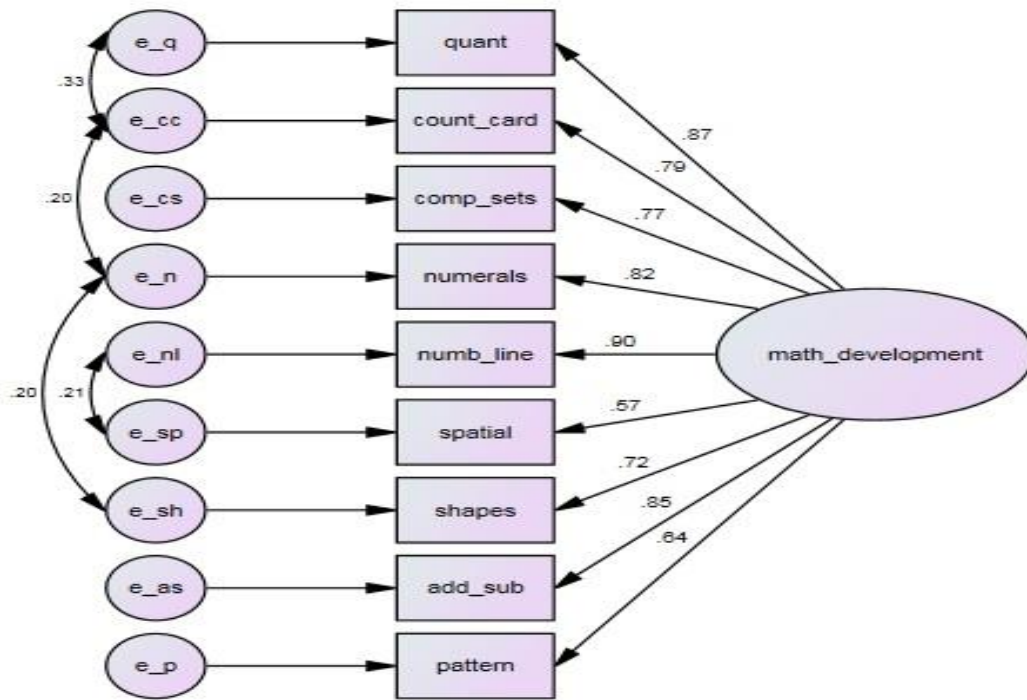

There were two specific questions for the analysis:

1. What is the contribution of each sub-construct to the general construct?
2. What is the technical adequacy of the TBPMA?

Regarding question 1, confirmatory factor analysis (AMOS 22) was used to evaluate the hypothesized model for the TBPMA. Results indicated good model fit:  $\chi^2(23, N=146)=25.297$ ,  $p=.335$ ; NFI=.974; CFI=.998; and RMSEA=.026. All standardized path coefficients were highly significant ( $p<.001$ ), with robust standardized regression weights ranging from .57 to .90 (Figure 2), indicating all scales were strong contributors to the latent variable mathematical development.

For question 2, technical adequacy was assessed through Cronbach's alpha, test-retest reliability, and criterion validity. Cronbach's alpha was .922, indicating high internal consistency.

Test-retest reliability was assessed with paired t-tests on mean differences for the nine scales and total score (Table 1). Differences significant at the .05 level occurred with the addition/subtraction scale, in which the mean retest score was one point higher on the 16 point scale, and with the total TBPMA score, about 2.5 points higher on the 118 point scale. Given that the average time between the initial test and the retest was 24 days, these small increases do not appear to affect the reliability of the TBPMA. Reliability is further confirmed by the highly significant correlations between the initial and retest scores. For all scales and the total score, all correlations were strong, above .50.

**Figure 2: Standardized Path Coefficients for the Confirmatory Factor Analysis for the Teddy Bear Preschool Math Assessment**

Scale	Max score possible	Initial Test		Retest		Difference in means		<i>T</i> test on difference in means		Pearson correlations	
		<i>Mean</i>	<i>SD</i>	<i>Mean</i>	<i>SD</i>	<i>Mean</i>	<i>SD</i>	<i>t</i>	<i>Sig.</i>	<i>r</i>	<i>Sig.</i>
Quantification	20	14.58	4.77	15.04	4.49	0.46	2.42	1.34	.186	.864	.000
Counting/Cardinality	20	12.52	4.84	13.32	4.47	0.80	3.30	1.72	.092	.752	.000
Comparison of Sets	16	7.32	4.30	7.48	4.02	0.16	2.97	0.38	.705	.747	.000
Numerals	9	5.92	3.43	5.90	3.39	-0.02	1.17	-0.12	.904	.941	.000
Number Line	12	7.22	4.86	7.38	5.06	0.16	2.61	0.43	.666	.863	.000
Spatial	6	5.02	0.96	5.18	1.17	0.16	1.02	1.11	.272	.560	.000
Shapes	12	5.96	2.76	5.52	2.87	-0.44	2.44	-1.27	.209	.623	.000
Addition/Subtraction	16	4.72	4.29	5.76	4.78	1.04	3.55	2.07	.043	.698	.000
Patterning	7	2.58	2.98	2.72	2.98	0.14	2.08	0.48	.636	.756	.000
Total	118	65.84	27.30	68.30	27.67	2.46	6.80	2.56	.014	.969	.000

Note: This table uses data from the 50 subjects who were assessed twice.

**Table 1: Test/Retest Reliability: Means, Test of Differences between Means, and Correlations between Means of Initial Test and Retest**

TEMA-3 (Ginsburg & Baroody, 2003), a recognized measure of early mathematical ability, was used to assess criterion validity. The correlation between the total TBPMA score and the TEMA-3 raw scores was high ( $r=.867$ ,  $p=.000$ ), demonstrating criterion validity.

These results indicate that the TBPMA was a valid and reliable measure of mathematical development for this sample.

## Significance

Preschool educators and funding sources recognize the need for accountability and for monitoring children's development. Conversely, they understand that testing is often stressful for children, unreliable, and unrelated to the curriculum. The TBPMA offers a validated approach to quantifiable assessment that is compatible with young children's social and emotional development; all children assessed to date have enjoyed the experience.

The TBPMA is a novel alternative to traditional quantitative assessments. It can provide both formative data for teachers and summative data for program evaluation. Because it assesses multiple domains of mathematics, it can indicate areas of strength within a curriculum and areas that may require more attention. Based on acknowledged developmental trajectories, it informs teachers of the child's current level of thinking so that they can target their interactions to move the child forward. This is the essence of constructivist teaching.

It is natural for educators to focus on material from class or program assessments (i.e., teach to the test). The TBPMA reverses this process. It evaluates the types of experiences and interactions that are highly recommended for preschool classrooms and the areas of mathematics designated as focal points (NCTM, 2006).

# Examining difficulties in initial algebra: Prerequisite and algebra content areas for Irish post-primary students.

Aoife O'Brien<sup>1</sup> and Máire Ní Ríordáin<sup>2</sup>

<sup>1</sup>School of Education, National University of Ireland, Galway; [a.obrien47@nuigalway.ie](mailto:a.obrien47@nuigalway.ie)

<sup>2</sup>School of Education, University College Cork; [maire.niriordain@ucc.ie](mailto:maire.niriordain@ucc.ie)

*This research aims to investigate the algebraic under performance of second year post-primary students in Ireland (approximate age 14 years). To this end a diagnostic test for algebra has been developed to profile and identify students who are struggling with algebra. This paper examines the development of the test, which involved the identification of key mathematical content areas that are critical for success in algebra. Both prerequisite, and algebra content areas are key to a students' success in algebra and how each of these areas contribute to a students' progress with algebra is discussed in this theoretical paper. Test items have been selected and adapted from the literature which are aligned with both the key content areas and the Irish mathematics syllabus at junior cycle, the initial three years of post-primary education in Ireland.*

*Keywords: Algebra, diagnostic test, secondary education.*

## Introduction

This paper reports on the development of a diagnostic test for algebra, designed specifically for second year post-primary students in Ireland. It is noted in the literature that few adequate assessments are available to provide formative information on a students' progress with algebra, but they are essential to allow timely and informed instructional decisions for teachers (Ketterlin-Geller, Gifford, & Perry, 2015). A key outcome of this research will be a validated diagnostic test specifically designed to identify students' conceptual errors when working with algebra and aligned with the Irish post-primary mathematics syllabus. The test can be used by teachers in a normal class period (35-40 minutes as relevant to the Irish context) to help inform their instruction of algebra. This paper focuses on identifying key content areas which are required for success in algebra and accordingly developing a bank of questions to support the development of a diagnostic test.

## Background and rationale

The mathematical deficiencies of students entering third level education in Ireland and internationally is widely reported and commonly referred to as the "Maths Problem" (Treacy & Faulkner, 2015). Over a decade ago it had become apparent that there were issues with the mathematics curriculum at post-primary level in Ireland resulting in radical reform of the syllabi, introduced as "Project Maths" (Treacy & Faulkner, 2015). The vast majority of students study mathematics throughout their time in post-primary education and the syllabus is delivered in five interwoven strands; 1. Probability and Statistics, 2. Trigonometry and Geometry, 3. Number, 4. Algebra and 5. Functions. Mathematics is offered at higher, ordinary and foundation levels throughout. Despite the changes made to the Irish syllabus and teaching methods, it is clear that problems with algebra persist. This is evidenced in the latest chief examiners report which states students need to "gain comfort and accuracy in the basic skills of computation, algebraic manipulation and calculus" (Department of Education and Skills, 2015 p. 29). Algebra serves as a gateway to higher mathematics and deficiencies in basic algebra result in overall mathematical deficiencies in students (Lawson, 1997). However, issues with the

teaching and learning of algebra remain internationally, and research into progress measuring instruments to inform the area continue (Ketterlin-Geller et al., 2015). Given the poor performance of Irish students in algebra a diagnostic test has been developed to give insight into how second year students perform in this area. It is noted that many tests exist to measure performance in algebra and these provide useful information about the content areas in which students need further assistance. However, few of these tests provide information about why students are struggling (Russell, O'Dwyer, & Miranda, 2009). This test may help inform part of why students are struggling by looking at the conceptual errors students make in other content areas. These content areas, which include fractions, equality and patterns for example, have been identified in the literature as essential for the understanding of algebra (Bush & Karp, 2013; Warren & Cooper, 2008).

## **Theoretical frame**

The theoretical framework guiding this research is that the conceptual errors students make in working with algebra perpetuate the difficulties they encounter, subsequently interfering with their understanding of various algebraic concepts (Russell et al., 2009). The test is designed to identify the conceptual errors students make when working with a particular concept. The test results could inform the teacher who can then guide instruction aimed at alleviating these conceptual errors (ibid.:2009). It is possible that many teachers do not realise the essential connections that algebra has to numerous other mathematical content areas, and that how conceptual errors in one or more of these areas can hinder a students' progress, which will be discussed in more detail below (Bush & Karp, 2013). This test, in conjunction with an appropriate framework to interpret students' answers, could help inform instruction. The teaching and learning of algebra in Ireland aligns closely with Kieran's (2004) model, which outlines three activities that learners of school algebra must participate in: 1. Generational activities, 2. Transformational activities and 3. Global/Meta Level activities. It is noted that two aspects of algebra underlie all others, namely generality and abstraction (Department of Education and Skills, 2016 p. 26). These aspects have led to the definition of three types of algebraic activities that mathematics students in Ireland must engage in - representational, transformational and activities involving generalising and justifying. The test items have been designed to support the implementation of the new syllabus and in line with the approach to algebra being used in Ireland.

One potential criticism of the approach used in developing this test instrument is that it is a test of mathematics globally, given the broad range of content areas included. However, difficulties with algebra lie with both algebra itself and also with other areas of mathematics that students will have encountered, which are seen as prerequisites for the learning and understanding of algebra (Bush & Karp, 2013). Problems and conceptual errors in any one of the content areas can lead to problems in another area thus hindering a student's progress in algebra as a whole. Although these prerequisite areas support other areas of mathematics learning such as number and numerical operations, they are identified in the literature as core areas for the learning and understanding of algebra (Bush & Karp, 2013). The following section outlines the content areas identified throughout the literature as pertinent to success in algebra, on which test items have been based.

## **Prerequisite and algebra content areas**

As stated the focus of this paper is the key content areas required for success in algebra. These content areas are outlined in Table 1 (Bush & Karp, 2013; Warren & Cooper, 2008).

Content Areas	Junior Cycle Syllabus
<b>Ratios and proportional relationships</b>	<i>3.1 Number Systems:</i> - consolidate their understanding of the relationship between ratio and proportion. 4.4 Examining algebraic relationships: – proportional relationships
<b>Fractions</b>	<i>3.1 Number Systems:</i> - Investigate models to think about operation on fractions. - Use the equivalence of fractions, decimals and percentages to compare proportions.
<b>Decimals and Percentages</b>	<i>3.1 Number Systems:</i> - Calculate percentages - Use the equivalence of fractions, decimals and percentages to compare proportions.
<b>Integers</b>	<i>3.1 Number Systems:</i> - Investigate models, such as the number line, to illustrate the operations on integers
<b>Exponents</b>	3.2 Indices
<b>Order of operations</b>	<i>3.1 Number Systems:</i> - Appreciate the order of operations, including use of brackets
<b>Properties of numbers</b>	<i>3.1 Number Systems:</i> - Investigate the properties of arithmetic and the relationships between them.
<b>Compare and order numbers</b>	<i>3.1 Number Systems:</i> - Use the number line to order natural numbers, integers and rational numbers. - Use the equivalence of fractions, decimals and percentages to compare proportions.
<b>Equality</b>	<i>3.1 Number Systems:</i> - Consolidate the idea that equality is a relationship in which two mathematical expressions hold the same value.
<b>Variables</b>	4.6 Expressions: - Using letters to represent quantities that are variable.
<b>Algebraic expressions</b>	4.6 Expressions: - Arithmetic operations on expressions. - Transformational activities
<b>Algebraic equations</b>	4.7 Equations and inequalities: - Selecting and using suitable strategies for finding solutions to equations and inequalities.
<b>Functions</b>	<i>4.2 Representing situations with table diagrams and graphs:</i> - use tables, diagrams and graphs as a tool for analysing relations – present and interpret solutions, explaining and justifying methods, inferences and reasoning.
<b>Patterns</b>	<i>4.1 Generating arithmetic expressions from repeating patterns:</i> - use tables and diagrams to represent a repeating-pattern situation – generalise and explain patterns and relationships in words and numbers – write arithmetic expressions for particular terms in a sequence.

**Table 1: Content Areas for Diagnostic Test and alignment with the Junior Cycle syllabus**

Related content domains from the Irish syllabus were used as a framework to align the prerequisite and algebra content areas identified in the literature. The Number Strand (3) of the syllabus builds on primary school learning and facilitates the transition from arithmetic to Algebra (Strand 4). The Common Introductory Course (CIC) is the minimum course to be covered by all students at the beginning of the junior cycle, elements from the CIC are in italics within Table 1. The numbering

within Table 1 refers to the strand numbers, for instance 3.2 refers to section 2 of strand 3. The diagnostic test has been developed for use with students in second year and therefore it was important to align the test items specifically with the content of the CIC. Once the CIC is complete teachers use their own discretion to introduce their topics (Department of Education and Skills, 2016). There is no prescribed structure for following the syllabus however, it is desirable that students will have completed their basic algebra skills including equation solving by the end of first year (Project Maths, n.d.-a).

### **Prerequisite content areas**

Difficulties with algebra lie with both algebra itself and also with other areas of mathematics that students will have encountered, which are seen as prerequisites for the learning and understanding of algebra. Proportional reasoning is a key aspect of numeracy and it leads to relational thinking which is important in the development of algebraic skills, it is highly conceptual and a skill that develops gradually. Equally, fractions are an integral part of algebra and can be found as coefficients, constants and solutions to equations, the slope of a line, and, in general, proportions are written in fraction form in algebra (Bush & Karp, 2013). Knowledge of decimals, their value and placement on a number line, computation with decimals, and the ability to convert between decimals, fractions and percentages is also important for success in algebra (Bush & Karp, 2013). Studies have been conducted to identify what element of decimal and fraction understanding best indicate a students' performance in algebra. It has been found that the relational understanding of the bipartite format of a fraction and unidimensional magnitude, measured with the placement of decimals on a number line are the best predictors (DeWolf, Bassok, & Holyoak, 2015).

In learning about fractions, decimals and percentages, with the use of number lines and graphs, students at junior cycle are expected to be able to compare and order numbers. This provides students with the skills and knowledge to apply the rules correctly when working with variables. It also enables a student to assess if a solution to an equation or inequality is reasonable. However, if students do not understand a fraction, decimal or percent, they are unable to extend their understanding to which is greater than or less than or equivalent (Bush & Karp, 2013).

Furthermore, a solid understanding and procedural fluency with integers is required for success in algebra. Misconceptions about negative integers can impede progression, where, for example, a student may fail to accept a negative number as a solution to an equation. Research has suggested that the number line and graphs of functions can be used to help correct students' misunderstandings and conceptual errors with integers (Bush & Karp, 2013). Equally, an understanding of exponents is required for both the transformational skills, in dealing with expressions, and the generational and global/meta level skills, where knowledge of the shape of functions are required (Bush & Karp, 2013). Moreover, to succeed in the transformational rules of algebra it is essential to understand the order of operations. Some students believe that order of operations do not matter, that the same answer will result regardless. Others believe that the context of the problem determines the order of operations and in the absence of context operations should be performed from left to right. Research suggests that students should learn the hierarchy of operations more naturally by attending to more complicated operations first (Bush & Karp, 2013).

Finding equivalent expressions is frequently required in algebra, and this manipulation requires an underlying sense of the properties of numbers. Allowing students to investigate the properties of numbers will assist in learning, retaining knowledge and developing relational understanding, which in turn will create a strong foundation for algebra (Bush & Karp, 2013). Numerous studies have focused on development of the concept of the equal sign in the early stages of learning algebra (Bush & Karp, 2013). Students often misinterpret the meaning of the sign viewing it as an operational sign. Those who interpret the equal sign correctly and see it as a relational symbol have more flexibility when working with equations.

### **Algebra content areas**

Kieran (1992) asserts that many misconceptions and common errors in algebra are generally rooted in the meaning of symbol or the letters used in algebra. Much research has been conducted into students' difficulties in working with algebraic variables and the misconceptions students hold. These misconceptions include viewing variables as labels, the belief that the value of a variable has something to do with its position in the alphabet, and the belief that a variable is just a missing value rather than something which has varying values. These difficulties are then compounded when a student attempts to create and manipulate an algebraic expression (Bush & Karp, 2013).

The underlying misconceptions and difficulties students hold in relation to variables, expressions and indeed all the prerequisite content areas can then lead to difficulties in solving algebraic equations. The ability to solve equations is reliant on both procedural and conceptual understanding. Conceptual understanding is strongly related to student's equation solving performance, as without it students learn by rote a series of transformational rules for dealing with equations. A solid understanding of how to use variables to write algebraic expressions, form subsequent equations and solve when necessary is the essence of success in algebra at junior cycle level (Bush & Karp, 2013).

A function is defined as a correspondence between two sets (Kieran, 1992), and there are two general approaches to teaching and learning functional relationships mentioned in the literature; a correspondence approach and a covariation approach (Ayalon, Watson, & Lerman, 2015). The correspondence approach deals with an input-output model, whereby an output value  $y$  is calculated for a given input value  $x$ , often listed in a table of values or as couples. This approach allows for determining the rule which generates the  $y$ -value from the  $x$ -value and is in line with the approach to teaching functions in Ireland. The concept of a function is not simple when you consider that at least three representations are used to convey the notion of a function; a table, a graph and an equation. True procedural fluency and competency in working with functions is obtained when one can move between the different representations of a function with ease and this aligns with the multi-representations approach advocated in the Irish syllabus (Bush & Karp, 2013; Project Maths, n.d.-a)

Finally, algebra can be seen as the language used to describe patterns and relationships for the ultimate goal of problem solving and as a systematic way of expressing generality (Project Maths, n.d.-a). Students at junior cycle learn to identify the relationship which lies between the pattern and its position is a functional relationship meaning an expression or formula must be created using variables. In doing this a context for the use of variables is set for Irish students, assisting their understanding of a variable as a varying quantity rather than a specific unknown, laying down the

foundation for understanding expressions and solving equations in what is known overall as a functions based approach to algebra (Project Maths, n.d.-a).

### The diagnostic test

Test items were taken from previous relevant studies pertinent to measuring ability in the core content areas required for algebra outlined in Table 1. The diagnostic test currently contains twenty one questions summarized in Table 2 where the source of each test question is detailed.

Content Areas	Test Question Number and Source
Ratio and proportion	1. Number Line/Decimal Magnitude from DeWolf et al. (2015) 7. Proportional reasoning from Hilton, Hilton, Dole, and Goos (2013)
Fractions	2. 4. 5. Fraction Knowledge from DeWolf et al. (2015) 3. Fraction Knowledge multiplication (Bush & Karp, 2013)
Decimals and Percentages	1. Number Line/Decimal Magnitude from DeWolf et al. (2015) 11. Comparing and Ordering Numbers, Project Maths (n.d.-b)
Integers	15. Integers and equations adapted from Vlassis (2008)
Exponents	6. and 8. adapted from discussion in Mok (2010)
Order of operations	9. Order of operations adapted from Linchevski and Livneh (1999)
Properties of numbers	10. Distributive property, adapted from discussion in Mok (2010)
Comparing and ordering numbers	11. Comparing and Ordering Numbers, Project Maths (n.d.-b)
Equality	12. 13. adapted from Stephens, Knuth, Blanton, Isler, Gardiner, and Marum (2013)
Variables	14. Variable as label adapted from Küchemann (1981)
Algebraic expressions	16. adapted from Hodgen, Kuchemann, Brown, and Coe (2009) 17. Simplifying expressions based on errors discussed in Kieran (1992)
Algebraic equations	20. adapted from Clement, Lochhead, and Monk (1981) 18. 19. Next step of solution adapted from Chung and Delacruz (2014) 21.3 Forming equations adapted from Ayalon et al. (2015)
Patterns	21 Interpreting from a geometric pattern from Ayalon et al. (2015)

**Table 2: Summary of content and source of items on the diagnostic test**

An example of a test item, which assesses relational fraction knowledge, together with understanding of a variable and algebraic expression is taken and adapted from (DeWolf et al., 2015) as follows;

$n$  is a whole number greater than 0. If  $n$  continues to get bigger in value, please circle one of the following options A, B or C in the answer box for what happens to  $\frac{1}{n}$ .

Hint: Think about the following sequence of numbers  $\frac{1}{10}, \frac{1}{20}, \frac{1}{30}, \dots$

**Figure 1: Question 5 on the diagnostic test based on relational fraction knowledge**

Students have space for workings and are then asked to circle the correct answer from the following options; A.  $\frac{1}{n}$  gets very close to 1, B.  $\frac{1}{n}$  gets very close to 0, or C.  $\frac{1}{n}$  increases in value too. Adaptations from the original question include changing the word “integer” to “a whole number” and offering the “Hint”, to ensure the question is more in line with the age profile of those being tested as informed by the pilot of this test and feedback from teachers. The above question was included as relational understanding of a fraction was an element identified in the DeWolf et al. (2015) study to predict performance in algebra. All test items have been developed with such a theoretical underpinning that is using multiple choice responses based on possible conceptual errors. In addition language was adjusted where necessary to make the test items more accessible for fourteen year old students.

## Conclusion

There are fresh concerns in relation to student attainment in mathematics in Ireland, specifically algebra and for progression to third level education (Treacy & Faulkner, 2015). There is a clear need to intervene early in the effort to address the issues students are facing with learning and understanding algebra. The overall aim in using this test is to identify conceptual errors that students make in both algebra and the prerequisite content areas required for success in algebra, therefore assisting to identify possible root causes of the students’ errors, and as a result, through appropriate intervention improve students’ knowledge of algebra and therefore general mathematical ability. Ultimately, this will be a tool for teachers to use in the classroom allowing them to make informed decisions and to plan appropriate interventions (Russell et al., 2009).

# Analysing students' graphicacy from a national test

Oduor Olande

Linnéuniversitetet, Sweden; [oduor.olande@lnu.se](mailto:oduor.olande@lnu.se)

*The present study explores a task containing graphical artefacts from the Swedish national test (Nationella provet – NP) for a sub-sample of grade 9 students' solutions. The sub-sample comprising of 115 students' solutions to the task is closely analysed, using an analytical construct founded on "identification" as well as the "critical-analytical" approach to problem solving. Based on this construct it is observed that a sizable number of students' solutions follow a visual strategy with strong reliance on everyday forms of expression. Given the nature and purpose of NP we posit that students use the methods and tools that reflect general school practice. The analysis used in this study is perceived as problematising the assessment of competency from high stake tests, and the educational setting in general.*

*Keywords: Assessment, examinations, graphical artefacts, misleading diagram, competencies.*

## Introduction

National tests generally play a vital role in the evaluation of educational systems, informing educational reforms and policy implementations as well as serving as a local comparative instrument (Eurydice, 2009; cf Skolverket, 2016). This implies that results from national tests can be used to explore the effects of curriculum documents on teaching and learning. Some researchers, (e.g. Boesen 2006) have suggested that centrally administered tests can influence instructional practices, for instance by guiding the time set aside to teaching specific topic strands in the mathematics classroom. Given the orientation towards competencies in the mathematics classroom, it is also envisaged that the Swedish national test (Nationella provet – NP) might be a suitable indicator of teaching and learning of mathematics competencies. Thus, national tests can be perceived as having the potential to provide insight on students' fluency with mathematical concepts, as well as mathematics competencies (NCTM 2000; Niss & Højgaard, 2011; Skolverket, 2011; see also Sáenz, 2008).

## The goals of the study

The aim of the present study is to gain insight into the strategies and approaches that some students at the end of the compulsory school in Sweden employ, as they interact with a mathematics task containing graphical artefacts. This study is based on written solutions from NP. The purpose is to explore the strategies and tools used to solve this task, as well as to determine the potential provided by a model focusing on mathematical tools and forms of expression as a means of exploring students' mathematics competency.

## Background and theoretical construct

Several methods have been used to analyse students' responses to test items (e.g. Åberg-Bengtsson, 2005; Goodchild & Grevholm, 2007). In some of these studies the focus has been on general performance with microanalysis done at topics strand levels. While there are models proposed for examining the response to tasks (e.g. Gal, 2002, 1998; Ben-Zvi & Arcavi, 2001; Watson & Callingham, 2003), these seem to suggest general skills needed to solve the task with a bias towards statistical literacy. Friel, Curcio and Bright (2001) developed a three-tier model entirely devoted to

graphical artefacts: without loss of generality this can be collapsed into two tiers (cf. Gal, 1998; Bertin, 1983; Olande, 2013). While there are models for analysing students' test results, there is a dearth of studies exploring the use of subject specific tools and forms of expression in students' solutions.

In the present study an analytical construct (see Olande, 2013), focusing on the application of mathematics tools and forms of expression while solving test items, is employed. In this construct response to test items is perceived as being oriented towards *identification* and *critical-analytical approaches*. Items eliciting the identification approach are largely “self-evident” and as such, problem solvers might not need to unpack their mathematical skills entirely in order to solve the problem. On the other hand, items seen as demanding a critical-analytical approach require focused engagement from the problem solver. For example, this could be in the form of a critical analysis of underlying factors in the task, evaluation and selection of appropriate tools for interacting with the task, as well as reporting the solution with relevant subject specific forms of expression.

The construct guiding the present study borrows from a socio-semiotic paradigm where the emphasis is on artefacts as a means of coming to know. Radford (2008) posits that the investigation of students' interaction and use of semiotic means of objectification is a methodological way of accounting for learning (see also Radford, 2003; Vygotsky, 1978). It is recognised that a sign or symbol does not exist in isolation but is always bound with intentions, motives and the objects of action (Roth, 2008; Olande, 2014). Thus, in a critical-analytical approach, “being critical” encompasses more than visually interrogating a graphical artefact, but also includes the means and the tools used in the sense making process. The assumption about what can be perceived as a non-hierarchical path to cognition is significant for the analytical framework: i.e. it is access to tools and forms of expression that is perceived as largely determining a problem-solving trajectory.

### **The research questions**

Thus, the concern of the study is to outline and analyse tools and forms of expressions used by students as they interact with a task from NP. This task was picked from section C of the national test, a section that requires students to justify in one way or another how they arrive at their solutions. The task (figure 1) was selected for further analysis given that it provided a combination of *visual-identification* as well as *critical-analytical* components. This way of assessing the task is different from the marking process employed by graders while awarding credit to students' solutions. The marking scheme used by graders did not indicate assessment of diverse solutions provided by students but largely gave written statements as guidelines. Thus item *a*) scored full credit when the solution contained the expression TRUE with corresponding justification such as making a comparison based on the sizes of the shaded areas. For item *b*) partial credit was awarded where the solution contained the expression FALSE with corresponding justification indicating an understanding that the pie charts express different quantities e.g. “Australia has more medals than Spain”. Full credit was awarded where the solution, in addition to the general statement FALSE, explicitly made comparisons based on mathematical forms of expression e.g. computation with fractions. A reliability check conducted by an independent entity (Skolinspektionen, 2010) from a representative sample of Swedish students for section C of the test, indicated that for items scoring grade G - (for the purpose of this study *partial credit*) in 51% of the cases the graders gave higher grades than the assessors. In 27% of the cases there was correspondence in the credit award. For items scoring VG - “*full credit*” in 37% of the cases

the graders' credit award was higher than that of the assessors, with 41% indicating correspondence in the credit award.

From a competency perspective (Skolverket, 2011), this task might be considered to focus on developing competencies in the following: using and analysing *mathematical concepts*, use of appropriate *mathematical methods* to solve problems, and the use of mathematical forms of expression to discuss, *reason and give account* of questions, calculations and conclusions. However, given that the task explicitly called for a justification of the student's given solution, it was generally perceived as eliciting a critical-analytical approach. The success rate for item 9a was 78% for both girls and boys, while the success rate for item 9b was 47% and 55% for girls and boys respectively.

**Figure 1: Task No. 9 from NP Sweden**

The research questions are outlined as:

1. What range of tools and forms of expression are made manifest as students interact with the task containing graphical artefacts?
2. How does tool selection and use impact on the characteristics of the task solution provided?

## Task analysis

Students' solutions to task No. 9 were closely analysed with respect to: *a*) forms of expression (see Table 1 for typical examples of student responses) mathematical, everyday, graphical or one-word and *b*) tool use/sign of tool accessibility – mathematical operators and symbols. With regard to tool use seven approaches to task solving were identified, namely: *i*) visual comparison of graphical artefact, *ii*) critical - questioning the production of the graph *iii*) fraction *iv*) proportion *v*) percent *vi*) division *vii*) multiplication and *viii*) other solutions.

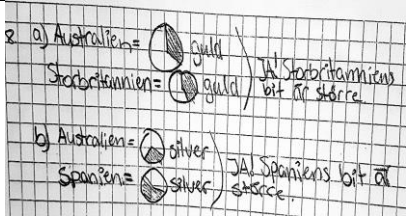

Mathematical	Everyday	Graphical	One-Word
Britain $\approx 5/12 \approx 0,40$ 40% gold (18,8 medals) Australia $\approx 35/120 \approx 0,30$ 30% gold (13,8 medals) Answer: true	True: Britain obtained most gold in its diagram and Australia more silver.	 <p>Yes! Britain's bit is larger</p> <p>Yes Spain's bit is larger</p>	False

Table 1: Forms of expression identified from test task

Based on aspects of *identification* and *critical-analytical approaches* (Olande, 2013) and aspects of Sfard's (2008; cf. Schleppegrell, 2007) categories of mathematical discourse, the author developed a coding scheme and analysed the students' solutions. The focus was on the forms of expression and *mathematical* tools – concepts used in working out a solution, rather than the correctness of students' solutions. The correctness or otherwise of the item solution was pegged on the test score awarded by test graders within the framework of the test situation. Significantly, within this coding scheme the perception of the forms of expression was as follows: 1) everyday – the use of causal expressions wherein aspects of the *obviousness* of solution are embedded. In Table 1, while the type of language used in the solution is *everyday*, it is apparent that there are quantities being compared: “Britain obtained **most** gold” and “Australia **more** silver” 2) mathematical – the use of mathematical concepts and methods in the solution 3) graphical – the use of illustrations in an attempt to amplify the visual aspects of the task. In the illustration given in Table 1 above while the solution for item *b*) did not receive credit award from the graders, the solution appears to be appealing to the visual faculties in a comparison exercise. Zooming in on gold or silver, the student seem to be posing the question *can't you see they are different?*

### Results and analysis

The success rate for task No. 9 seems to indicate that students did not have as much difficulty with aspects of item *9a* as compared to item *9b*. This can be explained in part by the nature and the array of tools needed for effective interaction with the different items. Thus, the different forms of expression of the items were analysed.

	Everyday	Mathematics	One-word	Graphical
Form of expression	0.72	0.15	0.11	0.02
Correct responses	0.89	0.95	0.32	1.00
Incorrect responses	0.11	0.00	0.60	0.00
No response	0.00	0.05	0.08	0.00

Table 2: Forms of expression identified from item *9a*

For this item, a majority (72%) of the students' solutions used everyday forms of expression, of these 89% provided successful solutions. While only 15% of the students used mathematical forms of expression, the success rate was relatively high at 95%. Students providing a one-word response to the task gave the majority of unsuccessful solutions. For this item it was observed that more than 50% of the students used visual comparison and/or the comparison of totals.

The general pattern for forms of expression for item 9b was no different for item 9a (see Table 2).

	Everyday	Mathematics	One-word	Graphical
Form of expression	0.50	0.32	0.13	0.04
Full credit	0.29	0.91	0.00	0.25
Partial credit	0.43	0.04	0.13	0.00
Incorrect responses	0.27	0.02	0.79	0.75
No response	0.00	0.05	0.08	0.00

**Table 3: Forms of expression identified from item 9b**

It is noteworthy that students providing one-word answers and those using graphical strategies recorded rather higher rates of incorrect responses. Evidently, students' results indicate that the use of forms of expressions reflects one way or another on the success rate of their solutions. Consequently, it is of particular interest to explore the subject specific tools and forms of expression used in solving the task, and how these might have impacted on the quality of the response provided. This analysis is conducted for item 9b (see figure 2)

**Figure 2: Frequency of tool use and credit award**

From figure 2 it is shown that most of the solutions awarded full credit included the application of mathematical symbols and calculation. For these solutions the predominant tools of manipulation/calculation were fraction, division and percent. The solutions providing incorrect responses seem to be largely based on visual strategies.

From the results it is apparent that students using mathematical tools and forms of expression had a relatively higher success rate. The predominant tools used in solving the task were fraction, division and percentage. The frequency with which fraction and division are used is not entirely unexpected since these tools are closely related; the same applies to some extent to percent. It could be suggested that the task in some way elicits the use of fraction: It is not uncommon for mathematics teachers to use pie charts in the teaching of, or in the introduction of, the topic strand of fraction. From this approach there is a natural connection to percentage; a circle divided into two gives two halves – this is often perceived as 50-50 (%). The results also indicate that some of the students using these tools (fraction, percentage) experienced some difficulty in application. It is worth noting that the students using multiplication obtained full credit. These students seem to employ a tool that might not be considered “self-evident” for the task. This necessitated using the tool in a creative manner, thus indicating a higher level of confidence and “proficiency” in using the tool.

For the students scoring full credit for the items, it is observed that most of them are proficient in the use of item specific tools namely, fraction, division and multiplication. From the students’ solutions it seems that only a small number indicate some aspect of interrogating the purpose of the graphics. Indeed there seems to be a general scarcity of solutions communicated using subject specific forms of expression, that is, mathematical language.

## Discussion

The present study sought to apply a construct focusing tools and forms expression in solving mathematics tasks containing graphical artefacts. The purpose was to outline the usage of tools and forms of expression, and the quality of the solution thereof. A deeper analysis of task No. 9 provided more insight into strategies and tools used in interacting with graphical artefacts. It is observed that it is in part the grasp of the tool in use that determines the quality of the solution given. Based on the level of confidence in tool use, it is possible for the test taker to interrogate the task from different perspectives. Based on what can be considered as overlapping tool use (see figure 2), the results are perceived as suggesting that “reading” a graphical artefact can be a complex undertaking that might involve *reading the graph* – *reading within the graph* – *reading beyond the graph* (cf Friel et. al., 2001). In the case of this task, there is indeed a different array of tools available to the students as they solve the task. However, it is communication using subject specific forms of expression that appears to be wanting – this might be an indicator that as much as the tools are available and “visible” to some of the students, the competency to apply and organize the same to produce a sound solution is a major challenge. This was observed in the case of students indicating knowledge of appropriate tools needed to solve the task, but apparently lacking the necessary skills to effectively apply the same in a problem-solving situation. Thus the observation made in the present study underscores the importance of having a solid foundation in the use of mathematical tools and forms of expression (concepts) in different settings. The importance of the use of subject specific forms of expression is also observed. For item *b*) there was higher correspondence in credit award between the graders and assessors as compared to item *a*) which did not elicit the use of the subject specific forms of expression as such. The analytical framework employed in the present study also helped to identify the strengths and weakness in students’ written solutions, thus providing valuable indicators for developing classroom practice.

Given the interest in, and the focus on mathematics competencies in the Swedish mathematics classroom, the present study can also be perceived as drawing attention to the practice of assessment: if the concept of mathematical competencies implies imparting aspects of such skills as mathematicians use in the processes of mathematisation (cf Niss & Højgaard, 2011; Sfard, 2008), then assessment practice might need to be refocused to examine such use of tools and forms of expression that enable the learner to understand, and to participate in, activities within the mathematics community.

*In this paper, we are presenting our analytical tools to characterize assessment activities as part of teachers' practice, on a specific mathematical content (algebra). We are also presenting the principles of our collaboration with high school teachers, inside a particular workgroup (LéA), to explain why we came to consider assessment as a potential lever to enhance both the students' learning in mathematics, and the teachers' development. We are presenting a few results on the effects of this collaborative work on teachers' practice when assessing students' learning, and on our means to analyze the students' results throughout the process.*

*Keywords: Assessment, algebra, teachers' practice, teachers' professional development, collaborative work.*

In this paper we are presenting the analytical framework that we are building to characterize the practice of high school teachers in mathematics regarding student assessment. We study assessment through one of its particular functions, promoting learning, with a didactical point of view, focussing on a particular content (algebra). We consider three inputs for assessment: assessment as a framework to characterize teachers' practice, assessment as a tool to enhance students' learning in mathematics, assessment as a lever for professional development. We will present some results on teachers' professional development, from the collaborative work we lead with high school teachers on assessment.

## Assessment as a framework to characterize teachers' practice

In this first part, we are presenting the framework that we have built to analyze teachers' assessment practice, leaning on previous studies about teachers' practice, and on the teaching of algebra in particular.

### Defining assessment practice

Assessment can be found in many aspects of the teachers' activity, and it would be easy to call assessment any interaction between the teacher and the students. To restrain our observations, we draw upon De Ketele's definition (1989), and call assessment any gathering of information by the teacher on the students' activity and knowledge, and the interpretation and use of this information.

By activity, we mean everything the students do, say, think, (or do not do). Of course, not everything is accessible to neither the researcher nor the teacher, but we consider that students' learning happens through their mathematical activities, at least partially (cf. Rogalski, 2013, about the use of Activity Theory as a framework for research in the Math Education field). These activities may consist on participating in a debate around a task or listening to a mathematical discourse in class. But in many occasion, they result from the tasks proposed by the teacher, and on the choices that the teacher makes

to manage the solving of the task, which are elements that we consider when analyzing the teachers' practice in class.

Assessment is easier to pinpoint for the researcher, when it is formal, for example a written summative test at the end of a teaching sequence, or short diagnostic tests happening at the beginning of every session. Informal assessment, on the other hand, is more difficult to identify, but can happen in many occasions during the class, through the interactions between the teacher and the students, giving information on the students state of knowledge, to the teacher or to the students themselves. To be able to characterize assessment practice in any case, we have drawn a list of criteria, whether the assessment is formal or not, and at any point in the teaching sequence.

### **Characterizing assessment practice**

One of the elements that we take into consideration to characterize assessment practice, is the distance between each assessment task and the similar tasks previously given by the teachers on the same mathematical content (Horoks, 2006). For example, when a teacher is assessing the students' knowledge on a mathematical content through a final test, we can question the choices of tasks made by this teacher and their link with the tasks that were actually worked on before the test. A certain gap between the test's and previous tasks (or between tasks from a diagnostic test and all the possible prerequisite tasks) can be interpreted in different manners: it could be explained by the function given to this test, (rewarding or challenging the students for example) or maybe by a lack of pedagogical content knowledge (Shulman, 1986) for the teacher. The epistemological and didactical analyses of the mathematical contents are crucial here to make the comparison between the two sets of tasks. In the case of informal assessment, each new task given by the teacher has to be considered among a set of previous tasks, depending on the "study moments" (Chevallard, 1999; Barbé & al., 2005), related to the distance from the first encounter with the mathematical notion. The distance between the tasks allows us to measure the complexity for the students compared to the tasks that they have already worked on. More globally, the whole range of tasks proposed by the teacher on a mathematical content, with the absence of particular tasks in the related assessments, can tell us some of the intentions of the teacher for assessment, in relation with teaching.

Another element that we take into account, is the "depth" of the information: indeed, the process of "taking / interpreting / exploiting information on students' activity" in mathematics, can take its roots in the solution that the students produce (the result of a task), the way they solve the task (procedure to achieve a result), or the knowledge that is put into action to complete this procedure. Linking the activity to the student's knowledge requires, from the teacher, an understanding of the conceptualization of the mathematical contents behind the procedure, which is usually specific to the particular content. Regarding algebra in particular, it leads us to consider some specific elements, such as the form of writing for calculations or the type of reasoning. Indeed, some forms of writing for the calculation for example (cf. figure 1) can inform the teacher on the meaning of the equal sign for each student (computation, equivalence), or on the student's structural / procedural view of numerical or algebraic expressions.

$$\begin{array}{l}
 - (3 + 4) \times 2 - 8 = 6 \\
 - 3 + 4 = 7 \times 2 = 14 - 8 = 6 \\
 \quad + 4 \quad \times 2 \quad - 8 \\
 - 3 \text{ -----} > 7 \text{ -----} > 14 \text{ -----} > 6 \\
 - 3 + 4 = 7 \\
 7 \times 2 = 14 \\
 14 - 8 = 6
 \end{array}$$

**Figure 1: Different writings for the calculation, giving information on the students' knowledge**

The interpretation of the information can also differ, depending on the reference taken for this interpretation: a comparison with what is expected by the institution (curricula, external assessment), or what could be expected by the teacher, considering all the previous work and the teacher's knowledge of the didactics of the mathematical notion at stake (errors, obstacles and breaches, steps in the conceptualization, etc). It can also be a comparison between the students' different procedures or a comparison in time for one student, to appraise his or her progress. These comparisons can be made explicit or not to the students. Here again, it can be linked to the various possible functions of the assessment.

Finally, the exploitation of the information differs depending on the moment when it occurs: whether it leads to immediate feedbacks related to students' result, procedure or knowledge or, in a more or less short term, when it influences the planning for the next activities.

Before giving an example of teachers' formal assessment practice, we will first describe our working context with a group of teachers.

### **Description of the collaborative work inside the *Léa***

A "Lieu d'Education Associé (*Léa*)" is an instance created by the French Institute for Education (IFE) to promote research with people who play an acting part in education. For 3 years, they are associated with a team of researchers to investigate questions about education and to build realistic resources for teachers or educators. Our *Léa* takes place, since May 2014, in a high school (students from 11 to 15 year old) in an Educational Priority Area, with 9 teachers (4 at the beginning) and 7 researchers, who meet every month to work together, to build teaching materials for algebra and to discuss assessment practice that could promote students' learning. The *Léa* can give us access to those teachers' evaluation practice in the long term.

### **An example of a comparison of teachers' formal assessment practice**

We asked *Léa* teachers to design a diagnostic test at the beginning of the year for their 7th-grade students, to assess their numerical and pre-algebraic knowledge before introducing algebra. The tasks of the tests that they individually proposed were not covering all the range of the required knowledge for the introduction of algebra (Carraher & Schliemann, 2007, Kieran, 2007). The teachers justified their choices by giving institutional or social reasons, rather than epistemological or didactical ones.

Teachers	G	M
Variety of tasks	Repetitive task	Different tasks
Complexity of test's tasks / previously given in class	Similar to the previous ones in class	More complex than the previous ones in class
Information (declarative)	On the result	On the procedure
Feedback to the students (declarative)	Marks on the paper	Marks on the paper
Function of the formal test (declarative)	<ul style="list-style-type: none"> <li>- To be able to give marks for the institution</li> <li>- To work on the basics</li> </ul>	<ul style="list-style-type: none"> <li>- To learn by adapting to a different situation</li> <li>- To adapt the teaching plan ahead</li> </ul>

**Table 1: Formal assessment (summative test)**

We also conducted interviews with these teachers to find out about their views about assessment, after they had proposed their first summative test of the year. They were asked questions about their choices of tasks and the feedbacks they gave to the students afterwards (cf. table 1 for two of the teachers). Their answers showed a great variety in the tasks they proposed, regarding the distance with previous tasks, and probably resulting from different views on the functions given to formal assessment, despite the fact that these teachers often worked together. What was common to all the teachers on the other hand, is that they did not usually give many feedbacks to their students. Indeed, those teachers gave a mark without informing the students with the necessary elements to understand their mistakes and the limitations of their reasoning. Another comparison, related to informal assessment, for one teacher at different moments, will be made in the last part of this paper.

## **Assessment as a tool to enhance students' learning in mathematics**

### **Definition of formative assessment**

For Black & Wiliam (1998), an assessment can be formative when a teacher uses the information on the students to help them engage in the work on a task, or to help each of them auto-evaluate their knowledge:

The term 'assessment refers to all those activities undertaken by teachers, and by their students in assessing themselves, which provide information to be used as feedback to modify the teaching and learning activities in which they are engaged. Such assessment becomes "formative assessment" when the evidence is actually used to adapt the teaching work to meet the needs. (page 2)

In terms of gathering/interpreting/exploiting information, formal assessment can play a more or less formative function, depending on the chosen tasks (if the tasks are way too complex or too simple; the students' productions might not reveal many useful information for the teacher). It depends also on the feedbacks made to the students. These facts can both be witnessed and analyzed by the researcher.

But when it comes to informal formative assessment in class, even if it is possible to see a teacher going around in the class when the students are working on a task, we can only witness the information actually gathered if the teacher is using it right away to guide the students' work. Deciding not to use the information right away, but reorganizing the plan of the next sessions, for the entire class or a particular student, could also be an exploitation of the information to promote the students' learning, but the researcher would then hardly acknowledge it. In any case, the research time allowed to the students to work on the task will probably have an influence on their mathematical

activity, and on the information that the teacher will be able to take on this activity, depending on the task.

### **A key moment: sharing the students' productions after letting them work on a task**

The moment of pooling of students' procedures, after letting them work on a task, alone or in groups, seems to us like a good opportunity for informal formative assessment, where students could compare their solution with others' and know if they are close to what was expected. It depends of course on how the teachers choose to manage this moment of the session, and on the use they will make of the students' productions. This is why we will look more closely at those moments in the classrooms to analyze the use that the teachers make of the students' productions: how is the students' work taken into consideration?

What kind of productions do the teachers choose to share with the entire class? Is there a variety in these productions, regarding the result of the task or the possible procedures? Are there errors, typical or not, showed to the students? These elements are indicative of the information probably gathered by the teacher on the students' work while they were working, but depends also on an *a priori* analysis of the task, strongly linked to the mathematical contents to be mobilized, in order for the teacher to anticipate the possible outcomes.

We also analyze the exploitation of these productions. However, the interpretation of the information by the teachers remains mostly invisible to the researcher, except when the teachers explicitly mention the reference they use to compare (with what is expected at the end of the year, with what the students already did before, between students...). We note if the teachers organize a comparison of the results or of the procedures. Do they rank them to show the relevance and limits of each solution? How is organized the (in)validation of the solutions? Who is (in)validating them? With which arguments? And which conclusion? These elements can inform us on the role given to the students in the validation and institutionalization process and in the assessment process in general. We will give an example of this type of analysis for one teacher, in the last part of this paper.

We have hypotheses on the conditions that we consider more favorable towards student's learning, for example by making use of various students' procedures and errors and by implicating them in the validation, using mathematical arguments. We will confront these hypotheses with the results in algebra of a hundred of high school students, whose teachers' assessment practice was analyzed in this study. In order to do that, we will analyze each task given by each of the teachers participating in the *Léa*, as part of the formal assessment process in algebra during 3 years, in terms of kinds of tasks (Chevallard, 1999) and adaptations (cf. Robert 2003), to determine their variety and complexity. We will collect the students' productions, analyze their answers and characterize them according to the different degrees of algebraic competencies defined by Grugeon & al. (2012) and Chenevotot-Quentin & al. (2015) for the design of a diagnostic assessment in algebra. This analysis is now in progress, as we are beginning the third year of our work inside the *Léa*.

## **Assessment as a lever for professional development**

### **Our tools to analyze professional development**

For our research, we already have collected a wide range of data inside our *Léa*, that we still have to fully process: to document the teachers' assessment practice, we gathered their personal documents

for the class and asked them to film themselves regularly in their own class; to measure the possible effect of this practice on the students' learning in algebra, we collected many students' productions; and at last, to try to estimate the effects of our collaborative work on the teachers' practice, we recorded the discussions during our meetings, and kept the reports of these meetings, when written by the teachers.

The analysis of the teachers' assessment practice takes into account, as explained before, the list of tasks proposed to the students in algebra and the management of the resolution of these tasks in class (informal assessment) or after a test (formal assessment). Their point of view about assessment is also visible through the interviews we conducted at the beginning of the project, or through the discourse of the teachers during the meetings of the *Léa*. More specifically, we are interested in the ways they argument their choices for their class, through the type of reasons they give for their choices of tasks or management (institutional, social, didactical, mathematical, etc). The moments when the teachers disagree with the researchers, or try to convince new teachers who joined the collaborative workgroup, are particularly interesting for us for that matter; to gather information on a possible evolution on the teachers' point of view on assessment, and more globally, on the teaching of algebra.

### **Some results about the changes in the teachers practice and arguments**

To illustrate our analyses of the teachers' practice and their development, we are giving here an example of two sessions, for the same teacher, filmed one year apart. We analyzed the moment of sharing the students' productions, after working on similar tasks. These tasks both involve testing a calculation program with several numbers to notice an unchanging result or property and proving it with algebra. Our analyses are based on the indicators that we have already listed (the variety of the productions chosen to be displayed, the exploitation of students' errors, the initiatives in the validation, the arguments for justification).

Our analyses after the first year of collaboration (see table 2 "year 1") tend to find that teachers' assessment practice are very settled and stable. It seems that our didactical contributions about the teaching and the learning of algebra have helped teachers' practice to evolve (Horoks & Pilet, 2015): indeed they have better indicators to select the students' productions that they will use for the discussion after a task. But the exploitation that they make of these productions hasn't really changed after the first year: when sharing them with the class, the *Léa*'s teachers don't usually organize a comparison between the students' productions nor give a validation based on mathematical reasons. We also found that these teachers usually leave no initiative for students when working on the more complex algebraic tasks, which leads to the impossibility to rely on their production (see table 2, "year 1").

After the second year, where we decided to share some of our tools to analyze the sessions in class with the teachers, we can notice some evolution in the exploitation of the information (see table 2, "year 2"). Even though the second part of the task is more complex, this teacher still relies on the students' productions, even if they are not mathematically correct, to build, along with the students, the reasoning that will allow the class to invalidate the proposed solution.

However, even if the tasks are similar between year 1 and year 2, students have a higher grade in year 2 which may also explain the different choices made by the teacher. We should go on studying practice for a longer time, to identify its stability, and this is what we plan to do in the *Léa* project.

		M(year 1)	M(year 2)
Testing with numbers	Duration of individual work	6.00	this numerical step is not part of the second task
	Variety and comparison on results/procedures from the students' productions	3 procedures not compared	
	Presence of errors in the displayed productions	error in the procedure	
	Student's initiative in the validation	yes	
	Mathematical arguments of proof	no	
Proving with algebra	Duration of individual work	2.30	6.30
	Variety and comparison on results/procedures from the students' productions	this algebraic step is handled by the teacher without any support on the students' productions	4 procedures compared
	Presence of errors in the displayed productions		yes
	Student's initiative in the validation		yes
	Mathematical arguments of proof		counter-example

**Table 2: Evolution of informal assessment practice for teacher M**

Both the cognitive (contents and tasks) and mediative (organization of the sessions in class) elements of the teacher activity play a part in the assessment process that we are trying to analyze here. But, as emphasized by Robert and Rogalski (2005) there are other constraints of this professional occupation to be taken into account: the social (type of school), the institutional (curricula) and personal (career and education) components, playing a significant part when interpreting teachers' practice, including for us their choices in terms of assessment. We analyze teacher's practice through all these components, at different levels: locally in the classroom or globally within all the teaching plan, and we believe that it can give us access more deeply into the teachers' consistency and explain their stability. Yet, after the second year, we noticed some changes in the arguments that the teachers are giving to justify their choices, shifting a little from social and institutional reasons to mathematical or didactical ones, that we would hope to link to our work together, that is still going on..

*This paper explores primary teachers' accounts of their responses to major changes in the curriculum and assessment system in England, which has recently re-designated expected standards of achievement and progress. Analysis is informed by Foucauldian poststructural understandings of power/knowledge and truth to examine how they reorganise their practices as mathematics teachers within a policy context which continues to compel schools to focus on performance. By means of a small-scale empirical study, we identify the tensions created when the 'rules of the game' change and how technological assessment tools require and enable teachers to reproduce levels and labels to categorise pupils. Our aim in undertaking this analysis is not to compare teachers' assessment practices to an ideal, beyond policy, but to illustrate how government-driven changes to assessment are insufficient to change underlying discourses of performativity which ultimately shape practice.*

## Introduction

The examination [assessment] combines the techniques of an observing hierarchy and those of a normalizing judgement. It is a normalizing gaze, a surveillance that makes it possible to qualify, to classify and to punish. It establishes over individuals a visibility through which one differentiates them and judges them. (Foucault, 1977, p. 184)

The quote from Foucault begins to set out both our substantive interest and the theoretical stance, namely, an interest in mathematics assessment from a sociological perspective. Our focus is on assessment not simply as a technical activity to improve pupil outcomes, but as a mechanism through which teachers manage their professional selves; the way in which mathematics assessment is used as part of their ongoing professional identification and as the basis, and evidence, of their success. Our starting point is the claim that in English primary (5-11) schools, assessment, and the curriculum alongside which it takes place, plays a major – perhaps *the* major – role in influencing teachers' actions. There are many reasons why this is the case but, as Pratt (2016a) argues, in essence they revolve around the marketized and high-stakes, accountable nature of the English system and the 'performativity' (Ball, 2003) this manifests in teachers' work.

## The changing context of English mathematics education

It is difficult in a short paper to describe fully the complex landscape of an education system and how it is changing and we refer the reader to Pratt (2016a) and Keddie (2016) for more detailed discussions of English primary schools. However, in summary the system is based in a neo-liberal, neo-conservative framework which affords an increasingly marketized, competitive and accountable approach to school improvement. This has led to a strong discourse of 'progress', since it is the change in pupils' levels of attainment across each year which has been the key measure against which schools, and individual teachers, have been judged. In turn this leads to a strong discourse of control, a belief that pupils' progress is predictable and controllable across time; and therefore of teachers' responsibility for learning outcomes obtained through their teaching (Pratt, 2016b).

However, over the last 18 months, both the curriculum for mathematics and the assessment system have been reformed. The new primary national curriculum (NC) (DfE, 2013) stipulated increased expectations in mathematics with more challenging national tests. Perhaps most importantly for teachers, previous NC ‘attainment levels’ have been superseded by an ‘expected standard’ set for 2016, at a higher level than in 2015 (DfE, 2016). The rationale for this change is described in the final report of the government’s Commission on Assessment Without Levels (McIntosh, 2015, p. 5), as follows:

Despite being intended only for use in statutory national assessments, too frequently levels also came to be used for in-school assessment between key stages in order to monitor whether pupils were on track to achieve expected levels at the end of key stages. This distorted the purpose of in-school assessment, particularly day-to-day formative assessment. The Commission believes that this has had a profoundly negative impact on teaching.

Too often levels became viewed as thresholds and teaching became focused on getting pupils across the next threshold ... Depth and breadth of understanding were sometimes sacrificed in favour of pace.

Guidance specifies that the majority of pupils should move through the programmes of study of the NC at broadly the same pace (DfE, 2013), crucially replacing previous advice to accelerate high attaining children through new content. At the classroom level, ‘progress’ *through* the curriculum has been replaced by ‘progress’ *within* it; and a new language of ‘mastery’ has sprung up to describe this, which “denotes a focus on achieving a deeper understanding of fewer topics, through problem-solving, questioning and encouraging deep mathematical thinking” (McIntosh, 2015, p. 17). Progress measures of pupils and schools across key stages are also calculated differently. Monitoring progress by levels and sub-levels has been replaced by a value-added measure. Pupils’ results at the end of key stage 1 and key stage 2 (at ages 7 and 11) are compared to the achievements of other pupils with similar attainment nationally, and a new ‘floor’ standard requires that at least 65% of pupils meet the expected level in mathematics (and English), or that a school achieves sufficient progress scores (DfE, 2016). Schools not achieving the floor standard will be scrutinised through additional inspection and may have their freedom curtailed. Indeed, the Commission notes that “with freedom, however, comes responsibility” (McIntosh, 2015, p. 10) and “recognises that the transition to assessment without Attainment Targets and levels will be challenging, and that schools will have to develop and manage their assessment systems during a period of change” (p.16). However, it justifies this on the basis of “a much greater focus on high quality formative assessment as an integral part of teaching and learning”; the raising of “standards” in line with neoliberal policy. As we have previously pointed out, in a performativity culture such as this one, assessment has become a means by which teachers gain and maintain professional capital (after Bourdieu, see Pratt, 2016a).

## Theoretical Framework

To understand the effect of changes to the ‘rules of the game’ of assessment, we draw on Foucault, particularly his notion of governmentality (Foucault, 1977) that surrounds English education (Ball, 2013; Llewellyn, 2016); the notion that dominant discourses become normalized to such an extent that (teacher) subjects consent to particular action and hence come to govern themselves. (Note, discourse here refers to “a group of rules proper to discursive practices ... [which] define the

ordering of objects” (Foucault, 1972, p. 49) and is more than just language.) Our aim is to make visible the ways in which assessment discourses normalize certain practices and relations between teachers, school systems and pupils, rendering them common-sense, irrevocable and change-resistant – but not to judge these against some ideal version of practice. In theorising these forms of governmentality in and through assessment, two related ideas are in play: power/knowledge and truth. Power, according to Foucault, is enacted, not held by individuals, and

is not exercised simply as an obligation or a prohibition on those who 'do not have it'; it invests them, is transmitted by them and through them; it exerts pressure upon them, just as they themselves, in their struggle against it, resist the grip it has on them. (Foucault, 1977, p. 27)

We emphasise that this can be a good or bad thing; power can liberate and is not oppressive per se, but either way, ‘power produces knowledge’ (ibid). ‘Experts’ in a field (teachers in their classroom settings, but also senior managers in the school as a whole, policy makers and children as ‘expert pupils’) produce knowledge through their language and activity which positions and exerts pressure in terms of the way it influences what can and cannot be said and done. In this sense, it forms a ‘game of truth’. For Foucault, truth is not something to be found outside of relations. Rather it is something produced through such relations so that “each society has its regime of truth, its 'general politics' of truth: that is, the types of discourse which it accepts and makes function as true” (Foucault, 1980, p. 131). Thus, the question is not what the truth ‘is’, but how things come to be taken as true; how this is used in order to make manifest and exert power relations. This is

the truth which does not belong to the order of what is, but to the order of what happens ... a truth which is not found but aroused and hunted down: production rather than apophantic. This kind of truth does not call for method, but for strategy. (Foucault et al, 2008, p. 237)

It is through this theoretical lens that we return to mathematics assessment, and the following questions: how do teachers respond to the changes that a new curriculum and assessment system impose; and in doing so, how do they re-organise the economy, and politics, of truth in assessment practices in order to (re)empower themselves as experts?

## Methodology

The project involved extended semi-structured interviews with primary teachers in 9 different schools (12 teachers in total) in the first year after the removal of levels. Teachers and schools were chosen purposively to reflect a range of ages, experience, school types and locations, but in this paper we draw on just three of the participating teachers – Ann, Jill and Mike, all working in state schools – in order to keep the analysis manageable. Mike and Jill are in their late 20s and both are coordinators of mathematics in their schools and are both on a programme of training to develop leadership in ‘mastery’ of mathematics. They work in a village and an urban school respectively; Jill has been teaching for 8 years and Mike for 7. Ann is in her late 30s, has been teaching for 19 years and in her current, town, school for 5 of these. She is a class teacher, but not a specialist in mathematics. Data from all the interviews were analysed thematically in relation to the substantive and theoretical framework – teachers’ assessment practices, as we understood them in relation to power/knowledge and truths. Whilst we can only present a small set of data we have selected this carefully, ensuring that teachers’ views, though sometimes individual, are never contradictory of the data set as a whole. Our aim is not to claim that the specifics are generalizable to every teacher beyond, or even within, the data set. Rather, the analysis is of the system of governmentality and the

dominant discourses that constitute it. We think it offers a trustworthy and useful analysis in this sense, meaning that it is likely to be generalizable to other teachers in terms of the way in which their work becomes problematized, even if not in terms of how individuals are able to respond. All our work conformed to the ethical procedures of the British Educational Research Association and were approved by our employing institutions.

## **Analysis – Reproducing the truth**

The DfE's Commission on Assessment without Levels is very clear over the point of their removal.

Removing the 'label' of levels can help to improve pupils' mind-sets about their own ability. Differentiating teaching according to pupils' levels meant some pupils did not have access to more challenging aspects of the curriculum. (McIntosh, 2015, p. 15)

Interestingly, this critique itself illustrates Foucault's central point about governmentality, namely that it is through labelling that subjects are categorised, normalized and objectified. They 'become' their label – and act accordingly in the common-sense, normal(ized), way that this affords. Whilst removing the language of levels is well-intentioned in order to remove such labels, we noted above that teachers' work takes place in a culture of performativity with dominant discourses of control and responsibility. Central to governmentality, they require teachers to 'know' what their pupils can and cannot do so that they can take responsibility for 'filling the gaps' in their knowledge by "identifying specific 'corrective' activities to help them do this" (ibid. p.17). These, then, become questions of truth, of what pupils 'actually' and 'really' know. However, as Foucault notes, a truth statement is "contingent on the instruments required to discover it, the categories necessary to think it, and an adequate language for formulating it in proposition" (Foucault et al., 2008, p. 236). The language of levels may have gone, but the imperatives for control remain and so a new language is needed for teachers with which to think and speak it. Our interviews suggest that the language of 'mastery', codified through other national continuing professional development programmes, has offered teachers such an alternative, so that:

For every child you can click on an objective and say whether you are working towards it, achieved, secure, or greater depth. (Ann)

Basically we have developed a system throughout the year. So, we haven't bought a system in. We've simply developed our own system as a school where we've given the children a grade of either 1, 2, 3 or 4. (Mike)

When we were talking, as a school, what we were going to put for our levels, we said "what shall we call them?" We've got to have things and labelling them "emerging, developing, secure, exceeding". (Jill)

Ironically then, the notion of mastery which was meant to take teachers away from codifying and levelling has provided alternative "types of discourse which it [the system] accepts and makes function as true" (Foucault, 1980, p. 131). Classification continues, but with new levels. What is significant in terms of governmentality is that, despite the best intentions, this replacement is inevitable since it is founded in the performative discourse which underpins pedagogic activity. In English primary schools this performance is measured by 'progress'; in the past meaning the movement up levels and sub-levels of attainment. Although the removal of levels has meant that there might be a new official understanding of it – that "progress can involve developing deeper or

wider understanding, not just moving on to work of greater difficulty” (McIntosh, 2015, p. 12) – it has not removed the imperative of being able to make it demonstrable as the way in which schools are judged. In other words, knowing ‘where pupils are’ is still central to “the status of those who are charged with saying what counts as true” (Foucault, 1980, p. 131) and is not therefore optional.

### **Hunting for truth with technology**

Foucault (1980, p. 131) has pointed out that the political economy of truth is characterised by, amongst other things, the form of scientific discourse, economic and political demands and the ways in which it is diffused and consumed amongst different organisations. Each school in our study has made use of some form of tracking system, either commercial software or a spreadsheet of some sort, as a technology for capturing data and in different ways teachers are looking for these technologies to help them seek the truth about the progress of their pupils. In each case, there are two technologies at work. Firstly, a tracking system recreates labels:

you've got all the statements and you can say whether the children are working towards it, expected for it, or exceeding for it, or something. Then it breaks it down into them being, for each year group, they are beginning to access or beginning plus, working towards or working at plus, secure, secure plus. There are six basic, what would have been sub-levels. (Mike)

But, he notes, “it can't generate something that tells you your child probably is secure or probably is working at” and “it's not comparing your children to anyone else. It's not saying anything.” Whilst teacher judgement is “fine and good” it does not seem to represent a sufficient truth for the accountability purposes to which it is to be put. Mike’s school has therefore turned to commercially produced online tests. These give him “beautiful data” and whilst it also serves a formative purpose in identifying “gaps” it “provides a comfort blanket” because “it gives you a standardised score and it’s based against however many thousand children from around the country”.

Whilst Mike has turned to comparative statistics to produce knowledge of progress, Jill agrees that numbers and labels mean that “it somehow feels like it's clearer, but if it's not well-defined that's quite dangerous, really”. Rather than seeking a truth in statistics though, Jill is committed to the idea of illuminating pupils’ mathematical understanding and somehow mapping this onto the new labels so that they can say, “these children are where they should be and these children aren't ... so that the gaps that they have got [can be] filled”. Rather than comparisons to other pupils nationally, Jill’s plan is to exemplify for colleagues a truth about what each label (developing, secure etc.) looks like in terms of the objectives from the curriculum that pupils can achieve. In this way she hopes that “it would be very clear where the children were and where their next steps were more clearly” and that “within the following year’s teaching you can see that clear progression, and then that becomes a way for teachers to show progress”. Jill’s belief seems to be that professional judgement, evaluating pupils’ understanding against exemplar materials, will, in time, allow teachers to learn what the new levels “feel like”.

The rationale for the removal of levels and a focus on mastery was, in part, based on the assertion that “too often ... teaching became focused on getting pupils across the next threshold instead of ensuring they were secure in the knowledge and understanding defined in the programmes of study” (McIntosh, 2015, p. 5). We have illustrated how levels have been recreated by teachers to serve the function of performativity, yet this is not to say that the idea of refocusing on pupils’ understanding of the curriculum was not welcomed and encouraged by this move. Mike notes that alongside the

security of knowing how their pupils rank against others “we are thinking about 'OK they are working at expected levels or just below but what are their gaps and how am I going to fill their gaps?’” Jill claims that “I think the move away from levels has been absolutely fantastic” because it allowed them to “take the time to sit back and actually think about the underlying maths”. Ann also welcomes the focus on ensuring that “gaps are filled” and considers this as central to pupils’ success. However, in her experience

it was just a lot that had to be covered and part of it was because there were gaps that I needed to go [over]. So for example my class didn't have a very good understanding of decimals, so rather than teaching thousandths and all of what was in the year 5 curriculum, I've had to go right back to the start and doing tenths. And that is your year 3 and year 4 objectives. (Ann)

This has led to her being reluctant to say that any child is secure and to her “feeling that almost, as a teacher, you've failed”, with her confidence being affected as a result. The school uses a system called School Pupil Tracker Online (SPTO) which, unlike the other systems, is meant to calculate whether pupils are emerging, developing or secure, but Ann does not trust its output.

I just experimented with 'what if I made that [objective] mostly achieved?'. And by doing that I could see that it was literally one little click turns that level up. ... I didn't like the fact that just one click sent that judgement over, particularly when it didn't look like it was right.

She notes that even if the company that runs the software alters this in the coming year “it sounds like the standard is going to slightly change every single year, which just makes it completely confusing. How can you work towards something that you don't know what it is?” This lack of clarity over the truth of her pupils’ learning is leading to some tension for Ann.

So within what I do with the children I see progress but I don't always see it in what I've got on paper, on SPTO. The progress isn't always reflected there ... I thought I was a good maths teacher, maybe I'm not, because of what's coming out ... In some ways I'm almost fighting against it and saying 'you will not do this to my confidence' [laughs], yeah.

### **A new normalizing gaze**

We noted above that one intention of removing levels was to avoid labelling pupils in ways that prevented access to the curriculum. As the quote that begins this paper makes clear, however, from Foucault’s position any examination “combines the techniques of an observing hierarchy and those of a normalizing judgement” which “establishes over individuals a visibility through which one differentiates them and judges them” (Foucault, 1977, p. 184). Foucault’s use of normalizing here is two-fold. On the one hand it points to the standardisation and categorisation of pupils; their allocation into categories, in this case ‘emerging’, ‘secure’ etc. which are then used to define normal, and hence abnormal, and to take remedial action. Mike refers to “the ones who haven’t quite got there” and Jill to those who are “where they should be” and those that are not. On the other hand, it refers to the notion of making this categorisation ‘normal’ practice; common-sense, inarguable, defining what can and cannot be thought and said. Thus, although removing levels is meant to avoid differentiating pupils and restricting their access to the curriculum, the need to track progress makes such differentiation necessary. To speak of progress is to speak of changes in category as the only “type of discourse which [society] accepts and makes function as true” (Foucault, 1980, p. 131); “a truth provoked by rituals, captured by ruses, seized according to

occasions” (Foucault et al., 2008, p. 237). Such rituals create a practical tension in the idea of normalisation. As Mike notes,

It's that challenge we're set of trying to keep together and moving forward together but having children still working at a greater depth but closing the gap for the ones that are lower.

For those already ‘succeeding’ as secure, mathematics involves a range of activities. Mike describes “10 children who we saw as working at greater depth and they worked in groups with teaching assistants and had some really different kind of problem solving”. However, Jill points out that the governmentality around floor targets means that for “the children who are almost secure but not quite, there is a real push to get them [over the threshold]”.

Yes, but I think the secure one [is key] at the moment. I think at the moment with the new system it's different, it's difficult, it's unknown. I think it's that ‘where are we for secure?’ (Jill).

Hence, whilst the change in the curriculum structure is meant to ensure that children move together through the content, the manner in which assessment inevitably “establishes over individuals a visibility through which one differentiates them and judges them” (Foucault, 1977, p. 184) means that the way in which they experience the subject is far from equal.

## Discussion

Our analysis suggests that although superficially things might look different and teachers may feel that their practice has changed, this appears to be largely a reconstruction of the same dominant discourses in new language. Whilst the specific practices of governing might have been altered, the fundamental forms of governmentality have not and teachers are in the process of reconstituting much of what they had before. We recognise that the recent changes have opened up opportunities for discussion, collaboration and reflection within and between schools and made teachers pause and take stock of assessment in ways that feel positive to them. However, they have also reproduced pressures and tensions which can work to deflect attention away from questioning the responsibilities of policy makers and the implications for the teaching and learning of mathematics in the new system. Whilst there is a significant impact on teachers’ day-to-day teaching and assessment practices, and how these are evaluated, the performative role of the teacher remains largely the same. There does seem to be more consideration of pupils’ development in mathematics; though this is produced in particular ways: an atomised curriculum and filling in gaps. There are signs too that far from alleviating the problem of access to the curriculum for all children, there is a new normalizing gaze; one that focuses teachers’ efforts on an even slimmer tranche of pupils who might just be normalized – literally, to the middle of the normal distribution. Similarly, only those who are ‘secure’ in their ‘knowledge’ of the subject get access to a rich version of mathematical problem solving. These points raise questions about the way in which such tightly managed forms of assessment affect pupils’ relationships with the subject and about the equity of pupils’ access to the curriculum. The nature of these authoritative discourses of progress, control and responsibility that make up performativity, and the version of mathematics and assessment produced within them, appear difficult for the teachers in our study to identify. All schooling operates within policy and its incumbent discourses and can never be free of it, however the value of a Foucauldian analysis is in making such discourses visible to those responsible for making changes to the assessment system.

# **Towards an empirical validation of mathematics teachers' intuitive assessment practice exemplified by modelling tasks**

Xenia-Rosemarie Reit

Goethe-University Frankfurt, Institute for mathematics education, Germany; [reit@math.uni-frankfurt.de](mailto:reit@math.uni-frankfurt.de)

*The identification of intermediate steps in student solutions as a basis for assessment is a common procedure in mathematics teaching. Modelling tasks, providing more than one solution approach, are considered hard to assess. This is not least a reason for the unsatisfactory proportion of modelling in school. Assuming that task difficulty is strongly connected with assessment, the implications of a study about the difficulty of modelling tasks are discussed. Starting point for the discussion is the question whether intuitive assessment practices like the identification and scoring of intermediate steps, can be supported by empirical findings. The focus is on the influence of cognitive aspects regarding structural characteristics of solution approaches. Results indicate that a pure sequential consideration of thought structures in a solution approach lead to reasonable results and might justify its application in school due to its straightforward implementation.*

*Keywords: Assessment, cognitive structure, modelling tasks, mathematics teaching.*

## **Introduction**

Within the mathematics community it is mostly agreed upon the positive impact of modelling tasks on the learning of students. Mathematical modelling is promoted and there are many votes for its broader implementation in school mathematics. However, several studies provide evidence that modelling is far away from playing an integral role in everyday school teaching, in Germany and also elsewhere (Blum, 2007, p. 5). Jordan et al. (2006) confirm that the proportion of modelling in daily school routine is low. Research focusing on the teachers' point of view reveals several difficulties that teachers are confronted with. In a study of Schmidt (2010) it has been found out that 67% of the interviewed teachers indicate assessment as being the major challenge in the implementation of modelling tasks. Blum (1996) also speaks of an increased difficulty in the context of modelling tasks. These findings are comprehensible in view of the multiple solution approaches of modelling tasks.

A common opinion is that modelling tasks cannot be assessed as objectively as traditional task formats (Spandaw & Zwaneveld, 2010). However, if we want modelling to be part of mathematics teaching, it must part of the grading (Hall, 1984). With the striking quotation "What you assess is what you get" Niss (1993) also argues in favor of a provision for modelling activities in the grading. The aim of the present paper is not to discuss and contrast formative and summative assessment since the advantages of formative assessment as assessment *for* learning movement could be confirmed in different settings (e.g. Black & William, 1998) and are not denied. However, in view of the fact that summative assessment aspects hinder the implementation of modelling tasks in everyday school live, it is necessary to provide tools or possibilities in that direction.

Besides a number of assessment methods which aim at assessing modelling competence (e.g. Berry & Le Masurier, 1984; Haines, Crouch, & Davis, 2000), there is hardly any assessment instrument which can be used for assessing modelling tasks in everyday school live. In this context so far only Maaß suggests an assessment scheme which can be adapted to different modelling tasks by a variable

weighting of several categories (Maaß, 2007, p. 40). However, an empirical validation is lacking such that the assessment scheme might serve as orientation but it cannot give detailed instruction.

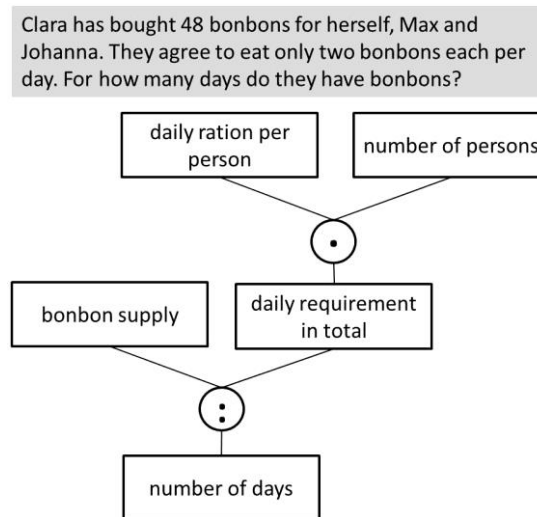

On the way to an assessment scheme for a mathematics task, a common procedure of mathematics teachers (in the following referred to as “intuitive assessment practice”) is to identify reasonable intermediate steps in a solution which are worthwhile to be scored. On that basis an assessment scheme is set up which determines the conditions to be fulfilled for a differentiated scoring of those intermediate steps. Hence, there is a procedural difference between the phase of identifying scoreable aspects in a solution and an assessment scheme. The former is the requirement for the latter. At this point the present paper ties on by discussing the use of so called thought structures to identify reasonable intermediate steps in solution approaches of modelling tasks in connection with its difficulty. The question of identifying intermediate steps and the influence of their structure within a solution approach to its difficulty has been analysed by Reit (2016). In this study different models are developed and evaluated to determine the difficulty of solution approaches. Assuming that assessment of a mathematics task is strongly determined by its difficulty, interesting conclusions can be drawn concerning common assessment practice in school. Results of the study of Reit (2016) indicate that there is quantifiable influence of structural characteristics of a solution approach on its difficulty. However, it is also stated that a sequential model which is based upon a sequential arrangement of thought operations, similar to the intuitive assessment practice of mathematics teachers, can also be confirmed.

## **Theoretical framework**

The core of the study of Reit (2016) is a structural analysis of students’ solution approaches of modelling tasks. These thought structures of solution approaches indicate the chronology of thought operations to be done to arrive at a solution. Assuming that parallel thought operations complicate a solution approach, a non-weighting difficulty model (addition model) is contrasted with four models varying in their weighting of parallel thought operations.

## **Thought structure analysis**

Recalling structures is a wide-spread procedure in mathematics (Bourbaki, 1961, pp. 163). In this context Breidenbach (1963) looks at the structural-substantial complexity of a word problem to decide amongst others about its difficulty. He formulates that tasks with one operation deal in the simplest case, with one issue in which three factors play a role and every factor is uniquely determined by the two others (Breidenbach, 1963, p. 200). Breidenbach named such tasks *Simplex*. A linking of several *Simplex* is called *Komplex*. Further developments of Winter and Ziegler (1969) lead to the arithmetic tree which is still used in mathematics textbooks (Figure 1). An obvious but so far empirically not validated conclusion is that a larger number of *Simplex* and a more complicated nesting of them, has an effect on the difficulty of the tasks’ solution (Graumann, 2002).

**Figure 1: Arithmetic tree of an exemplary task following Winter and Ziegler (1969)**

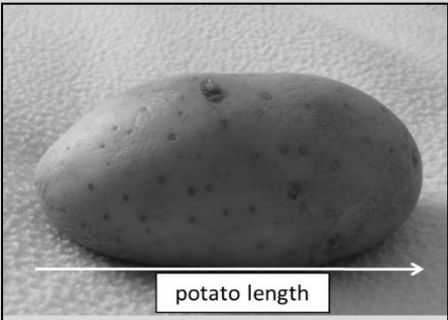

The study of Reit (2016) investigates the cognitive complexity of a solution approach on the basis of its structural complexity represented by its arithmetic tree-like structure. At that point the coherence of structural considerations and cognitive psychological theories play an important role. In a study of Fletcher and Bloom (1988) it is assumed that text comprehension is a kind of problem solving process, where the reader must find a causal chain which links start and end of a text. Furthermore they assume that information must be kept simultaneously in the working memory to be able to form such a causal chain. Results of their study show that readers must keep that information available that is the direct predecessor in the causal chain. It can be concluded that the task of the working memory is to keep information available which is necessary to link old and new information (Baumann 2000).

By relating these findings to structural considerations of a solution approach represented as an arithmetic tree, statements can be made about its cognitive complexity. On the one hand the arithmetic tree-like structure (Figure 1) can be interpreted as causal chain since the start (given information in the task text) and end (solution of the task) is linked by chain links (intermediate steps in the solution process). On the other hand direct predecessors can be identified as relevant intermediate steps. Thus, it can be concluded that the previous intermediate step must be kept active in the working memory to master the following. The assumption that the mental processing capacity is limited (Sweller, 1988) leads to the statement that several information which has to be kept active at the same time, complicate the solution process. Thus, it can be deduced that the load of the working memory is dependent on the number of intermediate steps necessary to master the current intermediate step. That means that the load of the working memory increases with increasing number of information needed at the respective point in the solution process.

Based on these considerations a study has been performed where theoretical difficulty of a solution approach is characterized as its cognitive complexity (Reit, 2016). Starting point is the so called thought structure of a solution approach which can be interpreted as kind of arithmetic tree (Figure 1). To formulate a thought structure all student solutions of a modelling task have been clustered into several solution approaches according to the mathematical model or solution process used. An aim of the study was to investigate whether the number of sequential and parallel thought operations has an effect on the cognitive complexity and thus, the theoretical difficulty of a solution approach.

## Study design

Approximately 1800 grade 9 students (15 years of age) from German grammar schools took part and completed a booklet consisting of three out of five modelling tasks (see modelling task “potato” in Figure 2) under seatwork conditions. The total processing time for a booklet lay within one teaching unit.

Industrial manufactured French fries are supposed to be equal in size and the single sticks are cut out lengthwise. Therefore not the whole potato can be used. The potato tubers look similar to the picture above, are regularly formed and approximately 10 cm in length.

How many of these potato sticks can be obtained from one potato?  
Reason mathematically.

**Figure 2: Modelling task “potato” (Reit, 2016)**

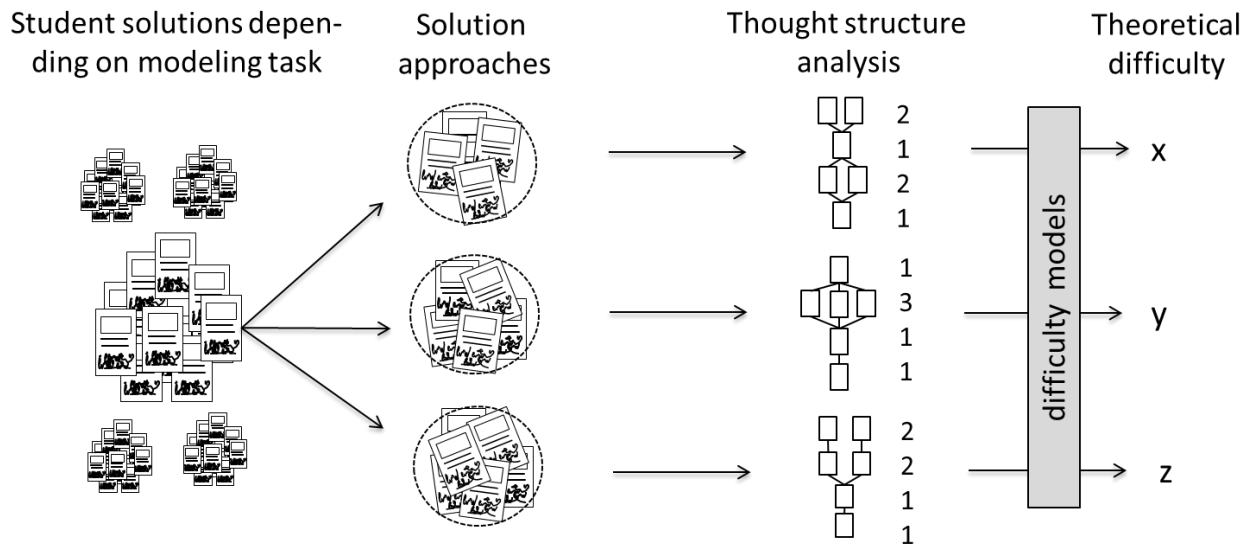

## Method

In the following the method in the study of Reit (2016) will be briefly explained. For a detailed description of the methodical implementation it is referred to Reit (2016).

All student solutions of a modelling task were analyzed and different solution approaches could be identified (two to four solution approaches per modelling task). These solution approaches within one modelling task differed in their underlying mathematical model used or, if similar to this, in their solution process. Every student solution was finally assigned to a solution approach (Figure 3). A structural analysis of these solution approaches then lead to individual thought structures indicating the chronology of thought operations. Based on thought structures of solution approaches different difficulty models have been developed to translate the respective structure into a scalar difficulty value. In a first step a thought structure was mapped onto a so called *thought structure vector* (Figure 3). These thought structure vectors represent the tabular-compact form of a thought structure. Each vector component indicates the number of parallel thought operations on the respective level of the thought structure.

Due to the fact that it was not clear yet if parallel thought operations lead to a higher difficulty than sequential thought operations, different operationalization of a thought structure vector into a scalar value were imaginable. Therefore different difficulty models have been set up (four accounting for parallelism of thought operations by weighting them and one non-weighting model (addition model)) which lead to solution approach specific difficulties.

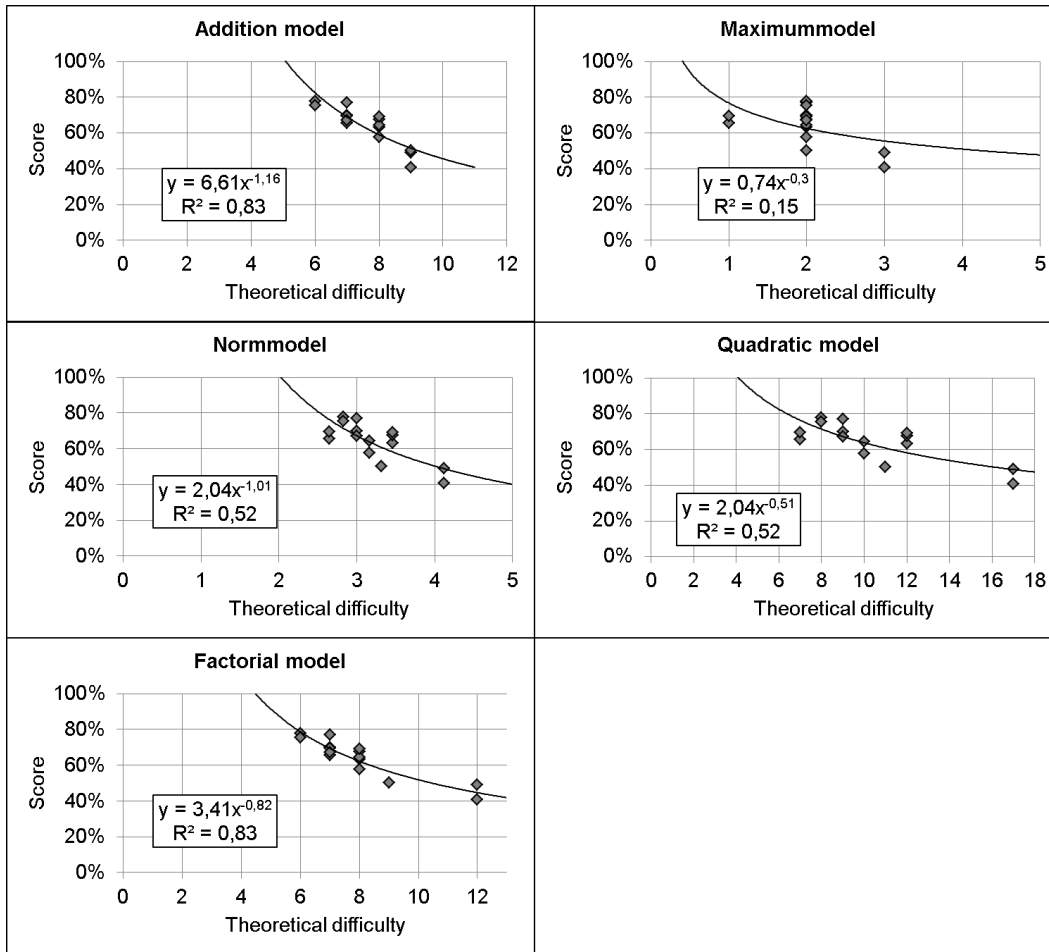

**Figure 3: Identification of solution approaches, setting up thought structures (together with its thought structure vector) and applying difficulty models which lead to theoretical difficulties**

## Results

Whether and to what extent parallel and sequential thought operations have an influence on the difficulty was evaluated by comparison with the corresponding empirical difficulty, as a measure of the average score of a solution approach. To determine the empirical difficulty all student solutions have been assessed by two independent raters on the basis of a predefined assessment scheme set up by experts. The question was whether the theoretical difficulty reflected the associated empirical difficulty of a solution approach. In this case structural characteristics of a solution approach can be taken as a basis for assessment of modelling tasks. Of special interest are the results of the non-weighting difficulty model as analogy to mathematics teachers' intuitive assessment practice. The non-weighting difficulty model (addition model) adds up all thought operations to arrive at a theoretical difficulty as it is done, more or less intuitively, by mathematics teachers when identifying scoreable intermediate steps.

The results (Figure 4) indicate that addition and factorial model (pseudo- $R^2=0.83$ ) map the coherence of theoretical and empirical difficulty best. The factorial model weights parallel thought operations. In regard of the focus of the paper the results in Figure 4 clearly show that the addition model lead to significantly better results than the most weighting models.

**Figure 4: Comparison of theoretical and empirical difficulty of solution approaches taking account for different difficulty models**

## Discussion of results

Particular reference is made to established but so far not researched assessment practices in mathematics teaching. The focus is on whether intuitive assessment practices of mathematics teachers can be empirically confirmed and transferred to modelling tasks. Intuitive assessment practice means the common procedure of mathematics teachers of scoring intermediate steps in student solutions without accounting for structural-cognitive particularities. These intermediate steps usually then serve as a basis for an assessment scheme. The portrayed procedure is commonly used when assessing performance tasks in mathematics (summative assessment). Modelling tasks with its multiple solution approaches are considered to be hard to assess. This problem not least leads to the fact that modelling tasks are sparsely used in mathematics class. Results of a study investigating the difficulty of modelling tasks support the intuitive assessment practice of mathematics teachers and thus, legitimate transferring this assessment practice to modelling tasks.

In detail the results show that the addition model which treats sequential and parallel thought operations equally lead to reasonable results. This indicates that difficulty of a solution approach can be described well by the number of thought operations needed to arrive at a solution. By applying the addition model it is assumed that parallelism of thought operations has no influence on the complexity of a solution approach. This assumption is also made, more or less intuitively, in common assessment practice in mathematics teaching. Intermediate steps are identified and scored. Thus, on the one hand

the results support the everyday procedure in mathematics teaching where the difficulty of a mathematics task is often interpreted as the number of intermediate steps to complete a solution. On the other hand the results might justify a similar assessment procedure when assessing modelling tasks. In view of the widespread problems concerning assessing modelling tasks in everyday school life as part of the grading, the results clearly highlight a possible and furthermore practicable way.

In summary it can be concluded that the so far intuitive assessment practice in school of identifying intermediate steps in a solution, can be supported by empirical findings. It can be a worthwhile procedure to identify thought structures as a basis for assessment especially when assessing modelling tasks. By assuming that assessment is connected with difficulty of the respective solution approach, parallelism of solution approaches has an influence (see the results of the factorial model) but might be neglected in favour of a straightforward applicability in everyday school practice. Thus the results of Reit (2016) can serve as a basis for the development of a manageable assessment scheme for modelling tasks and might promote their implementation in mathematics teaching.

# Mathematics teachers' assessment of accounts of problem solving

Anna Teledahl

Dalarna University, Falun, Sweden; [ate@du.se](mailto:ate@du.se)

*In mathematics education it has been argued that traditional assessment provides insufficient evidence of students' overall achievements. Assessment of problem solving has been put forward as a more comprehensive form of assessment. This however entails a subjectivity which raises concerns regarding the reliability. This study aims to investigate mathematics teachers' assessment of mathematical problem solving. Nineteen teachers have been interviewed in five groups and asked to discuss a sample of 16 accounts of problem solving by 10-year-old students. The analysis focused on examining how five mathematical abilities, described in the Swedish mathematics syllabus, were addressed and discussed by the teachers. Preliminary findings indicate that the accounts provide teachers with very little evidence of students' mathematical abilities. One of the reasons for this appears to be that the accounts do not offer clear descriptions of the problem-solving process.*

**Keywords:** *Assessment, mathematical problem solving, abilities, teachers.*

## Introduction

Assessment forms a large part of teachers' practice yet studies indicate that teachers feel inadequately prepared for the task of judging students' performances, skills and understandings. (Cumming & Wyatt-Smith, 2009; Mertler, 2004). Research that has investigated teachers' assessment practices has also criticized such practices for failing to meet standards of reliability, objectivity and validity (Allal, 2012). Assessment is inherently a process of professional judgment in which the element of interpretation is salient. In mathematics education Morgan (1998) has shown that teachers can interpret the meaning of the same passages of texts, produced by students in mathematics, very differently. When teachers interpret observed test results or other types of information to come to a conclusion about a student's level of knowledge or skill such a conclusion may be referred to as inference, and although some inferences can be made with more confidence than others, no conclusion about a particular student's knowledge or skill can ever be made with certainty (Cizek, 2009). Assessment in school mathematics has always relied heavily on students' written work (Morgan, 2001b). Written responses to mathematical tasks, such as problem solving, require that students explain both their thinking and the proposed solution. For such written material to act as valid evidence, from which judgements regarding students' problem-solving processes and mathematical abilities may be inferred, it has to be clear and comprehensive. There is reason to believe that not all students possess the ability to produce clear and comprehensive accounts of their mathematical problem solving (Monaghan, Pool, Roper, & Threlfall, 2009).

This study represents a microstudy on groups of teachers' assessment of a specific set of accounts of solving mathematical problems. The accounts were collected from two classes of 10-year old students. The aim of the study is to investigate the aspects of mathematical problem solving which are addressed and discussed by the teachers and to relate these to the five mathematical abilities set by the Swedish mathematics syllabus. These abilities are related to: *problem solving, mathematical concepts, mathematical methods, mathematical reasoning and communication.*

## **Students' writing in mathematics**

It can be argued that the written mathematical work of students in school mathematics typically serves two very different functions. It can be seen as a part of a learning process in which writing is used to record and perhaps reflect on various mathematical ideas; hence, the text is written by and for the student herself. It can also however, be seen as a product for the purpose of assessment; hence, written for a teacher or examiner. Unlike the work of professional mathematicians, which is often thought to be the model for school mathematics, the work in school mathematics often serves these two functions at the same time (Morgan, 2001a). When problem solving is viewed as an individual cognitive activity, students use their writing to understand, explore, record, and monitor their own problem solving (Stylianou, 2011). Several studies indicate that writing poses problems for students. Evidence suggests, for example, that it is far more common for children to experience problems with semantic structure, vocabulary and mathematical symbolism than they do with, for example, standard algorithms (Ellerton & Clarkson, 1996).

## **Assessing mathematical problem solving**

Assessment of students' mathematical problem solving is complex. There are different definitions of what mathematical problem solving is and what constitutes a problem. A generally accepted definition suggests that problem solving can be seen as a response to a question for which one does not already know or have access to a method (Monaghan et al., 2009). This understanding is also used by OECD in the PISA 2012 Assessment and Analytical Framework (OECD, 2013). Problem solving can be seen as a goal, a process, and a skill and problem-solving activities are thought to engage students in a number of different processes such as reasoning, communication and connections (Rosli, Goldsby, & Capraro, 2013). In a situation where traditional assessment in mathematics is increasingly seen as providing insufficient evidence of mathematical knowledge and abilities beyond routine skills and algorithms there are high hopes for alternative forms of assessment of which problem solving is one (Jones & Inglis, 2015; Rosli et al., 2013). Despite its power to engage students however, problem solving has been problematic to use as a source from which to make inferences about students' mathematical achievement. Reliance on the traditional mathematics test has often been justified on the grounds of reliability and comparability, but this has often been at the expense of validity (Watt, 2005). The challenges to assessment of problem solving are several. The first is that it requires access to evidence of the process. Most test situations do not include the option of observation to provide such evidence but rather require students to produce an extended written account which includes an explanation of both their problem-solving process and their proposed solution(s). This is problematic because considerable skill is required to produce clear and comprehensive accounts of problem-solving processes, a skill that students may or may not have (Monaghan et al., 2009). The second challenge is the element of interpretation and, thus, subjectivity. As teachers read and assess students' texts, their professional judgment is formed by a set of resources which varies with their personal, social and cultural history as well as their relation to the particular discourse. These resources are individual, as well as collective, and they include: personal knowledge of mathematics and the curriculum, beliefs about the nature of mathematics and how these relate to assessment, expectations about how mathematical knowledge can be communicated, experience and expectations of students and classrooms in general, and experience, impressions, and expectations of individual students (Morgan & Watson, 2002). Individual teachers

may also have particular preferences for particular modes of communication as indicators of understanding. A study from Australia has also indicated that teachers themselves object to the use of alternative assessment methods such as problem solving on the grounds that it is perceived as too subjective (Watt, 2005). In Sweden there have been calls for national tests to be assessed and graded externally instead of by the teachers who already know the students. External grading is seen as a way to secure objectivity and fairness.

## Mathematical abilities

Assessment in mathematics has many concerns, of which perhaps the most important one is: what is it that is being assessed? This issue has been dealt with and given many names throughout the history of mathematics education including numeracy, mathematical proficiency, mathemacy, matheracy and quantitative literacy, to name a few (Wedeg, 2010). Competency frameworks in mathematics are constructs that build on the assumption that mathematics is a domain in which it is possible to provide a generic set of mathematical practices (Säfström, 2013). Given that mathematical activities have to be about something, arriving at a common and generic set of such skills and abilities proves a challenging task, as has been pointed out by many (see for example Jablonka, 2003; Kanen, 2002; Kilpatrick, 2001; Wedeg, 1999). Some frameworks have focused on this ‘something’ whereas others have focused on the mental processes that are associated with mathematical activities in general. Influential examples of the latter include the five strands of mathematical proficiency introduced by the Mathematical Learning Study of the NCTM in the US (Kilpatrick, Swafford, & Findell, 2001) and the KOM project in Denmark (Niss, 2003; Niss & Højgaard Jensen, 2002).

One of the motives behind the above referenced frameworks is the clear intention to break with a traditional teaching of mathematics associated with rote learning and procedures and instead promote a more dynamic view of what it means to do mathematics (Boesen et al., 2013). In Sweden the Swedish national curricula has been influenced by the ideas from these frameworks and in the Swedish syllabus in mathematics, introduced in 2011, five different abilities which the teaching in mathematics should provide the students the opportunity to develop, are described. These include the ability to:

- formulate and solve problems using mathematics and also assess selected strategies and methods,
- use and analyse mathematical concepts and their interrelationships,
- choose and use appropriate mathematical methods to perform calculations and solve routine tasks,
- apply and follow mathematical reasoning, and
- use mathematical forms of expression to discuss, reason and give an account of questions, calculations and conclusions. (SNAE, 2011, pp. 59-60)

In the syllabus the abilities, described above, are actualized in a set of knowledge requirements which define what constitutes an acceptable level of knowledge for the grades E, C, and A, where A represents the most advanced. In the results section the five knowledge requirements are shortened to: *problem solving, mathematical concepts, mathematical methods, mathematical reasoning and communication*.

## Data collection

The study sets out to investigate teachers' assessment of a specific set of accounts of mathematical problem solving and aims to identify the aspects of mathematical problem solving which are addressed and discussed by the teachers. Nineteen elementary school teachers from four schools in a middle-sized town in mid-Sweden were interviewed in groups. There were five groups of 3, 4 or 5 teachers respectively. At the time of the interview all nineteen teachers were teaching mathematics. They were initially chosen by their principals and asked to participate based on their own interest. The interviews were all recorded on video and an additional audio recorder. The teachers were presented with 10-16 accounts of problem solving produced by students, aged 10. The problem-solving was centered on two specific problems. They were both Diophantine equations involving the identification of a number of ways to distribute: a) 30 legs on 12 animals or b) 36 wheels on 11 vehicles (see figure 1). This type of problem can be formulated in this way where there is only one possible combination or as an open problem to which there are many solutions. A small number of legs or wheels also results in a small number of combinations; the problem can therefore be adapted to fit different students or age groups. The students can also be asked to demonstrate that they have found all possible combinations and explain how they know this. The problem offers opportunities to adopt a more or less systematic trial-and-error strategy, but there are also other ways to solve the problem. Given that the problem involves concrete objects it also offers students opportunities to draw. All these properties contributed to the choice of the problem type.

The teachers in the interviews were given information on the problems but very little information on the situation in which the texts were created. Being faced with an account of mathematical problem whose origin you know very little about forces a teacher to focus on the account itself and the interpretations derive to a larger extent from the account than it would had the teacher been asked to comment on their own students' written material. The teachers were asked to discuss the different accounts from an assessment perspective and to provide arguments for their reasoning. The group interview was chosen so as to create room for discussions but also for eliciting the teachers' idea of possible 'common grounds' in evaluating students' accounts. The interviews, which amounted to a total of 4 hours 26 minutes, were transcribed.

## Analysis

The analysis was performed in two steps. In the first step the transcribed interviews were analyzed with the intention of identifying instances in which the teachers discussed what the students seemed to be **doing**. This focus was inspired by the understanding that knowing mathematics is doing mathematics, as described above. This analysis included identifying verbs connected to instances of action such as *understand*, *know*, *think*, *draw*, *calculate*, *see* and *show*.

The second step in the analysis was focused on relating the identified instances to the different abilities described in the syllabus. The five abilities *problem solving*, *methods*, *concepts*, *reasoning*, and *communication*, did not have to be mentioned specifically. A discussion regarding a method such as trial-and-error was considered as relating to method even if the term *method* was not used. Discussions about failed attempts or deficiencies were also considered as belonging to the category of the ability in question. Examples of quotes from the teachers are shown below together with the abilities they were thought to relate to. One quote can be related to several of the listed abilities.

- Teacher: Here they have really tried...drawn all the tires... (problem solving, method, communication)
- Teacher: He has counted the number of fours he has taken away and those are plus signs... it is plus 7... (problem solving, method)
- Teacher: There is no reasoning to show that this is correct... (reasoning, communication)
- Teacher: They cannot reason without explaining a little bit more... she has not used any concepts for example... (concepts, reasoning, communication)
- Teacher: It is not enough to just write an answer...you have to be able to show in writing how you arrived at this... (communication)
- Teacher: Yes but she...she does know how to solve the problem... (problem solving, communication)
- Teacher: And then you try different numbers... that is how they have done it... you can see that they have erased... (problem solving, method, communication)

## Preliminary results

The preliminary results are presented under headlines which are consistent with the five abilities described in the syllabus. In some cases the teachers' discussions are covering two abilities at the same time and in these cases they are either presented under both headlines or presented as a compound ability which is treated under one headline.

### Problem solving

Many of the teachers' discussions are focused on the students' choice of method or strategy for solving the problem and the teachers spend considerable time trying to identify the specific method of each student. Once this has been identified however, the discussions tend to turn to other issues. A problem solving strategy is seldom judged based on its appropriateness or sophistication. Other aspects of problem solving that are addressed by the teachers include the ability to describe a problem-solving approach. The ability to describe a method, strategy or problem-solving approach can be seen as part of a problem-solving ability and this aspect is also mentioned in the knowledge requirements. This aspect however is very difficult to distinguish from the ability to account for and communicate a method, strategy or problem-solving approach. The teachers' discussions on students' ability to communicate are treated under this headline below. The ability to reason about the plausibility of results of the problem solving, or to propose alternative approaches, which is mentioned in the knowledge requirements, is not discussed.

### Mathematical concepts

Very few discussions deal with mathematical concepts. The four operations are mentioned but they are referred to as calculations which illustrate the process rather than as concepts. One student is identified by several teachers as having used the equals sign in a non-standard way which can be interpreted as relating to the concept of equality but this can also be connected to the way students choose to present their calculations.

## **Mathematical methods**

As was presented above this is the ability which many of the teachers' discussions are focused on. The method that most teachers identify is the trial-and-error method. Several teachers claim that this is the method that all students have used. There are several accounts which show different ways in which the students have carried out and represented this method but these differences are most often referred to as relating to the ability to communicate. There are examples of accounts where the trial-and-error method is not used systematically and other examples where the representation indicates a calculation that precedes the trial-and-error since the account either contains no errors at all, or displays errors that have been erased but which are still traceable. This difference stirs many discussions among all the teacher groups. They are discussing whether they can tell if a student has tried different combinations and ruled some out or if the student came by the right combination by chance or by doing mental calculations that are not represented in writing. Sometimes they agree that they cannot tell and that this is due to students' lack of ability to communicate their problem-solving processes, other times they have different opinions regarding what can be inferred.

## **Mathematical reasoning**

There is only one teacher who addresses the students' mathematical reasoning. This teacher argues that any account of problem solving which describes a method or strategy constitutes evidence of some form of mathematical reasoning. The rest of the teachers in this group are not questioning her but they are not offering her support and the issue of mathematical reasoning does not come up again.

## **Communication**

There are very few discussions that do not involve students' ability to account for and describe their approaches to solving the problem. Practically every instance involves a question from the teachers regarding what the students have done or what they mean. Even in cases where the teachers have identified a successful strategy along with a correct answer to the problem they still raise questions regarding the clarity and coherence of the account. The discussions on presentation are focused on the students' [lack of] logic, neatness, clearness, abstraction, accuracy, appropriateness, and comprehensiveness. When discussing students' choice and employment of different method a typical comment from the teachers is "if she had only shown...". This fictional comment summarizes the teachers' frustration with what they perceive as lack of evidence on which they can base their judgements regarding other abilities.

## **Discussion**

The preliminary results presented above can be used in response to the calls for external grading of national tests in mathematics in Sweden, and elsewhere, as a way to ensure objectivity and fairness. The results indicate that students' lack of communicative skill makes it difficult for the teachers to use these written accounts to assess other mathematical abilities. The study thus confirms Monaghan et al's (2009) claim that students' ability to communicate, to describe and to account for, their processes or their thinking, is crucial for teachers as well as for students. In order for teachers to evaluate students' abilities, they need to understand what the students have done and why. In order for students to write in a way that reflects their mathematical knowledge they need to know

how to represent their problem-solving process along with explanations and arguments for their various choices. The fact that there are different ways to interpret what the students have written, further strengthens the conclusion that using this writing, to assess other mathematical abilities, may be problematic. The results should not be interpreted as suggesting that problem-solving should not be used to assess students' mathematical abilities but rather that both teachers and students need to know more about different ways to clearly and comprehensively account for problem-solving processes.

# Using classroom assessment techniques in Chinese primary schools: Effects on student achievement

Xiaoyan Zhao<sup>1</sup>, Marja van den Heuvel-Panhuizen<sup>1,2</sup> and Michiel Veldhuis<sup>2</sup>

<sup>1</sup>Freudenthal Institute, FBW, Utrecht University, the Netherlands; [x.zhao@uu.nl](mailto:x.zhao@uu.nl)

<sup>2</sup>Freudenthal Group, FSW, Utrecht University, the Netherlands

*In an experimental study with a pretest/posttest/delayed posttest and control-group design, we investigated the effects on students' mathematics achievement of using classroom assessment techniques in Chinese classrooms. Participants were 47 third-grade teachers and their 608 students in Nanjing, China. The teachers were assigned to either the experimental condition, participating in two two-hour workshops on classroom assessment, or the control condition, in which the teachers followed their regular teaching plans. The workshops focused on the use of classroom assessment techniques to reveal students' understanding of multiplication and to enable teachers to adapt teaching to their students' needs. Students from the teachers in the experimental condition slightly improved their mathematics achievement scores. However, no statistically significant difference was found between the two conditions.*

**Keywords:** Classroom assessment, student achievement, China, multiplication, teachers.

## Introduction

The guidance teachers provide in their mathematics classes to their students can be more or less effective for stimulating students' learning processes, depending on whether their instruction is attuned to students' needs and possibilities for further development. Therefore, at practically every moment teachers need to know where the students are in their learning process (Wiliam, 2011). This was also recently emphasised by Schoenfeld (2014) when he wrote that "[p]owerful instruction 'meets students where they are' and gives them opportunities to move forward" (p. 407). Classroom assessment, i.e. assessment in the hands of the teachers that is interwoven with instruction and integrated in daily teaching practice, can inform teachers of 'where their students are' and as such enable them to adapt their further instruction to their students' needs.

Since the importance of classroom assessment on raising students' achievement was revealed by Black and Wiliam (1998), much attention has been paid to professional development to enhance teachers' classroom assessment practice. The rationale for this is that providing professional development to teachers on the use of classroom assessment can lead to teachers gaining more information on their students' understanding and skills. Through this information teachers can adapt their teaching to their students' needs, which in turn is expected to lead to improved student achievement. Whether professional development indeed has impact on student achievement was investigated in several studies (Phelan et al, 2012; Randel, Apthorp, Beesley, Clark, & Wang, 2016; Thompson, Paek, Goe, & Ponte, 2004; Veldhuis & Van den Heuvel-Panhuizen, 2014, 2016). The results of these studies are mixed. Facilitating teachers to use classroom assessment has been shown to lead to considerable improvement of students' achievement (Phelan et al, 2012, Veldhuis & Van den Heuvel-Panhuizen, 2014, 2016). It also happened that professional development on classroom assessment had only a small but consistent positive effect on student learning (Thompson et al, 2004)

or failed to yield any statistically significant impact (Randel et al, 2016). These mixed, but generally positive, results on the effects of professional development on classroom assessment were all found in the western educational context. As there are important differences between mathematics education in Western and East Asian countries (Leung, Graf, & Lopez-Real, 2006), we aimed to find out whether giving support to Chinese teachers on the use of classroom assessment would have an effect on their students' mathematics achievement.

In China, recently, classroom assessment has received increasing attention from primary school mathematics teachers, as evidenced by an increasing number of teacher-written papers addressing classroom assessment (Zhao, Van den Heuvel-Panhuizen, & Veldhuis, 2017). Moreover, in Chinese primary mathematics education, teachers generally agree that assessment is useful for the improvement of teaching and learning, and they assess their students at least weekly by employing various methods, for example observing, questioning and assigning textbook tests (Zhao, Van den Heuvel-Panhuizen, & Veldhuis, 2016a). It seems that classroom assessment has been widely embraced and implemented in teaching practice. However, professional development focused on classroom assessment seems sparse (Zhao et al, 2016a), let alone investigations into its effect on students achievement.

In our study, classroom assessment is conceived as the use of what we call 'classroom assessment techniques' (CATs): short teacher-initiated assessment activities that teachers can use in their daily practice to reveal their students' understanding of a particular mathematical concept or skill. These CATs have been used in earlier research in the Netherlands (Veldhuis & Van den Heuvel-Panhuizen, 2014, 2016). Our main research question was: *What are the effects of supporting Chinese primary school mathematics teachers' use of classroom assessment techniques (CATs) on students' mathematics achievement?*

## Method

An experiment with pretest/posttest/delayed posttest and control-group design (see Table 1) with 47 third-grade mathematics teachers from 18 primary schools was carried out in Nanjing, China. All teachers used the same textbook, namely 苏教版 textbook published by Jiangsu Phoenix Education Publishing House (2014). Based on the participating schools' reputation, educational quality, and location, pairs of matched schools were allocated either to the control or to the experimental condition. Teachers in the experimental group participated in two two-hour workshops on the use of classroom assessment techniques, whereas the teachers in the control group followed their regular teaching plans.

Condition	January	March			May
		Week 1	Week 2	Week 3	
Control	Pretest			Posttest	Delayed posttest
Experimental	Pretest	Workshop	Workshop	Posttest	Delayed posttest

**Table 1: Time schedule of the experiment in 2015**

In the workshops, the teachers were introduced to eight CATs. These CATs are low-tech and low-cost, and can easily be implemented by teachers. Every technique consists of a short activity (less

than 10 minutes) and helps teachers to quickly find out something about their students' understanding of mathematics, provides indications for further teaching. Also, the teachers could adapt the techniques to their own practice; they could choose when and how to use the CATs. The focus of the assessment techniques was on the first chapter of the second semester of Grade 3, in which students learn how to solve multiplication problems of two-digit numbers mainly by written digit-based algorithm. In the following we illustrate three examples of these CATs. During the workshops, the teachers in the experimental condition were provided with a detailed teacher guide describing the eight CATs that all fitted to the content of their textbook. Detailed information about the purpose of the CATs and suggestions for how to use them was provided and discussed during these workshops. It was also explained that the teachers were free to decide how they would use the CATs in practice in the following two weeks of multiplication teaching.

### CAT 1: Family problems

This CAT (see Figure 1) is aimed at assessing whether students recognize similarities among analogous problems and can use the given answer to one of these problems to solve the others.

It is known that  $97 \times 8$  equals 776.  
 Do you think you can solve the following problems?  
 (Yes- Green card ; No- Red card )

a)  $97 \times 80$     b)  $97 \times 800$     c)  $97 \times 8000$     d)  $970 \times 8000$

**Figure 1: CAT 1: Family problems**

One strategy to solve a multiplication problem with either the multiplicand or the multiplier being a multiple of 10 is making use of an analogous problem of which the answer is known or which is easy to calculate. A requirement for students to choose and use this strategy is that they understand the analogous relationship, even when the numbers involved in the multiplication are bigger than two digits. CAT 1 is meant to elicit information of whether and to what extent students have this understanding. The students are provided with the answer of  $97 \times 8$  and are then asked whether they *think* they are able to solve mentally a number of other, related multiplication problems that, at first sight, are not easy to solve by mental calculation. CAT 1 differs from the regular assessment tasks in the textbook in which the students have to carry out the calculation and the focus is on detecting whether students can do this correctly. In CAT 1 it is assessed whether the students recognize the analogue structure of the problems and are aware that they can use this for solving these problems. In CAT 1, the teacher asks for every problem whether students think they are able to solve it. All students have a green card (for the answer: “Yes”) and a red card (for the answer: “No”) with which they can show their answers (see Figure 2). By inspecting the waving green and red cards the teacher gets an immediate overview of the students' responses and whether they see the analogy between the problems, and whether their understanding is affected by the number of zeroes in the family problems.

a)  $97 \times 80$ d)  $970 \times 8000$ 

Figure 2: Students showing their cards in CAT 1 for the problems  $97 \times 80$  and  $970 \times 8000$

### CAT 2: Breaking down a multiplication

This CAT (see Figure 3) is aimed at assessing whether students can identify the components of a multiplication by filling in the blanks on a work sheet.

$24 \times 53$  means that you have to calculate

- a)  $3 \times 4$  and  $3 \times 20$  and  $\underline{\quad} \times 4$  and  $\underline{\quad} \times 20$   
 b)  $4 \times \underline{\quad}$  and  $4 \times \underline{\quad}$  and  $\underline{\quad} \times 3$  and  $20 \times 50$   
 c)  $20 \times 50$  and  $20 \times \underline{\quad}$  and  $4 \times 50$  and  $\underline{\quad} \times 3$

Figure 3: CAT 2: Breaking down a multiplication

Students may be able to find the correct answer of a problem like  $24 \times 53$  by performing the standard multiplication algorithm perfectly; however, this does not necessarily mean that students understand what they are doing and that they understand the structure of multiplications with multi-digit numbers, which is the focus of CAT 2. This approach of requiring students to unravel multiplication problems differs from the regular approach to assessing students in which finding the correct answer of a multiplication problem receives most attention of mathematics teachers. In the case of CAT 2, the multiplication of 24 and 53 can be unpacked into four sub-multiplications, namely  $3 \times 4$ ,  $3 \times 20$ ,  $50 \times 4$ , and  $50 \times 20$ . The sum of the results of these sub-multiplications gives the answer of  $24 \times 53$ . By asking students to identify the components of a multiplication problem of multi-digit numbers it can be revealed whether they understand what is ‘behind’ the multiplication algorithm. For example, the student work in Figure 4 shows that Student 1 has difficulties in being fully aware of the values of the digits (having  $5 \times 4$  and  $5 \times 20$  instead of  $50 \times 4$  and  $50 \times 20$  in Task a, and having  $2 \times 3$  instead of  $20 \times 3$  in Task b), while Student 2 could not clearly distinguish the different components of the multiplication  $24 \times 53$  (having  $4 \times 3$  instead of  $20 \times 3$  in Task b, and having no answer filled in Task c).

$24 \times 53$  就是算

- a)  $3 \times 4$  和  $3 \times 20$  和  $5 \times 4$  和  $5 \times 20$   
 b)  $4 \times 3$  和  $4 \times 50$  和  $2 \times 3$  和  $20 \times 50$   
 c)  $20 \times 50$  和  $20 \times 3$  和  $4 \times 50$  和  $4 \times 3$

Student 1

$24 \times 53$  就是算

- a)  $3 \times 4$  和  $3 \times 20$  和  $50 \times 4$  和  $50 \times 20$   
 b)  $4 \times 3$  和  $4 \times 50$  和  $5 \times 3$  和  $20 \times 50$   
 c)  $20 \times 50$  和  $20 \times \underline{\quad}$  和  $4 \times 50$  和  $\underline{\quad} \times 3$

Student 2

Figure 4: Work of two students in CAT 2

### CAT 3: Fruit language

This CAT (see Figure 5) is aimed at assessing whether students can use the associative and distributive property of multiplication to restructure a multiplication problem.

On this worksheet you have to rewrite the problems in fruit language.  
Use the given info and look at the examples.

Problem	In fruit language
<b>Given info</b>	
$7 \times 18$	
$5 \times 18$	
<b>Examples</b>	
$14 \times 18$	 
$12 \times 18$	 
$18 \times 20$	_____
$24 \times 18$	_____

Figure 5: CAT 3: Fruit language

Making use of the associative and distributive property of multiplication is the basis of solving multiplication problems. By using these properties students can convert a difficult multiplication problem into a number of easier multiplication problems. For example,  $25 \times 36$  can be solved by calculating  $20 \times 36$  and  $5 \times 36$  (distributive property) or by calculating  $25 \times 4 \times 9$  (associative property). For solving multiplication problems in this way it is very important that students understand the associative and distributive property of multiplication and that they can identify the possibilities of restructuring a multiplication problem. CAT 3 provides an opportunity for students to show this understanding. In order to avoid the difficulty of formal notations, fruit is used as a substitute.

The student work shown in Figure 6 reveals that Student 3 has arrived at a high level of the understanding of the associative and distributive property of multiplication and is able to notate this in a proper mathematical way, although not using a formal notation with number or letter symbols. Student 4 only ‘rewrote’ one of the multiplication problems ( $18 \times 20$ ) by drawing four bananas. Moreover, the worksheet of this student shows that he/she did not use the properties of multiplication but instead was calculating the multiplications and then tried to express the answer by using the fruit.

Figure 6: Work of two students in CAT 3

In order to measure students' mathematics achievement, three tests were used, which were designed and arranged by the local teaching research office. These tests have the same structure in terms of the type of questions and total score (100 points). However, the mathematical domains that are tested are different. The immediate posttest was an end-of-chapter test and focused on the multiplication of two-digit numbers. The pretest and the delayed posttest were end-term and mid-term tests, which also

included problems related to measurement, fractions, and geometry. Nevertheless, multiplication is the main focus of all the three tests (30% of the points in the pretest and delayed posttest and 90% in the immediate posttest were related to multiplication tasks).

Originally, 3040 students took the tests. Since it was found that mistakes were made when grading students' examination papers, we decided to choose 608 (20%) students systematically, based on their student number in every class, for data checking to be included in the final analysis.

## Results

Unexpectedly, on average, students in both conditions had decreasing mathematics achievement scores from pretest ( $M_{exp} = 89.2$ ,  $SD_{exp} = 8.7$ ;  $M_{con} = 90.8$ ,  $SD_{con} = 7.7$ ) to immediate posttest ( $M_{exp} = 88.5$ ,  $SD_{exp} = 9.3$ ;  $M_{con} = 89.5$ ,  $SD_{con} = 9.0$ ) and to delayed posttest ( $M_{exp} = 86.4$ ,  $SD_{exp} = 12.2$ ;  $M_{con} = 87.7$ ,  $SD_{con} = 11.2$ ). When looking at the standardized scores this image becomes a bit less clouded by the different tests measuring different domains at the different time points, therefore we report the  $z$ -scores in Table 2. The pattern remains almost the same, with relatively higher scores in the control condition than in the experimental condition, but, in the experimental condition, a slight improvement of the scores appears after the intervention.

Condition	Pretest score		Posttest score		Delayed posttest score		<i>n</i>
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>	
Control	0.104	0.930	0.059	0.986	0.058	0.952	278
Experimental	-0.088	1.049	-0.050	1.010	-0.049	1.038	330

**Table 2: Descriptive statistics of students' standardized mathematics ( $z$ ) scores per condition for the pretest, posttest, and the delayed posttest**

We performed an analysis of covariance (ANCOVA) on the immediate posttest scores to see if this small improvement was statistically significant. In this ANCOVA the pretest score was entered as covariate and condition as fixed factor. It turned out that no significant effect for condition was found ( $F(1, 605) = 0.08$ ,  $p = .776$ ,  $\eta_p^2 = 0.000$ ).

## Discussion

The students of the teachers that participated in the workshops on the CATs only very slightly improved their standardized mathematics achievement scores after the intervention. This improvement was not significant, neither in size, nor in the statistical sense. Contrary to these findings in the experimental group, the students in the control group did not improve their standardized scores from one test to the other. However, on average the students in the control condition outperformed the students in the experimental condition on all three tests. A possible reason for the minor changes in students' mathematics achievement could be that there appeared to be a strong ceiling effect on the tests (average success scores of around 90%). Maybe students' extant high achievement level could also have caused that the use of the CATs did not further optimize the teachers' instruction. Another explanation for the small improvement in the experimental condition could be the short period of time of the intervention. In less than three weeks, the teachers in the experimental condition needed to understand how to use the CATs, to incorporate them into their teaching plans, and to reconcile the new insights into their students with their original understanding of students and teaching. For

teachers to really get used to and to make the most of the implementation of the CATs, probably more time needs to be reserved and more guidance needs to be offered in the professional development workshops.

Also the context of the experimental study may have influenced the effect of the CATs on the students' mathematics achievement. First of all, as we found in an earlier study (Zhao, Van den Heuvel-Panhuizen, & Veldhuis, 2016b) Chinese primary school mathematics teachers have detailed lesson plans and tend to include CATs in their pre-arranged lessons as extra exercises rather than implementing them as formative assessment activities. As such, the teachers may not have used the information gathered with the CATs for adapting their instruction. Another issue is that the planned lessons have for every addressed topic a fixed time schedule for instruction and practice. By including the CATs less time could be spent on teaching these topics and students may have had less practice in solving the problems as used in the regular tests. A promising finding is that despite this smaller investment in the regular program the students in the experimental condition did not perform really worse in the regular tests than their counterparts in the control condition. In this way, our study provides some evidence which may encourage teachers to go beyond the straightforward testing of the standard operations and pay also attention to examining students' deeper understanding of these operations, and use the assessment information adaptively for improving instruction and student learning.

### Acknowledgments

This work was supported by the China Scholarship Council (CSC) under Grant 201206860002; and the Netherlands Organization for Scientific Research (NWO) under Grant NWO MaGW/PROO: Project 411-10-750. The authors thank Prof. Lianhua Ning of Nanjing Normal University, China, for helping to contact schools and all the teachers involved in this study for their cooperation and contribution.

# The complexity of mathematical thought and the quality of learning: Portfolio assessment

Fernando Luís Santos<sup>1</sup> and António Domingos<sup>2</sup>

Instituto Piaget, Almada, Portugal; [fernando.santos@almada.ipiaget.pt](mailto:fernando.santos@almada.ipiaget.pt)

UIED, DCSA, FCT da Universidade Nova de Lisboa, Portugal; [amdd@fct.unl.pt](mailto:amdd@fct.unl.pt)

*This poster presents an instance of portfolio assessment by two students on a geometry problem in a pre-service teacher training course analysed through a model designed to access the mathematical thought and the quality of student learning outcomes. This analytical model, supported by the SOLO taxonomy, uses Activity Theory as a contextual framework that integrates the different relations, namely advanced mathematical thinking concepts like procept and proceptual divide. Results allowed us to see the different pathways taken by the students to solve the same problem.*

*Keywords: Assessment, geometry, portfolio, quality of learning, mathematical thought.*

## Introduction

Portfolio assessment brings an open evaluation method into the mathematical classroom and allows the mathematical abilities of the students to grow. In this study, students chose three of 15 problems and were given one month to solve them and to explain in detail their solution process. This solution process involves brainstorming sessions centred on the best solution, and the detailed explanation necessarily involved in self-regulated learning processes. This teaching method aims to extend the mathematical knowledge of future teachers, involving them in activities more open and less structured than the traditional ones.

The data presented here were chosen because the students show a similar path (12th grade mathematics) and took different approaches to the same problem. Data was studied using the analytical model that highlights these differences and integrates the SOLO taxonomy (Biggs & Collis, 1982) with the advanced mathematical thinking theories and concepts of Tall (1991) alongside the conceptualization of the proceptual divide (Gray & Tall, 1994), and activity theory (Engeström, 2001) as a contextual structure. The SOLO taxonomy allows us to identify five progressive levels of understanding from the *prestructural* (lowest level), through the *unistructural*, the *multistructural*, the *relational* to the *extended abstract* (highest level).

The problem statement asks to find the length of  $\overline{BC}$  (to the second decimal place) knowing that  $\overline{AC} = 10\text{cm}$  and  $\angle BAC = 30^\circ$  (do not use any trigonometry) with the aid of figure 1.

**Figure 1: Visual representation of the problem**

Raquel, one of the participants, struggled with this problem due to the limitation stated in the problem (do not use trigonometry), but she sketched another triangle making an isometry using  $[AC]$  as a

symmetry axis, creating with  $B'$  an equilateral triangle  $ABB'$  because if  $\angle BAC = 30^\circ$  then the resulting isometry makes  $\angle CAB' = 30^\circ$  therefore  $\angle BAB' = 60^\circ$  and a equiangular triangle is also an equilateral triangle. By using the Pythagorean theorem, she calculated:

$$\begin{aligned} \text{If } \overline{AB} = x, \overline{BC} = \frac{x}{2}, \overline{AC} = 10 \text{ then } x^2 &= \left(\frac{x}{2}\right)^2 + 10^2 \text{ simplifying } x^2 = \frac{x^2}{2^2} + 100 \Leftrightarrow 4x^2 = x^2 + 400 \Leftrightarrow \\ &\Leftrightarrow 4x^2 = x^2 + 400 \Leftrightarrow 3x^2 = 400 \Leftrightarrow x \cong 11,55 \Leftrightarrow \overline{AC} = \frac{x}{2} \cong 5,77 \text{ cm} \end{aligned}$$

Mariana on the other hand started calculating  $\angle ABC$  by subtracting the other two angles known so:

$$\text{If } \angle BAC = 30^\circ, \angle BCA = 90^\circ \text{ then } 180^\circ = 90^\circ + 30^\circ + \angle ABC \text{ so } \angle ABC = 60^\circ$$

And then she made a relation between the sides of the triangle by using the ration of special triangles (a trigonometry concept) what gives the following outcome:

$$\text{If } \overline{AB} = 2a, \overline{BC} = a, \overline{AC} = a\sqrt{3} \wedge \overline{AC} = 10 \text{ therefore } a\sqrt{3} = 10 \wedge a = \frac{10}{\sqrt{3}} \text{ so } \overline{BC} = a \text{ so } \overline{BC} \cong 5,77 \text{ cm}$$

## Final remarks

These students are very familiar with being tested by closed book exams (and they were expecting that also), but portfolio assessment was a different approach and they were in an *unknown territory*.

Raquel clearly surpassed the proceptual divide and her outcome was classified as an *extended abstract*. She made connections to other concepts, explained her pathway and was able to justify the outcome, supplying evidence to support her solution. Activity theory was used to identify the contradiction arising by the use of different mediating artifacts namely the use of isometries to produce the equilateral triangle.

Mariana knew something about what she was doing, but by breaking the mathematical rules she did not surpass the proceptual divide. Her outcome was classified as *multistructural*. After the presentation of the results it is clear that her answer could be *unistructural* because she made simple connections without identifying their role. She could not describe what's the process she had followed but could not justify what she did and how she obtained the outcome. The use of activity theory revealed two major contradictions related to the mediating artifacts and the limitations.

*In this report the themes and points for discussion of the Thematic Working Group 22 on Curricular Resources and Task design are briefly explained and summarized. These related to design principles and task characteristics, also of digital curriculum resources, and perspectives on the development of digital resources were identified. At the same time the role of teachers in task design, whether as “designers” or “partners in task design” or as mediators of tasks designed by others, and of course the role of students working with the tasks/resources, were acknowledged as crucial issues. Concerning teachers, pre-service or in-service teacher education, and generally teachers’ work in collectives, were perceived as stimulating contexts for the design of and work with curriculum resources: how can teachers develop design capacity and knowledge when working with curriculum resources, and which affordances (and constraints) are provided by digital resources? Concerning students, discussions evolved around issues related to how digital resources can provide feedback for enhanced student learning.*

*Keywords: Curriculum resources; task/curriculum design; design principles; teacher collective work; design capacity.*

### **Background**

The TWG 22 received 25 paper and poster submissions: 17 submissions were accepted as papers, 6 as posters, and 2 were withdrawn (for various reasons: lack of funding; lack of time). The contributing authors came from 17 different countries.

The sessions were organised into five paper sessions organised under four themes, one poster session, and one report & discussion session. For each session we now briefly present the authors and titles of the individual presentations, followed by a summary of themes discussed in the sessions.

### **Session 1 & 2**

Theme: Issues linked to the design of tasks and resources

- Gijssbers & Pepin: Context based tasks on differential equations to improve students' beliefs about the relevance of mathematics
- Nagari Haddif: Principles of redesigning an e-task based on a paper-and-pencil task: The case of parametric functions
- Borys & Choppin: Tensions between resource perspectives and trends in the design and dissemination of digital resources

- Brocardo, et al.: Tasks to develop flexible multiplicative reasoning
- Seidouvy & Eckert: Designing for Responsibility and Authority in experiment based instruction in mathematics
- Cohen-Eliyahu: The role of design in conceptual change: The case of proportional reasoning

The issues identified in these two sessions related to four main themes. First, participants discussed the relationships between design principles and task characteristics. This is particularly important, if the design is expected, for example, to afford conceptual change (see Cohen-Eliyahu), or to support student reasoning competency involving aspects of authority and responsibility (see Seidouvy & Eckert) or to enhance students' beliefs about the relevance of mathematics (see Gijssberg & Pepin), or to facilitate noticing and visualization when developing flexible multiplicative reasoning skills (see Brocardo, et al.). It is also pertinent for tasks that were re-designed from paper and pencil to e-tasks (see Nagari Haddif). Second, perspectives on the development of digital resources were identified, and tensions between conceptions of teachers' interactions with digital resources and the ways other actors (e.g. policy makers, curriculum developers) frame the purpose for and development of digital curriculum resources (see Borys & Choppin). A third point of discussion was the role of teachers in task design, whether as "designers" or "partners in task design" or as mediators of tasks designed by others. In fact, it was concluded that often teachers were left out, or insufficiently considered, in relation to their role of mediating tasks. A fourth point of discussion was related to the role of students working with the tasks/resources, which was addressed in the majority of the papers presented in these two sessions.

### **Session 3** (poster session)

In this session all posters were presented in order to provide additional opportunities for contributors to participate in this TWG.

- Noll, et al.: How to design educational material for inclusive classes
- Jukic Matic: Teachers' pedagogical design capacity and mobilisation of textbook
- Wynne & Harbison: Task design within the Universal Design for Learning Framework to support inclusion in the mathematics classroom
- Llanos & Otero: Changes in the images and arguing from mathematics textbooks for the secondary school in Argentina along 67 years
- Dooley & Aysel: Using variation theory to explore the re-teaching phase of lesson study
- Cizmesija et al.: Asymptotes and asymptotic behaviour in graphing functions and curves: an analysis of the Croation upper secondary education within the anthropological theory of didactics

### **Session 4**

Theme: Issues linked to prospective teachers' work with tasks and resources

- Dempsey & O'Shea: Critical Evaluation and Design of Mathematics Tasks: Pre-Service Teachers
- Kilic, et al.: Pre-service teachers' reflections on task design and implementation

- Stylianides & Stylianides: Promoting prospective elementary teachers' knowledge about the role of assumptions in mathematical activity

The issues identified in this session related to four main themes. First, although not directly addressed in the three papers, the issue of design capacity building was raised: what teacher design might mean (see also sessions 1 & 2), who is designing what (see also sessions 1 & 2), and how design capacity building relates to teacher education. Linked to latter, a second point was discussed: the relationship between teacher knowledge (see Stylianides & Stylianides) and design capacity. As a third point for discussion, participants reflected on the implementation process in terms of pre-service teacher learning/knowledge development (see Kilic, et al.). Under a fourth issue it was discussed how teacher knowledge (in teacher education) could be enhanced through task design (Dempsey & O'Shea).

## Session 5

Theme: Issues linked to design and use of resources in professional development and collective work

- Eckert: Agency as a tool in design research collaborations
- Essonnier, et al.: Factors impacting on the collaborative design of digital resources
- Gueudet & Parra: Teachers' collective documentation work: a case study on tolerance intervals
- De Moraes Rocha & Trouche: Documentational trajectory: a tool for analysing the genesis of a teacher's resource system across her collective work

The issues identified in this session related to three main themes. First, it was emphasised that teachers' learning trajectories of professional learning are typically not short-term, and hence that there is a need to research them longitudinally (see De Moraes Rocha & Trouche). Second, the dynamics in collaborative task design of teachers and teachers working/designing collaboratively with curriculum resources, were highlighted (see Eckert; Gueudet & Parra): in terms of lesson preparation, design of learning trajectories, and/or teacher re-design in class. Linked to that a third point was raised: the cultural aspects of teachers working with curriculum resources (see Essonnier et al.).

## Session 6

Theme: Issues linked to teacher and student use of resources/curriculum materials at primary level

- Daina: From textbook to classroom: a research on teachers' use of pedagogical resources in the context of primary school in the French
- Delaney: Children's performance on a mathematics task they were not taught to solve: A case study
- Gaio: Programming for 3rd graders, Scratch-based or Unplugged?
- Rezat: Students' utilization of feedback by an interactive mathematics e-textbook for primary level

The issues identified in this session related to four main themes. First, although not directly addressed in all papers of this session, the choice, design and use of digital as compared to non-digital curriculum resources were discussed. This was seen as particularly relevant, as often digital curriculum resources are combined with traditional materials (see Gaio), such as textbooks. Second, participants discussed the use of mathematical tasks/curriculum resources to promote particular learning goals (see Diana), in particular as textbooks often do not provide information on how to organize the teaching of particular activities. This links to the third point, the enactment/implementation of tasks depending on teacher goals (see Delaney). A fourth point related to task design and feedback, that is ways in which teachers or curriculum developers can provide effective feedback, i.e. feedback that actually influences the development of mathematical concepts (see Rezat).

## Session 7

In session 7 the following themes were identified as overarching issues:

- Task design: what does task mean; what does design mean?
- Teacher design capacity & the role of the teacher in “design” (incl. implementation)
- Digital resources/tasks/curriculum materials
- Plurality of theoretical frameworks & clarity
- Operationalization of theoretical frames
- High inference claims & evidence

Whilst the first three have been addressed under previous sections, the last three deserve a special mention. It was noted that a plurality of theoretical frames was used. This is not an issue in itself, but it becomes a problem, when the diversity of theoretical frameworks diverts from, and sometimes covers, the problem addressed, that is obscures the clarity of the research. Linked to that selected participants would have wanted a better, or clearer, description of how the theoretical frames were actually operationalized. Moreover, it was mentioned that too often the researchers made high inference claims based on insufficient evidence. This was seen as a shortcoming of such research. Overall, participants emphasized the positive and constructive atmosphere in the group, where criticism was welcomed as a vehicle for developing deeper insights and sharpening up of ideas.

# **Tensions between resource perspectives and trends in the design and dissemination of digital resources**

*Teachers are increasingly using digital resources to design lessons. We describe three perspectives for describing teachers' interactions with digital resources, perspectives that denote different assumptions with respect to teacher agency and the connections between capacity development and resource use. This paper examines the tensions between these conceptions of teachers' interactions with digital resources and the ways other actors – including policy makers, curriculum developers, and purveyors of online content – frame the purpose for and development of digital resources. Our analysis suggests that the assumed role of the teacher differs across different sets of actors and different visions related to the design and development of digital curriculum resources. The implications relate to the opportunities for teachers to transform digital resources to suit their purposes and to develop and grow professionally as a result.*

**Keywords:** *Digital curriculum, teacher practices, curricular resources.*

Teaching is design work: Teachers actively interpret and mobilize resources to attain pedagogic and curricular goals. Moreover, teachers increasingly use, and are expected to use, digital resources to design lessons. However, there are tensions between education technology discourses, curriculum design trends, education policies, and the work teachers do with digital resources. As a case in point, in Sweden a public/private partnership endeavor created a repository of resources and lessons for teachers that was little used because the design of the repository did not take into account how teachers actually take up digital resources, illustrating the lack of alignment between teachers' professional practices, education policy, and the design of instructional resources (CERI, 2009). As Remillard (2012) notes, teachers do not simply interpret authors' intentions as they engage with curriculum resources, they engage with the artifact itself (p. 114). Given that teachers' work with resources can promote teachers' professional development and meaningful experiences for students, it is important to understand how tensions between teachers' practices and the assumptions about teaching and teachers embedded in digital resources potentially constrain teachers' opportunities to develop design capacity.

To illustrate how digital resource design and dissemination limit teachers' agency – and thus their roles as designers – we examined tensions between conceptions of teachers' interactions with digital resources and the ways other actors – including policy makers, curriculum developers, and purveyors of online content (commercial publishers, large philanthropies) – frame the purpose for and development of digital resources. These actors constitute the largest source of resources and information regarding digital resources and thus their influence merits attention from the research community. The ways digital resources are framed and promoted by policy makers and other actors may be at odds with the actual work teachers do and the needs of their students.

## Conceptualizations of teachers' work with digital curriculum resources

The meaning of the term resources depends on the perspective of the researcher and what is being researched (Ruthven, 2013). Researchers frame the relationship between teachers and their use of resources in three ways: resources function as tools that mediate the act of teaching; resources function as artifacts (instruments) that signify outcomes of processes; and resources function as objects whose creation is a key component of teachers' professional work (Remillard, 2013). These are elaborated in more detail below.

The most common framing in teachers' design work is that resources are tools that mediate teachers' work, in line with sociocultural notions of tool mediation (e.g., Wertsch, 1998). The resource's function is primarily to help/aid/assist teachers in the work of teaching. Teachers' use of resources allows them to improve practices they already engaged in or, sometimes, to engage in new practices altogether. Often, the affordance or benefit of the resource is located within the resource and teachers perceive the affordance or benefit and apply it to their local context. Kasten and Sinclair (2009), for example, showed that teachers selected digital applets to help present topics in new ways. Also, Duncan (2010) demonstrated that teachers made their classroom practices more student-centered because the resources they were using automatically provided students feedback and gave students more agency over their interactions with content. These teachers crafted lessons that capitalized on this shift in the student-content relationship. In these two examples, the benefits or affordances were thought of as residing in the resource.

Considering resources as an artifact – rather than as a tool – connotes place and time: teachers' use of resources is inseparable from when they are used and teachers' purposes for using resources. The theory of instrumental genesis (Rabardel, 2002) considers three factors: the impact of the design of tools on how they are used (instrumentation); the users and their previous experiences with using the tool (instrumentalization); and the purposes and goals users assign to tool use (schemes of utilization). Acknowledging the different factors that impact how teachers take up tools makes the processes associated with using the tool rather than the tool itself the object of study. Rabardel defined an *instrument* as an artifact coupled with the schemes of utilization users assign to it. It is important to note that the theory of instrumental genesis is focused on the resource *in use*, not the resource itself. The use of the term instrument emphasizes a process of transformation where the focus is on how teachers use resources to attain goals, not some innate quality of the resources. This is especially important when considering teachers' work with resources because teachers increasingly draw from a variety of sources when crafting instruction and use resources differently over time according to their context (e.g. Gueudet, Bueno-Ravel, & Poisard, 2014).

The third conceptualization is framing resources as objects, where a key component of teaching is to create resources. Document genesis (Gueudet & Trouche, 2009) is a theory focused on teachers' creation of resources for teaching. Stemming from the instrumental approach, document genesis explains how, in the creation of resources, teachers develop schemes of utilization that are comprised of teachers' knowledge and processes for using resources. Document genesis offers a window into teachers' evolution of practices with their resources. Since teachers often reuse resources from previous years, the documents from one year become resources for the next year and are embedded with teachers' experiences and modifications (Gueudet & Trouche, 2009). Often, when resources are considered tools, teachers are not producers: their work is of application and applies to one instance

of enactment without connection to future use. However, when treated as objects of design, the focus is on how teachers create resources to meet their local contextual challenges and on how the teachers' understanding and use of resources evolves over time.

In a complex landscape where teachers weave together various resources in the design of lessons, treating resources as an object of teachers' design work provides researchers with a theoretical grounding to make sense of and explain interactions in online spaces, such as resource repositories. The resources being downloaded and shared by teachers are not solely resources (tools) to mediate teaching: their creation and transmission constitute important facets of teaching. For example, Trglaova and Jahn (2013) examined how teachers improved resources posted to a repository based on the feedback they received from other teachers. Also, this framing allows researchers to situate teachers in broader collectives and to determine how the impact of belonging to and participating in collectives has on teachers' practices (Guedet & Trouche, 2012).

These perspectives on resources suggest different roles for the teacher with respect to how digital resources get taken up. In the first, resource as tool, the resource is considered to have innate qualities that teachers can employ to varying degrees in their lessons but not substantially revise. The latter two perspectives outline a more active role for the teacher, suggesting not simply a mediating role between resource and student, but a transformative role for the teacher with respect to the design and use of the resource. More generally, thinking about teachers' design processes positions teacher capacity as an important goal in the design and use of digital resources; consequently, perspectives on digital resources that minimize teachers' role have potential impact in terms of agency and ultimately the development of teacher capacity. Below, we explore how trends in the design and dissemination of digital resources may be in tension with conceptualizations of active roles for teachers with respect to the design and use of digital curriculum resources. We consider how different actors influence the design and dissemination of digital curriculum resources, and that these efforts may neglect the role of the teacher. An aim is to show that there are potentially conflicting values between perspectives focused on teaching as design and perspectives that promote characteristics of digital resources that constrain teachers' roles and their ability to be responsive to their local context.

### **Trends in the design and dissemination of digital resources**

In this section, we articulate broad trends in the design and dissemination of digital curriculum materials and then connect those trends to the perspectives that emphasize the design role of teachers. We characterize these trends by focusing on the actors who emphasize particular perspectives – and exercise considerable influence – related to the design and dissemination of digital resources. We focus on the following three broad sets of actors because of the considerable influence they exercise over the design and dissemination of digital curriculum materials: designers, policy makers, and purveyors of online content (e.g., commercial publishers, for-profit educational websites, large philanthropic or corporate organizations). Included in the group of corporate entities are philanthropies and corporations not previously engaged in educational publishing (e.g., the Gates Foundation, Amazon, Mark Zuckerberg's funding efforts), who strive to influence both content as well as delivery mechanisms for that content, especially in the U.S.

These groups make a number of claims about the potential transformative features of digital curriculum materials. We focus on three features to highlight the roles of the sets of actors identified above:

- Content can be more relevant and interactive;
- High quality content can be inexpensive and widely accessible; and
- Content can be customized to meet the needs of individual students.

We selected these features because they are the primary focus of the design, dissemination, and publicity efforts of the actors described above. Below, we describe how these features are emphasized by the various actors and how they are in tension with the perspectives on resource use, with implications for how teachers get positioned as active designers who can develop increasing capacity to design and enact curriculum materials.

### **Content can be more relevant and interactive**

Advocates claim that content in digital materials has the potential to be more interactive and relevant, as it can be updated and revised to fit the local context. In terms of interactivity, digital texts can be flexible with respect to navigation (e.g., hyperlinks) and with respect to creating documents with resources and materials from a range of sources, including the web (Zhao et al., 2010). Other kinds of interactivity include the use of sliders or buttons to manipulate parameters in a model to investigate problems or phenomena (Dede, 2000). More powerful forms of interactivity involve the use of tools with flexible purposes in open working environments, such as curriculum programs developed in Israel and Korea (cf. Lew, 2016; Yerushalmy, 2016). In general, interactivity can be conceived in terms of the choices users can make to influence their engagement with the content.

We focus on the set of actors we call *designers* to highlight how interactive features are incorporated into digital resources. We refer to designers as those who conceptualize features of digital materials based on research on learning and learning systems. Of the sets of actors described above, the curriculum resources designed and disseminated by designers are the most aligned with teaching as design perspective. These resources offer the greatest flexibility in terms of adaptation by teachers and in terms of generating interactions with students that provide opportunities to understand how student thinking develops. Designers emphasize learning experiences that augment or enhance what is possible in paper curricula. Moreover, designers emphasize the development of tool-rich workspaces that enhance interaction, communication, and exploration. Designers incorporate ubiquitous access to tools that allow for dynamically linked representations and the ability to record and curate work (Confrey, 2016; Lew, 2016; Yerushalmy, 2016). Confrey, Lew, and Yerushalmy emphasize that workspaces should provide access to a suite of tools that learners strategically select as they engage in complex problems. These workspaces facilitate the use and manipulation of multiple representations, including symbols, in ways that are intuitive and that communicate increasingly formal inscriptions of the mathematics. Furthermore, these workspaces should allow students to store and curate their work, for future reference for themselves and external audiences.

In terms of developing teachers' design capacity, and thus align with the artifact and documentation perspectives described above, designers emphasize more complicated and idiosyncratic learning paths for students in terms of deviating from a rigid demarcation and flow of mathematical activity (Confrey, 2016). Curriculum materials differ from open tools, such as Sketchpad, Cabri, or

Mathematica, in that they are intended to provide structure by bounding and sequencing mathematical activity. Integrating rich problems and work spaces provides opportunities for the kind of complex activity that involves non-linear processes (unproductive approaches may precede more productive approaches), complex interactions of tools and representations, and the collective negotiation of the viability and validity of solution paths. Such complex activity can disrupt well-defined lesson structures and allocations of time (both duration and synchronicity)(c.f. Ritella & Hakkarainen's [2012] discussion of chronotype), interrupting the potential flow of a lesson, with implications for following a prescribed scope and sequence of mathematics. Managing these non-linear activity flows calls for more prominent roles for teachers and entails developing new forms of capacity in terms of understanding curriculum progressions and coordinating (orchestrating) multiple tools and artifacts in the workspace.

The work of designers focuses on the interactive and flexible features of digital resources, while other actors – policy makers and purveyors of online content (mostly commercial interests and philanthropies operating from a neoliberal perspective) – emphasize different features, explored below. The different features emphasized by these other actors have implications in terms of the roles and capacities envisioned for teachers.

### **Free and open digital content**

Policy makers have pushed digital content that is freely available and open source. They argue that this would make high-quality content accessible to low-resource high needs districts. Internationally, there has been a push for Open Education Resources (OER) for nearly a decade now: “The open educational resource (OER) movement aims to break down such barriers [from proprietary systems] and to encourage and enable freely sharing content” (OECD, 2007). Recently, the US Department of Education launched an initiative designed to encourage districts to adopt open resources and to share their efforts and experiences with others, in part to make access to high-quality instructional resources more equitable (USDoE, 2016). The use of open resource content, however, can be time-consuming and the resources themselves are of uneven quality. There is little quality control with respect to content, and much of it requires little interactivity or minimal educative features for explaining the design rationale to teachers. Furthermore, these efforts assume that teachers have considerable capacity to evaluate, select, and sequence content chosen from a variety of sources. Given that much of these efforts are aimed at low-resourced districts, especially in the U.S., there is an assumption that teachers can use the materials without modifications, which aligns with the resource as tool perspective. Recently, there have been efforts to curate content in ways that provide quality control and articulate curriculum progressions (Confrey, 2016); however, these efforts have yet to be coordinated with the larger policies for open resources and their impact on teacher design capacity is not yet determined.

### **Customizing content for individual learners**

Policy makers, commercial publishers, and large philanthropies have emphasized the promise of digital content to be customized to meet the needs of individual learners. Customization has been discussed in a variety of ways. This can be achieved through systems that emphasize mastery learning, in which software dictates the sequencing of content for a learner based on the learner's performance on skills-based assessments (e.g., Means, Peters, & Zheng, 2014). Or, it could involve personalizing

the software settings so that the user has control over video and audio as well as the presentation of the text. A third way is for the teacher to make content selections within a program so that different students would see different content. Mostly, however, the personalized systems entail diagnostic assessments administered through online programs that dictate the pacing and sequencing of content (Choppin, Carson, Borys, Cerosaletti, & Gillis, 2014). These efforts, largely funded and publicized by large philanthropic or corporate entities, push to embed digital content in comprehensive learning management systems that include data reporting and classroom management systems. They also emphasize adaptive programs based largely from the mastery learning perspective (e.g., courseware funded by the Gates Foundation). Some educational websites, either for-profit or philanthropy-funded, create collections of lessons, sometimes developed by a small group or by larger author groups (e.g., Khan Academy, [sofatutor.com](http://sofatutor.com)). While these programs may eventually involve sophisticated adaptive systems and customized learning tools that allow learners to explore content in complex workspaces, the initial versions of these programs typically entail low-level content and reporting of percentage of correctly answered multiple-choice questions (Choppin, Carson, Borys, Cerosaletti, & Gillis, 2014), characteristics that constrain opportunities for learning. Furthermore, the programs minimize the role of the teacher, impacting development of teacher capacity.

### **Implications of tensions between perspectives**

Teachers' interactions with digital resources involves agency: in the act of designing, teachers take up digital curriculum resources, interpret their purposes, and transform them to respond to their pedagogical purposes and their evolving understanding of how those resources can be used to engage students. This assumes that teachers are designers, actively interacting with and transforming curriculum resources to engage students. The three perspectives describing teachers' interactions with digital resources denote different assumptions with respect to teacher agency and the connections between capacity development and resource use. The assumed role of the teacher differs across the perspectives of the different sets of actors that relate to the design and development of digital curriculum resources.

The analysis illustrates that different perspectives on the design and dissemination of digital resources have implications for the opportunities teachers have to understand, adapt, and transform digital resources and thus develop capacity as a result. The designer perspective offers the greatest possibility of alignment between views of teachers as designers and the affordances of digital curriculum materials, though much of their focus and expectations is on creating a medium for rich student interaction rather than informing teacher use and capacity development. Other actors – such as policy makers, commercial publishers, large philanthropies – have different perspectives, and motives, for designing and disseminating digital curriculum. The programs associated with these perspectives show little sensitivity to the complexities involved with how teachers take up digital curriculum resources, and minimize the role of teachers to transform digital resources to suit their purposes. Many of these programs emphasize personalized learning, which entails little interaction with teachers, and little flexibility on the teacher's part to construct learning experiences for students. These entities exercise great influence on which programs are available, and their impact on teacher autonomy and teacher capacity needs to occupy the attention of researchers.

*The project 'Numerical thinking and flexible calculation: critical issues' aims to study students' conceptual knowledge associated with the different levels of understanding numbers and operations. This paper presents the conjectural theory used to design and articulate the tasks of an explorative instructional sequence that promotes flexibility in reasoning and calculating in grades 2 and 3 in the field of multiplicative thinking. We focus our analysis of task design in the development of the first task of the sequence, illustrating how data analysis of students' solutions is used to reformulate the task.*

*Keywords: Task design, multiplicative thinking, flexible reasoning.*

### Conjectural theory

Our approach aims to foster flexibility in multiplicative reasoning and calculation by systematically developing both factual knowledge on numbers and the ability to operate with them as mental objects. The schemes and situations associated with multiplicative thinking constitute the referential field of modeling the relationship between quantities/magnitudes with multiplication and division (e.g. Greer, 1992, 2012; Thompson & Saldanha, 2003; Tzur et al., 2013; Vergnaud, 1983, 1988). Against this background, we develop a conjectural theory assuming that flexibility in the transition phase of addition to multiplication requires the ability of operating with products and quotients as mathematical objects, using different symbolisms for the same object (Gray & Tall, 1994; Tall, 2013) (e.g. 60 seen as  $6 \times 10$ ;  $12 \times 5$ ;  $4 \times 15$ ;  $\frac{1}{2} \times 120$ ). We envision the development of this ability along the experimental sequence as follows.

*Starting point: product as representing some numbers of some amount.* In Portuguese textbooks, as in many other countries, “times” and the notation ‘ $\_ \times \_$ ’ is introduced as symbolization of the sequence of repeated addition executed to quantify a relative big collection of identical objects in situations where these objects are combined in equal groups (e.g. Greer, 1992). The first cycle of activities introduces the expression “*some numbers of some amount*” (with or without remainder) as common way of describing the result of combining objects into equal parts, putting an amount into parts of a given size (partitive or ratio/measurement division) and distributing an amount of something among a given number of persons (e.g. Thompson & Saldanha, 2003). It is conjectured that this should foster the later understanding of the numerical equivalence of this three processes. The symbolic notation ‘ $\_ \times \_ + \_$ ’ represents the underlying multiplicative structure. It ties conceptually and numerically the initial meaning of multiplication with the two meanings of division. It explains, at the same time, why both repeated subtraction and repeated addition allow to find how many times does an amount of things go into a given quantity - inverse relationship between

multiplication and division (e.g. Freudenthal, 1983; Greer, 2013). Last but not the least, reasoning in “some numbers of some amount” allows to apprehend the inverted/reciprocal relationship between the involved quantities (e.g. if sharing 52 pictures between 4 children results in 13 pictures each, each child receives  $\frac{1}{4}$  of the collection, which implies that the initial amount (52) is 4 times as large as each part (13) (e.g. Thompson & Saldanha, 2003).

*“Times” as multiplicative comparison.* From the above understanding of the symbolic ‘ $\_ \times \_$ ’ we conjecture that students should extend the use of familiar products of the tables to compare quantities or magnitudes reasoning in terms of “so many times as much as  $\_$ ”. The number that in the situations above operates as ‘*multiplier*’ gets now the sense of ‘*factor*’ (e.g. Freudenthal, 1983; Greer, 1993). The above inverted relationship comes back: saying that Bernardo has 4 times as many volumes of Asterix as Fernanda, means that her number of volumes is  $\frac{1}{4}$  as large as Bernardo’s collection (and vice versa).

*“Times” as operation that emerges from a rectangular arrangement.* Until now, multiplicative reasoning and calculations are limited to situations where combining, partitioning and distributing are modelled with sequences of multiples (times tables). The following cycle of measurement activities extends stepwise multiplicative reasoning by mean of the rectangular arrangement of objects. First the multiplication of factors emerges from pacing concrete units in the length and width and using familiar products to find the number of units. This way of reasoning is then adapted to (1) calculate the number of tales of a given arrangement and to transform it by substituting the initial units in bigger or smaller ones; (2) to recognize the two rectangular arrangements of the stars of the American flag. The operative notion of commutativity ( $12 \times 6 = 6 \times 12$ ) and distributivity emerges from these activities. This increases the power of multiplicative reasoning and extends the application of the available factual knowledge.

*Endpoint: multiplicity goes together with divisibility and proportional relationship.* The last inquiry is conceived to connect the conceptual, procedural and factual knowledge constructed along the reflection about the ways of reasoning and calculating in the above multiplicative setting. The challenging question is why hours do have 60 minutes. Students are engaged to “unroll” the time line of a clock segmented in units of 5 and 15 minutes and to symbolize the accumulation of time with the underlying numbers’ pattern and the corresponding product to identify how one hour is divided in equal parts (5, 10, 15, ...  $\rightarrow 12 \times 5$ ; 10, 20, 30  $\rightarrow 6 \times 10$ ; etc.). The inverted number relation met before comes back by the connection of  $4 \times 15$  and  $2 \times 30$  with respectively 15 minutes as “a quarter of an hour” and 30 minutes as “half an hour”. Finally, by identifying all the possible ways of grouping 60 chairs in a rectangle, children discover the hidden equivalents of the ‘products of the clock’. 60 then appears as ‘an object’ that can be composed and decomposed in “many ways” (e.g.  $4 \times 15 = 15 \times 4$  related to  $60 \div 4$  and  $60 \div 15$ ).

## **Key principles of designing task with focus on flexibility**

The chosen approach prompts the systematic extension of the numerical relationships, arithmetic operations and factual knowledge using multiplication and division to model situations. We foster that students come to act and reason in a “mathematical reality” (e.g. Freudenthal, 2003; Tall, 2013; Gravemeijer, Bruin-Muurling, Kraemer & van Stiphout, 2013), manipulating flexibly mathematical

objects and relationships at hand through symbolic representation as professional mathematicians do (e.g. Gray & Tall, 1994).

We use the framework above to develop three kinds of tasks with a specific function and to articulate them transversally and vertically in cycles of inquiries (Bell, 1993). *Open tasks* as “Prawn skewers” (Figure 1) prompt the exploration of a key idea (e.g. envisioning multiplicities of identical things thinking in some numbers of some amount) and the development of a symbolism to express it (e.g.  $\_ \times \_$ ) to express it (e.g. Bell, 1993; Back, 2011). *Numerical tasks* (without context) promote the organization of numbers as ties in a web of number relations (Van Hiele, 1985) which extend the personal factual knowledge (Threlfall, 2002) and the development of specific skills such as analyzing numbers multiplicatively and using the process-object symbolic to explore unfamiliar forms of operating with numbers as mental objects (Gray and Tall, 1994). *Conventional tasks* focus on understanding how a particular relationship (theorem-in-action) of a scheme works and can be adapted in a limited class of situations.

The constructed webs of number relations connected to the schemes of reasoning and the classes of situations form the horizontal junctions between the tasks. The same tasks are articulated vertically, considering the transitions from a lower (informal) to a higher (formal) level of reasoning, symbolizing and computing.

The task ‘Prawn skewers’ (Figure 1) exemplifies this approach. The task provides an opportunity to explore “partitioning” as a process of structuring quantities on the own level of understanding the relationships involved in equal group situations (see draft of conjectural theory above) and using the number patterns in the available tables of multiplication. We conjectured that the majority of the children would notice that 61 is an odd number (ending by 1), near 60 ( $60+1$  and/or  $62-1$ ). Focusing by turn on number 60, they would in first instance notice it can be reached counting by two and/or ten which suggests partitioning the pile of prawns by way of repeated addition ( $2+2+2+2\dots$ ;  $10+10+10+10+10+10$ ). Students that operate on a higher level of understanding two-digit numbers would associate 60 with  $6 \times 10$  seen as “six tens”. Then, one can explore other grouping possibilities, varying additively or multiplicatively the number of prawns of each stick or transforming a founded partition in a new one, substituting smaller composite units by bigger ones and vice versa.

Considering the current phase of development of grade 2 students, we expect difficulties with the symbolization of founded structures with products (e.g. difference between “6 times 10” written as  $6 \times 10$  and “10 times 6” written as  $10 \times 6$ ) and related misunderstanding in the communication about the transformation of one possible structure into another one (e.g. 6 times 10 into 12 times 5;  $6 \times 10 = 12 \times 5$ ). Finally, we expect that some students could first approach the task by describing the process of exhausting the pile of 61 prawns with an arithmetical sequence of repeated subtraction and then (quickly) invert their modeling to avoid the (arising) computing difficulties.

## Methodology

The project plan is based on a qualitative and interpretative methodology (Denzin & Lincoln, 2005) with a design research approach (Gravemeijer & Cobb, 2006). The preparation of teaching experiences is a crucial aspect of the project plan.

To prepare teaching experiences we design and reformulate mathematical tasks using a three-step cyclic process: (1) design tasks, (2) analyze what children noticed in the numbers and how they use

their knowledge about numbers and operations to solve the task presented along clinical interviews and (3) reformulate the previous task.

This text refers to one teaching experiment that involved 24 grade 2 students (age 7-8) and focuses on the students reasoning to solve the task ‘Prawn Skewer’ (Figure 1). Students knew how to add and subtract numbers until 1000 and had some experience in solving word problems. They hadn’t yet learned the multiplication tables. Data was collected through video and audio recordings of the classroom work, researchers’ notes, audio recordings of the preparation and reflection meetings with the school teacher involved.

The proposed task was designed and reformulated according to the data analysis of four clinical interviews, where students (4 students, 8-year-old) solved a first version of the task (Figure 2) analyzed in Brocardo, Kraemer, Mendes and Delgado (2015).

It is Vasco’s birthday. To His birthday party he wants to prepare skewers with the same number of prawns. His mother bought a sac with 61 prawns.

If you were Vasco how would you prepare the skewers? How many would you prepare? Why?  
... 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61!

**Figure 1: The tasks ‘Prawn skewer’ (reformulated)**

For Vasco’s birthday lunch he prepares prawn skewers. He hesitates between using three or five prawns in each skewer.

1. Can you explain what Vasco is thinking? How would you explain it to one of your colleagues? Which type of skewers would you prepare? Why?
2. Vasco is counting the prawns that his mother bought: 52, 54, 56, 58, 60, 61!

Think about your choice. Imagine the number of skewers you can do with this number of prawns. How many, more or less? More than 5? More than 10? More than 20? How would you find the exact number of skewers?

**Figure 2: The tasks ‘Prawn skewer’ (first version)**

Since the given alternatives in the first version (groups of 3 or groups of 5) seemed to hinder the *envisioning* of other ways of grouping, we decided to give students the freedom to experiment and evaluate different ways of grouping, taking into account two conditions: the given quantity of prawns and the freedom to invite more or less friends. We also ‘opened’ the illustration of the task, to stimulate the students’ own constructions. Finally, by giving only the number of prawns, and by continuing to choose the ‘ugly’ number 61 (in the sense of Thompson & Saldanha, 2003), we created a problem that these students surely never encountered before.

Under these conditions, we expected that students would envision different possibilities of sticking a pile of 61 prawns, modeling from two ways of understanding “division”. This is to say, reasoning in terms of exhausting the pile by a sequence of repetitive subtraction (ratio/measurement division), and/or reasoning from the converse idea of accumulating 61 by counting on  $n$  by  $n$  (division as converse of multiplication) (Freudenthal, 1982). In second instance, we expected that the choice condition of the task should stimulate students to compare envisioned ways of grouping, considering the relation between the multiplier (number of sticks) and the multiplicand (number of prawns in each stick). Exhausting, taking away a smaller set of prawns go together with making more sticks and subtracting a bigger set with obtaining less sticks. And, increasing the number of sticks by accumulating goes together with decreasing the number of prawns in each stick, as putting a bigger set of prawns goes together with obtaining less sticks, while sticking less prawns provides more sticks. Finally, we expect a great variety of modeling, verbal explanation, and calculations, according to

levels of memorizing the products/multiples of the tables, and understanding ‘multiplicity’ and ‘proportionality’ in the experienced contexts of multiplicative thinking.

## Results

The analyses of the working sheets of the students and of some dialogues occurred in the classroom gave us a global idea of the patterns of reasoning that students used to solve this task.

Globally, we identified the following patterns of reasoning: trying with 18 sticks (they counted the sticks represented in the illustration); drawing the prawns' skewers one by one (with 18 sticks); putting 2 by 2 we will arrive to 60; putting 10 by 10 gives 60; adaptation of grouping by 10 making one skewer with 11 prawn (Figure 3); adaptation by "grouping by one"; putting 5 by 5 and/or 15 by 15 gives 60 (Figure 4); intuitive notion/feeling that putting by  $n$  would give 61.

$$11 + 10 + 10 + 10 + 10 + 10 = 61.$$

$$5 + 6 = 7 + 1 + \boxed{11} + \boxed{10} + \boxed{10} + \boxed{10} + \boxed{10}$$

**Figure 3: Adaptation of grouping by tens, making one skewer with 11 prawns**

$15 + 15 + 15 + 15 = 60$   
R: Cada espetada fica com 15 camarões e à 4 espetadas.  
 $5 + 5 + 5 + 5 + 5 + 5 + 5 + 5 + 5 + 5 + 5 + 5 = 60$   
R: Cada espetada fica com 5 camarões e à 12 espetadas.

**Figure 4: Putting by 15 and by 5 with verbal description of the result**

The most frequent way of modeling was trying to reach 60 arithmetically, by repeated addition. Some students shortcut their long addition by mean of doubling consecutively the terms (Figure 5).

Three diagrams illustrating the associative property of addition:

- Diagram 1:  $10 + 10 + 10 + 10 + 10 + 10 = 60$ . Groupings:  $(10 + 10) = 20$ ,  $(10 + 10) = 20$ ,  $(20 + 20) = 40$ ,  $(40 + 20) = 60$ .
- Diagram 2:  $5 + 5 + 5 + 5 + 5 + 5 + 5 + 5 = 60$ . Groupings:  $(5 + 5) = 10$ ,  $(5 + 5) = 10$ ,  $(5 + 5) = 10$ ,  $(10 + 10) = 20$ ,  $(20 + 10) = 30$ ,  $(30 + 30) = 60$ .
- Diagram 3:  $15 + 15 + 15 + 15 = 60$ . Groupings:  $(15 + 15) = 30$ ,  $(30 + 30) = 60$ .

**Figure 5: Shortcutting by successively doubling as way of controlling / justifying**

Some dialogues suggest that some pairs of students are jumping to 60 in a kind of mental sequence of multiples, without keeping track. Having arrived at 60, they must then count the numbers of “tens” to derive the multiplier from their long addition.

Some pairs of students initially understood that they could choose the number of guests but failed to connect the given 61 prawns with the 18 sticks they counted in the picture. In a short dialog with the teacher, they envisioned ways of grouping with units, leaded by a kind of intuition (feeling) that the repeated addition they had in mind would give 61. Vera was thinking about  $11 + 11 + 11 \dots$ , and moved to  $5 + 5 + 5 \dots$  as response on the teacher's question "Why 11?". Her colleague Martin was expecting that putting prawns by 7 would give 61, "since  $7 + 7 = 14$  and  $14 + 7 = 21$ ".

José drew the 18 sticks and then 'sticks' 4 prawns in each (Figure 6). He then symbolized the represented accumulation with the long addition  $4+4+4 \dots$  and tried to determine the total number of prawns, by doubling 4 and 8, transforming  $4+4+4+4 \dots$  (18 times four) into  $8+8+8 \dots$  (9 times 8) and  $16+16+16+16+8$ .

Only one group used repeated subtraction (viewpoint of exhausting 61; Figure 7). They began to subtract 1 to obtain 60 but it seemed they changed their idea and begun to work with 61, subtracting 5 until they have a remainder smaller than 5.

**Figure 6: Wrong modeling by drawing 18 skewers with 4 prawns in each**

**Figure 7: Modeling by repeated subtraction**

Finally, two pairs of students associated the information of the story and the illustration of the task with the decomposition of 61 into two parts. One pair is thinking about a combination of 18 children (the number of sticks of the illustration) and 40 children (a multiple of 10). The other pair proposes “as  $41 + 20 = 61$ , one has 41 and the other 20” and does not add any other justification.

### Implications for task Design

From data analysis, we may conjecture that the formulated instruction does not scaffold the expected mathematization including: (1) finding and representing adequately different forms of sticking the prawns, (2) choosing the preferred way, and (3) justifying this choice. It seems that “Why” is interpreted as an instruction to demonstrate and/or control that the modeling with the sequence of repeated addition indeed gives 60 prawns. This interpretation explains the spontaneous short-cutting of long additions (Figure 5). A solution to avoid this is to structure the task in an exploring phase asking explicitly to look for possible ways of sticking and a reflective one including the choice and the justification of the referred form of sticking.

On relating the choice of 61 as cardinal of the set, we can argue that the complexity of taking away, could explain the high frequency of the modeling by repeated addition and the single use of repeated subtraction. Since more students associate 61 with the near even number 60, and since the table of two and 4 are memorized, it would be meaningful to replace 61 by 62 to increase the chance that more students balanced between modeling by jumping back to exhaust 62 and jumping forwards to reach 62. We might expect that, being aware that this way of grouping would give a lot of ‘small’ sticks, more students would try to subtract a bigger quantity and finally move to jumping forwards to avoid annoying calculations.

Finally, since the representation of some stick may suggest some students to fix the multiplier and model the process directly by drawing all the set of prawns, stick by stick, we have to change the illustration to avoid the observed try-and-error approaches.

### Implications for task design in the field of multiplication

In this text, we explicit how we analyze the influence of contexts, numbers and pictures/images aiming to potentially facilitate *noticing* (Threlfall, 2002) relevant numerical relations and *envisioning* different approaches that emerge from noticing.

Another aspect of our analysis is related with the importance to propose non-conventional equal group problems to develop flexible multiplicative reasoning. In all conventional equal group problems, two values are given. Consequently, children learn to identify the 'kind' of problem from the story and the given numbers. Then, they solve it applying the standard scheme of reasoning. Children's approaches and solutions of the task 'Prawn Skewers' show the advantage of the missing multiplier and multiplicand as stressed by Back (2011). They have to adapt their common way of thinking to the unusual conditions of the task (Vergnaud, 2009) noticing numerical relations and envisioning different approaches. Some fixed the multiplier counting the sticks of the pictures. Others inferred that they had to fix the number of prawns on each stick and to look how many skewers can be made. The vast majority envisioned the all process of sticking, using the knowledge that counting by ten leads to 60. A crucial advantage of these non-conventional problems is that the teacher can focus the reflection on the relationship between "continually putting prawns by  $n$ " and "taking again and again  $n$  prawns" and the use of asymmetric role of the multiplier and the multiplicand to symbolize both process.

# The role of design in conceptual change: The case of proportional reasoning

Noa Cohen- Eliyahu

The Hebrew University of Jerusalem, School of Education, Teacher Education Program, Jerusalem,  
Israel ; [noa.cohen-eliyahu@mail.huji.ac.il](mailto:noa.cohen-eliyahu@mail.huji.ac.il)

*Conceptual change is extremely difficult to trigger in mathematics and science education. The present study shows the special role of design – in the fact that design can afford behaviors that lead to conceptual change. We chose the domain of proportional reasoning. The design was based on collaborative and argumentative scripts, provision of a tool for checking hypotheses, and arrangement of students with different strategies. Above all we created a task, the Blocks Task, that invites students with different strategies different solutions, whereby creating (socio-)cognitive conflicts with the possibility of enhancing conceptual change. The participants were 496 ninth graders. A central result is that performing the task resulted in conceptual change. It was also shown that the provision of a tool for checking hypotheses yielded substantially larger gains. We conclude by providing design principles for fostering conceptual change in mathematics.*

*Keywords: Conceptual change, cognitive conflict, task design, proportional reasoning, collaborative work.*

## The present paper

### The focus of the present paper

The present paper aims to expose whether the *block task* is effective in triggering conceptual change in proportional reasoning. While triggering conceptual change in mathematics and in science education is a very challenging task. We have defined conditions for task design and we showed that they can dramatically boost conceptual change and learning in the field of proportion reasoning: Collaborative scripts, the arrangement of students in small groups and the provision of a hypothesis testing device for feedback were central design decisions. Above all, we created a special task, the Blocks Task, which invites students with different strategies in proportional reasoning (that reflect different levels in proportional reasoning) to exhibit different solutions, by such creating socio-cognitive conflicts

### Theoretical framework

The process of conceptual change had been described in literature in various ways. The pioneering model of Posner, Strike, Hewson, and Gertzog (1982) had described the conceptual change of replacing the earlier premature, and somewhat naïve, conceptions (which, at times, contradicts the scientific explanations) with more up-to-date scientific conceptions. The trigger for this change had been the dissatisfactions with the earlier conceptions. Other scholars (e.g. Vosniadou, & Verschaffel, 2004) replaced Posner et al.'s model with a model they called a synthetic model which is based on the combination of a scientific concept with the student naïve preliminary concept. Cognitive conflict had been for a long time considered as a major, necessary ingredient in the development of psychological theories that explain conceptual changes. The role of cognitive conflict is important in many mathematical fields Stylianides and Stylianides (2009) related to the potential concealed in

cognitive conflict to support the development of the student knowledge. In the domain of proof, counterexamples play a great deal as a pivotal means in creating and resolving a cognitive conflict (Zazkis, & Chernoff, 2008, Stylianides, & Stylianides, 2009). However, it was also found that introducing conflicting data was generally not sufficient for triggering conceptual change (Limón, 2001). Collaborative and argumentative settings as well as the provision of feedback are among the means described in the literature which may prompt the development of conceptual change among students (Schwarz, 2009). The *block task* which was designed for the purpose of the present study has been a sophistication of the *blocks task* developed by Harel, Behr, Lesh and Post (1992). Harel and colleagues designed the original Blocks Task as a diagnostic tool to assess the level of proportional reasoning of adolescents. I modified the task as a learning task with the potential for triggering conceptual change (Cohen-Eliyahu, 2001). The modifications consisted of posing the task in a dyadic setting, providing a collaborative and argumentative script in their interactions, and providing a hypothesis testing device (a balance) for checking hypotheses. This mathematical task has the potential to create socio-cognitive conflicts based on the three aforementioned conditions. Schwarz and Lichevski (2007) showed that the design yielded conceptual change. In an additional study, Asterhan, Schwarz and Cohen-Eliyahu (2014) examined the mechanisms that govern conceptual change with the Blocks task. In the present paper, I examine the role of design in triggering conceptual change. Let us first describe succinctly the study. More information can be found in Asterhan, Schwarz and Cohen-Eliyahu (2014).

## Method

### Participants

The participants were 496 Israeli ninth graders from large metropolitan areas (After studying the subject proportion ratio and percentages). 16 groups were formed with different conditions for each group: individual or pair work, with or without weighing condition (the hypothesis testing device). Students were paired according to their initial solution strategies, in order to create varied social settings based on differing initial cognitive levels. Three strategies were focused on: Students with additive strategies (N=196), students with proto- proportional strategies (N=194) and students with proportional strategies (N = 106).

### Tools

The Blocks tasks were designed according to three aforementioned conditions in the field of mathematics, and its aim was to facilitate learning (i.e. conceptual change) of ratio and proportion, as follows: (a) The task enables collaborative or individual work. (b) There is a tool (scales) with which one may check (or not) whether hypotheses are correct. In other words, students receive feedback on their solutions by using scales (c) The task allows the activation of a variety of strategies by which students may be differentiated according to their levels of thinking, which may facilitate teaming them up according to their levels of proportional thinking. In each task students are shown 4 three dimensional blocks constructed from bricks (A,B,C and D). They are told the bricks in A and C is identical (the same weight = the same color) and the same is true for bricks in B and D. In each trial, students are given information about the relation between the two base block constructions A and B (A is heavier than B, B is heavier than A, or they are of equal weight). They are asked to determine the relation between the weights of the two target blocks, C and D, choosing one of the following

four options: “C is heavier than D”, “D is heavier than C”, “They are of the same weight”, or “Impossible to determine”. They are required to provide a verbal explanation for their choice.

**Figure 1: Blocks Task 1**

In the current study seven configuration of the Blocks tasks had been designed. The design was aimed at leading wrong reasoning strategies to wrong answers. For example, a student using Visual explanations typically would claim that “it has less bricks in it”. A student adopting an additive reasoning strategy would use an explanation such as “when B has 6 more bricks than A, A and B weigh the same. D has 13 bricks more than C so D weighs more than C.” A student adopting a proto-proportional reasoning strategy would typically draw a wrong conclusion: For example, he would say “B has more bricks than A but they have the same weight so each brick in A is heavier than single brick in B. C is 13 bricks less than D but each bricks weigh more so it's impossible to decide.” Students adopting a proportional reasoning strategy would typically predict the right conclusion that C weighs more than D. They would say something like, “10 bricks in A(10a) have the same weight as 16 in B(16b) i.e. one single brick in A weighs 1.6 times one single brick in B  $a=1.6b$ . so 24 bricks in C weigh  $24*a=24*1.6b = 38.4b$  that is more than 37b bricks in D.” We see then that the Blocks task was designed to lead students with inferior strategies to give wrong answers.

## Procedure

The current study consisted in three stages: pre- test, intervention and post- test.

Stage 1: Assessment and selection– pre-test. Five Blocks Task Test was administered in pen-and paper format to all students in the ninth grade classes to assess their initial level of proportional reasoning. In each tasks the blacks' constructions (A, B, C and D) were presented to the class and trained research assistants called aloud the instruction. According to their initial reasoning strategy students were arranged in order to create socio-cognitive conflicts.

Stage 2: Learning stage. Students were asked to solve collaboratively two different Blocks Tasks according to the aforementioned condition. They were provided a collaborative and argumentative script: The dyads asked to solve the tasks together. they were invited to collaborate and to argue with each other. Additionally, students that work with hypothesis testing condition get a scale after they finished each task to check their answer. An experimenter helped them to put the blocks constructions (C and D) on the scale and told them the correct answer, and asked them to explain it. All students, dyads or individuals with or without hypothesis testing device, were interviewed while this stage by trained research assistants who, repeated the instruction again and asked the student to explain their answers.

Stage 3: post – test the student answered the five Blocks Task Test again individually.

All the participants completed the three stages in less than one month.

## Results

Over the entire sample, it appears that in all conditions, conceptual learning was attained. T-test showed significant results in comparing differential from pre-test to post-test to zero.

Analyses were conducted with a mixed model (SAS PROC MIXED) with random effects of dyad within condition and of individual within dyad and condition. Differentials means and standard deviations between pretest and posttest performance per condition are reported in Table 1.

Pairing condition			
	Single	Peer	Sum
With Feedback	0.22 (.06)	0.28 (.03)	0.25 (.04)
No Feedback	0.17 (.06)	0.10 (.03)	0.13 (.04)
Sum	0.19 (.04)	0.19 (.02)	

**Table 1: Differentials mean (and SD) between pretest and posttest scores on the BlocksTask (N=488)**

There is significant different between Students who worked with feedback (single or peer) ( $M=.25$ ,  $SD=.04$ ) and students who worked without feedback (single or peer) ( $M=.13$ ,  $SD=.04$ ). The results confirmed that hypothesis-testing improved learning ( $F(1,422)=5.10$ ,  $p=0.024$ ). But in general there is no advantage to work with peer over individual work.

Further analyses were made in purpose to reveal what accord in different pairing condition. Focusing on students who lacked full proportional reasoning, non-Proportional students (Proto – proportional students (ProtoS) and additive –students (AddS)). Differentials means between pretest and posttest and standard deviations performance for non-Proportional students are reported in Table 2.

Pairing condition						
		single	The same strategy-peer	Different strategy-peer	Proportional strategy-peer	Sum
hypothesis-testing condition	With Feedback	0.20 (.08)	0.12 (.06)	0.16 (.08)	0.58 (.06)	0.26 (.03)
	No Feedback	0.22 (.07)	-0.02 (.06)	0.22 (.08)	0.24 (.07)	0.16 (.03)

	Sum	0.22 (.05)	0.05 (.04)	0.19 (.05)	0.41 (.05)	
--	-----	---------------	---------------	---------------	---------------	--

**Table 2. Differentials mean (and SD) between pretest and posttest scores for non-Proportional students (N=382)**

There is significant different between non-Proportional Students who worked with feedback (single or peer) ( $M=.26$ ,  $SD=.03$ ) and students who worked without feedback (single or peer) ( $M=.16$ ,  $SD=.03$ ). The results confirmed that hypothesis-testing improved learning ( $F(1,239)=4.13$   $p=0.043$ ). In addition, Focusing on the non-Proportional students revealed that apart from the hypothesis-testing condition, there is significant affect to the pairing condition ( $F(3, 225)=10.98$ ,  $p<.0001$ ). and the Tukey-Kramer post hoc test showed that most efficient pairing was with a partner with full proportional reasoning. The interaction between the hypothesis-testing condition and the pairing condition is significant ( $F(3,225)=3.22$ ,  $p=0.024$ ). The Tukey-Kramer post hoc test showed that with feedback condition students who worked with student who reached proportional reasoning gained more than student who worked with any other pairing. But, without feedback condition the result wasn't significant.

We present here the example of two students, Ido and Shira, and show how the design of the task helped them advancing their strategies in proportional reasoning. Ido and Shira both started, according to their pre-test, in a proto-proportional stage. Neither of them had a fully proportional answer to any of the tasks, but they were well aware of the importance of looking at each of the cubes separately. After the interaction, they both progressed: Shira gave one full-fledged proportional answer and Ido, two. Right from the start, elements of the proportional discourse were apparent in both Shira and Ido's interaction. Interestingly, the additive discourse co-existed with elements of the proportional discourse all through the interaction about the first task (see figure 2). Thus, for instance, Shira first suggested an additive argument:

24 Shira: I think, I think this (C) is bigger than this (D) because here they tell us that this (A), no, sorry, because here they tell us that this (A) is smaller than this (B) although here (A) there are more, but only by one cube more, so if here (C) there is more in three cubes, so that says that this (C) is big.

Ido, on the other hand, starts referring to multiplicative routines:

25 Ido: Look, if you take- this (A) is 11, this (A) is bigger than this (B) by 1 and here (C) it's bigger times 3 than this (A)

26 Shira: right

27 Ido: yeah, try multiplying both of them by 3 and you'll see what happens because it's thirty something. 10 times 3 is 30 so 10 times 3 is 30 and 11 times 3 is 33. If you multiply it by 3 it comes out 33.

28 Shira: oh, so, like I got it, I got it, so here it's one

29-30 Ido: and thirty one, two... that means if you put this (A & B) times 3 you'd get here 33 and 30 and if you add another one to each one of them so it will be 34 and 31.

**Figure 2 :Learning stage Blocks Task 1**

Interestingly, Ido and Shira's solution, though not accurately proportional (Ido found a linear relationship between the block structures, not a proportional one), still leads the two students to a correct solution. In other words, it leads them to predict that  $C < D$  (by preserving the linear relationship), and the scales do not contradict it. Thus, there is no resistance of material agency. During the second phase (where  $10A_{\text{cubes}} = 12B_{\text{cubes}}$ ), it is Ido's disciplinary agency (that is, the previous mathematical knowledge obtained by Ido) that resists the additive discourse. The pair starts out by trying to implement the successful routine that they had employed in the first task:

106 Shira: Now, OK here there are 10, can you show me the calculation again? This (A) times 3.

After some calculations, Ido realizes this solution brings them to a dead end:

115 Ido: OK, look, we multiplied both of them times two, it (A) turned out 20 and this (B) turned out 24. Now, if we add to both of them 3, you get this  $(B \times 2)$  plus 3 gives 27 like this (D) and this  $(A \times 2)$  plus 3 gives 23, it didn't get to 24.

According to this linear relationship, Ido and Shira agree that C and D are not equal. However, they do not have a way of determining which block (C or D) is heavier. This, because the only way they know to use the linear relationship is by applying it to affirm the relationship between the C and D blocks stays the same as between A and B. Realizing that the former routine does not work (resistance from disciplinary agency), Shira goes back to the additive discourse:

120 Shira: so look here (C & D) this is by 3 more (meaning D has 3 more than C) and here (A & B) it's only by 2 more (meaning B has 2 more than A), get it?

After quite a long discussion (24 turns), Shira convinces Ido of her additive solution. But as she writes up her argument on the paper, Ido continues calculating numbers. The experimenter turns Shira's attention to that and Ido explains to Shira:

147 Ido: look, this (A) is 10 and here (B) it's 12. Just saying, I'm not saying it's true but let's suppose each mass here (A) is 3 and here (B) each cube is 2.5 cause that's less and they are equal cause 3 times 10 is 30 and also 2.5 times 12 is 30 and the weight between them is equal, but each cube is different like they said here. If you multiply to get to 24 you'll get 72. If you multiply this (a cube in D) times twenty s... twenty..

148 Shira: Oh, I get it like 2.5 times 27.

149 Ido: yes if you multiply you'll get  $67\frac{1}{2}$  that means that C is bigger, (the) weight is higher than D, see?

We can see that Ido changed his mind before the balance scales proved Shira's additive solution to be wrong. We can only hypothesize why this happened. It seems the resistance that was most important here was that of disciplinary agency. Both Shira and Ido could not initially find a multiplicative routine that would satisfy them. But once such a routine was found by Ido, they happily switched to it, being aware all along of the appropriateness of the multiplicative discourse for the problem at hand. Ido and Shira were actively engaged in convincing each other and questioning each other's solutions. Especially impressive was Shira's attempt, once she was convinced by Ido's new multiplicative solution, to critically examine her previous solution:

181 Shira: so how could it be (true) if like this (*covers one cube from the D structure with her hand so that there is a difference of only 2 between D and C*) it's equal and like this (*raises her hand to expose the whole structure*) it (C) is bigger?

182 Ido: because the weight of the cubes is not the same.

Shira is not convinced. She repeats her argument that  $D - 1 \text{ cube} = C$ , but now Ido challenges this assumption: "who said it's equal?" He then goes on to explain

188 Ido: you told me that there are two points (probably means cubes) less so you add two here and another one but you don't know, the two point here (A & B) and the two points here (C & D) are not the same.

189 Shira: The mass is different, I get it.

Thus, even though Ido is the main one to pursue the proportional solution and substantiate it, Shira is very active in her attempts to follow his logic, and to compare it with her own previous solution. Only then she is convince that the additive solution is invalid.

## Conclusion

The Blocks task resulted in substantial learning which may be termed conceptual change, since under all conditions the students improved their solution strategies very significantly from the pre to the post – test. These are impressive findings that suggest the crucial role of design in triggering conceptual change. The additional results consistent with the assumptions based on previous researches (Schwarz and Lichevski, 2007) about the conditions that promote conceptual change. The very rich dialogue between Ido and Shira revealed the crucial role of task design in triggering conceptual change that lead to learning. In the pre-test both student initial strategy were proto-proportional reasoning. During the Learning stage (intervention) they both made a huge advance and promote their strategies reasoning to proportional as been founded in the post-test. The Blocks task design afforded and invited, as we saw in Shira and Ido very rich dialogue, a variety of reasoning strategies (Additive, Proto-proportional & Proportional). Shira and Ido considered those antithetic strategies by justify their claims and explain to each other their opinions this socio and cognitive conflict lead them to collaborate and argument in dyad and that lead to the desired conceptual change. Also in Ido and Shira case the scale's checking hypotheses "just" confirmed their solution. After the first task confirmation done with the scales, for Ido it was a trigger in the second task to continue searching for other option even if the AddS sound acceptable (120 Shira). The deep dialogue showed the power of the collaborative work, investigating each other ideas (an additive and a proto-proportional solutions) cause emerging of a new insight (proportional –solution). The case of Shira

and Ido exemplifies the importance of collaborative and argumentative scripts, of a tool for receiving feedback (the scale), of the arrangement in dyads, but foremost of the design of the task that led students with inferior strategies to arrive to wrong conclusions, to check them with the scale and to revise them accordingly. In conclusion, as the statistical result and Ido and Shira's dialogue showed, the task design allows the use of variety of confronting strategies that may led to socio- cognitive conflict between the dyads. In the statistical result we find that gap between students play a major role. Non-proportional students with hypothesis-testing condition is significantly advanced proportional reasoning when they work with proportional students. In Ido and Shira case also it looked they started with the same strategies we reveled in the rich dialogue gap between their strategies. when Shira used automatically additive strategy Ido looked for another option that explain his proto-proportional strategy. The hypothesis-testing condition that confirmed his first answer helped him to persist in finding satisfactory solution.

It seems that the next step is to expand the study to examine the effectiveness of the conditions defined in designing mathematical tasks in other areas.

# From textbook to classroom: A research on teachers' use of pedagogical resources in the context of primary school in the French speaking part of Switzerland

Audrey Daina

Geneva University and HEP Vaud, DiMaGe, Switzerland; [audrey.daina@hepl.ch](mailto:audrey.daina@hepl.ch).

*In French speaking Switzerland, primary school teachers use uniform textbooks edited by the government. These official textbooks are specific, they provide a source of activities but do not give information about how to organize the teaching. In this context, it is interesting to observe how teachers choose and organize in-class activities, the different ways they use textbooks, and the consequences in the classroom. Our research is a case study, which is based on interviews with teachers and classroom observation. The analysis we will present in this contribution were conducted using the model of Robert and Rogalski (2005), which allows us to describe teachers' choices as a coherent system that does not depend only on learning objectives but also on characteristics of the profession and on certain constraints.*

*Keywords: teachers' practice, textbooks, primary school, cross-analysis.*

## Introduction

School textbook is a field of research which has been widely increasing since the last three decades as described by Fan, Zhu and Zhenzhen (2013) survey study for the special issue of ZDM "Textbook Research in Mathematics Education". The authors conclude this survey by suggesting future directions in this field of research:

it is necessary for researchers to establish a more solid fundamental conceptualization and theoretical underpinning of the role of textbooks and the relationship between textbooks and other variables not only in curriculum, teaching and learning but also in a wider educational and social context" (Ibid, p. 643)

The large-scale cross national research study TIMSS allowed us to have a wider vision on the role of textbook in connection with social or political issues as presented by Valverde and al. (2002) who analyze textbooks in terms of cross-national differences in *educational opportunities* "the configuration of social, political and pedagogical conditions to provide pupils chances to acquire knowledge, to develop skills and to form attitudes concerning school subjects" (Ibid, p. 6).

Our contribution goes in this direction by presenting the results based on our PhD theses (Daina 2013), which aimed to describe and analyze:

- the social and political context in which the uniform textbooks are designed in French speaking part of Switzerland, known as "Moyens d'Enseignement Romand pour les Mathématiques"(MERM);
- how five teachers in Geneva use this resource for mathematics, considering their "ordinary" practices.

Our research brings a different focus on the question of the connections between social and political issues and teachers practices by considering a qualitative methodology and a theoretical framework which allowed us to understand the practice we observe as a complex but coherent system that is dynamic and does not depend only on learning objectives but also on characteristics of the profession and on certain constraints we can infer from the study of the context (Robert & Rogalski, 2005).

## **Research design**

Our research is a case study, which is based on interviews with teachers and classroom observation. The data were collected from April to June 2009 in five classrooms in Geneva in two different schools. In every class, we collected the following data: an interview before the teaching sequence; the observations in class with video recordings of the various activities of the teaching sequence on the theme of area measure; an interview at the end of the teaching sequence.

To understand the political and social issues connected to our context of study, we collected selected documents, which showed different aspects of the official textbook design process (institutional requirements, project design, review report, etc.)

## **Theoretical frameworks and research questions**

Our project aimed to study how teachers use the textbook and prepare their lessons which is an “invisible” part of the teachers’ practices. In addition, we wanted to observe ordinary practices, with all the complexity implied. Therefore, to build our theoretical framework and our methodology we lean on two theoretical approaches: Margolinas’ model (2005) and the model of Robert and Rogalski (cross-analysis of the teacher’s activity). We did not combine this two framework, instead we asked different independent questions relating to these two theoretical frameworks which we study using tools and methodology from the relevant framework. In this presentation, we will focus on the second model and the results related to it.

### **The model of Robert and Rogalski: Cross-analysis of the teacher’s activity**

This model combines two different approaches. Firstly, a didactic approach: teacher’s practices are linked with the learning objectives. In this sense, the knowledge content of the teaching and the way the teacher organizes his teaching are analyzed using a didactic theoretical framework. Secondly, a psychological approach from cognitive ergonomics: the teacher is considered as a professional whose practices are subject to a professional contract, with particular goals, repertoires of action, representations of mathematical objects and their learning, and, more generally, personal competencies which determine his activity.

Robert and Rogalski (2002) determined five dimensions to analyze teacher’s activity.

- The cognitive and mediation dimensions which concern the set of teacher’s choices about the content and the organization of the knowledge before (cognitive dimension) and during the class-time (mediation dimension).

The combination of this two dimensions allows us to trace what “kind” of mathematics is proposed in the class « la fréquentation des mathématiques qui est installée, ce qui est valorisé par les scénarios et leur accompagnement et ce qui pourrait manquer » (Robert & Rogalski, 2002, p. 514).

This first part relates to the description of the teacher activity, then we would like to interpret and highlight what determines these practices. We refer to three dimensions:

- The social, the personal and the institutional dimensions which permit to define the constraints and the personal aspects of each teaching project.

These three dimensions are studied based on interviews, deduced from the observed teaching sequence and also from the study of the institutional and local context.

This brings us the following research questions:

- What type of mathematics is promoted by various teachers, according to different scenarios and their execution in different contexts? Which kind of logic of action can we observe? Are these practices compatible with the didactic and pedagogical choices of the MERM resource designers?
- What hypotheses can be formulated concerning the dimensions (social, personal, institutional) that determine the teachers' practices of our study? How do the MERM influence the observed practices?

## **Method of analysis**

The analysis was realised according to the following stages:

- A transcription of the lessons we observed was made using Transana, a software which allowed us to have permanently the video and the transcription on the same screen and give the possibility to introduce time codes and keywords. Referring to methodology used in various research using the double approach framework, we divide each lesson in temporal phases, which we call an episode and corresponds to a content unity.
- The scenario of the whole teaching sequence was then reconstituted and analysed to clarify on the one hand what kind of mathematical content is presented during the teaching (cognitive dimension) and, on the other hand, the dynamics in which the content appear during the classes (mediation dimension). The episodes we defined in the first stage of the analysis were coded according to the mathematical content and the teaching strategies (for more details, see Daina 2013).
- we wrote a report based on the interviews with teachers which allowed us to define the "profile" of each teacher, a synthesis of all the information we collected, which give information, among other aspects, on social, personal, institutional dimensions.

## **Selected results**

### **French speaking Switzerland context and pedagogical resources**

Switzerland has a highly decentralized system with no federal or national Ministry of Education. Each of the 26 cantons which composes the country has its own education legislation. However, four Regional Conferences, including French-speaking Switzerland which is represented by the CIIP (<http://www.ciip.ch>), have led to some effective coordination since the last five decades, drawing up common curricula, publishing material, jointly managing institutions and recognizing qualifications and admissions.

In the 1970s in all French speaking Switzerland a common official set of pedagogical resources, the *MERM*, was designed by the CIIP appointed group of experts and teachers from the different cantons. This first edition originates from a double necessity: a will of « inter-cantonal » coordination of

education (mathematics but more widely all the disciplines) and the introduction of a new curricula (CIRCE I), linked with the reform of the "modern mathematics ". In the 1990s, modern mathematics were abandoned and the pedagogical resources have been renewed in the 1990s according to a new educational paradigm based on problem solving, strongly influenced by the socio-constructivist approach.

Switzerland has therefore a long tradition of diverse cantonal educational policies but also the willingness to coordinate the educational system in order to facilitate in particular communication and student mobility. The *MERM* are the “symbol” of this process, especially in mathematics because they were the first to be done. In fact, the *MERM* are the result of a long process of discussions and compromises because they have to be approved and accepted by all the cantons of the French speaking part of Switzerland. It is necessary to allow three or four years to realize the *MERM* for one degree. We have to take into account this complex context in our observation and analysis of this resource (institutional dimension). The *MERM* must for example be compatible with all the plans of studies. They cannot thus be too prescriptive and require an opening.

Besides, the pedagogical resources are central to the reforms and innovations regarding mathematics education and more than just simple resources, they have the role of promoting innovation, in particular thanks to the teacher's textbook which describes the didactic and educational choices. They have to introduce the changes and harmonize the practices. This is also a critical element we have to take into account in our analysis (institutional dimension).

The *MERM* have been thought as a set of resources, therefore they mostly consist of a succession of activities for class, regrouped in 6 to 8 main themes, without hierarchy. Contrarily to textbooks in other countries, they do not give a day-to-day organised plan for teaching, which remains the teachers' responsibility. To do this, the teacher must provide a considerable amount of preparation prior to the lesson and our PhD theses aimed to study the ordinary practices in connection with this resource in order to make visible this essential part of the work of the teacher.

### **Case study: Mathilde and Sophie**

To exemplify our methodology and present some results of our research, we will now present two examples of our case study. We will first provide the chosen information about their “profile”, which gives information about the personal and social dimensions. Then we will present and compare their teaching sequences.

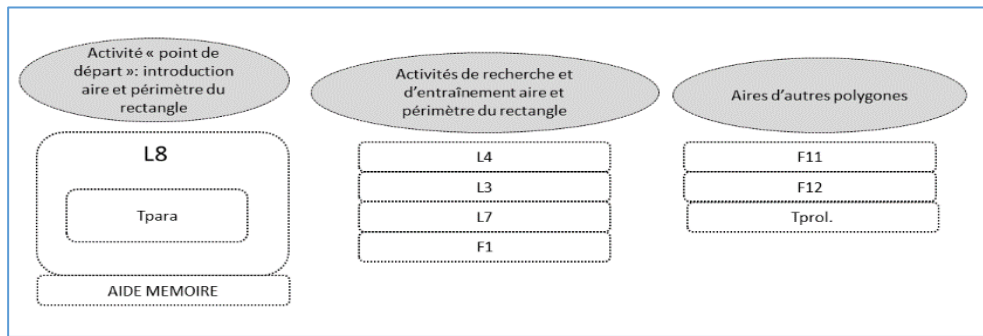

Mathilde and Sophie were both young teachers (4 and 5 years of experience) and they worked in the same school. The year of our experiment, they taught the same degree (6P) and they met twice a month and collaborated to develop mathematics lesson plans. Looking at the exchanges between the teachers during this meeting, we saw that they spoke little about the teaching objectives which seemed to be implicitly known and shared.

Mathilde said that the textbook was the reference and did not feel the need to talk more about the objectives. She specified during the interview that her colleagues “trust” her concerning the choice of the activity because it's impossible, according to her, to choose the activities in the textbook without assistance. Sophie also speaks about "trust" during the interview what shows the importance of the collaboration in the preparation, by filling what is felt as a "lack" of the resource.

However, the study of Sophie's and Mathilde's profiles allows us to highlight that the objectives of both teachers are very different. For Sophie the calculating procedures in particular the introduction of the techniques of calculation of areas for triangles and parallelograms represent an important aim in the sequence. For her part, Mathilde considers that the main objective concerns the understanding of the notion of area and the formula to calculate the area of a square. Even though their objectives are different, this point remains implicit throughout their collaboration.

The scenarios analysis and their carrying out in class will allow to see how will evolve the educational projects of the two teachers whose starting point, by the way, is the same list of activities.

Figures 1 and 2 allow to have a global vision of Mathilde's and Sophie's scenarios. Mathilde provides a teaching sequence we analysed in three parts: an introductory session, three sessions dedicated to the area of square and rectangle and a session of introduction of the area of other polygons. This corresponds to what is proposed in the textbook.

**Figure 1 Mathilde's scenarios**

The analysis of the series of activities proposed in Sophie's classroom show a split teaching sequence where activity from the official textbook are often mixed with improvised tasks on the blackboard.

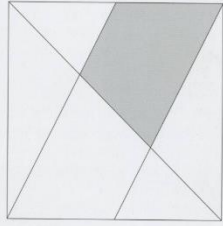

**Figure 2 Sophie's scenarios**

We represented a structure in four parts: an introductory activity, a series of activities on the area of square and rectangle, an introduction in the measure of areas of the other regular polygons and a session of revision.

Although Sophie and Mathilde based their teaching sequence on the same common project, we see well how both scenarios evolved. While the starting point is almost identical, the gap is widening in the course of the sessions, leading to different mathematics promoted in each class (considering the cognitive dimension, Daina 2013). It is nevertheless interesting to note that in the interviews, Mathilde and Sophie did not seem conscious of these differences.

The analysis of the first session, while Sophie and Mathilde proposed the same activity, "Fraction of a field", allowed to see more in details this difference.

<p>8. Fraction of a field</p> <p>Father Joseph has a square field. He splits it using three ropes passing through the vertices or the midpoints of the sides. One of his sons, Francis, will inherit the grey part of the field.</p> <p>What fraction of the field will he receive?</p>	<p>8. Fraction de terrain</p> <p>Le père Joseph a un terrain carré. Il le partage par trois cordes tendues passant par des sommets ou des milieux de côtés.</p> <p>Un de ses fils, François, héritera de la partie grise du terrain.</p> <p>Quelle fraction du terrain recevra-t-il?</p> 
---	--

The table below synthesizes the succession of the phases during the carrying out of the activity in Sophie's and Mathilde's class.

Sophie		Mathilde	
Phases	Duration	Phases	Duration
Instruction	7 minutes	Instruction	3 minutes
Pupils work on the activity	6 minutes	Pupils work on the activity	10 minutes
Pooling	3 minutes	Pooling	7 minutes
Pupils work on the activity	3 minutes	Aide mémoire	19 minutes
Pooling	8 minutes	Pupils work on the activity	39 minutes
Parallel task on white board (interruption)	5 minutes		
pooling (reprise)	8 minutes		
Aide mémoire	4 minutes		
Parallel task on the white board (interruption)	8 minutes		

Here we see very clearly that, although the same activity was proposed to the pupils, its management in class is totally different between the two teachers (mediation dimension).

In the class of Mathilde the number of phases is limited. The instruction is very short. During the pooling, the interactions testify of a discussion between the teacher and the pupils who have an active participation in advancing the discussion. Corrections are made individually.

In the class of Sophie we observe at first a longer instruction time. Sophie testifies of a will to make sure that the pupils understand well « what they have to do ». The progression of the project is managed collectively. Sophie makes regular pooling in the course of which, she directs the pupils on a strategy of resolution which is going to become common. However, the task is also diverted on secondary tasks which are in connection with knowledge bound to calculate the area of parallelograms or triangles which are central objectives for her. Sophie's more personal project enters thus in tension with the progress of the main activity which becomes a material medium to introduce new knowledge in a lecture style of teaching on whiteboard.

We can thus observe a big variability in the practices of these two teachers. What is really questioning is that these differences do not seem to worry them and in spite of their various ways of functioning, the teachers find an interest to prepare together the teaching sequences.

The space provided in this paper only allows to give a limited insight into our research result but some analysis made permit to identify tensions bound to the use of MER. The first cause of tension results from the "shape" of this resource. Indeed, the quantity of the activity proposed is too important and a novice teacher can't know them all and make a real choice. As said in the introduction, there is no supplied sequence and not much piece of information given about each activity. This leads the teachers to follow what make other colleagues, even if sometimes they did not share the same objective and teaching strategy. Furthermore, as we show in the first part, the specific status of this resource will act as a strong constraint on the teacher who will use it to be in "conformity", even if

they do not follow the socio-constructivist approach and will finally distract from the goal of the activities.

# Children's performance on a mathematics task they were not taught to solve: A case study

Seán Delaney

Marino Institute of Education, Dublin, Ireland; [sean.delaney@mie.ie](mailto:sean.delaney@mie.ie)

*A teacher documents how a task was used to elicit children's knowledge of multiplication as a precursor to learning the long multiplication algorithm. Data include samples of children's written work, and transcripts of two 30-minute lessons. Children discussed solution strategies. The teacher used time between the two lessons to select and sequence representative strategies to share. Strategies used by the children were diverse showing a range of multiplication-related knowledge among the children ranging from knowledge of repeated addition to knowledge of place value and the additive decomposition of numbers to various applications of the distributive property.*

*Keywords: Long multiplication, problem solving, third grade, mathematics laboratory.*

## Introduction

A common pattern of mathematics teaching is for teachers to present a problem to children, demonstrate how to solve it, and then set similar problems for the children to solve applying the demonstrated strategy (Lyons, Lynch, Close, Sheerin, & Boland, 2003; Stigler & Hiebert, 1999). Calls have long been made for mathematics instruction to focus on teaching thinking strategies and to promote goals like creativity, forming and changing hypotheses, and reflecting on one's own thinking and the thinking of others (e.g. Streefland, 1992). This case study describes one teacher using heuristics to introduce long multiplication to children who have completed third class.

Children in Ireland learn short multiplication in third class and long multiplication in fourth class. The study describes and analyses work done over two days in a mathematics laboratory school which took place in July 2016 in Dublin. Two research questions are addressed in this study. First, what knowledge did children draw on to solve a long multiplication problem they had not been taught to solve? Second, what knowledge does the class possess that prepares the children for future work on long multiplication? The data consist of children's written work and transcripts of two 30-minute lessons on consecutive days.

## Theoretical framework

Three research areas frame this study. The first is progressive schematisation or progressive mathematisation as inspired by the work of Freudenthal and Realistic Mathematics Education. It describes how children solve problems using their own ideas and informal strategies (Streefland, 1992). These ideas and methods become more sophisticated as students begin to understand and use formal, more efficient algorithms (Treffers, 1987). Although others have written about invented algorithms (e.g. Kamii, Lewis, & Livingston, 1993), Treffers (1987) formalises the process and refers to vertical mathematisation (where algorithms are reorganised and refined) and to horizontal mathematisation (connecting the mathematics to real-life) (Selter, 1998). The second area of research relates to the conceptual field of multiplication: the grounding of mathematical analysis of situations and problems, and the development of children's ideas over time. It includes paying attention to children's past and future learning to inform present learning (Vergnaud, 1988).

The third area of research framing this study is the teaching of multiplication (Lampert, 1986). Lampert identifies four categories of knowledge used when learning mathematics: intuitive, computational, concrete and principled. Intuitive (or naïve) knowledge refers to how people in particular contexts invent ways to calculate in order to do their work; it may not transfer well to other contexts. Computational knowledge is procedural knowledge, like standard algorithms, that children typically use in school. Concrete knowledge is used when objects are manipulated to find answers. This may include rectangular grids which are sometimes used to compute answers to multiplication problems. Finally, principled knowledge is knowledge children can use, without necessarily understanding the meaning of what they are doing. Such knowledge might involve children drawing on principles such as place value, the commutativity of addition or multiplication, or the distributive property of multiplication over addition.

This framework will help to identify stages in the heterogeneous work of a class (Selter, 1998) of children as they attempt to solve problems for which they do not have a solution. It will also help to categorise the knowledge that children used and shared in solving the problems.

## **Method**

### **Participants**

Twenty-four children – 17 girls and 7 boys – were in the class which lasted for two hours per day over five days. The children had just completed third class in ten different schools and therefore could be expected to be familiar with short multiplication but not to have worked on long multiplication. The mathematics laboratory class was taught by the author and was observed by twenty-five teachers who were completing a summer course in mathematics. Although several topics were taught in the summer school, the focus of this study is on the introduction of long multiplication. A word problem was chosen from Van de Walle: “The parade had 23 clowns. Each clown carried 18 balloons. How many balloons were there altogether?” (Van de Walle, 2001, p.182). Children worked on this problem collaboratively in pairs; they were encouraged to solve the problem and to be prepared to justify their solution.

### **Data analysis**

Two data sources were used: samples of children’s written work and transcripts of dialogue from the lessons. Children did their written work in squared exercise books using black pen to ensure that they would not erase work they were unhappy with or that contained errors. This rationale was shared with the children. All lessons were video recorded by two cameras – one focused on the children and one focused on the teacher. The videos were used to prepare lesson transcripts.

The research questions relate to the knowledge used by the children and available to the class as a resource for future learning. All children’s written work completed in response to the problem was studied and compared to ensure that samples of every approach used were represented in the four samples of work selected for more detailed analysis. The chosen work samples were subsequently analysed to identify categories of knowledge that were evident in the work. The four categories outlined by Lampert (1986) guided this analysis. The transcripts were analysed for evidence of student mathematical knowledge. Although the categories identified by Lampert informed this

analysis, the analysis was open (Corbin & Strauss, 2008) so references to knowledge not covered by the four categories could be identified.

## Results

### Lesson plans

Children were asked to work on the multiplication problem in pairs. The following day the plan was to continue working on the same problem. Prior to lesson 2, the author (as teacher) looked at the children's work to select and sequence four approaches to share with the entire class. The strategies selected involved repeated addition, repeated addition with some multiplication, multiplying using partial products and an attempt at the standard algorithm for long multiplication. The lesson plan refers to a pictorial representation of the problem that would help the children get an understanding of the dimensions of the problem. This was introduced in response to a similar approach used for various scenarios by Lampert (1986). The lesson plan concluded with the intention to ask the children to independently solve a second long multiplication problem.

### Day 1

The calculation was embedded in a word problem referring to a setting familiar to most children in the culture – many clowns each holding several balloons. Two two-digit numbers needed to be multiplied. The combination of relatively low two-digit numbers and the concrete image of clowns with balloons made it relatively easy for children to draw the scenario if they decided to do so. After a class discussion of the problem conditions, children worked on it in pairs for seventeen minutes. The teacher circulated among the children monitoring the work of pairs. Teachers participating in the summer course walked around the class observing the children working. Although they were asked not to interact with the children, on one or two occasions some did.

After the children had worked in pairs, the teacher asked one pair of children – Sandra and Lisa – to tell the class how they went about solving the problem. They had added eighteen and eighteen to make thirty-six. Then they added another eighteen. The teacher asked the class if this strategy were implemented properly, would it yield the correct answer, and based on their responses reminded them of the need to be systematic in recording their work.

Two more children, Chuck and Róisín, shared a different approach. They wrote down twenty-three eighths and multiplied twenty-three by eight and twenty-three by one. This represented an understandable mistake, forgetting that the one digit in the eighths represents ten rather than one.

At this stage the teacher adjourned the discussion and moved to another mathematical topic. Having concluded that part of the work for the day, the teacher could examine and reflect on the children's work in order to select and sequence material for discussion in the following day's lesson.

### Day 2

Overnight the teacher looked at each child's work. No one had successfully used the long multiplication algorithm suggesting that, as expected, it had not been taught to the children prior to the summer school. Four examples were selected and sequenced in a way that was anticipated to tap into the children's current understanding, to show increasing efficiency or sophistication of solutions – progressive mathematisation – and to prepare the children for subsequent work on long

multiplication. Although all children had worked in pairs, work to be shared was selected according to the clarity of the work recorded in individual children's copybooks.

First was Christine who had used a straightforward repeated addition approach. She had a pictorial representation of the problem with twenty-three faces and eighteen balloons over seven of them (see Figure 1). Next was Donal who had no pictorial representation but who also used a repeated addition approach. He had grouped ten eights where possible to multiply them and had multiplied twenty-three by ten (see Figure 2). Third was Fintan who solved the problem by calculating ten eighteens, another ten eighteens and three eighteens and then added the three calculations (see Figure 3). All three students had the correct answer of 414. The fourth student, Eileen, got the wrong answer but the strategy used seemed closer to the standard long multiplication algorithm. She wrote an account of what she did and of how she was thinking rather than just recording the calculation. She multiplied the three from twenty-three by the eight in eighteen and got twenty-four. She then multiplied twenty by ten to get two hundred. She refers to multiplying two by one and it is unclear if that is a precursor to multiplying twenty by ten (see Figure 4).

Despite the fact that Christine had set up the calculation to be solved using repeated addition (see Figure 1), she stated that to solve the problem she and her partner "drew a picture and we did loads of dots and we counted them all up." When challenged by the teacher about the repeated addition work in her copy, Christine responded that "I had a long sum but that didn't really work because I kept on losing count." This provided an opportunity to discuss a problem that arises with repeated addition, and to prepare the class for seeking more efficient ways to calculate using long multiplication. The teacher did not ask Christine why it was easier to keep track of counting the balloons individually than adding 18 twenty-three times and that may have yielded information about a system she had developed to keep track of the balloons already counted.

Donal had a more sophisticated way of working with repeated addition (Figure 2). Although his layout of the problem looks similar to Christine's, he approached it as follows

$$(8 \times 10) + (8 \times 10) + (8 \times 3) + (10 \times 23)$$

In solving it this way Donal and his partner showed understanding of the distributive property of multiplication. They noted that the ones in the eighteens represented tens and not units. However, Donal's written recording of the work and his oral explanation of it suggests that he was not yet familiar with multiplying numbers by ten. In contrast, his classmate David stated that "When I'm multiplying by tens, I just add on another zero at the end of the number." Although the wording of "adding" another zero may not be helpful, he is referring to the fact that multiplying a number by ten shifts each digit one place to the left requiring zero as a placeholder in the units place.

A more condensed understanding of the distributive property was apparent in Fintan's work (Figure 3). Unlike Donal or Christine he did not write out the calculation using repeated addition. Nor did he separate the tens and units in order to complete his calculation, which took the following form:

$$(18 \times 10) + (18 \times 10) + 18 + 18 + 18$$

Fintan sees his approach as being similar to Donal's and he states that "we basically did the same as Donal; we used hundreds, tens, and units." However, whereas Donal's approach was limited by

apparently not being able to multiply two-digit numbers by ten, Fintan was able to make the calculation more efficient by multiplying eighteen by ten.

When the children were asked where the twenty-three (clowns) could be seen in Fintan's strategy, two children (Katherine, Ethna) found it difficult to identify. One, Doireann, successfully constructed an explanation with the teacher in the following exchange.

- Doireann: So the eighteen times ten is done twice. So that would be like twenty there. And then...
- Teacher: So, you're saying that this is ten clowns with eighteen balloons, and this is another ten clowns with eighteen balloons.
- Doireann: Yeah.
- Teacher: Is that what you're saying?
- Doireann: Yeah.
- Teacher: Okay. And what then?
- Doireann: And then if you add that together that's twenty...
- Teacher: Twenty clowns with eighteen balloons.
- Doireann: Yeah, and down the bottom there, it's three eighteens. Add them onto the twenty and it's twenty-three.

When asked to choose a preferred strategy from those presented by Christine, Donal and Fintan. Four children preferred Fintan's approach on the basis that it is quicker and it requires less writing. Two claimed to prefer the repeated addition approach because it looked less complicated.

When children solved the first long multiplication problem, twelve of them used a variation of repeated addition, three used a form of the distributed property, three a variation of the conventional algorithm, the work of three children was unclear and one used counting. Following the discussion, seven children used repeated addition, four used a form of the distributive property, five used a form of the conventional algorithm, the work of six students was unclear and one used counting.

Finally, Eileen was asked to share her approach. Initially she stated that she and her partner got the wrong answer. After reassurance from the teacher that the class could learn from the wrong answer, she shared her approach. She writes that "in her head" she laid out the problem as it would be laid out in the conventional algorithm for long multiplication. She multiplied the three units by the eight units and got twenty-four. Then she multiplied the two tens (of twenty-three) by the one ten (of eighteen). She added them together and got 224. Although the teacher sequenced Eileen's strategy after Fintan, it is conceivable that her understanding is more naïve than his because she may have been attempting to apply the algorithm for short multiplication to long multiplication without really understanding the distributive property. Nevertheless, it provided an opportunity for the teacher to introduce an illustration of the distributive property of multiplication to all children.

Eileen failed to multiply the eight by twenty and the ten by three. In order to help her and her classmates visualize this, the teacher proposed a drawing of the scenario based on Lampert (1986). In this drawing (see Figure 5) twenty clowns were on a bus travelling to the parade and three clowns

had to walk because there were only twenty seats on the bus. Twenty strings with balloons on them could be seen emerging from the bus, each string with one group of ten and one group of eight and the three clowns outside the bus held similar strings of balloons.

The class was asked how they could calculate the number of balloons held by the clowns altogether. The idea of the picture was to make it clear that the numbers that need to be multiplied are  $(20 \times 10)$ ,  $(20 \times 8)$ ,  $(3 \times 10)$  and  $(3 \times 8)$ . The first two calculations correspond to the clowns sitting in the bus with the strings containing ten balloons and eight balloons and the second two calculations correspond to the clowns standing outside the bus holding strings with ten and eight balloons on them. The diagram helped children see that Eileen had neglected to calculate the  $(20 \times 8)$  and the  $(3 \times 10)$ .

## Discussion and conclusion

That multiplication was the operation needed to complete this task was uncontested by the children. In solving the problem, they drew on different categories of mathematical knowledge. Some relied on intuitive, context-specific knowledge and drew versions of the clowns in order to solve the problem. Computational knowledge of multiplication was widely held, as would be expected by children who had completed third class. Although occasional errors were made, children had access to multiplication table cards if they wanted them so that even a lack of computational knowledge would not pose a barrier to solving the problem.

Little evidence of the children using concrete knowledge emerged in the lessons. This may have been because no manipulable objects were made available to them to help them find an answer. Some children may have used the diagrams they drew as a form of concrete knowledge to support their solution but that is unclear from the data sources used.

Much evidence of principled knowledge emerged from the children. Donal and David showed understanding of place value, by separating the tens and the eights in eighteen (Donal) and in stating how numbers can be easily multiplied by ten (David). Several children had a tacit knowledge that numbers can be decomposed additively and of the distributive property of multiplication (e.g. Donal, David, Caitlin, Fintan and others). The teacher attempted to make this aspect more explicit by introducing the diagram with the clowns in and beside the bus. Students like Eileen have some understanding of the distributive property but it needs to become more explicit if she and others are to be ready to apply it in taking the next step to understand and use the long multiplication algorithm automatically. They need to grasp the principle that  $(a+b) \times (c+d)$  requires multiplying  $a$  by both  $c$  and  $d$  and multiplying  $b$  by both  $c$  and  $d$  and not just multiplying  $a$  by  $c$  and  $b$  by  $d$ .

At the end of the week around fourteen children were still either using repeated addition for similar multiplication tasks, using counting or not showing evidence of how they found their answer. Nine showed willingness either to apply the distributive property of multiplication or to at least attempt the conventional algorithm. Of those who were still applying the repeated addition algorithm, four had become more sophisticated in using it (moving closer to Donal's approach than to Christine's) following the class discussion documented here. This highlights the importance of children learning from each other through working on and explicitly discussing their completion of a task.

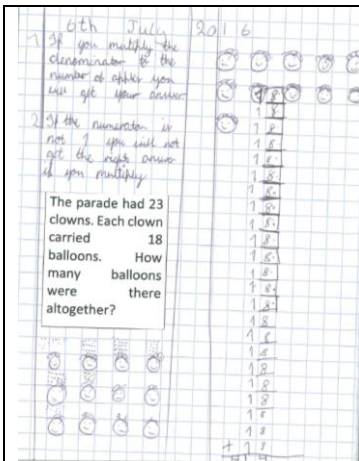

Figure 1. Christine's work.

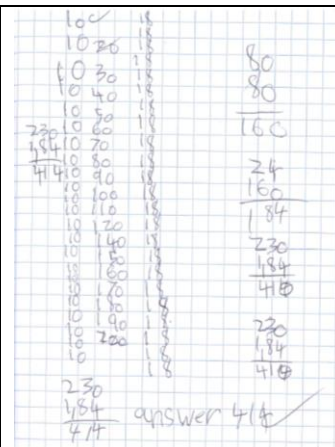

Figure 2. Donal's work.

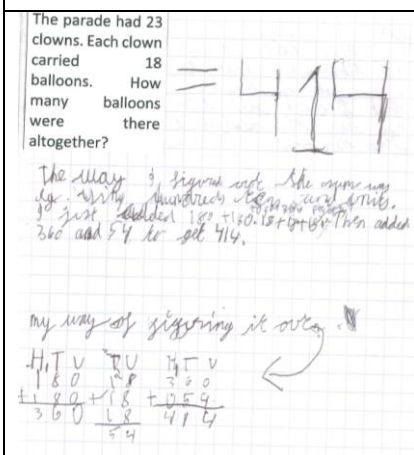

Figure 3. Fintan's work.

Figure 4. Eileen's work.

Figure 5. Visual representation of long multiplication problem.

Half the children used a form of repeated addition to solve the problem. However, additive reasoning differs from multiplicative reasoning (Nunes & Bryant, 1996). It remains unclear from this study if children reverted to additive reasoning because long multiplication was unfamiliar to them or if they have made the leap from additive reasoning to multiplicative reasoning at all. Future study could involve assessing children's grasp of multiplicative reasoning in short multiplication scenarios (Sherin & Fuson, 2005), exploring the use of arrays (Fosnot & Dolk, 2001) and introducing long multiplication tasks that would more likely elicit responses that exhibited multiplicative reasoning.

## Introduction

This paper reports on a research project undertaken with a group (n=19) of Irish pre-service student teachers (PSTs) during the third year of a four-year undergraduate education course. A series of workshops were carried out on the critical evaluation and design of mathematics tasks. For the purpose of this research a 'mathematical task' is a problem or set of problems that address a specific mathematical idea, they are situated between teaching, learning and assessment (Smith & Stein, 1998). The types of tasks that students engage with have been shown to influence their development (Jonson et al., 2014), and studies have shown that students spend the majority of their time in mathematics classes working on tasks (Boston & Smith, 2009; Haggarty & Pepin, 2002). Furthermore, Smith and Stein (1998) asserted that the highest learning gains in mathematics were related to the how mathematics tasks were set up and implemented in teaching and highlighted the importance of students being engaged in high levels of cognitive thinking and reasoning (see also Swan, 2011; Boston, 2013). Many challenging questions arise from this assertion for pre-service mathematics teachers, such as, what is a good learning task? How is a good learning task set up? How is it implemented in a mathematics classroom? These questions are especially relevant in Ireland, given that a report on mathematics education found that traditional approaches to teaching and learning were widespread and recommended that students engage with more tasks which require higher order thinking skills such as problem-solving and justification (Jeffes et al., 2013).

## Research questions

In what ways did pre-service teachers' knowledge of the cognitive demands of mathematical tasks change following their participation in a module on critical evaluation and design of mathematical tasks?

How did this knowledge impact on their competences in curriculum making?

In this paper we present a review of some key research on mathematics task design. We provide an overview of the module implemented as part of the research project and the methodology used to

collect data. We present the key findings from the research and discuss the salient themes emerging as they pertain to pre-service teacher education. Finally, we summarise our recommendations and conclusions.

## Literature review

The dependence of mathematics teachers on textbooks in their teaching appears to be a phenomenon in many countries (Haggarty & Pepin, 2002; Jeffes et al., 2013.). Haggarty and Pepin (2002) write about the dominance of the textbook in the mathematics classroom and conclude that without time to prepare for teaching, and, we would add, the skills to enrich the curriculum materials available, textbooks take on a prominence in “relation to teacher thinking and planning” (p.588). This is of concern as a recent review of mathematics books in Ireland found that all available books fell short of the standard needed to support mathematics teaching at that time and furthermore they especially fell short on the integration of technology, approaches to teaching for understanding and problem solving (O’Keeffe & O’Donoghue, 2011).

Synder, Bolin and Zumwalt (1992) describe three teacher curriculum approaches: the *fidelity approach*, where teachers are transmitters of the written curriculum without changing it; the *adaptation approach* where the teacher adapts the curriculum to suit their context; and the *enactment approach* where the teacher develops the curriculum in action depending on the student experience. Shawer (2010) builds on this work and identifies *curriculum-transmission strategies* where the textbook and teacher’s guide are the source of pedagogical instructions. He describes *curriculum-making strategies* as where the teacher develops their own materials in addition to those available in response to a needs assessment. *Curriculum-development strategies* on the other hand include experimentation, material writing and evaluation and involve both macro and micro level curriculum development. Within the Irish education system opportunities for curriculum-development strategies are limited since the curriculum is centrally devised with little space for school-based curriculum development, this coupled with a teaching culture that has a dependence on textbooks would point to a need for PSTs to engage with research on task development.

Studies have previously looked at this issue as part of professional development courses for in-service teachers. For example, Boston and Smith (2011) describe a *task-centric approach* to such courses where the focus is on teachers’ ability to select and implement cognitively demanding tasks. They found that after a series of workshops, where teachers analysed both the cognitive demand of tasks and the implementation of tasks, the participants increased their ability to select high-level tasks and this improvement was sustained over time. The workshops also influenced teachers to consider the impact of the tasks they selected on their students’ learning (Boston, 2013). Arbaugh and Brown (2005) used a similar approach and found that introducing teachers to criteria for high-level tasks influenced their task selection, and ultimately their pedagogical content knowledge.

A number of different frameworks have been developed to classify mathematical tasks and have proved useful in research, professional development and pre-service teacher education (Boston & Smith, 2011). In this research we used three different but complementary frameworks with the participants. The first framework is that of Smith and Stein (1998) which looks at the level of cognitive demand (LCD) of tasks. They identify two levels of LCD: Lower-level demands (with task types of *Memorization* and *Procedures without connections to meaning*), and higher-level

demands (*Procedures with connections to meaning* and *Doing Mathematics*). The distinction between tasks is relevant, as the level of cognitive demand in a task provides different learning opportunities for the learner and demands a different learning environment for the development of competences required by the task. Our second framework is the mathematical reasoning framework developed by Lithner (2008). This framework can be used to classify the opportunities for different types of mathematical reasoning afforded by tasks. Lithner (2008) describes two types of reasoning: Imitative Reasoning which consists of *Memorised reasoning* and *Algorithmic reasoning*; and Creative Reasoning which involves local and global *Creative mathematically founded reasoning*. Creative reasoning tasks fulfil the criteria of novelty, plausibility and mathematical foundation. Lithner (2008) is concerned with how tasks can be used to promote creative reasoning as opposed to imitative reasoning. He contends that the teacher's task is to "arrange a suitable didactic situation in the form of a problem" (p.271) so that the learner can take responsibility for the problem solving process, and use creative reasoning.

These two frameworks can be used to classify tasks using either the degree of cognitive effort required or the type of reasoning needed. They both divide tasks into two broad categories - either high or low levels of cognitive demand in the case of Smith and Stein (1998) or imitative or creative reasoning in Lithner (2008). They have been used in professional development to alert teachers to the effects of different types of tasks (e.g. Arbaugh & Brown, 2005). In order to help the PSTs to move from classifying tasks to designing them, we introduced a third framework. Swan's framework (2008) describes five task types that encourage concept development and provides very clear design principles to inform task development and implementation. There are many examples of Swan's mathematics tasks available on-line (see, for example, Mathematics Assessment Project, n.d.). The five task types that he posits will encourage concept development are: classifying mathematical objects, interpreting multiple representations, evaluating mathematical statements, creating problems, and, analysing reasoning and solutions.

## Methodology

Nineteen pre-service teachers in the second semester of year three of a four-year post-primary teacher education course took part in the research project. At the time of the research the PSTs were midway through their second school placement experience and were teaching a minimum of two hours per week. All participants were taking mathematics in their degree and one other science subject (either biology, chemistry or physics). The research is presented as a case study using mixed data collection methods looking at the group of PSTs as a whole, over a sustained period of time as they developed competences in task design (Yin, 2009). This allowed us to build on earlier research (Boston, 2013) and incorporate PSTs reflections on the design process. Jones and Pepin (2016) contend that when teachers interact with mathematical tasks, they develop knowledge; this is done individually in preparing and planning for teaching and collectively when they are afforded opportunities to develop and discuss tasks with peers. In designing curriculum materials PSTs need both *subject matter knowledge* (SMK) and *pedagogical content knowledge* (PCK) (Ball, Thames & Phelps, 2008). With this in mind we designed a module for the group of PSTs based on task evaluation and ultimately task design.

In order to investigate any gain in knowledge for the group over the course of the intervention, we administered a pre- and a post-test designed by Boston (2013). This test asked students to classify 16 tasks as either High Level or Low Level tasks, and to give a rationale for their choice. At the end of the module, the pre-service teachers were asked to complete an evaluation questionnaire which asked them: to report on a key learning moment during the module; whether their teaching had changed as a result of the module and if so, in what way; what they would change about the module; and to indicate their level of agreement with some statements about the reading from the Mathematics Education literature. 13 of the 19 students submitted the evaluation questionnaire.

The assessment for the module consisted of the assignment outlined in Figure 1. All 19 pre-service teachers submitted this assignment and gave their consent to use it for research purposes. The tasks designed by the PSTs were analysed using the LCD and Lithner Frameworks. The classification was conducted by two researchers who were familiar with the curriculum, assessment, and textbooks relevant to the classes taught by the PSTs. The researchers used their knowledge to decide if (in the context of the PSTs' classes) the tasks should be classified as either high or low level tasks. We also looked for evidence that PSTs employed aspects of Swan's (2008) framework in their design. A general inductive approach as advocated by Thomas (2006) was taken to analyse the students' reflections on the differences between types of tasks. Analysis was guided by the research questions and a number of a priori themes (such as MKT), allowing flexibility for other themes to emerge.

### ***Task Development***

For a topic of your choice design (or significantly adapt) a series of tasks. One task/s should be suitable to be used in class while teaching, and, one for use as homework. Design an examination task/s for the topic. Present your rationale for each task based on your readings. Reflect on the differences between classroom task, homework task and examination tasks.

**Figure 1: End of module assessment**

## **Findings**

### **PSTs' specific learning about cognitive demands**

Thirteen participants completed the Boston (2013) pre- and post-tests on levels of cognitive demand; a paired t-test was used to investigate whether the mean of the group had increased significantly over the course of the module, and found that it did ( $p=0.037$ ). There was also evidence for PSTs developing knowledge about cognitive demand in their response to the question on the end of module evaluation asking what was their key learning moment.

Realising the different reasoning and thinking about the type of question. In the textbook, where homework is usually given from, questions are repeated, low demand. In the maths exam students are faced with high level conceptual questions so there is a big gap there that needs to be addressed. (S14)

Here we see that S14 is *noticing* the level of demand and reasoning in the artefacts available to them in their teaching, the textbook. This text-guided Algorithmic Reasoning (AR) is supported and encouraged by the rote use of the textbook for homework (Lithner, 2008). The recognition of this by the PSTs was notable in many comments such as:

Having completed this module, I seriously consider what I give my students as homework. Beforehand I generally gave a list of questions at the end of the chapter but now, having seen the different levels, I generally spend more time selecting and developing questions .... (S16)

The PSTs seem to be linking the levels of cognitive demand with the level of reasoning required, bringing the two theories together in their own thinking about the mathematics curriculum and assessment. The knowledge of the different frameworks is enabling the PSTs to move from a role of curriculum transmitters dependent on the text book to being curriculum makers as described by Shawer (2010).

### **Pedagogical design capacity and moving from curriculum transmission**

The analysis of the PSTs' end of module assignments gave further evidence of them making this transition. All students showed that they were able to design or modify tasks to get high level questions. The PSTs classification of their tasks using the LCD and reasoning frameworks demonstrated that they were competent in using the frameworks for classification.

We noted the types of tasks designed by the PSTs for the three different situations of classroom tasks, homework tasks, and examination tasks. The types of tasks designed seemed to fall into two broad camps: open-ended exploratory tasks (which were mainly found in the classroom setting) and more traditional formats (which were mainly found in homework and examination tasks). The latter types of tasks mostly consisted of word problems with a real-life context; the PSTs designed a small number of other types of tasks for use as homework or examination questions, including tasks which required students to make a conjecture, provide an example, or evaluate a mathematical statement. In addition, one PST designed a homework task which involved a pre-class investigation. The majority (13 of 19) of the PSTs used card-matching designs for their classroom tasks. These tasks were based on Swan's "Interpreting Multiple Representations" (Swan, 2008, p. 3) task type. The PSTs were introduced to this idea through the Swan (2008) article and also participated in a card-matching task (on the topic of fractions) during one of the module sessions. Three of the PSTs used games (such as 'Battleships' and dice games) to devise tasks for use in the classroom, two PSTs used investigations as the basis of their task, and one designed a series of worksheets with problems of increasing difficulty.

The PSTs showed creativity and an appreciation for tasks with high levels of cognitive demand. However, an analysis of their designed tasks showed that the design process was not without difficulty for the group. Some of the questions were not always clear due to missing or confusing instructions, and sometimes the context made the question ambiguous (this has also been a problem in state examinations in Ireland). Occasionally it seemed as if the PSTs did not have a clear understanding of the underlying mathematics themselves, possibly owing to their level of SMK, and sometimes their use of mathematical language caused difficulty (such as using the term 'equation' instead of 'expression' for something like  $2x+1$ ). The learning trajectories for the tasks or sets of tasks were not always clear - sometimes it was not clear what understanding and what concept the PSTs were trying to develop.

### **Pre-service teachers' pedagogical content knowledge**

The PSTs' knowledge of levels of cognitive demands challenged their deeply held view of how best to teach mathematics. Previous research with a similar co-hort of PSTs found that they focused on

content when planning for teaching and placed little emphasis on the learner or prior learning (Nolan, Dempsey, Lovatt & O'Shea, 2015). Most of the respondents said the module impacted on how they taught mathematics with the majority citing a change in how they asked questions, placing more emphasis on higher level of cognitive demand in questions. Prior to this module, these PSTs would have completed a module which included a significant input on questioning skills for teaching; they seem to have needed the knowledge of cognitive demand in order to have changed their questioning practices. It must be noted that this was reported but may not have been the reality when one takes into account the examples provided by the PSTs in their end of module assessment. However, an increased emphasis on discussing mathematics problems appears to be evident with comments such as

I try to think more about pushing my students to reason more when completing tasks. I try to ask questions, give tasks to my students with much less information, and I want my students to rely less on me giving them the answer. (S11)

This PST also spoke about the effect of the intervention on her teaching:

I never really thought much into the differences between the tasks that I give during class, homework or exams or the impact it could have on my students' development in a subject. Having studied and researched the classification of math's tasks and implementing my own selection/adaption of tasks into my class, I now feel that I have gained a deeper understanding into the effect my choice of tasks can have on the progression and learning... (S11)

The PSTs who implemented their tasks in their teaching placements, realised the effect that the teacher or set-up can have on the cognitive level of the task and this led to them thinking about different types of tasks or redesigning their original tasks:

The students struggled very much with it at the beginning and due to my own fault I went through an algorithm with them and then the task immediately became a lower demand one, just requiring the students to reproduce an algorithm each time. If I were to redesign the tasks, I would change tasks E and F [card-matching tasks] to tasks where the students have to spot a mistake in a question/statement and justify their reasoning and how they would alter the question/statement ... in order to encourage them to develop critical thinking skills. (S12)

This reflection would suggest that the PST is developing her thinking on organising pedagogical content, adapting materials to suit students and adopting curriculum planning and making strategies (Shawer, 2010).

## Discussion

Increasing the PSTs awareness of different levels of tasks and giving them an opportunity to design and modify tasks would appear to have allowed them to develop skills such as the ability to classify tasks and design tasks at different levels. They also seem to have developed knowledge especially PCK which linked to their knowledge of cognitive demand has enabled them to adapt their practice especially around questioning. We note though that the evidence we have presented in this regard is based on self-reported data. The importance of applying frameworks in order to increase awareness of concepts such as levels of cognitive demand is significant for PST education; awareness may be a crucial first step in knowledge acquisition. Similar to findings from Boston (2013) and Swan

(2007) who worked with practicing teachers, our research appears to demonstrate the need for an awareness of cognitive demand in order for mathematics educators to be able to select and develop rich and engaging tasks. This increase in knowledge and skills seems to be crucial in order to make the transition from curriculum transmitters to curriculum makers (Shawer, 2010). The space in our intervention for discussing textbook questions and State Examinations materials was cited as being the most impactful for the PSTs. They suggested that the module could be enhanced with more time devoted to this kind of peer interaction in task evaluation and design. This need for space for curriculum making and professional learning, and, the challenges therein has not been fully explored within PST education.

This research has highlighted a gap in the PSTs' education on task design in the case study institution, and, as such will be used to make changes to the module design and implementation. PSTs' practices and beliefs around tasks for homework merits further exploration. We intend to carry out more analysis on our data such as on the tasks assigned by PSTs (pre- and post-intervention) and of their reflections on tasks linking back to Lithner's (2008) concept of sociocultural milieu.

# Agency as a tool in design research collaborations

Andreas Eckert

Linnaeus University, Sweden; [andreas.eckert@lnu.se](mailto:andreas.eckert@lnu.se)

*The aim in this paper is to shed light on interactional aspects of researcher and practitioner collaboration in design research in mathematics education. Symbolic interactionism is used to gain understanding of interactional aspects as it has potential to take both individual and social aspects of the interaction into account. Aims and agencies are in focus of the retrospective analysis of the collaboration between two researchers and two practitioners as they collaborate to develop instructional design. The analysis show how referring to authoritative disciplines as the mathematics community influence agency and therefore has great potential to influence how the negotiation of meaning progress and participants acts. I argue that agency could be viewed as an indirect tool that has the potential to direct the collaboration when designing tasks based on what aim different actors put in the foreground.*

*Keywords: Collaboration, agency, interaction, design research.*

## Introduction

Collaboration is at the core of design research in mathematics education. A key characteristic is that it is research conducted with researchers and practitioners in real-world settings (Plomp, 2013). This collaboration is often between one or more researchers and practicing teachers. It is essential that this team collectively has the competence to develop the design, conduct the lessons, and perform the retrospective analysis (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). This means that we have different actors in the activity, each with its interpretation of the aim and purpose, as well as of the actual activity and the mathematics involved. Since each actor has a specific set of competences and a vital role to play in the collaboration to develop the design, the question is how their differences influence the discussions during meetings and by extension the design? McClain (2011) explores this interplay of differences in the classroom interaction between students who performed the resulting tasks and the teacher who orchestrated the discussions. She views it as interplay between the students' contribution, the task and what she calls the proactive role of the teacher. One key aspect of the interplay is where the authority over the topic, the agency, lies. Agency is thought of as a capacity to act in social interaction. McClain (2011) emphasizes that it is important for students' learning that agency shifts between different actors in the activity.

The discussion in this paper focuses on the developing phases of design research. How does this shifting of agency that McClain (2011) identifies in the design research classroom appear in the development of tasks in between lessons? The aim of this paper is to further understand how the aim and agency fluctuate between the participants and its influence on how the negotiation develops as researchers and teachers collaborate to develop instructional design. Results could be viewed as a contribution to the mathematics design research methodology discourse of how collaboration between researchers and practitioners can support the design process.

## Previous research

Design research in mathematics education is described as a research design that is interventionist; iterative; process, utility and theory oriented; and has involvement of practitioners (Plomp, 2013). The idea is to develop tasks and activities, test them in real classrooms, evaluate the outcomes and then revise the design in an iterative process involving practitioners from the field. All in all, the research design enables the team to pursue multiple goals in the same project. The aim is to understand the processes involved in utilizing the developed tasks from the point of view of a chosen theory, design usable material for users in real life context and lastly to contribute to further development of theory. Plomp (2013) calls it the twofold yield of design research, producing both research-based intervention and knowledge about interventions in the form of theory.

Beside the global aims of design research, an intention to develop theories and instructional designs, there are local aims as well. The instructional design has an aim, an intention to stimulate learning, in the form of a hypothesised learning process and goal for the subjects (Cobb et al., 2003). The so-called Hypothetical learning trajectory (HLT) is defined by Simon (1995) as follows:

The hypothetical learning trajectory is made up of three components: the learning goal that defines the direction, the learning activities, and the hypothetical learning process – a prediction of how the students’ thinking and understanding will evolve in the context of the learning activities. (p. 136)

Cobb (1999) argues that the learning goal of a HLT should be from a group perspective rather than an individual one. Simon (1995) amongst others talk about a prediction of individual learning processes and thinking whereas Cobb (1999) call this line of thinking highly idealized at best. Instead, he proposes a focus on collective mathematical development in the classroom community. A HLT then consists of an “envisioned sequence of classroom mathematical practices together with conjectures about the means of supporting their evolution from prior practices” (p. 9).

Global and local aims are both individual interpretations as well as objects for the research team to negotiate. In this paper, it is assumed that this process is a social interaction within the team. Interaction is described with the theoretical background of symbolic interactionism (Blumer, 1986). It proposes that humans act according to the meaning that objects have to them and that the meaning of objects arise out of social interaction. This is an interpretative process where humans constantly interpret others’ actions and the meanings they indicate before acting themselves (Blumer, 1986). It means that participants of the research team interact according to how they interpret the local aim of the design as well as their own global aims and interpretations of the mathematics in question. Voigt (1994) calls this the negotiation of meaning in the mathematics education context. It is a negotiation because the actors contribute to a discussion based on their interpretation of what is being discussed and at the same time re-evaluate their own understanding, thus creating a negotiation of what is viewed as the community’s meaning of the objects.

As global and local aims and the design itself are negotiated, participants position themselves through their contribution to the negotiation. Burr (2003) talks of the capacity to take up positions for one’s own purposes and that agency lies in responsive actions in interaction. In the mathematics classroom context, McClain, Zhao, Visnovska, and Bowen (2011) defines agency as “authority over both the mathematics being taught and the sequencing and presentation of that content” (p. 63).

Combined, they frame the agency concept for this paper. For the purpose of this paper agency is viewed as involving one's intentions, sense of responsibility, as well as one's expectations of recognition and reward in taking a particular action. As the participants of a research team interact in the development of the design, they act according to their interpretations and their positioning in a community, for example as a representative for the mathematical community, and act with the authority of that discipline. Participant act according to different agencies as fits their purposes and evaluate its impact on the negotiation, also known as the dance of agency (Pickering, 1995). As the negotiation progress, agency shift between the participants and within them. Shifting agency enables the participants to contribute in different ways and from multiple perspectives, for example as mathematicians, practitioners or researchers. The result is an effect on the design of the HLT in line with different actors' fluctuating aims and their agency to contribute according to those aims.

## Method

The data used here is generated from video recordings of a small-scale teaching experiment involving probability with students from year 5 and 6 in a Swedish elementary school. The aim of the task was for the students to become able to discuss matters of relative frequency data and the law of large numbers in a probability context. Relative frequency is a way of analysing data from repeated random events, such coin flips, where the number of observations of each outcome is divided by the total number of events. The law of large numbers then states that as the sample size increases, the likelihood of a difference between the relative frequency and the actual probability of the event decrease. Thus, can the relative frequency be used as a measure of probability. The research team consisted of the author of this paper, a senior researcher (here called Paul) and two teachers (here called Karen and Tilly). The whole process was initiated by the two teachers who felt that they needed inspiration and experience in teaching probability, which they had never done before. The balance of numbers provided a sense of balance between researchers and teachers, which later has been recognized by Stephan (2015) to be an important factor to highlight teachers' unique knowledge in design research collaborations. The work was organized as such that after an introductory meeting, the two researchers drafted a design proposal in line with the requested topic. That design was further developed by a discussion within the team, which was video recorded, and then initiated by one of the teachers in the classroom. Minor adjustments were carried out between the two teachers' lessons and major changes of the lesson sequence were carried out after both teachers had used each lesson plan. A total of 5 lessons were designed, although one of the teachers divided the last lesson into two because of time management issues.

### The activity and hypothetical learning trajectory

The task design originated from a teaching experiment by Brousseau, Brousseau, and Warfield (2001), where the students were asked to investigate a chance event with an unknown sample space. The aim was to introduce basic principles of the Law of large numbers from probability as well as a frequency perspective on probability theory. We used an opaque soda bottle containing an unknown amount of small coloured balls (neither the students nor the teachers knew the content of the bottles) during the first lesson. When the bottle was turned over, the colour of one ball was revealed while remaining inside the bottle. Thus, creating a constant but unknown sample space. The activity was presented as a race in the first lesson with three contestants on a six-step track. As one of the three

colours was observed on a bottle turn, that colour advanced one step down the track. The students were asked to guess which colour would first get six observations during each race. Based on the topics discussed by the students in the first lessons, the following three lessons made use of a transparent bottle with a visible sample space. Here the students were asked to discuss chance, random variation, sample space, sampling and the law of large numbers. The importance of the sample space was highlighted in the second lesson because of ideas discussed in the first lesson. The students got to return to the opaque bottle in the last lesson(s) and again, in an organized manner, investigate the unknown sample space from the first lesson with the use of the law of large numbers. By producing a large enough sample, they could reason about the sample space in the opaque bottle by translating the relative frequency of each outcome into the probability of that outcome. Overall, one class needed a total of five lessons and the other class six lessons, to reach an agreement about the unknown sample space in the opaque bottle.

### **Method of analysis**

The analysis of the transcript in the forthcoming section is inspired by retrospective analysis from the design research methodology. It is based on open inquiry and constant comparison (Glaser & Strauss, 1967) where you retrospectively analyse and compare small instances of data from the whole set with one another to gain insights into the processes (Gravemeijer & Cobb, 2013). Trustworthy accounts of possible meanings can be developed by immersing oneself in the social setting, using participant observation, alongside systematic coding of data in retrospective analysis (Cobb, Stephan, McClain, & Gravemeijer, 2001). Instances of active contribution to the negotiation, utterances by the teachers or researchers, are coded with open codes. These instances are then compared to each other to find differences and similarities in their actions as they indicate the participant's interpretations, aims and agency. When looking at longer sequences, patterns are sought after, especially how participants' aims and agency influence the development of the negotiation. Short excerpts used for constant comparisons are presented in the text and expanded upon. Tied to those excerpts are expansions on the continuing interactions not shown in the transcripts due to space limitations.

### **Results**

The excerpts from the transcripts presented here are all from a meeting with the two researchers and the two teachers between Karen's first lesson and Tilly's first. The purpose was to engage in a mini-cycle to evaluate the initial design and revise it before Tilly used it in her classroom. One of the researchers, the author of this paper, was present during Karen's lesson and the discussion utilized their experiences as a main source of data to analyse. In the first episode, the two teachers discuss Karen's experience during the first lesson. She had asked the students to reflect on the notions statistics, chance and probability at the beginning of the lesson and then proceeded to carry out the design outlined here in an earlier section. Notice how the focus shifts from being about implicit aspects of the activity to being about students connecting knowledge.

Karen:           What fascinated me was that their engagement induced the use of the concepts that we highlighted and reconnected to what we did at the beginning. Statistics, chance and probability, well, that Kim said "This is what I think! Statistics is what

we're doing, and the balls drop by chance but you may still calculate the probability". He started...

Tilly: He added that, you didn't guide him?

Karen: No, he was like "This is what I think, I figured out this with statistics". So, it kind of extracted their knowledge.

Tilly: They latched on on the correct incident somehow.

Karen: Exactly, and they could use the concepts to describe it, what we had done.

Karen acts with an interest in the activity as an eliciting factor for a student's development of concepts. Tilly indicates that she is interested in how Karen carried out the activity in the classroom and both act as if their main aim is to further develop the task. Tilly then subtly indicates that she has shifted her focus towards the students' learning process in the second utterance. She acts as if her interpretation of the aim has shifted towards the global aim of contributing to theory on students learning processes. The negotiation takes off in another direction, initially being about gaining understanding of the design aspect towards being about understanding aspects of learning. The global aim of understanding the students' learning in respect of making connections as well as developing language is pursued long after this extract ends. The following episode picks up this chain of events further into the meeting. Karen admits that the development of the lesson had made her unsure of how she interpreted the three concepts statistics, chance and probability. We start off with her reading her own notes from what she found out from a dictionary after the lesson.

Karen: "Not be able to calculate in advance. Statistics, summarization of information, nah, Probability, the chances of getting" for example blue.

Paul: So what it becomes, Heads or Tails, aren't known in advance. Is that what you mean?

Tilly: Why did you pose that question like that? What were you thinking? Since you do this professionally... Why did you ask that question?

Paul: Well, because I thought the sentence was incomplete. "we calculate in advance", I just wanted to emphasise ... what is it we can't calculate in advance?

Tilly: Aaa, okay

The initial statement was copied from a dictionary and Karen acts as if she trusts and places the authority within that community. At least in the case of chance and probability, she relies on the dictionary and achieves agency with the use of it. The group's prior negotiation of meaning of statistics makes her less confident in the case of statistics; she indicates that she gives primacy to the group's interpretation. Paul questions this authority altogether. Tilly seems to pick up on Paul's questioning and probes the nature of Paul's agency; is he acting from a mathematics education researcher perspective, or a mathematical community perspective or something else? Paul continues by acting as if there are better interpretations of these concepts by questioning the wordings. He later on continues to negotiate the meaning of these concepts by means of examples and more mathematically precise definitions and thereby achieves agency by referring to the mathematical community. This exchange impacts the negotiation towards being even more focused on language.

It also becomes apparent that Paul's agency influences how Karen and Tilly use technical terms in the remainder of the session. Paul's aims and agencies remain in focus as they are given more space and remain unquestioned as the work progresses. The following episode is from the later parts of the meeting. It shows the impact of Karen's and Tilly's interaction in the first episode regarding the topic but also how Paul is left as an authority. Notice how Paul remains unopposed even though his claims and sentences are incomplete just as Karen's were in the previous episode.

Paul: My question about statistics springs from that fact that statistics is a rather large subject... A large topic so to speak

Karen: Mm

Paul: And I think that the curriculum sort of... Even in our ... our curriculum contains what this student is saying about the ratings of a TV-show. That you compare... often just think about observations, or we usually say frequencies, frequency tables and so on, so you limit the whole field of statistics to what one might call data collection, frequencies and such.

Tilly: Mm

Paul: What do you think, we could think about beginning to establish this type of concepts like... What is the frequency of blue? What is the frequency... How many observations of blue? How many observations of red? So, you insert this type of technical terms to become more precise. Specify a little bit more. That is, I imagine, a part of learning, that you learn to... You use a language and start to become a little bit more precise.

Paul acts as if he wants to shift focus to the local aim of the activity. He offers an alternative, or additional, learning goal in students developing their language through the activity. He pushes his agenda by referring to the authoritative mathematical community and therefore achieving agency. Both Karen and Tilly accept Paul's agency and leave his claims unopposed and instead adjust their use of language after the episode to fit Paul's. Paul's agency also results in a shift of focus in the following interaction. The continuing negotiation still involves interpretations of language but also aspects of the design and how language development can be anticipated and sequenced in a HLT.

To sum up the analysis, I exemplify how rearranging the aims of the activity, placing the aim of understanding students' learning in the foreground instead of the aim to develop the design, can have huge impacts on the course of the developmental process. Karen's and Tilly's interaction in the first extract refocused much of the remaining discussion towards negotiating the meaning of language use and development. An example of the dance of agency in designing educational activities has also been offered. Especially how some agency has higher authority and thus also more impact on the negotiation process.

## Discussion

Shifts of agency emerged in the presented episodes. Karen and Tilly both seemed to mostly rely on personal agencies in their actions, trusting in their professional experience in teaching for learning and language development. Paul on the other hand was perceived to rely on agency achieved from highly regarded disciplines as the mathematics and mathematics education research communities

when he contributes with examples and language. It corresponds with results from when Pickering (1995) studied mathematicians in their work. He saw that mathematicians often relied on their personal agency as they created initial ideas but “surrendered” to that of the discipline, as they needed to resort to following standard procedures of (for example) proofs. A similar phenomenon was observed in the episodes. Karen and Tilly relied on their personal agency until Paul referred to the mathematics community; Karen and Tilly then surrendered to the formalized language of the discipline to a greater extent. Further on it resulted in worksheets handed to the students using this formalized language and thus re-evaluating the HLT in light of formal use of concepts. I suggest that it emphasizes how the dance of agency (Pickering, 1995) is a principle to regard in collaboration between researchers and practitioners as it has the potential to be an indirect tool to guide the negotiation process in different directions.

Shifts in aims emerged in the data. Karen initially acts in line with the global aim of developing aspects of the design but soon shifts to align with Tilly to negotiate the meaning of a student’s language development. Paul later uses the mathematics community to achieve agency to shift focus towards developing the design once again and then sits back to evaluate its impact. Blumer (1986) argues that not only individual aims should be regarded but also that of the group. When multiple actors interact over a period of time a joint action is formed. It is a social construct that extends from being merely the sum of all actions, for example it also has its own aim that is negotiated by its participants. One might look at Karen’s, Tilly’s and Paul’s shifts in aims as attempts to negotiate what aim should be in focus or in the foreground while the others remain in the background. It becomes apparent in the topics discussed that the negotiation of aims for the joint action has impact. In the extended data, patterns emerge of how shifts in the joint aim redirect the following interaction until it was renegotiated. The result was an added activity in the HLT that was meant to challenge students’ ideas of chance. Reasons for why the participants chose to contribute in this way did not emerge from the existing data but one could speculate whether it has something to do with the respective role of the actors, being from a tradition of research or education. It presents a way forward to further advance our insight in the collaboration between researchers and practitioners in design research in mathematics education.

## **Implications**

As Stephan (2015) highlights the importance of working with small groups of teachers instead of just one in design research collaborations, the dance of agency is yet another tool to create purposeful design research collaborations. In the case of Paul, agency is used to steer the negotiation of meaning towards more mathematically aligned use of vocabulary. In another setting, it is possible to rely on shifting agencies to empower teachers in the collaboration by placing it in the domain of mathematics teachers. There is also the possibility to put focus on the research agenda when discussions tend to steer away. One could also consider the interpretation that it has the potential to shift the power relations, creating an (even bigger?) imbalance between participants, making participants less likely to make substantial contributions to the development of the task. The conclusion is that conscious achievement of agency can be used as a tool for researchers in design research collaborations to manoeuvre the discussion and shape the HLT to fulfil different aims.

*In order to identify mechanisms that can support mediation, this paper analyses the decision making process in a collaborative design of a digital learning resource by two different Communities of Interest (CoI). It focuses especially on the influence of both the CoI contexts and the socio-technical environment. This research was carried out within the framework of the “M C Squared” European project aiming at studying social creativity in the resource design. Specific conceptual and technical tools were used in this project to ease and document social interactions in the design of innovative learning resources promoting Creative Mathematical Thinking in the users. We focus on two main forces: tools and culture, which supported the collaborative design work between two CoIs.*

*Keywords: Community of Interest, context, socio-technical environment, collaborative task design, Creative Mathematical Thinking.*

### Introduction

This paper focuses on the analysis of a collaborative design of an innovative kind of digital educational resources for teaching and learning mathematics by different teams of designers. This research took place in the frame of the European Research and Development project called “M C Squared (MC2)” (<http://mc2-project.eu/>) where innovative digital resources have been produced to promote creative mathematical thinking (CMT). These resources have been designed by four Communities of Interest (CoI) (Fisher, 2001) constituted within the project: the English, French, Greek and Spanish CoIs. One of the objectives of the project was studying the processes of social creativity occurring during the design of resources and uncovering factors fostering it. Moreover, as the design was carried out in four different countries, the question of the influence of the cultural and institutional context on the design choices, as well as on the processes of social creativity, was raised naturally.

In this paper, we focus on the design process that involved a collaboration between two CoIs, the inter-CoI interaction being considered as a window on contextual issues impacting the design. We report the case of a resource called “Limits” that was initially designed by the French CoI members, redesigned by the Spanish CoI, and finally redesigned again in the cross-CoI collaboration between the two CoIs. In this framework of a collaborative design of a resource, we explore the influence of the context and of the conceptual and technical tools on the design process. In other words, we are particularly interested in *how the CoI context influences the design process in a given socio-technical environment and which tools and mechanisms support the collaboration between different teams of designers in the process of task design.*

The paper starts by presenting the context within which this research was carried out and its theoretical and methodological background. The design of the “Limits” resource is then described and analysed and the findings are discussed bringing to the fore elements of answers to the research questions.

## **Context and socio-technical environment of the CoI**

### **Communities of Interest (CoIs) and their context**

According to Fischer (2001), Communities of Interest “*bring together stakeholders from different CoPs [Communities of Practice] (Wenger, 1998) to solve a particular (design) problem of common concern*”. Four CoIs were constituted in the MC2 project gathering together, around a digital resource design, mathematics teachers, teacher educators, researches in mathematics education, educational software designers, artists, etc.

The French and the Spanish CoI, whose experience is reported in this paper, present different compositions and characteristics; we consider these as contextual aspects. The French CoI consists of 13 members with varied professional background, including researchers, school teachers, teacher educators, and educational technology developers. They share a socio-constructivist approach to mathematics learning rooted in the French didactical tradition of teaching and learning mathematics (CFEM, 2016). This approach has shaped the CoI representation of creative mathematical thinking (CMT) that manifests itself through (implicit) task design principles, such as designing tasks aiming at revealing specific students’ misconceptions, using multiple representations to enhance conceptualisation of mathematical notions, fostering social aspects through collaboration between students and affective aspects through challenging problems and games, or focusing on tasks calling for generalisation. The Spanish CoI, composed of about 20 members, involves people from different communities of practice, including researchers in and out of mathematics education, secondary school and university teachers and publishers. Most of the resources designed by the Spanish CoI present many design principles that are especially important for mathematical modelling, such as proposing real questions to students in order to face linking mathematics with other disciplines (social sciences, history, etc.), articulating questions posed and mathematical tools to engage students in modelling processes, enhancing the exploration or the contrast and validation of mathematical tools and models.

### **The socio-technical environment and collaborative design**

The design of resources took place within a specific socio-technical environment developed in the MC2 project, called C-Book technology (<http://mc2dme.appspot.com/mcs/>). It integrates two main tools: i) an authoring environment enabling to create digital resources, called c-books (“c” for creative), which consist from pages including texts, pictures, hyperlinks, dynamic interactive widgets, and allowing to record successive versions of the c-book units; ii) a tool, named CoIcode that provides a workspace to organize and enhance interactions among designers. CoIcode enables each designer to post various kinds of ideas (“contributory”, “alternative”, “objection”, “off task” and “task organization”), each of them having a specific icon. When a designer posts an idea, the system captures several details: author’s name, date, title of the idea, comments, attached resources, hyperlinks, etc. The CoIcode system provides designers from a CoI or a CoI-pair (two collaborating CoIs) with a space for collaborative design. In CoIcode, the discussions can be visualised in form of threaded forum or in a mind-map view (Fig. 1), where nodes are ideas, and branches of the tree model

the evolutions of an idea. The reports in the form of a graph provided by the system are the main data gathered for the study of social creativity. A voting system has been implemented in the CoIcode allowing designers to evaluate in terms of creativity any idea posted by someone else. Such evaluation follows a “middle c” perspective of creativity (Moran, 2010), that views creativity as a competency developed through interactions between members of a community and through their participation in situations where they display their intentions and negotiate new alternatives for the interpretation of actions in situated activity systems.

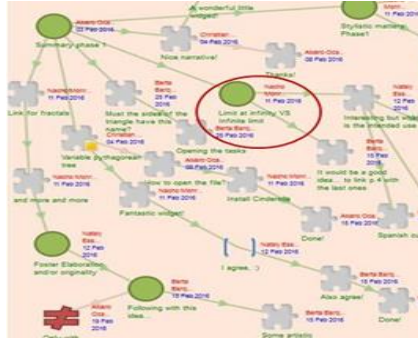

Figure 1. Excerpt of a CoIcode workspace in the mind-map view.

The cross-CoI collaboration on the re-design of the “Limits” c-book was organized in the following five phases: (1) a part of the French CoI, acting as the primary designers, designed a first version of the c-book; (2) four members of the Spanish CoI (two secondary school teachers, one researcher in mathematics education and one researcher in Calculus) evaluated the CMT potential of the c-book; (3) these members of the Spanish CoI redesigned the c-book according to their own approach, which constituted the first phase of the redesign; (4) a second redesign phase was carried out by the CoI-pair comprising this Spanish sub-CoI and two members of the French CoI (one researcher in mathematics education and one secondary school teacher); and (5) four new members (two from each CoI not involved in the redesign) evaluated the CMT potential of the redesigned c-book.

## Theoretical and methodological background

### Documentational and boundary crossing approaches

Our focus on the genesis of the c-book resource leads us to adopt the *Documentational Approach to Didactics (DA)* (Gueudet&Trouche, 2009) and thus consider the design of this resource as a documentational genesis. The analysis of resources coming into play in this genesis and of their successive versions unveils designers’ mathematics knowledge, CMT representations and culture. In addition, considering the collaboration between two CoIs, which can be viewed as two different activity systems, allows inferring the influence of the contexts on the design choices.

The *Boundary Crossing approach* (Akkerman& Bakker, 2011) enables enlightening the interactions between these contexts. It allows to highlight discontinuities, i.e. boundaries. Boundary objects (Star & Griesemer, 1989) and brokers support the communication and the understanding between and within the CoIs, allow to build new norms and a common frame of reference. Moreover, highlighting the mechanisms of *identification* (i.e., consciousness of discontinuities, awareness of multifold cultural background, which allows pointing out differences), *coordination* (i.e., creation of continuities between domains and bridges between cultures, which enables the construction of a common frame of reference), *reflection* (i.e., perspective making, perspective taking on the problem

at stake, which supports divergent thinking), and *transformation* (i.e., confrontation, recognition of a shared problem space, hybridization or combining ideas, and crystallization or keeping a perspective, an idea) helps us to better understand the design process.

### **Grid for the evaluation of c-book features fostering CMT**

The evaluation of the potential or affordances of a c-book to foster CMT was a central task in the MC2 project. Facing the necessity of CMT cross-evaluation, a need emerged for agreeing on and sharing common criteria, tools and methodologies, which had been developed independently in the first cycles of c-book production. A common CMT evaluation grid, which combines design criteria or principles proposed by the four CoIs involved in the project, has been elaborated by the researchers. This grid could be adapted by each CoI or CoI-pair to better fit its context, by adding specific criteria, and played a crucial role in the construction of a common frame of reference for all four CoIs.

The CMT evaluation grid is a questionnaire composed of three sections. The first and the widest section focuses on the evaluation up to what degree different dimensions of mathematical activity considered crucial for fostering CMT, such as conjecturing, questioning, evaluating, and establishing connections, are taken into account in the c-book design. With a total of 14 items expressing the indicators of different dimensions, evaluators of a c-book grade (from 1-4) their agreement on the items and explain their response according to the design being evaluated. For instance, the dimension of establishing connections is evaluated through the item: “The c-book provides users with opportunities to establish connections between various representations of the mathematical concepts at stake”, or the validation dimension through the item: “The c-book stimulates to think about, reflect, summarize and evaluate the mathematical work already developed”. The second section addresses social aspects through items like: “The c-book stimulates user's collaboration / cooperation / interaction with other users”. Finally, the third section focuses on affective aspects via items like: “The c-book actively promotes engagement by generating a perception of usefulness of mathematics, either in everyday life, or inside the mathematical context”. This grid, filled in for each c-book, provides the basis of the CMT study and development.

### **CoI Code analytics features**

In the MC2 project, a creative idea is defined as: (1) *novel* (original, unusual or new for the CoI members), (2) *appropriate*, that is it conforms to the characteristics and functions of the c-books, including their CMT affordances, bind to the CoI context, and (3) *usable*, that is available and ready to be used in the design of the c-book according to the designers' (the CoI members') estimation (Daskolia, 2015). CoI Code voting mechanism allows any CoI member to express his/her opinion about the three attributes of any idea posted by any other CoI member. The expressed opinions are aggregated into the creative score of an idea defined as follows: “creative score of the idea  $i$  ( $CR_i$ ) =  $0.5 \times \text{number of 'novel' votes} + 0.25 \times \text{number of 'appropriate' votes} + 0.25 \times \text{number of 'usable' votes}$ , if the number of ‘novel’ votes is at least a half of the number of CoI members involved in the c-book design, otherwise  $CR_i = 0$ ”. This definition reflects the fact that novelty is the sine qua non condition for an idea to be deemed creative; this is why the corresponding weight is the highest (0.5). On the other hand, the “middle c” perspective of creativity leads to considering an idea creative if the majority of the CoI members share this opinion. Thus, the interactions recorded in CoI Code allow

tracking communication among the designers during the design process and getting automatically the ranking of the ideas expressed according to their creativity score (Table 1).

USER	DATE	ID	TITLE	NOVEL	APPROP	USABLE	SC SCORE
CM	04/02/2016 11:03:51	45675	Variable pythagorean tree	4	4	4	4
NE	12/02/2016 11:01:13	45901	EpsilonChat to foster social aspects	3	3	3	3

**Table 1. Quantitative measurement to identify creative ideas.**

### **Data collection and observables for each phase**

The ideas and their organisation in CoIcode workspaces, the creativity score of ideas obtained automatically from CoIcode, the CMT grids filled in by the evaluators of the c-book and the successive versions of the c-book constitute the main data we analyse in order to highlight the impact of context, and cultural evolutions on the design decisions taken, as well as the role of the tools in the design process.

### **c-book design process in the cross-CoI collaboration and its analysis**

Our analysis focuses on two out of the five phases of the redesign of the c-book “Limits” (see above), namely phase (3), when the Spanish CoI redesigned the c-book and the phase (4) when the CoI-pair worked collaboratively on agreeing upon and conceptualizing the last changes of the redesigned c-book. We have chosen these two phases of the redesign process as they appear especially important with respect to our research questions.

### **Adopting the c-book and de- and re-contextualizing its design: mechanisms of coordination and reflection**

The initial version of the c-book “Limits”, designed by the French CoI, covered the notion of infinity through its meaning in solving equations, constructing the Pythagorean tree, analysing geometric sequences, comparing growth of functions, and calculating limits of real functions. The CMT representation of the French CoI members shaped the design of the c-book. In particular, it led the designers to embed tasks that enable intra-mathematical connections, generalisation, competition and challenge as levers for the CMT development. Following these principles, they proposed tasks offering various representations of the mathematical notions at stake (limits and infinity), by using algebraic, calculus, and geometrical settings, with the aim to provide students with alternative ways to make sense of these difficult notions in calculus and to generalise some properties. Moreover, the educational technology developers, involved in the CoI, enabled the development of specific widgets with features deemed as important to foster CMT, such as relevant feedback, written collaboration and discussions (a chat tool), and a framework for designing playful activities affording students’ self-assessment. Hence, the involvement of software developers in the designers’ team impacted the c-book design by creating new widgets in line with the French CoI culture. They also worked in close collaboration with the C-book technology developers, thus playing the role of technical brokers within the CoI.

As soon as the phase (3) started, the Spanish CoI began with the redesign of the c-book. The designers structured the workspace dedicated to the intra-CoI redesign work according to the results of their CMT evaluation with the grid (see section 3). For instance, they found the c-book improvable

regarding the connections that could be established with other disciplines or with other mathematical topics. They appreciated some characteristics of the c-book such as *connections* between several representations (numerical, geometric, and algebraic) of limits or the potential of the new widgets to simulate functions, sequences, limits, etc. and their practical use in activities focusing on evaluating students' work and progress. The decision to maintain these features can be interpreted as the agreement on the underpinning design criteria by both CoIs. They also detected several traits to further improve the c-book redesign, some of them being central for their own CMT representation; for example, they missed situations and questions that give sense and utility to the mathematical notions at stake (infinity, limits, etc.) – *questioning* or *problematization*. Likewise, they missed a global *articulation* of some of the activities dealing with a more general narrative and questions to focus on. This led the designers to organize the CoICode workspace around the eight design criteria or indicators they considered as crucial to be prompted (validation, connections, articulation, problematization ...) according to their CMT approach (Fig. 2, first column on the left) to orient further discussion. Therefore, the redesigned c-book urged students to investigate questions like the ones about fractal constructions and properties (guiding part 1 of the redesigned c-book), or the one about a cell phone password as the problem of the 9 points (guiding part 2), and to engage students in recognizing patterns in the process of mathematization of a problem, and in using the corresponding mathematical relations to check the validity of a conjecture.

**Figure 2. Excerpt of the workspace created for the intra-CoI redesign.**

In this episode, we can identify a mechanism of coordination initiated by the CMT evaluation which supported the subsequent mechanism of reflexion sustained by the structure given to the workspace. We note that the Spanish CoI instrumentalized CoICode, with a strong purpose of enhancing the c-book potential to foster CMT in students in line with their culture. Hence the mechanism of reflexion enabled to open new perspectives, related to the Spanish context, by adding tasks on fractals, the problem of 9 points and the mathematization of another problem.

### **The CoI-pair collaboration in the c-book redesign: mechanism of transformation**

The cross-CoI collaboration (phase 4), started with the translation of the redesigned c-book into English and the creation of a new workspace common to both CoIs. In order to organise and facilitate the communication between the two CoIs, the workspace was structured according to the four main sections of the c-book, and a summary of the main aims and changes introduced by the Spanish CoI in each section was added; the French team could thus compare the new version of the c-book with

its original design. During the CoI collaborative work, some design principles stemming from both CoIs were recognized and discussed to progressively become shared by both CoIs (confrontation and crystallisation of principles), such as the importance of tasks calling for conjectures, simulation, communication of results, and validation. Other design choices issued from the Spanish CoI were accepted by the primary designers of the c-book, such as the extra-mathematical connections included in the c-book or the new way of structuring and articulating activities in terms of chains of interrelated questions with increasing complexity. Furthermore, the quantitative information provided by the CoIcode data analytics, in particular in terms of creative scores of ideas (see Table 1) appeared as a powerful tool to identify ideas worth to be further developed in the CoI-pair collaboration. The two ideas that obtained the highest creativity scores came from two comments made by two members of the French CoI while analysing the c-book redesigned by the Spanish CoI. The first idea was related to the first part of the c-book devoted to the study of fractal properties and the appearance of the notion of limit at infinity. A French CoI member provided a link to a widget he designed with Cinderella dynamic geometry system to simulate fractals and predict their tendency in the infinity (Table 1, idea n°45675). The widget was subsequently integrated at the end of this first section with new questions that CoI-pair members suggested. The other idea was suggested by another French CoI member concerning the possibilities embedded in chat tools, developed within the French CoI, to foster social aspects (Table 1, idea n°45901). Chat tools were subsequently integrated in the c-book to enable students to communicate their results or to pose new questions. These episodes can be interpreted as hybridisation and elaboration of ideas.

Besides the importance that this phase had on creating a new and common CoI-pair design context, our analysis shows that the CMT grid, the CoIcode workspace the creative scores of ideas and the c-book versions used as boundary objects between the two CoIs constituted key mediation supports to enable the designers to agree on which ideas to accept (or not) and on the ways of further elaboration of some of these ideas, thus sustaining the mechanisms of coordination, reflection and transformation.

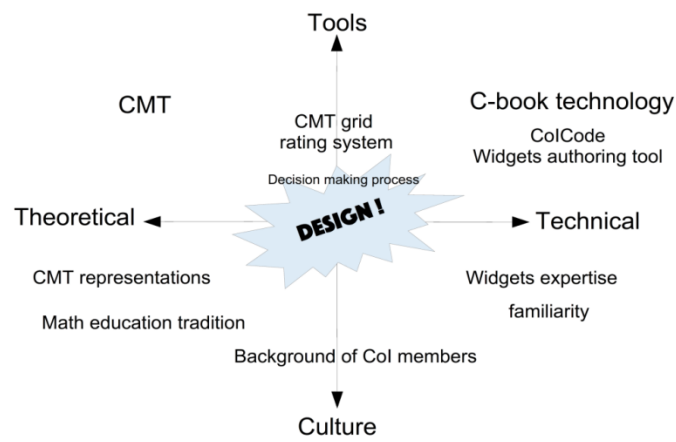

## Discussion and conclusion

The analysis of the c-book “Limits” collaborative design shows that different CMT representations that both CoIs held, influenced by each CoI own culture and traditions, enriched the cross-CoI collaboration, acted as a boundary object and participated in the key mechanism of coordination for decisions making in the intra-CoI and cross-CoI design work (Barajas, 2016).

In the two phases of intra-CoI and cross-CoI work (phases 3 and 4), it appeared that redesigning does not mean a total transformation and complete re-contextualisation either of the initial unit, of the empirical setting envisioned or of the academic approach (Barquero, Papadopoulos, Barajas & Kynigos, 2016), but rather an improvement of some aspects, and it helped to establish confidence and trust atmosphere. On the contrary, some design principles shared by the two CoIs were reinforced, crystallised through the mechanism of transformation, such as connections between multiple representations, or making and investigating conjectures. Others, coming from only one CoI, were negotiated and became shared by both CoIs, such as extra-mathematical connections or interrelations between the c-book activities, yet others were abandoned. The CoI-pair created a new, wealthier design context thanks to two different cultures close enough to create some overlaps yielding a common frame of reference, which enabled to build understanding and fostered the mechanism of

coordination. The understanding and respect allowed to share design decisions with the help of mediation tools used as boundary objects (different versions of the c-book, CMT grid, creative scores of ideas) and to cross some boundaries (different CMT representations, school cultures, research approaches, distance collaboration). The mediation tools favoured the dialogue between the CoIs and facilitated decisions, in conjunction with common good practices and CoI moderation strategies. The workspaces in CoIcode used as mediational artefact were instrumentalized to support reflection, enabling to make points of view explicit (perspective making) and to enrich ideas (hybridisation). The boundary objects, the structure of the workspaces and the moderation strategy played a major role in the mechanism of coordination, reflection and transformation.

This study brings to the fore two main forces that shaped decision making in the design process: *tools* and *cultures* (Fig. 3).

**Figure 3. Main forces shaping the decision making in a c-book design process.**

Both had either *theoretical* or *conceptual dimensions*, for example the CMT evaluation grid built on theoretical considerations about creativity, but they have *socio-technical aspects* as well because the C-Book technology, comprising authoring tools, widget factories and CoIcode, is the MC2 project social management main tool. The cultural context of the CoI includes mathematics education theoretical tradition, composition of the CoI, familiarity and expertise with the variety of widgets. The background of the designers impacts their attitude towards these tools, their CMT representations, their position in the collaborative decision making and the widgets they use. Eased by the proximity of collaborating cultures, the interplay of culture and tools in cross-CoI collaboration had enriched the scope of the designed tasks.

# Programming for 3<sup>rd</sup> graders, Scratch-based or unplugged?

Aaron Gaio<sup>1</sup>

<sup>1</sup>University of Palermo, Department of Mathematics and Computer Science, Palermo, Italy;  
[aaron.gaio@dmf.unict.it](mailto:aaron.gaio@dmf.unict.it)

*In this paper we describe a comparison between two different approaches to teach some algorithmic and computational thinking to children, mainly in 3<sup>rd</sup> grade. Children's learning is taken into main consideration and we want to analyze the difficulties students encounter using the different approaches. Before that, an introduction is done, describing the research framework and methodology, offering the background for this research and outlining the larger research project from which the paper is derived. We then describe the tasks used and look at some examples of the difficulties children face, on one side dealing with the problem of abstract thinking while programming, and on the other having troubles relating more practical activity with what the calculator does.*

## Introduction

Computer Science and algorithms in education are gaining more and more importance as the use of digital technologies is nowadays part of everyone's life. New educational trends are therefore emerging both from the computer science and mathematics education research community and from elementary and secondary school teachers (Franklin et al., 2015; Richtel, 2014). The question about how young children learn computer science is still a new area of research; and providing effective learning opportunities to K-5 students is a big challenge (Hills et al., 2015; Gelderblom & Kotze, 2009). Some good examples have been tried in the secondary school, while we feel that not much is present, at least in our country, in lower school grades. Topics in computer science and discrete mathematics are not clearly delimited in our curriculum and teachers are usually not aware that they actually could. We are thinking of our work as able to enhance the study of teaching and learning skills of mathematical practice through discrete mathematics problems, both general skills, such as reasoning and modeling, and skills particular to discrete mathematics, such as algorithmic and recursive thinking.

## Background and context

### Preliminary survey among teachers – relation with cryptography

We had a first survey, with results collected from about 150 teachers, mostly in service and quite evenly divided between primary, middle and secondary school. The survey was done with an online platform. The result analysis is mainly following a quantitative approach, the qualitative analysis was referred to the codification of some particular key words used by teachers.

Analysing the results, teachers, especially at lower levels, admit not to have the necessary knowledge to teach this in school. Question was about their previous experience in learning cryptography and graph theory, as well as the connection of these to mathematics and computer science. Some of these teachers see the connection between algorithms, cryptography and mathematics in general and computer science as quite necessary, while some don't have this idea clear in their mind. Also,

teachers were asked if they had any previous experience in teaching the topic or if "they would be interested in teaching some algorithm, cryptography and other discrete mathematics topic to students", and feeling from their answer is that this results can be taken as a first starting and promising point to make something of this into the national curriculum. A detailed analysis of these results is available in another article (Gaio & Di Paola, 2016, in press).

### **National Guidelines and teaching situation**

The Italian Ministry for Education, University and Research published the current National Guidelines for the first cycle (kindergarten to middle school) of education (Ministero della Pubblica Istruzione, 2012). These guidelines are not any longer a detailed description of school curriculum to follow, but just want to provide concepts from which the single schools and institutes, and teachers, can take the basic goals and competences to reach. Some general standards are set with objectives for the educational achievements and learning goals. In the section talking about mathematics, there is a great importance given to reading and understanding texts with logical content, build lines of reasoning, having own ideas and defending and comparing them with others; a positive attitude towards mathematics, realizing how mathematical topics are useful in the real world. Algorithms and logical thinking as also referred to as important in the technology chapter of the guidelines, for all school grades. Following these guidelines, and our idea as well, "the first education cycle has a prominent role in the school curriculum considering the importance of this time in every student's life. Within this, the school attributes great relevance to the education and teaching methods that can fully activate energies and potentialities of every kid".

### **Research question**

Our main general research problem lies therefore in a proposal to alleviate the substantial lack of activities in the national school curriculum about discrete mathematics and computer algorithms, especially for primary and middle school. Both in the school programs and in textbooks, activities of this kind are missing almost entirely, despite many agree that they can be really useful to improve the skills mentioned above.

The purpose of this specific paper is to deal with the introduction of programming reasoning to children as young as 8 or 9 years old. The question is whether *it is better to approach the subject with an unplugged approach and only later go on with computer-based coding or if it is ok to proceed using Scratch-based software and tools to serve the same purpose*. We do this by describing two different approaches which have been used in the teaching of these computer science and discrete mathematics topics. We will in particular analyze and focus on certain difficulties students encounter while using both.

### **Theory and methodology**

This is an overview, referring to our whole project's methodology and background theory.

#### **Background theory**

Teaching methods follow the model of Realistic Mathematics Education (Gravemeijer, 1994) and Guided Reinvention of mathematics (Brousseau, 1997).

Guided Reinvention of mathematics is based on Hans Freudenthal concept of mathematics as human activity. Education should give students the "guided" opportunity to "re-invent" mathematics by

doing it. This means that in mathematics education, the focal point should not be on mathematics as a closed system but on the activity, on the process of mathematization (Freudenthal, 1973).

Realistic Mathematics Education (RME) is an instructional design theory which centers around the view of mathematics as a human activity (Freudenthal, 1991); “The idea is to allow learners to come to regard the knowledge that they acquire as their own private knowledge, knowledge for which they themselves are responsible.” (Gravemeijer, 1994). The main goal is to develop a local (i.e. domain-specific) instructional theory (LIT) that will allow students to “[invent] the mathematics themselves” (Larsen, 2008). This need two steps: Step 1, in which “students are engaged in activities designed to invoke powerful informal understandings” (Weber & Larsen, 2008); Step 2, in which “students are engaged in activities designed to support reflection on these informal notions in order to promote the development of formal concepts” (Weber & Larsen, 2008).

### **Research methodology**

The methodology we are going to use is that of design research or design experiments (Cobb et al., 2003; Barab & Squire, 2004; Brown, 1992). For the purpose of this thesis, the developmental approach is taken into consideration (Plomp & Nieveen, 2007); development studies function is to design and develop a, research based, intervention (Steffe, 1983) and constructing design principles in the process of developing it. The goal is to explore new learning and teaching environments, to verify their effectiveness; to develop somehow new methods, instruments and teaching actions to further improve in the field of problem solving and logical thinking, using somehow unusual topics as algorithms and cryptography are for primary school students. Doing this the goal is to contribute to the development of new teaching and learning theories, taking into consideration learning processes in the specific situation, with contents and goals clearly defined. Design research is quite appropriate in this situation, as we are facing a brand new experience in an environment that we need to analyze carefully, i.e. on a local scale, considering all the different elements in the learning environment. The intended design experiment will be a classroom experiment in which the researcher (or researchers) will cooperate with the teachers in assuming teaching responsibilities. On one hand, the teacher is a part of the design team and will be a key role in the development and reviewing of the activities, on the other, they have no previous knowledge and need a guide to experiment with this new experience and new content to present.

### **Design, tasks, analysis and results**

As a first design step, based on theoretical framework and literature, two hypothetical learning trajectories were designed for the two different approaches. One approach is Scratch-based, and has been taken from the most popular book on curricular resources about Scratch programming in our country (Coding, DeAgostini publisher, Ferraresso, Colombini, Bonanome, 2014). The second approach was developed by our research team, taking idea and inspiration from the Computer Science Unplugged project (Bell, Witten, Fellows, 1998, 2015 review) and other related sources (Casey et al., 1992), with a development, after a preliminary teaching experiment, to better adapt the activities to the school level and local situation and norms. The two HLTs are taking into account the theoretical framework presented above, both in the choice of tasks (e.g. some tasks are chosen for their RME approach, others for the group and cooperative work students have to do, and so on) and in the way of presenting them to the classroom or students.

The tasks we are going to describe are just some of the many sequences of tasks that were proposed to various schools and age groups during the 2015/2016 school year in the bigger research project. In a design research paradigm (Plomp & Nieven, 2007), the activities were tried out many times, always with an a priori analysis together with the teachers and with a retrospective look after each lesson.

Schools	Grades	n. of Classes	n. of Students	Approach
1,2,4	3	4	78	Unplugged
1,2,4	3,4	5	80	Scratch-based
3,5	3,4	3	54	Unplugged
3,5	3,4	2	39	Scratch-based

**Table 1: Classes involved in different grades, with students numbers and curriculum used**

### Scratch-based teaching and learning

As mentioned above, the sequence of tasks we called “Scratch-based” is taken from this Coding book, which is getting popular in our country’s schools. Also we did use the M.I.T. official Scratch guide (Creative Computing, Brennan, Balch & Chung, 2014). It is following a similar approach to many school text books and even M.I.T.’s own guidelines on Scratch use and we feel it is good material for teachers. We did choose the tasks that are most popular among teachers already doing this kind of activity in their classroom, at least investigating the most popular in our area.

We did in particular choose tasks related to sequencing, selection and iteration. The goal is to have students learn basic ideas behind an algorithm (seen as a sequence of instructions), but also more complex concepts like selection instructions (i.e. do this only if something else happens) or iteration procedures. A sequence of tasks on those three topics were selected together with the classroom teacher and then tried out with the students during mathematics and technology lessons.

### Unplugged approach, teaching and learning

Our “unplugged” sequence of tasks occupies 3 or 4 lesson slots of about one and a half to two hours and follows a brief introduction given on how computer works and binary numbers, in form of games (this was given also the groups using the other approach). Briefly describing the tasks, task 1 was an activity on paper, about binary image representation. Students had to color a grid which was provided with 0s and 1s and produce a drawing following the numbers. This task goal was about following instructions and beginning to understand how a computer transmits information.

Task 2 was about giving and receiving instructions. Students were divided in pairs and given a series of shapes and objects they could move on their table. One student (1) for each pair was to create a composition on his table; without looking at each other (physical barrier between the two), student 1

had to explain to the other how to reproduce the same composition with the objects and shapes. Children were required to be as precise as possible while the game went on, and to try to find out compositions that were harder to form. Only oral communication were left them, not to make them “correct” the other mistakes or looking at the other composition. Slightly different versions of the game were tried out, e.g. with just one student giving instructions to all others, or with different kinds of objects, even with just drawing something instead of moving objects, and so on.

The following tasks had the goal to make programming even more tangible for children. We wanted them to learn to give instruction as a calculator, through a path to walk on. One student (blinded) was the “robot” walking along this path on the ground and the others were the “programmers” having to give him instructions how to move to get to the end. We did this both speaking and then written. The written exercise does not give the possibility to correct the robot while you are actually giving the instructions, kind of how a real computer program works. Finally, with some of the classes we went on to construct some more complex sequence of instructions, posing different games to strengthen the concepts, but always with similar goals.

### Methods of video selection and analysis

Analysis of the results is video-based, qualitative and fine-grained; both group activities and classroom discussion are recorded and we also have many of the transcripts, together with field notes, student’s sheets, and interviews as other sources of evidence. As already said, focus is put on students’ learning and thinking, in reaction to the different tasks proposed.

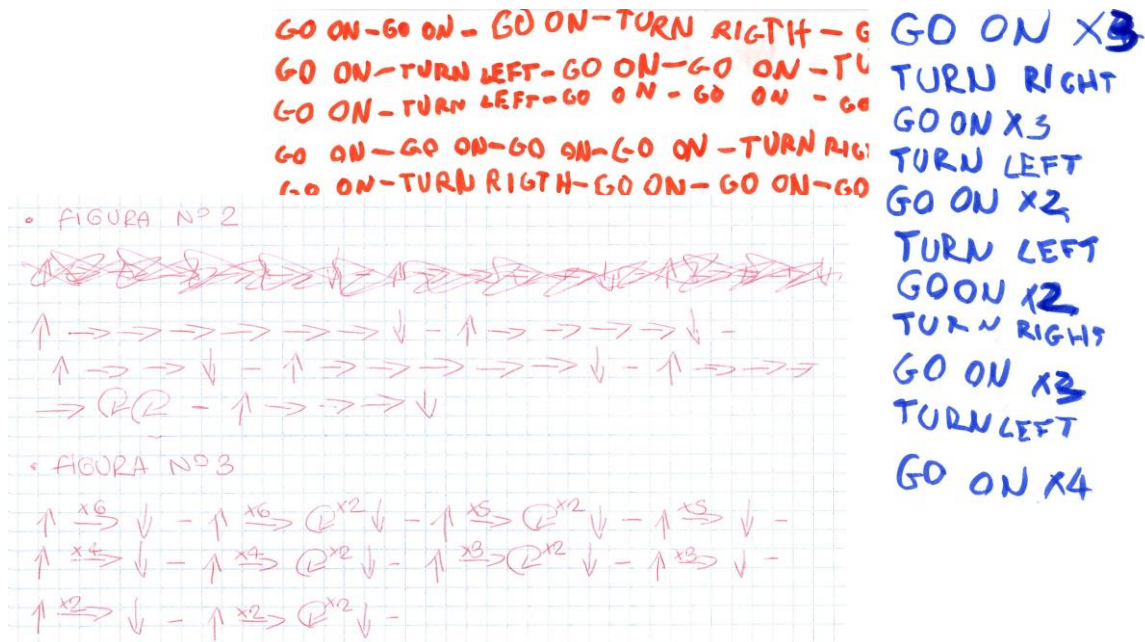

Following Zacks & Tverski theory, data is represented by events selected from the video recordings available. We used an inductive approach in video selecting, beginning with viewing the corpus in its entirety and focus on details later on. Indexing and summaries of videos, plus a content log, help in this process. Going on with the analysis some events which were particularly relevant were isolated. Although there are some recognizable recurring situation and choice of words we coded, our focus is more on a “play-by-play” description of these chosen events. We are, with this approach, analyzing selected episodes focusing on the same happening and constantly revising our finding and new hypothesis, as in Cobb and Whitenack (1996) with the involvement of “constantly reconciling provisional analytic categories with subsequent data and newly formulated categories”.

## Different difficulties emerging

The “events” we are focusing on does not pretend to show that one approach is better than the other, but which kind of, different, difficulties each of them can create in the children learning and thinking using the different approaches.

In the unplugged approach, children easily figure out what they are really and practically doing, drawing conclusions that they usually do not get in front of the computer. See for example the following figures where the transition from longer instruction in the first part to shorter instruction (switching to an iteration notation) in the second comes automatically. Almost every student quite naturally finds out that it takes a long time to write again and again the same instruction and is quickly asking himself if he might “make it somehow shorter”. This is probably due to the fact that they were left free to develop their own language with arrows, and they feel they can adapt it to what is more appropriate and efficient for the situation. Videos showing these moments when they realize this fact has been isolated from the data.

**Figures 5 and 6: Showing the transition from sequential instruction to iteration**

Or, on the other hand, as an example, see the following short transcript from a video (in front of a Scratch set of instruction on the computer), where the students do not realize the usefulness of shortening a computer program to make it simple and more efficient:

Teacher: Why aren't you writing it in a shorter way (more compact?). You don't need to write an instruction 6 times, you could write “do this ... times”.

Student: Well, but what's the need for it? The computer is doing it anyways.

In these examples, students doing it unplugged quickly find out they are more efficient if they switch to an iterative mode of giving their instructions, while students doing it on the computer do not really realize this. On the contrary, they should learn one more command (or Scratch block) they do not already know to do it, so in the beginning it does not seem so appealing. From many events observed, quite surprisingly, this shortening is not immediate on the computer. Following our qualitative video analysis, in general, it seems that both selection and iteration instructions do not come naturally in

the Scratch environment as they do in an unplugged approach. Setting the activities and game in a real world scenario, especially at this young age, seems to give children a better idea of the advantages of iteration and the working principles of selection programming. Maybe creating some highly inefficient situation could force this process to happen in this case, too.

A second aspect to consider is errors done while writing a program. Analyzing error situation we can observe that it is actually easier for the students to spot the errors in a Computer-based environment. In the unplugged approach, sometimes, error fixing does not work at all, i.e. they cannot even spot the error if told that there is one. Our conclusion is that, as they are controlling their own game, they, more or less, unconsciously, get to a right solution even with a wrong set of instructions. On the computer-based environment, trying the program and making it running, given that the computer executes exactly what it has been told, students easily spots where the mistake is.

Another aspect we are facing at this young age is abstraction capability. As many references states (see Kramer, 2007), abstraction capability is the key to be a good programmer and to have future programming abilities. Abstraction is a very difficult process and Scratch helps a lot in this direction; on the other side, the unplugged approach makes activities somehow too distant from the abstraction of programming and makes it more difficult to children to relate what they are doing with what they will later do on the calculator, as some video excerpts from these moments show. Aspects of a real world mathematics surely can help the transition to the abstract world of programming (Futschek & Moschitz, 2011), but we have to be careful in the subtle connection between the two areas.

## Conclusions

As conclusions, we could see pros and cons of both approaches, and we feel that obsessing over using just one is not the correct decision. Video and other data analysis show that there are aspects that ought to be dealt with in an unplugged way before writing them on the computer (algorithms, iteration processes and many others) and come really more natural to children if they use their own language, as can be seen in many “Aha! Moments” in the recordings. On the other side, it is really difficult for young children to relate the more real-world-oriented tasks to computer science, as we can see example when they get stuck in finding the connections. Future work will try to go into combining both approaches in a more comprehensive curriculum plan, creating new learning sequences that take both into account, which we will share with teachers and educators, in a relatively long developing process. Teachers willing to teach these topics are growing in number and they ought to be prepared for the challenge they will be facing.

# Principles of redesigning an e-task based on a paper-and-pencil task: The case of parametric functions

Galit Nagari Haddif

University of Haifa, Faculty of Education, Haifa, Israel; [gnagarih@campus.haifa.ac.il](mailto:gnagarih@campus.haifa.ac.il)

*Paper tasks are often redesigned to function as digital tasks. The research and design literature (Pead, 2010; Burkhardt & Pead, 2003) has reported on the challenges of such a transformation. We report on a study exploring the design principles of an e-task, originally designed as a paper-and-pencil task and converted into an interactive diagram. We describe a paper task in the content area of parametric functions, and report on results from an experiment conducted with 39 high school students, who dealt with an e-task based on a paper task. Analyzing the results, we demonstrate that in a redesigned e-task based on a paper-and-pencil task, technology should allow self-reflection, promote learning, and guide the students to focus on the important details without unnecessary distractions.*

*Keywords: Design, e-task, parameter.*

## Goals and theoretical framework

In this paper<sup>1</sup>, we explore design principles of an e-task that encourages exploration, based on a paper-and-pencil (P&P) task, in the area of parametric functions, which is central in algebra and is adequate for enhancing the abstraction of concrete situations (Drijvers, 2001). Solving parametric equations is different and more challenging than solving numerical algebraic equations, which are solved for an unknown that is a number. Naturally, when designing an e-task we should not translate from the paper but rather use successful principles of learning within the interactive environment to design the tasks. Research shows that many complex issues arise when transferring paper-and-pencil tasks to computers. For example, if students are not familiar with the tools, the online environment may be a potential source of an additional "cognitive load" (Pead, 2010). Interactivity can spoil some tasks: for example, by allowing students to check all their answers, or by encouraging them to persist in trial-and-error experimentation, rather than engaging in analysis (Burkhardt & Pead, 2003; Nagari Haddif & Yerushalmy, 2015). Although the transition from a paper-and-pencil task to an e-task is not trivial, there may be an added value in the use of technology. For example, multiple linked representations (MLRs) both support and require tasks that involve decision making and other problem-solving skills, such as estimation, selecting a representation, and mapping the changes across representations (e.g., Yerushalmy, 2006).

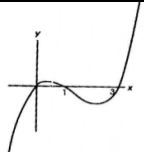

With the Cabri software, Healy (2000) introduced soft and robust construction and found that despite the intention to encourage students to build robust constructions, in practice, some students preferred to investigate a second type of Cabri-object, soft constructions, in which one of the chosen properties is deliberately constructed by eye in an empirical manner, under the control of the student. Laborde (2005) referred to soft constructions as the "private" side of the student's work, which is part of the solving process and serves as a scaffold to a definite robust construction. We suggest using soft constructions as a way of exploring and identifying dependences between

properties, and as a gateway to a definite robust construction from a purely visual solution. Below we describe a task (Figure 1) taken from Taylor (1992, p. 204), and the reasons for which we decided to redesign it and convert it to an e-task. In general, Taylor's rationale for this kind of task is to have a marked difference between being able to see ("sense") the solution geometrically and the ability to solve it algebraically. Interactive MLR technology offers dynamic interactions that can support the generalization of a graph into a family, offering sensuous support for finding an abstract parametric solution. This gap between interaction and abstraction is one of the challenges of using interactive MLR technology. The following description of the e-task design and of the experiment conducted with the students who worked with this e-task, demonstrates some basic considerations and principles of designing an e-task based on a P&P task.

### The original P&P task and its possible correct solutions

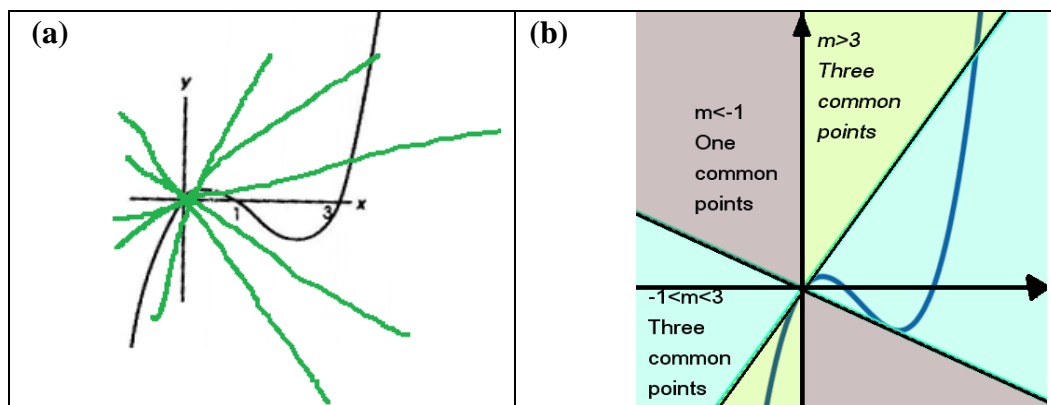

Research on mathematicians' conjecturing and proving activity suggests that use of examples plays a critical role both in the development of conjectures and in their exploration, as well as in the subsequent construction of proofs of these conjectures (Lockwood, Ellis, & Lynch, 2016). Therefore, when dealing with the task (Figure 1), we can expect work that would look like Figure 2 (a): the students would sketch for themselves some exemplary lines through the origin.

At the right is the graph of the cubic equation  $y = x(x-1)(x-3)$ . Consider the family of non-vertical lines through the origin. How many intersections does each line have with the curve? (I) Begin by making a conjecture based on the picture. (II) Describe the family of lines algebraically, and verify your conjecture.

**Figure 1: The original task as it appears in Taylor's book (Taylor, p. 204)**

In this case, it may be difficult to make a generalization and diagnose the three different numbers of common points: one, two, and three common points between the family of lines  $y = mx$  and the given function  $y = x(x-1)(x-3)$ . Moreover, one could start to investigate algebraically the mutual relationship between the two functions required in part (II) (Figure 1), and skip part (I).

**Figure 2: (a) Typical free-hand sketching used to conjecture about the intersections; (b) The domains and values of parameter  $m$  for all cases of number of common points**

The abstraction and generalization needed to find and define algebraically the domains of the parameter  $m$  for each case number of common points (Figure 2 (b)) is a challenge. Generally, solving the case of two common points requires using two approaches, as shown in Figure 3.

The algebraic approach	$x^3 - 4x^2 + 3x = mx \Rightarrow x^3 - 4x^2 + 3x - mx = 0 \Rightarrow x[x^2 - 4x + (3 - m)] = 0$ $x = 0 \text{ is one intersection point. Therefore, when the equation } x^2 - 4x + (3 - m) = 0 \text{ has single solution:}$ $\Delta = b^2 - 4ac = 16 - 4(3 - m) = 0 \Rightarrow m = -1$ $\text{The other case is when the equation } x^2 - 4x + (3 - m) = 0 \text{ has two solutions, one of which is } x = 0 \Rightarrow 0^2 - 4 \cdot 0 + (3 - m) = 0 \Rightarrow m = 3$
The calculus approach	$m = f'(0) \Rightarrow f(x) = x^3 - 4x^2 + 3x \Rightarrow f'(x) = 3x^2 - 12x + 3 \Rightarrow f'(0) = 3 \Rightarrow m = 3$ $\text{In the other case, let } (t, t(t-1)(t-3)) \text{ be the point of tangency}$ $m = \frac{\Delta f}{\Delta t} = \frac{t(t-1)(t-3) - 0}{t - 0} = (t-1)(t-3)$ $f(t) = t(t^2 - 4t + 3) = t^3 - 4t^2 + 3t \Rightarrow m = f'(t) = 3t^2 - 8t + 3$ $m = (t-1)(t-3) = 3t^2 - 8t + 3 \Rightarrow t^2 - 4t + 3 = 3t^2 - 8t + 3 \Rightarrow t = 2, 0 \Rightarrow m_{1,2} = 3, -1$

Figure 3: The two main ways of solving the case of two common points

In both the calculus and the algebraic approaches, there is an "easy" value of  $m$  and one that is less obvious. When grappling with this task, students should "see" (and be able to calculate) that there are two possible values for parameter  $m$ , for which both functions have two common points:  $m = 3$  or  $m = -1$ . Some students (see also Ron's thinking-aloud process in Figure 6) may skip one approach that reveals one of the values of  $m$  and move on to the other approach to obtain another value. A mathematical pedagogical discussion may address the manner in which the two approaches meet. This rich task concerns various mathematical concepts besides parametric functions: intersection points, tangency to a function, and mutual relationships between functions. It encourages making conjectures and aims to assess skills such as exploration, algebraic manipulation, and generalization of particular cases and examples.

## Study

We redesigned the task (Figure 1) and converted it to an e-task. We conducted an experiment with 39 10<sup>th</sup>- and 11<sup>th</sup>-grade students who worked with the e-task. The students studied the standard curriculum with different teachers in the same school, without special emphasis on technology. Ron, one of the students, was thinking aloud during the solving process (Figure 6). The video recording of his thinking aloud enabled us to follow the process of task completion as it was taking place, rather than consider only its final product, and to listen to the problem-solving process.

## Design considerations and possible correct solutions: Parts A and B

**MLR experimentation first.** In part A (Figure 4), the students used a dynamic applet that displays the function  $f(x)$  and the parametric family  $y = mx$  on the same coordinate system.

The following interactive diagram describes the functions  $f(x) = x(x-1)(x-3)$  and  $y = mx$ . By dragging the red point, you can create different examples of mutual relationship between these functions.

**Part A:** How many common points are there for both functions? Submit three different screenshots, each one representing a different number of common points.

**Part B:** For which values of  $m$  does the functions have one common point? Two common points? Three common points? Indicate all the possible values.

Figure 4: The designed e-task: parts A and B

Students became familiar with the activity and the givens, and were asked to submit three screenshots of three different cases of numbers of common points, in other words, three different "soft constructions" (e.g., Healy, 2000; Laborde, 2005), designed to support their generalization process and symbolic work required in part B. In the case of the parametric family in the MLR environment, any change in the value of  $m$  changes simultaneously the graphic representation of the relevant line. In designing this part, we wanted to make sure that students experimented with the applet, understood all the details and givens, and were exposed to many examples of the parametric function, so that in part B they could concentrate on the exploration activity with as little cognitive load as possible. An example of a correct solution is shown in Figure 5. The student submitted three different mutual relationships of the two functions, each with a different number of common points.

Figure 5: Example of a correct solution for part A

**Minimal necessary tool set.** There are deliberately very few tools available to the student: zoom in, zoom out, and move the coordinate system. The tools are designed to enable users to sense the task qualitatively, allow them to focus on the relevant parts of the graphing picture, and not to provide numeric information. This minimal design conveys the message that other parts of the tasks require numeric and symbolic calculation not provided by the interactive diagram. To summarize, the goals of part A are: (a) encourage student experimentation with the dynamic applet: feel/sense the givens and avoid cognitive load; (b) expose students to a variety of examples demonstrating the mutual relationship of the two functions; (c) engineer an experience-based conceptualization for solving the general case required in part B; and (d) assess the student's understanding of the givens and of what is expected of them (as well as some technical issues). Solutions for each number of common points appear in Figure 2 (b): one  $m < -1$ ; two  $m = 3$  or  $m = -1$ ; three:  $-1 < m < 3$  or  $m > 3$ .

## Findings and data analysis: Parts A and B

**(1) Part A:** Most students submitted correct answers for part A (Table 1). This is not surprising, because the purpose of this part was to encourage students to "sense" the problem and its givens. But 15% of students missed one case (of one or two common points). Possible reasons for this are that students were not experienced enough with the applet, that they did not use the tools to view all cases, etc. As mentioned above (Figure 3), it is easy to reach one of the two possible values of  $m$ , but while experimenting with the interactive diagram one may notice that there is another possible value of  $m$ . In Figure 6 we describe Ron's thinking aloud about a solution for part B.

<b>Correct answers</b>	Correct answer	29 (74.3%)
<b>Incorrect answers</b>	One missing case (of one or two common points)	6 (15.8%)
	Technical problem	3 (7.7%)
<b>Not submitted</b>		1 (2.6%)
<b>Total</b>		39 (100%)

**Table 1: Submission characteristics of correct and incorrect answers to part A**

In the beginning, Ron solved this part algebraically and found that  $m=-1$  is the case in which the functions have two common points. By zooming in and out, he found that there is another value for  $m$ . The interactive diagram allowed Ron to connect between the algebraic and graphic approaches (Figure 6, line 9). Through experimentation, he tried to find the other value of  $m$  (Figure 6, lines 4-9). This demonstrates the power of technology as a tool that provides students means to reflect their solution, allowing learning to take place during a test. In practice, during the experiment some students noticed the missing value of  $m$  and tried to find it (not always successfully), either by expanding the solution using the same approach, or by changing the approach from algebraic to calculus or *vice versa*, as described in Figure 3.

**(2) Part B** (Error! Reference source not found.): 18 of the solutions included one or both correct values for  $m$  ( $m=-1$ ,  $m=3$ ).

	<b>N=39 (100%)</b>		
<b>Number of common points</b>	<b>One</b>	<b>Two</b>	<b>Three</b>
<b>Correct answer</b>	15 (38.5%)	2 (5.1%)	2 (5.1%)
<b>Partial answer</b>	0 (0%)	16 (41%)	7 (17.9%)
<b>Incorrect answer</b>	8 (20.5%)	6 (15.4%)	13 (33.3%)
<b>Not submitted</b>	16 (41%)	15 (38.5%)	17 (43.6%)

**Table 2: Submission characteristics of correct and incorrect answers to part B**

Only two students submitted a completely correct answer; 15 students did not submit an answer. Others submitted other values, probably as a result of calculation errors or because they were guessing. Only two students submitted a correct answer for the case of three common points (the same students who submitted correct solutions for the case of two common points). This may imply that in addition to the difficulty of finding both "critical" values of the parameter  $m$  ( $m=-1$ ,  $3$ ), it is also difficult to generalize and formulate symbolically the possible domains of parameter  $m$  for the cases of three common points.

	Ron's thinking aloud	Ron's actions on and with the screen
1.	This is equivalent to solving this equation. Right? Right. Zero is always one common point... then... Then I can divide simply by x. Then I investigate the quadratic equation:	$mx = x(x - 1)(x - 3)$ $m = (x - 1)(x - 3)$ $x^2 - 4x + 3 - m = 0$
2.	I check when it has two solutions, one solution, or zero solutions. These are two common points in my opinion.	He looks at the case that is close to $m=3$ .
3.	No, these are three common points... There is a certain m... It has to be minus 1	This is the value that he got through the algebraic calculations.
4.	Then where did I go wrong?	Graphically, he sees that there is another positive m, but he got only $m=-1$ .
5.	I need to check this equation.	Refers to $mx = x(x - 1)(x - 3)$ .
6.	I always have one common point. Then I can simply divide by x. I have a neat equation. I have to see when it is equal to zero. We need to check when the discriminant is positive, negative, or zero. m must be different from zero to have two common points. Then m equals to -1. $m=-1$ for two solutions.	He checks again his calculations: $mx = x(x - 1)(x - 3)$ $m = (x - 1)(x - 3)$ $x^2 - 4x + 3 - m = 0$
7.	I need to zoom in.	Ron uses the zoom in and out buttons to explore and distinguish between different cases.
8.	I don't know what is my analytic mistake...	
9.	This is the tangent, the tangent.	He finds the graphic meaning of the case of two common points. Using calculus, Ron finds the other value of m.

Figure 6: Ron's thinking aloud while working on part B

## Discussion

Our first conjecture, that a dynamic and interactive MLR environment supports the generalization of a graph into a family was only partially confirmed. The results of part B reveal the complexity of the concepts involved in the tasks. Results may suggest the presence of a permanent tension when designing mathematical e-tasks. On one hand, we want to design an e-task for exploration that can be automatically checked. Therefore, we tend to give students the opportunity to explore without any hints and without leading them to the solution. On the other hand, the task may be too difficult, and we may have difficulty assessing the students' knowledge and mistakes. In retrospect, this exploration e-task was too difficult; we should have divided the e-task into more than two stages and ranked the sub-tasks: first concentrate on the case of two common points, and only later on other cases. We are currently considering a refined design of this e- task.

Below we describe some basic design principles we gleaned from the experiment described above. Other design principles are described in Yerushalmy, Haddif, and Olsher (under review), Haddif and Yerushalmy (under review). **When re-designing an e-task based on a P&P task, technology should provide the following: (1) Allow self-reflection:** When solving a P&P task, we have few means to reflect on our solution, especially not instantaneously. Use of an interactive diagram in an

MLR environment together with manual calculations helps students control their actions and reflect on them during assessment, and check whether they are right or wrong, without telling them directly what the correct solution is. **(2) Promote learning:** Using an interactive diagram with parametric functions allows seeing many instances of the same family. This is an opportunity to see the parameter serve as a "generator" of functions that belong to the same parametric family. Experiencing with the dynamic diagram also encourages students to make conjectures and conduct interactive exploration. As demonstrated in Ron's case, technology has the potential to create a cognitive conflict and thereby provide a learning opportunity (Figure 6, line 4). Ron tries and succeeds in solving the conflict between the manual solution and the graphic representation on the screen. Had he solved the original task, he may not have noticed the "conflict" between the graphic representation and the symbolic calculation. **(3) Guide students to focus on the important details, without unnecessary distractions:** Although it is tempting to use the varied capabilities of technology, these might distract the students and produce negative effects. Therefore, it is necessary to focus on the real needs of the students and redesign the e-task to make students concentrate on the important details, without unnecessary distractions. This also implies that students understand how to approach the question. The design must reflect in some way the purpose for which the tool was created (Yerushalmy, 1999), and the cognitive load must be reduced as much as possible. We demonstrated several ways of doing this: (a) designing the task in a way that students move in stages away from using sensory knowledge in soft constructions toward experimenting with the interactive diagram to produce robust constructions, abstraction, and generalization. (b) designing the environment and the required solution in a way that defers engagement in numeric and symbolic activity: for example, eliminating grids and the option to enter expressions conveys the message that conjecturing comes before computations. (c) determining the minimal necessary tool set that is familiar to the students and common to other e-tasks. In Yerushalmy et al. (ibid.) we described in detail the tool set needed for calculus e-tasks, which enables automatic checking of the students' submissions.

*Motivated and talented mathematics students are not always convinced about the relevance of mathematics. More insight into applications of mathematics can be beneficial for students in terms of preparing them for their future study and career. Using design research a particular intervention had been developed which differentiated by student interest, in order to improve students' beliefs about the relevance of mathematics. The students selected were those studying advanced mathematics at upper secondary school in the Netherlands. The intervention had been designed to teach differential equations through tasks with science-, medicine-, or economics- related contexts. The results show that the students appreciated the context-rich tasks, which provided them with insights into how mathematics can be applied in other sciences and contributed to the improvement of their beliefs about the relevance of mathematics.*

*Keywords: Mathematics education, task design, relevance of mathematics, differential equations, differentiation by interest.*

## Introduction

Students' beliefs about the relevance of mathematics has been a topic of much research over the last decades. However, in most studies the main reason for studying students' views on the relevance of mathematics has been the assumption that a positive notion of the importance of mathematics contributes to a positive attitude towards learning mathematics (Schoenfeld, 1989). Hence, most research studies conducted in this area have aimed at understanding and improving students' attitudes towards mathematics, and ultimately improving their performance in mathematics at school (Farooq & Shah, 2008; Mohamed & Waheed, 2011).

However, we start from the premise that already motivated and talented students can also benefit from a clear view on the usefulness of mathematics for their future education and career. Dutch secondary school students in an advanced mathematics course (aimed at improving students' algebraic skills and elaborating the connection between mathematics and other sciences) praised the course as being challenging and fun, but they also mentioned that it was not clear to them how the mathematics would be useful for their future study (Van Elst, 2013).

In our research project a design research approach has been used to develop and intervene with tasks aimed at simultaneously teaching a new (for students) mathematical concept (differential equations) and improving students' beliefs about the relevance of mathematics in general, and in particular with respect to their future study and career ambitions. The students sampled were those taking the advanced mathematics course (in their final year before university entry) in Dutch upper secondary schooling.

The mathematical topic of the designed intervention was the theory of analyzing, solving and interpreting first order differential equations. Differential equations are an important subject in any

undergraduate university curriculum in a broad range of domains, such as engineering, physics, biology and economics, which makes it a suitable topic for an intervention with a focus on the relevance of mathematics.

To improve the odds that the real-life problems posed in the designed tasks would appeal to the students, the designed intervention differentiated by student interest. Students were offered the opportunity to choose between different real-life problems, whilst ensuring that regardless of their choice they learned the same mathematical concepts of differential equations.

The research question of the study was the following: How does a learning strategy based on differentiation by interest for teaching ordinary differential equations (to upper secondary students in a “strong mathematics” course) improve the view of students on the relevance of mathematics for their future study and career?

In the subsequent section, we provide an overview of the relevant literature. Next, the research design including the context of the study and the data collection strategies used are described. Finally, we provide a discussion of the results and our conclusions.

## **Literature**

Students’ beliefs about the relevance of mathematics is considered as one of the factors that can play an important role in their attitude and motivation. Several questionnaires measuring the attitude of students towards (learning) mathematics use a scale for measuring students’ beliefs about the usefulness of mathematics: for example, the Attitude scale towards Math (Martinot, et al., 1988) contains a scale named Relevance of Mathematics.

Most studies using these surveys do not emphasize the improvement of students’ beliefs about the relevance of mathematics, as they are aimed at students’ attitudes towards mathematics. However, a recent study of first year university students in engineering focused on improving perceptions of the relevance of mathematics in engineering. In this study Flegg (2012) has described the use of context-based learning by applying mathematics to real-life problems as a promising approach.

The teaching of differential equations has undergone some major changes over the past decades in favor of more contextualized, problem-based education, and a less traditional, analytical approach (Boyce, 1994). This was in line with our planned design to incorporate real-life problems in the assignments. At university level several initiatives have reported good results using this new teaching approach (e.g. Huber, 2010) and the development of new course material using Realistic Mathematics Education (e.g. Rasmussen & King, 2000). In a comparison of a traditional textbook with a textbook that incorporated discipline-specific perspectives to teach the mathematical knowledge to engineering students, Czochoer and Baker (2010) conclude that a contextual approach is also more in line with recommendations from the research literature.

Task design is widely recognized as an important, albeit complex activity that is at the core of mathematics education. The term ‘task’ is used to describe a wide variety of student activities aimed at learning mathematics (Watson & Ohtani, 2012). In our research tasks are guided group assignments about a real-life problem.

## **The study**

### **The context**

The Dutch education system consists of eight years of primary education, and 4-6 years of secondary education (depending on the level of education). The highest level of secondary education is the pre-university education called VWO (voorbereidend wetenschappelijk onderwijs) with a duration of six years, which provides students access to university. For every student at VWO level mathematics is a mandatory course. However, in the last three years students can choose between two different mathematics courses: “wiskunde A” (mathematics A) and “wiskunde B” (mathematics B), the latter being the more mathematically demanding course, which is obligatory for technical and engineering studies at university.

In 2007 an advanced mathematics course called “wiskunde D” (mathematics D) was introduced to offer challenging and engaging mathematics, and where the relevance of mathematics and its connection to other sciences should become clearly visible (cTWO 2007). This course is aimed at students with an interest in sciences and engineering, and it includes mathematical topics, which are part of every first year university curriculum: e.g. complex numbers; analytic geometry; and differential equations. Students with ‘wiskunde B’ are offered the opportunity to take this advanced course in mathematics in addition to their regular course.

It might be expected that students who take this advanced course in mathematics are convinced about the relevance of mathematics, which is likely to fuel their obvious motivation to learn mathematics by taking this advanced course. However, studies on the implementation of ‘wiskunde D’ tell a different story. In a study by Van Elst (2013) students praised the course as being challenging and fun, but they also mentioned that it was not clear to them why the mathematics in the course was useful for their future study and career. According to a study by Cheung (2012) teachers of ‘wiskunde D’ stated that the course was well suited as a preparation for a future study in a technical or engineering environment, but they also stated that the curriculum did not emphasize enough the applications of mathematics and the connections to other sciences (Cheung, 2012).

To be able to understand the theory of ordinary differential equations, secondary school students require almost all basic mathematical knowledge taught in secondary education as pre-knowledge. Hence, this topic is scheduled near the end of the final (6th) year, to make sure all major mathematics/‘wiskunde B’ and mathematics/‘wiskunde D’ topics have been covered. It can also be expected that at that time the students have a good idea of their intended future study. This might motivate the students to choose tasks with real-life problems associated with their future study.

The real-life problems in the study by Flegg (2012) all had an engineering context, which was in line with students’ study (of engineering at university). However, from our experience secondary school students taking the ‘wiskunde D’ course are not all interested in engineering. Students typically also enroll for medical or economics studies after graduating with ‘wiskunde D’. Hence,

only focusing on real-life problems in engineering would have been a too narrow approach. To give students a good view of applications of mathematics to solve real-life problems, the learning strategy should offer differentiated instruction, based on students' interest.

Beside this “practical” reason to give students a choice of which problems they wanted to investigate, research shows that differentiated instruction based on students' interest supports their autonomy and improves students' motivation for the task at hand (Katz & Assor, 2006). Differentiation is commonly used to accommodate the different learning styles of the students; however, it can also serve to accommodate other differences between the students, such as their interests and plans for their future study and career (Tomlinson et al., 2003).

### **Research design and data collection strategies**

For the development of the intervention, a module consisting of tasks on real-life problems, a design research approach was chosen. The design process comprised of three phases: a preliminary phase; an iterative development phase; and a final evaluation phase. The preliminary phase included a context analysis and a literature review. The learning goals for teaching differential equations were defined, based on the five strands of mathematical proficiency (Kilpatrick et al., 2001).

In the second phase a partial prototype of the module was developed. In March 2015, a small pilot test was conducted, with a prototype consisting of only three tasks. In a second design cycle a module was developed, which comprised of 14 tasks covering five different types of differential equations. Validation of separate tasks was done (1) by expert appraisals from university experts in mathematics education, focusing mainly on relevance and consistency of the design; and (2) by secondary school teachers focusing on the consistency and expected practicality of the design.

The designed intervention was carried out from January to March 2016. Three classes of ‘wiskunde D’ students of two different schools in the Netherlands, in total 49 students, participated. The three classes all had a different teacher, one being a researcher in this study.

The data collection strategies for the intervention included

- two student surveys (before and after the intervention) asking the students about their future study plans and their views on the relevance of mathematics, using the 8 question scale Relevance of Mathematics (Relevance scale) from The Attitude scale towards Math (Martinot et al., 1988);
- a student survey after the intervention to evaluate the module and the tasks;
- student interviews after the intervention about the module and the relevance of mathematics in general, and in particular for their own future study and career;
- the video recording of a teacher meeting about their experiences during the intervention;
- the collection of exam results after the intervention at one school. These results were compared to the results of the ‘wiskunde D’ students of the previous exam years, who were taught the same theory of differential equations but in the traditional classroom setting.

## The intervention

The intervention module comprised of five tasks, each covering a different type of differential equation. Of each task up to three different versions were developed, which applied the same mathematical concept to entirely different contexts. Prior to the first task students were given time to read short descriptions of each problem and were given the opportunity to make, for each of the five subsequent tasks, a choice which context (real-life problem) appealed to them most.

The different contexts for each of the tasks consisted of: a science/engineering related problem; a biological/medical problem; and an economical/social problem. Regardless of students' choices of contexts for the five tasks, the students worked with and learned the same mathematical concepts during their work on these parallel tasks. The students were guided through the process of modelling the problem and exploring the mathematical model analytically, graphically and numerically. After solving the mathematical problem the students were asked to interpret the results within the context of the chosen assignment. Table 1 gives an overview of the 14 tasks.

Task	Differential equation	Scientific/engineering problems	Biological/medical problems	Economic/social problems
1	$y' = \alpha y$	Nuclear disaster	Bacterial food poisoning	Forged paintings
2	$y' = \alpha y + \beta$	Mixing water problem	Intravenous infusion	Advertising effect
3	$y' = \alpha y + f(t)$	CO poisoning	Estimating time of death	Price indexing
4	$y' = \alpha y^2 + \beta y$	Oil production	The Ebola epidemic	Population growth
5	$y' = f(y, t)$	Skydive	Blood alcohol content	

**Table 1: Overview of the real-life problems used in the module**

## Results

40 out of the 49 participating students filled in the survey about the module. Responses to most questions were measured on a five-point scale, ranging from “I strongly disagree” to “I strongly agree”. The students were generally quite positive about the whole module. Asked to grade the whole intervention on a scale of 1 to 10, they rated the module 6.5 on average. Interestingly, this mean score differed greatly between the three groups, with one group scoring surprisingly lower than the other two (see Table 2). Additional comments in the survey from this group suggest that they lacked proper guidance of their teacher. Hence, the practicality and effectivity of the intervention can substantially benefit from a good description of the role of the teacher as coach, helping the students to advance in their assignments. In the teacher meeting the same recommendation was made.

Overall, 28 out of 40 students agreed (of which 6 strongly) with the statement “The tasks gave me a good view on how mathematics is applied in other sciences”, and only 3 students disagreed with this statement. The negative statement “I think that these tasks were not very realistic” was disagreed by 29 students (of which 12 strongly) and only two students agreed with this statement.

Schools	Group	Group size	#Respondents survey	Rating (mean)	#Respondents Relevance scale
School A	1	19	18	7.1	18
	2	17	14	5.5	7
School B	3	13	8	6.9	8
Total		49	40	6.5	33

**Table 2: Respondents and rating of the module by group**

The survey also contained open questions asking students what they liked about the module and what in their opinion should be improved. Positive points were working in groups (11 times) and the application of mathematics in other sciences (15 times) with statements like: “it was fun to experience that math is useful”, “clear applications of math” and “you get a better view on how mathematics can be applied”.

Some negative comments were about ICT problems encountered during the intervention (e.g. “slow laptops”). However, the majority of the feedback was about the way the mathematical concepts of differential equations were introduced to them. For example, they complained that having to read the theory by themselves made it harder to grasp the concepts. Some also missed the “traditional” teacher-led instruction, where the “basic” theory is explained by the teacher before the students start working on the assignments.

The student interviews were conducted by the teacher/researcher (one of the authors). In the interviews the students voiced the same concerns about the lack of teacher instruction and the ICT problems. However, they were positive about the tasks and the application of mathematics to real-life problems, as the extract shows.

Interviewer: Did the tasks have some added value?

Student 1: Yes, I think so. I think it adds quite a lot. It helps...

Interviewer: It helps? In what way?

Student 1: To give a lot of people the idea what can be done with mathematics. That there is mathematics behind everything. Not a lot of students would have realized that before, I think.

Comparison of the ‘wiskunde D’ exam results of the 36 students from school A with the results on a similar exam by the 27 ‘wiskunde D’ students of the previous year did not show a significant change in the grades. As can be seen in Table 3, the students of 2016 scored slightly better than their peers in 2015 but that was to be expected as their average grade before the exam was also better.

The intervention was not intended to improve the exam results, and the findings showed that the dual focus on both the mathematical concepts of differential equations and the relevance of mathematics to other sciences did not affect the grades of the students in a negative way.

Exam results school A	Group size	Average grade before exam	Average exam score
Students 2016 (intervention)	36	75.2 %	72.6 %
Students 2015 (traditional course)	27	74.6 %	71.4 %

**Table 3: Exam grades of the students in 2015 and 2016**

From the Relevance of Mathematics scale, conducted before and after the intervention, we obtained some promising results. Only 33 out of the 49 students completed both the pre and post survey, as shown in the last column of table 2.

A one-sided paired-samples t-test was conducted to compare the answers of the 33 students on 8 items of the Relevance of Mathematics scale before and after the intervention. The result of this test for the whole group of 33 respondents did not show a significant improvement with a p-value of 0.19. But the same test on the 18 results from the high response group gave a p-value of less than 0.02 indicating a significant positive change in their response to the questions about the relevance of mathematics. Due to the low response rate of the two other groups we were not able to get any significant results from these separate groups.

We also conducted the paired t-test on the answers of the 17 students who had the lowest scores on the pretest. They had scored relatively low on their beliefs about the relevance of mathematics, all with an average score between 2.38 and 3.63 for the 8 items on the five point Likert scale. On the same test after the intervention their average scores ranged between 2.63 and 4.63. 12 of these 17 students scored higher on the test after the intervention resulting in a p-value of 0.002, which indicates a strong significant positive change in these students' beliefs about the relevance of mathematics. This result indicates that students who do not already have strong beliefs about the relevance of mathematics benefit most from the context-based tasks.

## Conclusion

The intervention had positive effects on selected student views about the relevance of mathematics without affecting the examination results. Providing students with purposefully designed tasks where mathematics is applied to real-life problems cannot only challenge their assumptions about the relevance of mathematics, but also improve their awareness of its usefulness.

Teacher professional development is a topic for further study that will be the focus of a new design cycle of the module. Applications like a teacher meeting, where the goals of the module are explained and an extension of the teacher manual with guidelines how to introduce the module and how to coach the students during the group assignments, are expected to contribute to a better understanding of the role of the teacher during future interventions.

*In this paper we use the documentary approach to investigate teachers' collective work. We follow two teachers, preparing together a lesson on tolerance intervals for grade 11. We identify Mathematical Knowledge for Teaching (MKT) that influences the use of resources by the teachers. We evidence that their collective work fosters important documentation work; but we observe significant differences between the documents developed by the two teachers.*

*Keywords: Documentation work, resources, teachers' knowledge, tolerance intervals, variability.*

## Introduction

Teachers interact with curriculum resources in and out-of-class (TWG22 call for papers). In previous works we have identified the importance of these interactions in terms of teachers' professional development (Gueudet, Pepin & Trouche 2012), and we have evidenced that teachers often work collectively with resources. In this paper we study further this collective work of teachers with resources and its consequences.

The work presented here takes place within the French national project REVEA<sup>1</sup> (Living Resources for Teaching and Learning). We consider the case of two mathematics teachers at upper secondary school in France teaching sampling variability in statistics in grade 11. We firstly expose the theoretical perspective we use and our methods. Then we present the data we collected, and the context of teaching sampling variability in France. Finally we expose our analyses of the teachers' work and of its links with teachers' knowledge in particular.

## Investigating teachers' documentary work: Theory and method

We use for our research the theoretical and methodological perspective of the documentary approach (Gueudet et al. 2012). Mathematics teachers interact in their work with a large range of resources (Adler 2000). Resources designed for teaching purposes like textbooks or software, resources coming from the students, e-mails exchanged with colleagues etc. Teachers choose resources, transform them, use them in class; we call this work "teachers' documentary work". In previous research, we have evidenced that this work is closely linked with teachers' professional knowledge. The choice of resources by teachers, the way teachers modify and use the resources is driven by their professional knowledge (and this is called an instrumentalisation process, drawing on Rabardel's instrumentation theory, Rabardel 1995). In a reverse way, the features of the resources used modify teachers' knowledge (in an instrumentation process). In the documentary approach, we consider that from a set of resources teachers develop a document: transformed

---

<sup>1</sup> <https://www.anr-revea.fr/>

resources associated with a scheme of use (Vergnaud 1998). A scheme of use comprises the aim of the activity, rules of action and professional knowledge. The development of a document is called a documentational genesis.

Teachers' Communities of Practice (CoP, Wenger 1998) have a shared repertoire that the documentational approach interprets as shared resources. In previous works (Gueudet, Pepin & Trouche 2016) we have investigated the documentation work of a CoP (Sésamath, an association of teachers in France) designing online resources and identified the development of shared documents. Here we study a more "ordinary" CoP, composed of two teachers working together for the preparation of their courses. We are interested in particular in the commonalities and differences in professional knowledge within the documents developed by these teachers. The research question we investigate can be formulated as:

How do professional knowledge and resources interact in the collective design and implementation of a lesson?

Concerning teachers' professional knowledge involved in the schemes, we are especially interested in the identification of Mathematical Knowledge for Teaching (MKT, Ball, Thames & Phelps 2008): professional knowledge linked with the mathematical content to be taught.

The documentational approach is associated with a specific method, called "the reflexive investigation method". Documentational geneses are long term processes; moreover documentational work can take place everywhere and at any time. Thus we follow teachers over long periods of time; and involve them actively in the collection of data. These data are interviews of the teacher; videos of the teacher's work in class and out-of-class (videos of collective work, if teachers work together); resources chosen and transformed by the teacher.

For analyzing the data, we start with the transcribed interviews of the teachers. We identify in them the aims of the teacher's activity. For each aim, we search in the data for the resources used, and the other components of the document (rules of action and professional knowledge). We submit these elements to the teacher who corrects and complements them if needed. We present in the next section the data collected for the case we study here.

## **Data collected and context**

We follow since 2014 two mathematics teachers in an upper secondary school of a middle-sized town in France: Valeria and Gwen. They are both very experienced: Valeria teaches for 34 years, Gwen for 36 years, they both regularly follow teacher education sessions and are trainers for new teachers in their school. They also regularly work together, we consider them as a CoP (Wenger 1998). In 2015-2016, they decided to take two grade 11 classes called "economics and science", a specialty they taught for the first time. We followed their work for these classes, in particular for a chapter entitled: "sampling variability" (that they both used to teach grade 11 "science", with a similar content). For this chapter, we video recorded their common preparation (one hour), their individual courses (four hours each), and for each of them an individual post-teaching interview. We collected all the resources they used and produced, and the students' productions for the final assessment of the chapter. For both teachers we identify the professional knowledge/beliefs, the

possible origin of these beliefs, the consequences in terms of the activities/resources produced and the resources used.

Sampling variability is taught in France since 2010. This teaching starts in grade 10 where the idea of sampling variability is introduced using material like coins and dice and simulations on the calculator and on the spreadsheet. In the curriculum in France, the concept of tolerance interval is central in the teaching of sampling variability. In grade 10 the students have to learn how to identify the population; the sample and its size  $n$ ; the probability  $p$  of a given feature in the population, and the frequency  $f$  of this feature in the sample. A first tolerance interval is introduced, without justification:  $[p - 1/\sqrt{n}, p + 1/\sqrt{n}]$ . If  $f$  does not belong to this interval, the students learn to reject the hypothesis “the sample follows the population’s law” with a 5% risk level. At grade 11 (scientific or economics and scientific) the binomial distribution is introduced; it provides another tolerance interval, which can be found using the table of the binomial distribution produced for example with a calculator or a spreadsheet. The chapter we followed concerns the introduction and use of this interval. At grade 12, the normal distribution is presented; this leads to a new interval (the asymptotical tolerance interval).

Many research works have investigated teaching variability; they emphasized the specific nature of reasoning in probability (Steinbring 1991) and the need for particular knowledge to teach this subject (González 2013). Eckert and Nilsson (2013) used the notion of Mathematical Knowledge for Teaching Probability (MKTP) for characterizing the specific knowledge needed by the teachers in probability and statistics, and for sampling variability in particular. Finding situations in relevant contexts; emphasizing the idea of variability, using the different kinds of possible representations all require specific knowledge from the teacher. Our aim here is to investigate how the interactions with resources are shaped by, and contribute to MKTP.

## Results

In this results section, we firstly consider the two teachers’ documentation work, during the common preparation session, the lessons taught by each teacher and finally during the design of a common assessment. Then we present our analyses of the most important aspects of this documentation work (in terms of MKT involved), focusing on the collective-individual articulation.

### A collective documentation work

During the common preparation, Valeria and Gwen used several textbooks (9 different textbooks). They did not actually chose resources together, but drew on exercises and problems in the textbook to illustrate their declarations. They also talked about resources they intended to use: exercises, software (GeoGebra, spreadsheet) and the calculator.

Their discussion during the common preparation started by stating a difference: Valeria intended to use the spreadsheet from the beginning and during the whole lesson. The students have learned, in the “binomial law” chapter to produce with the spreadsheet and read tables displaying the value of  $P(X=k)$  and  $P(X \leq k)$ , when  $X$  is a random variable following a binomial law of parameters  $N$  and  $p$ . Valeria wanted to recall this, then to introduce the binomial law tolerance interval and the method for finding it, using the  $P(X \leq k)$  table produced with the spreadsheet. Gwen, in contrast, intended to use only the calculator, and no other software. After introducing the binomial law tolerance interval,

she wanted to ask students to write and implement on their calculator a program producing the tolerance interval.

In the other aspects of the common preparation, Valeria and Gwen agreed on all the points they discussed. They mentioned in particular the need to recall the grade 10 tolerance interval and to compare it with the new interval introduced.

All these aspects discussed during the common preparation are present in the lessons actually taught by Valeria and Gwen. We analysed these lessons drawing on the observations and videos in class, the resources collected and the post-lesson interview.

Valeria started indeed by recalling how to produce and read the binomial law table with the spreadsheet. She also recalled the grade 10 interval with exercises chosen in a textbook's "revision section". Then she introduced the new interval through a problem concerning overweight in USA. This problem came from another textbook, and she modified it in particular by suppressing the table giving  $P(X \leq k)$ , because she wanted the students to produce it themselves with their calculator. She presented how to find the interval from the table  $P(X \leq k)$ . Valeria insisted on the need to formulate very precisely the decision rule. At the end of the chapter, she worked with her students on the algorithm: the students implemented it on their calculator, but this program was actually not used as a tool to find the interval in exercises.

Gwen started with a problem that she built herself, about red-haired people in Scotland (inspired by a textbook problem with a different context). The first part of the problem recalled the grade 10 interval, and more generally the idea of sampling variability. The second part of the problem introduced the new interval. Just after this session, Gwen worked with the students on the production of an algorithm and its implementation on the calculator to find the binomial law interval. Afterwards this program was always used to find the interval. Gwen said that she found the binomial law interval too technical, she did not want her students to learn how to find it. She preferred to use it as an opportunity to work on algorithms. She distributed a sheet to the students presenting the interval and a diagram. Then she proposed different exercises about decisions; in particular one exercise with samples of different sizes.

The final assessment of this chapter was also the final assessment of the year for the two Grade 11 ES classes. Valeria and Gwen wrote it together; we analyse their documentation work drawing on the resources they used and produced; the e-mail they exchanged and their interviews. The control text comprised one exercise on tolerance intervals. This exercise, with an introductory text (figure 1) and three questions, concerned the rate of twins in India; it came from a textbook. Valeria and Gwen modified the initial text which was, in their opinion, too long and complex.

“ India: Kodinji, the mysterious twins village

In the state of Kerala (south-west India), there is an amazing village. The rate of twins is much higher than the national average. 440 twins live indeed in this town for 14600 inhabitants. This average is outstanding, since the national average is 16 twins for 1000 births”. *Extract of an article* (Courrier International, 2009)

Let  $X$  be the random variable counting the number of twins in a 14600 Indians sample.

**Figure 1: Introductory text of the control exercise (our translation)**

They modified the first question: in the textbook the parameters of the binomial law followed by  $X$  were given; they wanted the students themselves to find the parameters. They also changed the second question, where the students are asked to produce the tolerance interval, to display the two different methods expected for each class: use of a table (given in the text) for Valeria's class, use of the calculator's program in Gwen's class. Question 3 was left unchanged.

42 students were present at the final assessment. In the first question, 35 students justified that  $X$  followed a binomial law of parameters  $n$  and  $p$ ; 29 students determined correctly the value of  $n$ , but only 15 the value of  $p$ . In the second question, 19 students determined correctly the endpoints of the tolerance interval. In the third question, 19 students justified correctly the rejection of the hypothesis ("the Kodinji village follows the national figures").

### **Valeria and Gwen documentation work and use of resources: General statements**

We can notice that like other research works using the documentational approach (Gueudet et al. 2012) this description evidences that Valeria and Gwen are designers of their own resources. They use various curriculum resources, but transform most of them. Only some exercises texts are left unchanged, and one textbook extract presenting the binomial law interval (for Gwen). Moreover, textbooks (on paper, they do not use digital textbooks) are central resources, used as a reference to discuss the lesson plan, and to choose exercises for practicing the new methods, for the assessment/test, or to find an introductory problem (for Valeria). More surprisingly, they did not search the Internet for resources – this can be a consequence of their common preparation: Valeria and Gwen sometimes search the Internet for preparing their lessons, but always at home. For the common preparation they were at school with no Internet access. Another result already well known in the documentational approach is that the observation of students (their written texts, or oral discussions in class) constitute a very important resource for the teachers, leading to a constant modification of the resources produced along the documentation work. Both Valeria and Gwen intend to modify this lesson on tolerance intervals next year, because they consider that the students made too many mistakes in the final assessment/test.

### **Documents developed by Valeria and Gwen**

In this section we analyse our data in terms of documents developed by Valeria and Gwen. Since our focus is on MKT, we do not give a complete description of each scheme of use but only mention the aim of the activity and the MKT involved. We have chosen three examples of documents, corresponding to different situations in terms of similarities or differences.

Valeria and Gwen had a shared aim that can be described as "Recalling previous knowledge needed for the binomial law tolerance interval". They both considered that this new chapter must start by recalling the grade 10 interval, because they knew from their observation of students during the year that "many students do not remember this interval" (Gwen even added that some students perhaps never saw it, since some colleagues keep this content for the end of the year and run out of time). This shared MKT lead however to two different documents for this aim, because of the teachers' different resources: Valeria used a lot the classroom textbook, and thus proposed revision exercises coming from this textbook, while Gwen wrote her own problem text.

Valeria and Gwen also shared a general aim that can be presented as: "Teaching how to find a tolerance interval with a binomial law". During the previous years, Valeria has developed for this

aim a document including various resources: the spreadsheet (as software or in the calculator), exercise texts, the illustrating diagram, and MKTP: “The students must learn to find the endpoints of the interval by reading the table”. This knowledge can have different sources; we claim that it comes in particular from institutional texts (the official curriculum) and from textbooks. For the same aim, Gwen has developed a different document, including: the calculator, an algorithm, the illustrating diagram, exercise texts as resources; and MKTP like: “The binomial law interval is too technical”; “there are no questions about the binomial law interval at the baccalaureate<sup>2</sup>”; and the MKT “it is important to work with students on algorithms”. This knowledge comes from reading the texts of the baccalaureate, and from a personal mathematical difficulty: Gwen declared that she “cannot remember [herself] how to find the endpoint of the interval”. Moreover she considered that this grade 11 curriculum is only a transition between the grade 10 interval and the grade 12 interval (with the normal distribution) while algorithms are always present in the baccalaureate texts. Valeria and Gwen discussed this difference during the common preparation. Valeria integrated in her lesson the programming of the algorithm on the calculator, but she did not want her students to use it, because she feared that the students do not really understand the algorithm and use their calculator as a “black box”.

For the aim: “Assessing the students’ ability to determine and interpret a tolerance interval”, Valeria and Gwen used shared resources: they wrote the assessment text together drawing on the same textbook exercise. The choice of this exercise was guided by MKT firstly expressed by Gwen, and adopted by Valeria: “the students must learn to find information in a text”. Nevertheless, the text produced was also transformed to incorporate the use of two possible methods, because of their different MKT concerning how to find the binomial law tolerance interval.

In Table 1 below, we synthesise these three documents, evidencing the common and different elements.

---

<sup>2</sup> In France, the final secondary school assessment, at the end of Grade 12.

Aim	Resources used	MKT/ MKTP
<i>Recalling previous knowledge</i>	Valeria: Revision exercises in the classroom textbook	<i>“Many students do not remember the grade 10 tolerance interval”</i>
	Gwen: Her own problem text	
<i>Teaching how to find a tolerance interval with the binomial law</i>	Valeria: Problem and exercises texts from different textbooks, the spreadsheet, <i>algorithm on the calculator (coming from the collective work)</i>	Valeria: “The students must learn to find the endpoints of the interval by reading the table”; “they must not use the calculator as a black box”
	Gwen: Problem composed herself, exercises from different textbooks, <i>algorithm on the calculator</i>	Gwen: “it is important to work with students on algorithms” “the binomial law interval is too technical”
<i>Assessing the students’ ability to find and interpret a tolerance interval</i>	<i>Shared assessment text written together from a textbook exercise, but integrating two possible methods.</i>	<i>“The students must be able to identify information in a text” (shared)</i> + MKT/MKTP described in the above line

**Table 1: Synthetic presentation of documents developed by Valeria and Gwen. Shared elements are in italics.**

## Conclusion

In this paper we investigated the research question: “How do professional knowledge and resources interact in the collective design and implementation of a lesson?” in the case of a lesson on tolerance intervals for Grade 11 students in France. In the frame of the documentary approach, investigating how professional knowledge and resources interact means investigating the documents developed by teachers. For each of the two teachers we followed, we observed that they developed an important design work, choosing resources, associating and modifying them. This work was guided by their professional knowledge, in particular MKT and MKTP. We observe that this MKT is mostly of the type: “Knowledge of Content and Students”; deepening the analysis in terms of types of MKT is an interesting perspective for further work. In a reverse way, resources influenced the development of MKT, and this MKT can be different for each individual teacher. For example the official curriculum influenced Valeria and Gwen in different ways: while Valeria aligned with the curriculum about tolerance intervals, Gwen attached more importance to the algorithms. She developed a personal interpretation of the official curriculum, not focusing on the chapter she taught but taking into account the whole year.

In previous works (Gueudet et al. 2012) we evidenced that collective work is present in many aspects of teachers’ activity and that it is a stimulator of documentation work, especially when it takes place within CoPs. In (Gueudet et al. 2016) we analysed the common documentation work in a CoP: an association of teacher designing an e-textbook. We evidenced that they developed

common documents, drawing on their individual documents. In the present study we investigated a CoP composed by two teachers preparing their courses together. We evidenced that, in spite of the collective work the documents developed by the two teachers for the same aim are never completely identical. The consequence of the collective work is that these documents sometimes share common elements. The main reason for the differences seems to be the long experience of both teachers: they already developed in previous years documents for the same aims, and thus have MKT or MKTP associated with these aims and also specific resources. The collective work can bring new resources (the algorithm on the calculator for Valeria) or new knowledge (the students must be able to find information in a text, for Valeria again), but the previous knowledge developed during interactions with resources over many years is still present and produces differences in the documents.

These teachers will go on working together; with a longer common work, evolutions may take place, and we will try to analyse these evolutions. We also hypothesize that evolutions of practice are more likely to take place in teachers' CoPs when the members of the CoP are involved in a common design activity (for example in the Sésamath case, Gueudet et al. 2016, or in the context of professional development, Pepin & Miyakawa 20016). We intend to investigate this hypothesis in further research.

# Pre-service teachers' reflections on task design and implementation

Hulya Kilic<sup>1</sup>, Oguzhan Dogan<sup>2</sup>, Zuhay Yilmaz<sup>3</sup> and Pelin Donmez<sup>4</sup>

<sup>1, 2, 3</sup>Yeditepe University, Faculty of Education, Turkey; [kilichul@yahoo.com](mailto:kilichul@yahoo.com)

<sup>4</sup>Ulus Private Hebrew High School, Turkey; [pelindonmez99@gmail.com](mailto:pelindonmez99@gmail.com)

*In this paper, we will present a part of findings of a larger study in which we investigated both pre-service teachers' pedagogical content knowledge and middle school students' mathematical skills. A total of 17 pre-service teachers worked with 7<sup>th</sup> grade students on the mathematical tasks for a semester. The data was collected through inventories, videos of task implementations and written reflections. The analysis of inventories and written reflections revealed that the pre-service teachers had positive beliefs about using mathematical tasks in the lessons. They were able to evaluate the success or failure of a task by analyzing the implementation process. They recognized the importance of preparing appropriate tasks for students and implemented them as intended. They also noted that mathematical tasks provided them an opportunity to learn about students' mathematical understanding as well as to develop their scaffolding practices.*

*Keywords: Pre-service, middle school, mathematical tasks, reflection, teacher knowledge.*

## Introduction

The studies on mathematical tasks provide an opportunity to discuss not only students' mathematical thinking and understanding but also teachers' knowledge and skills (Zaslavsky, 2007). Tasks are accepted to be one of the curricular tools that help teachers to scaffold, foster and assess students' understanding when used appropriately (Stein, Grover, & Henningsen, 1996; Watson & Mason, 2007). Research on task design and implementation shows that "good" tasks or *cognitively demanding tasks* (Stein et al., 1996) have positive impacts on students' thinking and understanding (Henningsen & Stein, 2002). Such tasks encourage students to think about what mathematical concepts are conveyed in the task, what they know about them, how they are related to other concepts and which strategies, representations or materials are helpful in terms of arriving at a meaningful solution or answer. On the other hand, designing, selecting and implementing cognitively demanding tasks are related to teachers' pedagogical content knowledge (PCK) as well as to their content knowledge (Charalambous, 2010; Liljedahl, Chernoff, & Zazkis, 2007; Stylianides & Stylianides, 2008). Teachers' decisions about whether a task is appropriate for their students in terms of its complexity or if their students possess the necessary prior knowledge or the task's goal aligns with the lesson's objectives emerge from their PCK (Hill, Ball, & Schilling, 2008). The studies on task design and implementation showed that when pre-service teachers (PSTs) were given opportunities to develop and implement tasks, they were able to prepare "good" tasks in which they used real life context and multiple representations and they asked for explanation, interpretation or justification (Ozgen & Alkan, 2014).

In this study, we aimed to investigate how PSTs' involvement in task design and implementation process influenced their views about tasks and their PCK. We used tasks as a tool to build up an environment for PST-student and student-student interactions where the PSTs observed how students worked on the tasks both individually and as a group and then joined their discussions to elicit students' thinking and support their understanding. Thus, the PSTs had opportunity to learn

about students' mathematical skills and also to gain experience about how to implement a task without loss of fidelity, to scaffold students' understanding, and to manage the group work. In this paper, however, we will present some findings about PSTs' reflections on this task design and implementation process in terms of effectiveness of the tasks and their professional gains from this intervention study.

## **Methodology**

### **Research setting**

This study was conducted under university-school collaboration between the mathematics education department and a local middle school in Istanbul in Turkey. A total of 17 PSTs (10 of them in Fall 2015 and 7 of them in Spring 2016) and one of the 7<sup>th</sup> grade classes (aged between 12-13) from the partner school volunteered to participate in this study<sup>1</sup>. We arranged the students as mixed-ability groups of 4 students based on the results of an achievement test. We randomly assigned the PSTs to these groups. The PSTs worked with students in a 40-minute lesson for each week, a total of 11 weeks during the Fall and 12 weeks during the Spring.

All PSTs were senior students who volunteered to take an elective course that was carried out specifically for this study. During the first couple of weeks of the course, we talked about the design and implementation of tasks, effective ways of communicating with students and assessment of students' mathematical understanding through samples. Then, each week, prior to implementation, we discussed the tasks that they would use with the students and made revisions on the tasks when necessary. After each implementation in the school, we met the PSTs again and discussed how the implementation went. We wanted PSTs to write reflection on each implementation by analyzing the implementation videos of their own group and students' worksheets. We also asked PSTs to prepare and implement a set of tasks for their own group at the end of the semester.

### **The tasks**

We prepared the tasks in alignment with the 7<sup>th</sup> grade mathematics curriculum. In the Fall semester we prepared 10 tasks which were about integers, fractions, rational numbers and algebra. In the Spring term we prepared 11 sets of tasks which were about geometry, algebra and data and statistics. Each set of tasks consisted of 3 to 4 sub-tasks with some additional problems. The tasks were set up around a common theme which related to the use of mathematics in daily life. For instance, in one of the data analysis tasks, we conducted a short survey on students' preferences in the class such that we gave them a list of foods where each student would choose 5 of the foods from the list. Then we wrote down the frequencies for each food on the board and then asked them to answer questions about their preferences such as finding out the most popular food, making a bar graph of the drinks, etc. The majority of the tasks that we used were selected from the ones that we implemented in the previous years. However, we revised those tasks before the implementation based on the needs and performances of the students in our new sample.

---

<sup>1</sup> The school was located in a crowded neighborhood in terms of school-age children. There were 40 students in the class, average size according to national education statistics, but in the Spring semester 4 students dropped out. Since we had only 7 volunteers in the Spring semester, two researchers from the research team worked with two of the groups.

## **Data collection**

The data was collected through pre and post questionnaires, videos of PSTs' task implementations and group discussions, and PSTs' written reflections and assignments. One of the questionnaires (Kayan, Haser, & Isiksal-Bostan, 2013) consisted of 26 5-point Likert-type items asking for PSTs' beliefs about mathematics and mathematics teaching. The other questionnaire was developed by the research team and it consisted of open-ended questions where in the pre questionnaire the PSTs were asked to write about their prior teaching experiences and their expectations from the study and in the post questionnaire they wrote about whether their expectations were met or not and what they had learned from this intervention, etc. In their written reflections, we wanted PSTs to discuss about how the implementation went. Among the other questions, we asked them to comment on whether the students were able to complete the tasks, whether the tasks achieved their goals or not and why, and what they would do as follow up. At the end of the semester, we wanted them to discuss in which tasks the students experienced the most difficulty and what their suggestions would be to revise those tasks. Furthermore, we asked them to prepare tasks for their own groups and provide the rationale behind those tasks.

## **Data analysis**

We have not analyzed all data yet. However, because the knowledge of students' thinking and understanding, the ability of selecting or developing appropriate tasks, and using appropriate teaching strategies for particular groups of students are counted in teachers' PCK (Hill et al., 2008), we are basically looking for any instances that could be counted as an influence of task design and implementation process on the PSTs' PCK and their views about tasks. For instance, whether they paid attention to the students' earlier performances while preparing their own tasks, how accurate assumptions they were able to make about students' performances on the new tasks, etc. Yet, we did document analysis such that we analyzed the items related to task design and implementation from the questionnaires, written reflections and assignments. We attempted to figure out the frequencies of common issues that emerged from those instruments. We found out the mean scores of the items in the Likert-type questionnaire but we did not compare pre and post results because of low number of participants. We examined pre and post open-ended questionnaires, the assignments asking for making overall evaluation of the study and the reflection reports including PSTs' reflections on the implementation of their own tasks. We developed a coding scheme for the common issues that emerged from the reflection reports. For instance, when discussing the reasoning behind the success of the tasks, if the PSTs wrote that "they liked it" or "they enjoyed it" or "they had fun with it" then we coded that reasoning as "enjoyable" (see Table 1). However, out of possible 194 reflection reports, 6 of them were missing. Therefore, we coded a total of 188 reports. We achieved 90% agreement in initial coding. We discussed the discrepancies by re-reading the PSTs' reports and then we came with an agreement. Moreover, we all agreed on the common issues that emerged from the open-ended questionnaire and the assignments.

## **Findings**

### **PSTs' thoughts about use of tasks in mathematics**

The analysis of items in the Likert-type questionnaire showed that the PSTs agreed that teachers should encourage students to be active learners (The average of 3 related items; pre  $\bar{x} = 4.38$  ; post

$\bar{x} = 4.45$ ), the tasks are important for students' learning and understanding (The average of 2 related items; pre  $\bar{x} = 4.36$ ; post  $\bar{x} = 4.61$ ) and manipulatives and materials facilitate students' understanding (The average of 3 related items; pre  $\bar{x} = 4.09$ ; post  $\bar{x} = 4.60$ ). Their answers in the open-ended questionnaires were compatible with these results. The PSTs noted that doing mathematics through tasks enables students to participate in the lesson ( $f = 5$ ), love mathematics ( $f = 4$ ), discover or review mathematical concepts or facts ( $f = 4$ ), and use materials or manipulatives ( $f = 4$ ).

### PSTs' reflections on the implementation of the tasks

In the reflection reports, we asked the PSTs to comment on the following questions: 1a) Were the students able to complete the task? 1b) Did the task attain its goal or not? 1c) Why did the task attain its goal or not? 2) What more would you like to do about this implementation? 3) What is your suggestion for the follow up of the task? The PSTs gave various answers to these questions. For instance, for question 1a they noted that some of the students completed the task or just one student could not finish all of them, etc. Although we coded them separately, we re-coded them in terms of whether their answers were most likely "Yes" or "No". Similarly, we defined 12 different answers for question 1c. However, we preferred to present only the most frequent ones. In Table 1, the frequencies of PSTs' answers to these questions are given.

#### Q1a: Were the students able to complete the task?

	No	Yes
Fall	30 (29%)	75 (71%)
Spring	15 (18%)	68 (82%)
<b>Total</b>	<b>45 (24%)</b>	<b>143 (76%)</b>

#### Q1b: Did the task attain its goal or not?

	No	Yes	No Comment
Fall	38 (36%)	67 (64%)	
Spring	15 (18%)	63 (76%)	5 (6%)
<b>Total</b>	<b>53 (28%)</b>	<b>130 (69%)</b>	<b>5 (3%)</b>

#### Q1c: Why did the task attain its goal or not?

	No Comment	Enjoyable	Lack of Knowledge	Use of Materials	Recognize own Mistakes
Fall	28 (27%)	10 (10%)	32 (30%)	11 (10%)	14 (13%)
Spring	19 (23%)	5 (6%)	19 (23%)	1 (1%)	14 (17%)
<b>Total</b>	<b>47 (25%)</b>	<b>15 (8%)</b>	<b>51 (27%)</b>	<b>12 (6%)</b>	<b>27 (14%)</b>

#### Q2: What more would you like to do about this implementation?

	No Comment	Nothing more	Discuss more	Teach for Understanding
Fall	9 (9%)	17 (16%)	37 (35%)	29 (28%)
Spring	1 (1%)	58 (70%)	15 (18%)	6 (7%)
<b>Total</b>	<b>10 (5%)</b>	<b>75 (40%)</b>	<b>52 (28%)</b>	<b>35 (19%)</b>

#### Q3: What is your suggestion for the follow up of the task?

	<b>Nothing more</b>	<b>Review for Exercise</b>	<b>Review for Learning</b>	<b>Easier Tasks</b>
Fall	5 (5%)	46 (44%)	31 (30%)	6 (6%)
Spring	16 (19%)	42 (51%)	12 (14%)	3 (4%)
<b>Total</b>	<b>21 (11%)</b>	<b>88 (47%)</b>	<b>43 (23%)</b>	<b>9 (5%)</b>

**Table 1: The frequencies of pre-service teachers' answers to the questions about task implementation**

As seen in the table, the PSTs noted that in a 40-minute lesson the students were able to complete the given tasks and discuss their answers (76%). However, some of the PSTs wrote that the tasks were difficult for their students and they only answered one of the sub-tasks. For some of the tasks, the PSTs noted that although the students completed the tasks, there was no time for themselves to discuss students' answers as a group discussion.

The PSTs wrote that some of the tasks did not attain their goals (28%) mainly because of lack of students' prior knowledge (27%). In a few cases, they noted that the students did not understand the task because the text was unclear (3%). Some of the PSTs attributed the success of the tasks to use of materials (6%) and context of the tasks that attracted students' attention (8%). Furthermore, some of the PSTs wrote that the tasks attained their goal because during the group discussion the students recognized their own mistakes and learned from each other (14%). However, in 25% of the reports, the PSTs did not write anything about the reasoning behind the success or failure of the task. Furthermore, we analyzed the pattern in PSTs' perceived cause-and-effect relationship between Q1b and Q1c. Among the total of 141 responses to Q1c, the PSTs wrote that the tasks achieved their goals because students learned from each other while engaging in the task (f: 25), they used materials (f: 12) and they enjoyed it (f: 15). They noted that the tasks were not successful mostly because of students' lack of prior knowledge (f: 38).

As an answer to Q2, the PSTs noted that they were able to do whatever they wanted to do during the implementation (40%). However, some of them noted that there was not enough time to explore how students thought about the given tasks or they were unsure whether the students understood the reasoning behind the answers to the tasks or not, therefore they would like to discuss more about those issues (28%). In some of the cases, especially in the Fall term, because of students' lack of knowledge about fractions and rational numbers, the students could not finish the given tasks. In such cases, the PSTs wrote that they would like to teach about those concepts before or after the implementation if they had enough time (19%). On a total of 6% of the reports, the PSTs did not write relevant answers but summarized how the implementation went.

For the third question, 12% of the reports (not shown in the table) included irrelevant answers such as the PSTs suggested encouraging students to read more books to improve their reading skills or they criticized themselves in terms of not managing time better. In a few reports, they wrote that the tasks were difficult for the students; there should be easier tasks on the same content domain (5%). However, they mostly suggested making review exercises for students to reinforce their understanding of the tasks as well as the content domain (47%). When they realized that the students did not know much about the content, they suggested remedial lessons for them (23%).

### PSTs' reflections on the tasks and the intervention study

At the end of the semester, we asked the PSTs to evaluate this intervention study including the effectiveness of the tasks and the contributions to their own professional development. We specifically asked them to determine five mathematical issues in which students had experienced the most difficulty and two tasks that they would like to revise. We also asked them to give the reasoning behind the selection of those tasks and their revisions.

According to the PSTs, among the others, the students had difficulty in the tasks which were about fractions and rational numbers ( $f = 16$ ), algebraic expressions ( $f = 9$ ), solving equations ( $f = 7$ ), area problems ( $f = 7$ ), and discovering patterns ( $f = 5$ ). They wrote that the students could not do these tasks completely because of their lack of prior knowledge ( $f = 17$ ), lack of attention ( $f = 7$ ), lack of review exercises done at home ( $f = 5$ ), lack of understanding of the tasks ( $f = 3$ ), and personal insecurity ( $f = 2$ ). Specifically, they noted that students had difficulty in fractions, rational numbers and area problems because they did not know the algorithm for four operations with rational numbers as well as the area formulas of quadrilaterals and circle. They wrote that students failed in doing operations and discovering patterns because they did not practice enough at home or did not pay attention to the operations and procedures. However, the tasks that they would like to revise were mostly about integers ( $f = 7$ ), algebraic expressions ( $f = 4$ ), fractions and rational numbers ( $f = 3$ ), area problems ( $f = 3$ ), and transformations ( $f = 3$ ). The PSTs wanted to make revisions to the tasks about integers not because of students' lack of knowledge but because the context of the tasks was confusing for the students. Therefore, they noted that they would rephrase the text and change the order of the sub-tasks in those tasks. They decided to make the tasks about fractions and area problems easier because students did not possess the required knowledge to complete the tasks. Furthermore, in some cases the PSTs preferred to change the tasks that were done by the students but they were uncertain whether they understood them thoroughly or not.

The PSTs prepared a set of tasks for their own group of students at the end of the semester. Their rationale for their tasks was either to focus on the issues where the students experienced the most difficulty ( $f = 13$ ) or to make an overall review of what was done during that semester ( $f = 4$ ). In parallel with their comments about the students' mathematical difficulties, they prepared tasks about integers, fractions and rational numbers, area problems, algebraic expressions and solving equations. Some of the PSTs kept their tasks as simple as possible because of their students' poor performance on earlier tasks. Furthermore, 7 of the PSTs prepared their tasks around a common theme as we did in this study but 10 of them prepared separate problems related to the content domain that they focused on.

In the post open-ended questionnaire, the PSTs wrote that this intervention study contributed to their professional knowledge in several ways. Among the others, they noted that they practiced how to scaffold students' understanding without directly telling them the solution or answer ( $f = 7$ ), they got better in anticipating students' possible difficulties in mathematics ( $f = 5$ ), they learned to be patient ( $f = 4$ ), and they learned what kind of tasks attract students' attention more ( $f = 3$ ).

## Discussion

The findings of this study have potential to contribute to the relevant literature that teachers learn from their own task design and implementation practices in terms of better understanding of students' mathematical thinking and how to use or tailor tasks to scaffold students' understanding (Zaslavsky, 2007). Although we have not yet analyzed all data, we recognized that the PSTs were able to evaluate the task implementation process in terms of the facts related to the task itself, the organization, the students and their own professional development.

When we asked the PSTs to write their thoughts about the success or failure of the tasks, they were able to make reasonable inferences from the implementation. They recognized that the tasks were successful because the students were actively involved in the solution and discussion process (14%, see Table 1, Q1c), the materials were appropriate for the tasks (6%, see Table 1, Q1c), the tasks were aligned with the 7<sup>th</sup> grade curriculum and they were in the role of facilitator of group discussion (28%, see Table 1, Q1c and results of post questionnaire). In only a few of the cases, they noted that the students failed to complete the task because the task was unclear for the students (3%). For the other cases, they did not blame the tasks but the students because they did not possess necessary prior knowledge that they learned in previous grade levels or in their regular mathematics lessons (27%, see Table 1, Q1c). The PSTs' interpretations revealed that they began to recognize students' mathematical understanding as well as the importance of preparing tasks both aligned with the curriculum and appropriate for a particular group of students (Hill et al., 2008). For instance, while preparing their tasks, they preferred not to use higher cognitive demand tasks but the easier ones because some of their students did not know about the procedures required to solve given tasks, such as the rules of four operations with rational numbers. The PSTs also commented that students should revise the issues discussed in their mathematics lessons in order to understand the mathematics conveyed in the tasks (47%, see Table 1, Q3). Moreover, as we inferred from their answers in the questionnaire they appreciated the facilitator role of the teacher during the task implementation. They stated that they suppressed their feelings of telling and teaching when students could not figure out the solutions. Briefly, their reflections on the tasks and the implementations indicated that they were aware of the task implementation process which begins with selection of appropriate tasks, continues with implementation of the tasks and ends with evaluation of students' learning (Stein et al., 1996). Because orchestration of task implementation process is involved in teachers' PCK, such awareness of the PSTs can be counted as a sign of their PCK (Charalambous, 2010). However, because we have not yet analyzed the implementation videos, we are not able to validate PSTs' reflections on the tasks implementation process, especially whether they were able to implement the tasks without loss of fidelity and manage the group discussions appropriately. Indeed, it is hard for teachers, even more so for PSTs, to keep the cognitive demand of the tasks such that they might have provided hints or helped students when the students did not possess the required knowledge (Stylianides & Stylianides, 2008). Therefore, we are not able to comment on their "PCK in practice" even though we could make inferences about their PCK from their written reflections.

Finally, the analysis of pre and post questionnaires revealed that the PSTs had positive beliefs about use of student-centered teaching strategies, mathematical tasks and manipulatives while teaching mathematics and such beliefs sustained and even increased throughout the study. They recognized

that tasks provided an opportunity for them to elicit students' mathematical understanding and they could be used as a tool to foster students' mathematical understanding.

# Students' utilizations of feedback provided by an interactive mathematics e-textbook for primary level

Sebastian Rezat

University of Paderborn, Germany; [srezat@math.upb.de](mailto:srezat@math.upb.de)

*Feedback is acknowledged as an important influential factor on learning and achievement. An affordance of digital learning tools is that they provide different kinds of feedback to students. Research on the effectiveness of feedback has mainly focused on different forms of feedback and its timing assuming that different students react homogeneously to feedback. This paper provides a qualitative in-depth analysis of two third grade students' responses to feedback in an interactive e-textbook environment. Students responses to feedback are conceptualized in terms of utilization schemes within an instrumental approach. Results indicate that students utilize feedback differently, which has consequences for the effectiveness of the feedback.*

*Keywords: Feedback, e-textbook, instrumental genesis.*

## Introduction

Feedback is widely acknowledged as an important influential factor on learning and achievement (Hattie & Timperley, 2007). The fact that interactive digital learning tools constantly provide feedback to the learners' actions with the contents is indeed one of the most emphasized advantages of learning with digital tools (e.g. Mason & Bruning, 2001). In fact, an outstanding defining aspect of interactivity is that users get immediate feedback to their actions with the tool.

According to Hattie and Timperley (2007, p. 81) feedback is understood as “information provided by an agent (e.g., teacher, peer, book, parent, self, experience) regarding aspects of one's performance or understanding“. The goal of feedback is to support understanding and/or performance. In line with this, Shute (2008, p. 154) defines formative feedback as “information communicated to the learner that is intended to modify his or her thinking or behavior for the purpose of improving learning“. According to Hattie and Timperley (2007, p. 87) effective feedback has to address three questions: “Where am I going? How am I going? Where to next?”.

Research related to feedback aims at identifying features of feedback that increase its efficiency. Two aspects seem to be important for effective feedback: 1) the information provided by feedback and 2) the timing of feedback. Mory (2004, p. 753) distinguishes five categories of feedback regarding information complexity: “1. No feedback means the learner is presented a question and is required to respond, but no indication is provided as to the correctness of the learner's response. 2. Simple verification feedback or knowledge of results (KR) informs the learner of a correct or incorrect response. 3. Correct response feedback or knowledge of correct response (KCR) informs the learner what the correct response should be. 4. Elaborated feedback provides an explanation for why the learner's response is correct or incorrect or allows the learner to review part of the instruction. 5. Try-again feedback informs the learner when an incorrect response and allows the learner to one or more additional attempts to try again.”

Research has shown that both, the wrong form of feedback and the wrong timing might even have negative effects on learning and achievement (Fyfe & Rittle-Johnson, 2016a; Hattie & Timperley,

2007). The majority of studies in this context quantitatively measures effect sizes of different forms or timings of feedback in order to draw conclusions regarding the effectiveness of feedback. The underlying assumption in these settings is that students will react consistently to the respective form or timing of feedback. While different conditions of providing feedback that might influence its effectiveness have been studied, e.g. prior knowledge (Fyfe & Rittle-Johnson, 2016b) or feedback specificity (c.f. Shute, 2008) students' individual ways of responding to and making use of feedback have scarcely been studied in mathematics education. Bokhove (2010) presents an exception. He reports from a study where student inquiry about desired feedback was used in order to develop a feedback design of a digital tool to learn algebra. He concludes that "asking students when to use what feedback can improve a digital tool" (Bokhove, 2010, p. 125). Most of the research on feedback is based on experimental testing (Shute, 2008, p. 156). Shute (2008, p. 156) summarizes that „the specific mechanisms relating feedback to learning are still mostly murky, with very few (if any) general conclusions“. The aim of this paper is to contribute to the understanding of the mechanisms relating feedback to learning. In particular, the focus is on two research questions: 1) How do students individually utilize feedback in order to improve their understanding and performance?; 2) What are the consequences of students' individual utilizations of feedback with regard to the efficiency of feedback?

## **Theoretical framework and methodology**

In this paper, feedback is regarded as an artifact, which is developed in order to improve students' learning and achievement. According to Rabardel (2002) an artifact is transformed into an instrument in use. An instrument is a psychological entity that consists of an artifact component and a scheme component. In using the artifact with particular intentions the subject develops and adjusts utilization schemes, which are shaped by both, the artifact and the subject. This process is referred to as "instrumental genesis" (Rabardel, 2002). According to Vergnaud (1998, p. 167) a scheme is "the invariant organization of behavior for a certain class of situations". Vergnaud (1998) suggests that schemes are in particular characterized by two operational invariants, which refer to the knowledge included in schemes: theorems-in-action and concepts-in-action. The difference between both operational invariants is that of relevance and truth. While "concepts-in-action are relevant, or not relevant, or more or less relevant, to identifying and selecting information", "theorems-in-action can be true or false" (Vergnaud, 1998, p. 173).

With regard to research question 1, students' utilization of feedback is conceptualized in terms of their concepts-in-action and theorems-in-action, which guide their utilization schemes of the feedback. The situation that the scheme refers to is defined by the type of task with respective feedback.

## **Methods**

The study presented in this paper is part of a larger study, which aims at understanding students' learning with interactive e-textbooks at primary level. Therefore, we used an interactive e-textbook that is available on the German market. The e-textbook "Denken und Rechnen interaktiv 3"<sup>1</sup> was the only interactive textbook for primary level that was available on the German market when the study

---

<sup>1</sup> <http://www.denken-und-rechnen-interaktiv.de>

was carried out. The e-textbook was not developed for the sake of this investigation, but by one of the leading German publishing companies for textbooks. Consequently, the design principles for the feedback are not known and do not necessarily take into account the current state of research in this field.

In this paper, a case study with altogether 12 cases is presented. All students were at the end of third grade with an age between 8 and 9 years. Each case works on a tablet in experimental conditions on tasks from one unit of a beta-version of the web based interactive mathematics e-textbook. During data collection the students encountered the interactive e-textbook for the first time. The students were asked to verbalize their thoughts (thinking aloud). Additionally, the interviewer asks questions in order to understand the students' actions and thoughts. The interviewer also gives hints in order to assist students' instrumental genesis. The work of the students was video recorded. Data was transcribed and analyzed in terms of concepts-in-action and theorems-in-action. As the name of these concepts indicates, these are mainly inferred from students' actions. Only sometimes students explicate the concepts and theorems guiding their actions verbally. Concepts-in-action were inferred from the data by constantly asking 'what are the concepts / relevant categories / notions guiding the student's action?'. Accordingly, theorems-in-action were inferred from the data by asking 'what assertions / beliefs assumed as true by the student guides the student's action?'

Since utilization schemes are defined as "invariant organization of behavior" (Vergnaud, 1998) it might seem questionable to investigate them with children that encounter an e-textbook for the first time. However, utilization schemes do not develop from scratch, but can be understood as adjustments (accommodation) of existing schemes. In fact, this experimental setting allows for analyzing the instrumental genesis in terms of accommodation of existing schemes.

## Analysis

### Analysis of the artifact

An analysis of the task and related feedback is a prerequisite in order to understand students' utilization schemes of the feedback, because they are influenced by the affordances and constraints of the artifact in the instrumentation process (Rabardel, 2002). Task no. 2 on page no. 73 and related feedback is analyzed for the scope of this paper. It is depicted in figure 1. The task is to find solids in the picture ("Which solid shapes do you find?"<sup>2</sup>) and to enter their names into the empty fields. After pressing the OK-button on lower right corner of the screen the software provides knowledge of results (KR) feedback. Correct inputs are shown in green color with a green frame, wrong inputs stay as they were entered for a few seconds. Afterwards they disappear and the empty fields are shown again (figure 2). Correct answers stay on the screen and the student can enter new inputs into the empty fields. Students get the opportunity to correct their wrong inputs twice. After their third try knowledge of correct response (KCR) feedback is provided by showing all the correct answers in green color. The ones that were entered correctly by the student are framed. An answer is evaluated as correct if

---

<sup>2</sup> This was the task in the beta-version of the interactive textbook. In the latest online-version of the textbook the task was changed to "Enter befittingly sphere, cube, cylinder or pyramid".

the student entered the correct name of the solid in the correct spelling. The feedback does not differentiate between incorrect spelling mistakes or incorrect solid names.

Figure 1: Task

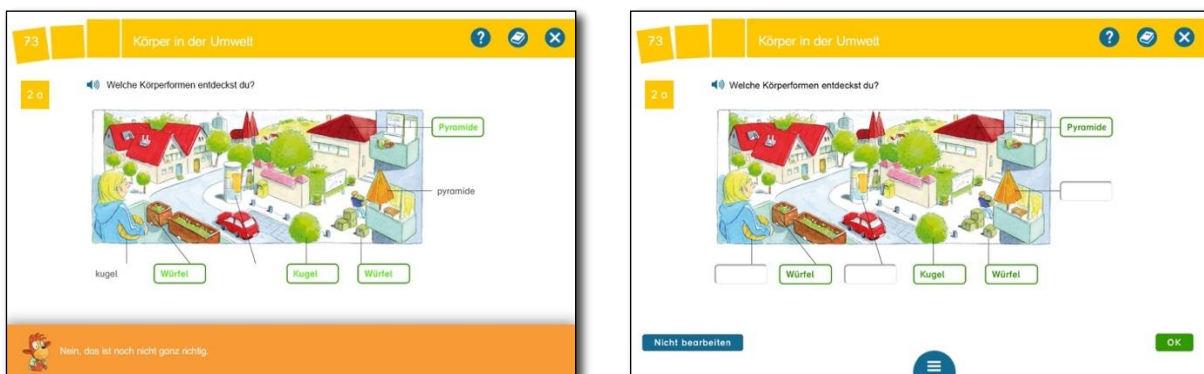

Figure 2: Task-level-feedback (KR) and screen for second try

### Analysis of students' utilization schemes of the feedback

In this section data of two cases will be analyzed. The analysis of both cases starts at the moment, when the students have filled in most of or all empty fields and press the OK-button at the lower right corner of the screen. After pressing the OK-button the KR-feedback appears on the screen.

#### Case 1: Farrell

On Farrell's feedback screen four out of seven answers are depicted in green color and with a frame and stay on the screen while three of his answers remain as they were entered and disappear after a few seconds. He gets the feedback "Sorry, wrong".

- 13'03" Interviewer What happened?
- 13'08" Farrell Correct answers are green and what is gone now was wrong
- 13'18" Interviewer Ok. And do you have an idea why it was wrong?
- 13'22" Farrell Wrong spelling? And wrong entry.
- 13'30" Interviewer Could be. ... Think about it. What else could you write or how could you write it differently if you think it also might be because of the spelling
- 13'35" Farrell *Tips into an empty field and starts typing 'Cube' in correct spelling.*
- 13'54" Interviewer Uhum, now you say it's a cube. What did you enter before?
- 13'56" Farrell Square.

- 13'57" Interviewer And why do you think it is the cube now?
- 13'58" Farrell Because, before, the square is not an object, no symmetrical figure
- 14'12" Interviewer Ah, ok, and now you believe it's the cube.
- 14'15" Farrell Yes, because the square can only be seen and not touched
- 14'19" Interviewer Ah, ok.
- 14'35" Farrell *Types 'cuboid' in one empty field in the same wrong spelling as the first time.*
- 14'08" Interviewer Which form could that be?
- 15'12" Interviewer Can the book help you somehow?
- 15'21" Farrell *Presses the '?'-button and choses "help" (the help screen appears). He reads the help screen.*
- 15'45" Interviewer Does that help you somehow? What do you see?
- 15'52" Farrell There is everything that could give me a hint.
- 15'56" Interviewer Hmm, ok. ... And does that help you for the task?
- 16'02" Farrell No.
- 16'04" Interviewer No. Is there maybe another function that could help you?
- 16'09" Farrell I will check. *Presses the '?'-button and points on the option 'Lexikon'. Lexikon.*
- 16'13" Interviewer Yeah, click it.  
*Farrell explores the lexicon. The interviewer asks questions, which are related to the use of the lexicon. He looks for 'form' and "solid".*
- 18'43" Farrell I believe it starts with a 'Q'. *At the same time, he opens the letter 'Q' in the lexicon and looks at the entries.*
- 18'58" Farrell No, but I found something different.
- 19'02" Interviewer Ok. What did you find?
- 19'04" Farrell The cuboid (in German: *Quader*) *Returns to the screen/tab with the task and tips into the field with the entry "Qader".*
- 19'09" Interviewer You already wrote cuboid there. So what did you find?
- 19'12" Farrell That in-between the Q and the A there is a U.
- 19'18" Interviewer Ah, that means the lexicon helped you a little.
- 19'28" Farrell *After completing to type the word 'cuboid' he presses the OK-button. All his entries are shown in green color with a frame. He gets the feedback "No, not correct yet."*
- 19'30" Interviewer And, what now?
- 19'31" Farrell I looked if what I wrote now is already correct.
- 19'38" Interviewer And, how does it look?
- 19'38" Farrell Correct.

The relevant concepts that guide Farrell's revision of his answers are verbalized in the beginning of the episode: Farrell verbalizes his interpretation of the feedback at 13'08" and also explicates two concepts of possible mistakes at 13'22". Accordingly, Farrell's utilization scheme of the feedback is guided by two concepts-in-action: 1) Correct answers are shown in green; wrong answers are shown in red (not explicit, but likely) and disappear (13'08"); 2) His concept-in-action of mistakes indicates that two kinds of mistakes are possible: Wrong names of the solids or wrong spelling of the names

(13'22"). The latter concept-in-action is supported by his way of proceeding with the task. On the one hand he thinks about different entries (13'35") and on the other hand he is sensitive about the spelling (18'58"-19'12").

#### Case 2: Edda

Edda gets the feedback "No, that it not quite correct". On the screen, the fields around her entries disappear and all her entries stay on the screen. An analysis of her answers reveals that five of her answers (from left to right and bottom to top: 1, 3, 4, 5, 7) named the solid correctly but were spelled wrong with no capital first letter, while two of her answers (2, 6) also contained a wrong name of the solid.

- 23'51" Edda            It says that it is all not quite correct. *Looks at the screen*
- 23'55" Edda            All (wrong) entries disappear. All fields are displayed empty again. Ah, boy!
- 24'02" Edda            Looks at the screen. Hm.
- 24'07" Edda            But this must be a sphere.
- 24'12" Interviewer    Do you have an idea what may could have been wrong? ...
- 24'16" Edda            Yes, this and this (*points at the two empty fields at the right side of the picture*)
- 24'20" Interviewer    ... because everything disappeared.
- 24'27" Edda            Well, this can't be a cone. ... Then I simply do again ... It's a sphere, definitely. *Types 'sphere' in the same (wrong) spelling as before in the empty field.*
- 25'00" Edda            Hm, it's bad, now I don't know what was wrong and now one cannot ...
- 25'10" Interviewer    What is it that you can't?
- 25'12" Edda            ... ehm, know what is wrong, I know ... ehm ... I have to do everything from scratch ... (not understandable) this and this was wrong (*points at the two empty fields at the right side of the picture*)

Edda's feedback screen shows all her entries in the way that she typed them. She seems frustrated that all her entries disappear from the screen (23'55"). Her answer to the interviewer's question at 24'12" reveals that she does not infer from the feedback that all her answers were wrong, but has her own beliefs about her wrong answers (24'16"). Her belief that her two answers on the right side of the picture were wrong seems to be stable throughout the episode (25'12"). However, these beliefs are not congruent with her actual performance on the task. At 25'00" it becomes apparent that she does not have the concepts available to make sense of the feedback given by the tool.

Although she does not say it explicitly, her actions seem to be guided by the concept-in-action that she has to enter the correct names of the solids. There is no indication of her being aware that it is not only the name of the solid that is relevant, but that correct spelling is also a relevant aspect of the name related to this task.

## Discussion

The analysis of students' utilization schemes of feedback shows that both students do not activate the same concepts-in-action when they utilize the software's feedback (research question 1). While Farrell's utilization scheme is guided by the two relevant concepts-in-action "name of the solid" and "spelling of the name", Edda's interpretation only refers to the "name of the solid". Edda seems surprised and disappointed that all her entries disappear on the screen and her belief that only two of

her entries were wrong seems to be stable. This indicates that she does not seem to have relevant concepts available in order to utilize the feedback.

However, it is important to note that the different utilization schemes of Farrell and Edda appear under different conditions. The intended interpretation of the feedback occurs in a situation when the student has got correct and wrong answers. In the case of Edda, it becomes apparent that she has difficulties to utilize the feedback. This is supported by findings from other cases in the study that have got all answers wrong in their first attempt. Two hypotheses can be inferred from this observation (research question 2): 1) In order to make effective use of the feedback it is important that students have both, correct and incorrect answers. If all answers are wrong it is more difficult to utilize the feedback, because it is more difficult to make sense of the feedback. 2) On the other hand, the findings might hint at an overall connection between the mathematical ability of the students and their ability to utilize the feedback effectively. Students who need the feedback most in order to improve their mathematical performance, because they have got many answers wrong in their first attempt have the most difficulties to utilize the feedback for improvement.

## Conclusions

The analysis of two cases' utilization-schemes of feedback in an interactive mathematics e-textbook, which was used for the first time, is too limited in order to draw far reaching conclusions. However, the results show that the feedback of this task can be optimized. For some students it seems to be important to get more detailed feedback about the kind of mistake they made, especially if mistakes from different domains such as mathematics and language are relevant for the evaluation of the solutions. Altogether, the results support the call for adaptive feedback systems in digital learning systems (Vasilyeva, Puuronen, Pechenizkiy, & Räsänen, 2007).

The fact, that the feedback of the software is not sensitive to different kinds of mistakes can in fact be appraised differently depending on the pedagogic perspective. From the perspective of concept development, it is a constraint of the feedback that it is not sensitive to the kind of mistake, because it does not provide detailed information related to the question "Where to next?", i.e. detailed information about "what is and what is not understood" (Hattie & Timperley, 2007, p. 90). Research has shown that "that feedback is significantly more effective when it provides details of how to improve the answer rather than just indicating whether the student's work is correct or not" (Shute, 2008, p. 157). From the perspective of integrated mathematics and language learning it might even be an affordance that the name and the spelling of the name of the solid have to be correct in order to be evaluated as a correct answer.

On the other hand, the reconstructed concepts-in-action and theorems-in-action that guide students' utilization schemes of feedback indicate that students interpret feedback differently. Therefore, the efficiency of feedback is not only a question of the features of the feedback, but also a question of students' utilization-schemes of feedback. Like with any other artifact, students have to instrumentalize and develop utilization-schemes of the feedback so that it becomes an instrument for improving understanding and performance.

## Acknowledgement

This investigation was supported by the Westermann Group by providing tablets and a beta-version of the interactive mathematics textbook used in the study.

# Documentational trajectory: A tool for analyzing the genesis of a teacher's resource system across her collective work

Katiane de Moraes Rocha and Luc Trouche

École Normale Supérieure, French Institute of Education, Lyon, France

[katiane.de-moraes-rocha@ens-lyon.fr](mailto:katiane.de-moraes-rocha@ens-lyon.fr); [luc.trouche@ens-lyon.fr](mailto:luc.trouche@ens-lyon.fr)

*Our contribution to TWG 22 is dedicated to discussing teachers' interactions with resources for planning their classroom instruction, particularly in the context of collective work. Each teacher during his or her professional life uses and creates many resources. To analyse the history of teachers' work with resources, we propose the concept of the "documentational trajectory". This idea is based on and aims to contribute to the development of the documentational approach to didactics. We will present a case study of one middle school teacher. The data related to this teacher's work allowed us to consider her documentational trajectory. We then used the teacher's documentational trajectory to analyze her professional development. The teacher's documentational trajectory demonstrates a strong participation in collective work, in particular a collective named SESAMES, has an essential role. This participation contributes to the emergence of a particular resource, called a metaresource, to structure her documentation work.*

*Keywords: Documentational approach to didactics, documentational trajectory, metaresource, reflective investigation, professional development.*

## Introduction

The new possibilities arising from communication and information technologies have had a significant impact on discussions on mathematics education, due to their impact on resources available to teachers and the way of designing them. This has led to a new conceptualization of teaching resources (Adler, 2000) and the consideration of teachers' new relationships with these resources (Remillard, 2005). Drawing on these studies, Gueudet and Trouche (2009) have analyzed teachers' professional development through the lens of resources: they introduced the *documentational approach to didactics* to analyze how teachers select, use, and produce their resources, along with a process called *documentation work* (ibid, 2009). More recently, Bozkurt and Ruthven (2015) have shown how digital resources structure classroom practices, evidencing five main features: *working environment*, *resource system*, *activity format*, *curriculum script*, and *time economy*. In this article, we will rely on and develop these approaches for analyzing teachers' history of their resource usage. We will propose a new concept for modeling this history: the teacher's *documentational trajectory*. We will mainly discuss here *the effects of a teacher's collective work on his or her documentational trajectory*. In order to do this, we will organize our contribution in four sections. In the first, we will introduce the keys concepts that structure our analysis. In the second, we will present our methodological choices. Next, we will develop a case study based on a middle school teacher, Anna. And in the last section, we will propose some final considerations and openings for future research.

## Theoretical framework and research issues

We will present and develop in this section the theoretical approaches that form the basis of our analysis: the documentational approach to didactics, the structuring features of teachers' practices, and the notion of *thought collective*. Then we will present our own propositions.

As stated by Gueudet and Trouche (2012, p. 24) “teachers interact with resources, select them and work on them (adapting, revising, reorganizing, etc.) *within processes where design and enacting are intertwined*”. This process is the central focus of the Documentational Approach to Didactics (Gueudet & Trouche, 2012) that grounds our work. In this approach, the term *resource* is used in a broad sense, as everything that nourishes teachers' work. To prepare their teaching, teachers work on resources, and the result of this process is called a *document*. A document is made of *resources* that have been modified and re-organized, and by the *knowledge*, both guiding, and produced by, teacher's work. The *document* is therefore subjective, because it is created through a process of knowledge development on the part of the subject. And the new resources generated or used in this process take place in a very structured set of teachers' resources, called a teacher's *resource system*. To develop this system, some resources introduced by Prieur (2016) as *metaresources* play a critical role. They design resources that support and guide the creation of other resources and, beside that, favor teacher's reflection about their documentation work.

Teachers' documentation work grounds teachers' classroom practices, structured, according to Bozkurt and Ruthven (2012) by five *features*: the *working environment*, where class takes place (infrastructure, social organization, etc.); the *activity format*, which comprises the body of work in the classroom, such as routines and models of interactions between teacher and student along teaching and learning; the *resource system*, which gathers tools and materials for class. The *curriculum script* is to be understood in the cognitive sense of structured organization of activity guiding a teacher's work in the classroom: goals, actions, activities, potential difficulties of students, among others. And *time economy*, based on the comparison between the teaching time and the learning time of students. Bozkurt and Ruthven use this framework for analyzing teachers' integration of new digital resources into classroom practices. We will extend this usage for analyzing teachers' design and usages of resources. Thus, we will retain the notion of a *resource system* as proposed by Gueudet and Trouche (2012):

“we consider here as resource system does not fully coincide with Ruthven's definition, because of the broader meaning of resources we retained. The resource system comprises material elements, but also other elements that are more difficult to collect, like conversations between teachers” (p. 27).

We consider that teachers' interactions with colleagues are likely to foster their documentation work and professional development (Gueudet & Trouche, 2012). This is the reason why we give a primary importance to *collectives*. We have retained the broad definition of *thought collective* (Fleck, 1934, p. 44) that exist when “two or more people are exchanging thoughts” and generating a *thought style* “characterized by standard features in the problems of interest to a thought collective, by the judgment which the thought collective considers evident, and by the methods which it applies as a means of cognition” (ibidem, p. 99). We will differentiate the natures of collectives, according to their duration

(stable vs. unstable), their organization (formal vs. informal) and type of participation (voluntary vs. obligatory).

Finally, our proposition for modeling a teacher's history with resources based on the notions of resource, collective, and *event*. An event is something that happens in a teacher's professional life, and that he or she has remembered as important regarding her documentation work. We define the teacher's *documentational trajectory* (Rocha, 2016) as the interplay, over time, between events and resources. This interplay is socially situated, because it happens in schools or collectives, or because the events or the resources themselves are social products. The design of a teacher's documentational trajectory is then a way to analyze *when, where, why, how* and *which* resources are created. We will focus in this article on the documentational trajectory as a tool for analyzing the development of a teacher's resource system across their collective work. We describe, in the following section, our methodological choices for such a design.

## Methodological design

Our methodology is inspired by the four principles of *reflective investigation* proposed by Gueudet and Trouche (2012): “*long-term follow-up*”, “*in- and out-of-class follow-up*”, “*reflective follow-up*” and “*broad collection of the material resources*”. This methodology gives a major importance to specific drawings made by a teacher (for example the ‘schematic representation of their resource system’). To retain this way of reflective investigation by the teacher of her documentation work, we propose some evolutions: instead of the word “representation”, we propose (Rocha, 2016) the word “mapping”, integrating the metaphor of a *progressive exploration* of a new territory. And we propose two kinds of mapping: *reflective* (made by the teacher herself) vs. *inferred* (made by the researcher) mapping. We differentiate then Reflective, vs. Inferred Mapping of a teacher's Resource System; Reflective vs. Inferred Mapping of a teacher's Documentational Trajectory. For the design and analysis of a documentational trajectory, we also use: interviews, follow-up of lesson preparation, and classroom observation, and a logbook filled by teachers.

Our current research is mainly based on case studies. To choose teachers, we searched teachers that had *Sésamath* textbooks as official textbooks in their class. *Sésamath* (<http://www.sesamath.net/>) is an association of mathematics teachers in France that collaboratively designs online resources (software, textbooks, etc.) at a very large scale, opening a window for us on advanced teachers' design, use and sharing of resources. We present here the case of Anna, a middle school mathematics teacher, whose school had chosen a *Sésamath* textbook. She has a strong partnership with a colleague from her school, Cindy, and both of them participate in various collectives and use a lot of digital resources beyond the *Sésamath* textbook.

Our work with Anna started in March 2015, when we followed her 6<sup>th</sup> grade class for three months. During this period, Anna created and shared with us a Dropbox folder, where she uploads resources that she used in her lesson or to prepare it. In addition, we also recorded four moments of interaction involving her documentation work. In the first one, she made a reflexive mapping of her documentational trajectory. In the second one, she reviewed her reflexive mapping (focusing on a particular resource and a specific year). In the third one, she prepared a lesson with Cindy about a new curricular subject. In the last one, she spoke about her usages of a particular digital tool, a padlet

(<https://padlet.com/>) used to save and organize resources found online. Also, we had her use a logbook to complement our data collection when we could not follow her documentation work.

We will explore in this paper different mappings of Anna's documental trajectory: inferred and reflexive mapping. To obtain the initial reflexive mapping, we asked her to write down above a timeline the main events that have influenced her use of teaching resources teaching, or the way of conceiving them, and to write down, below the same timeline, the resources associated with the event at stake. To help Anna, we gave her a sample of possible events: the arrival of a new person in her school; the participation in a new collective, an unexpected interaction with a student or colleague; a change of program; a change of teaching level or of textbook; a training course or the discovery of a new resource related to mathematics teaching (book, movie, website, etc.).

Our method of analysis is in development. In this article, we transcribed our first interview with Anna and we did a digital transposition of her reflexive mapping. Afterwards, we identified on the map, among the events she exposed, those related with collective work, following our hypothesis that knowledge is socially situated. After that, we identified the effects of collective work on her documentation work through associated resources at the event. Afterwards, we inferred from Anna's speech her role in collectives and the nature of each of these collectives, following the hypothesis that some features could inform us on the collective effect on a teacher's documentation work. For example, a collective where teachers are voluntary and have a long or permanent engagement nourishes teachers' work differently than an obligatory collective where they have a short time engagement. Then, we searched collectives that have an important status in Anna's documental work. For this purpose, we looked for the collectives that appeared more frequently and related to other events in the map. Afterwards, we analyzed how these collectives nourished her documental work exploring associated resources, and identifying in her words features relating resources and collective work. We will present the main results of this analysis in the following section. This work is still in progress.

## Analysis

This analysis is divided into two parts: (1) Anna's participation in collectives along her documental trajectory and the structuring role of a particular collective, SESAMES in it; and, (2) the structuring role of a particular resource, "Mise en train", on Anna's individual and collective documentation work.

### **Anna's documentation work in collectives along her documental trajectory and relationships with SESAMES."**

We start analyzing the first reflexive mapping drawn by Anna (Figure 1). The analysis of the events evidences Anna's strong involvement in collective work (she says: "I cannot work alone"). Eight (E6, E7, E8, E9, E10, E12, E13 and E14) over 14 events are related to collectives. For deepening the analysis, we study the *properties* of collectives, the *roles* of Anna in these collectives, and the *functions* of the resources that are designed.

The collectives have different natures:

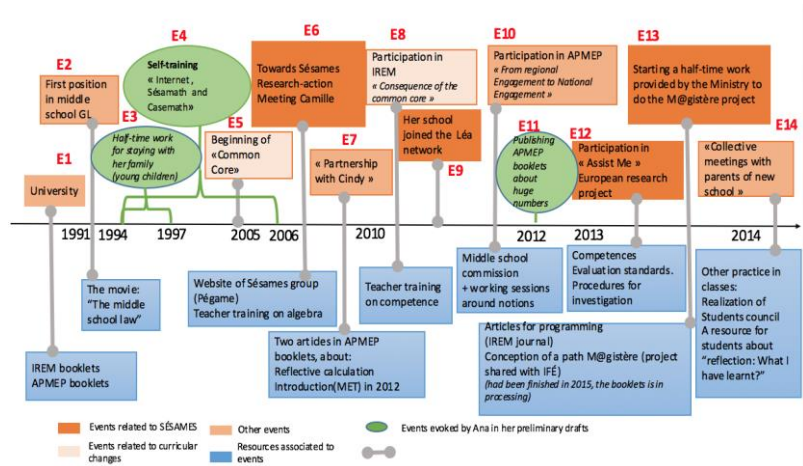

- some of them are transient, as a short episode of coworking with Sésamath (E4), or Assist Me (E12, linked to a European project), or M@gistère (E13, linked to the design of a

teacher training path); some of them are ‘permanent’ (meaning that, once Anna enters this collective and stays in it), as APMEP (E10/E11, the French national mathematics teacher association), or LÉA (E9, collective linking Anna’ middle school and the French Institute of Education), or SESAMES<sup>1</sup> (E6, a team associating researchers and teachers for renewing Algebra teaching );

- some of them are obligatory (as E14, meeting with parents), some of them are voluntary (as E7 the close partnership with Cindy).

In these collectives, Anna can have six different roles: *member*, reading and using their resources (E8 and E10); *author*, conceiving articles and resources for readers external to the group (E6, E8, E10, among others); *teacher trainer*, training middle school teachers (E6, E8, and E10); *teacher researcher*, reflecting about mathematics teaching (E6, E12 and E8); *partner*, exchanging and co-producing resources with colleagues (E6 and E10).

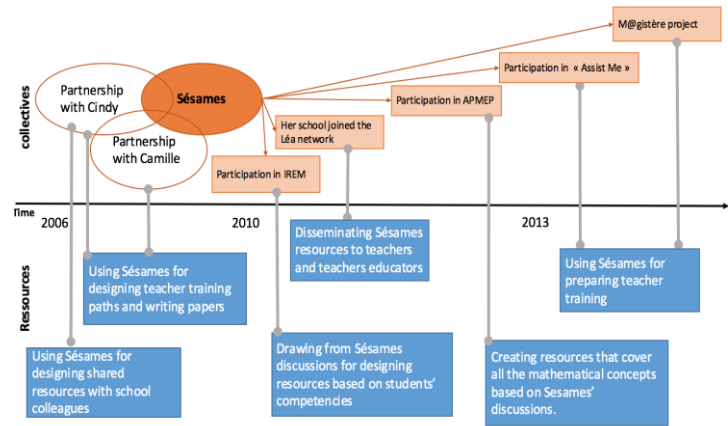

**Figure 1. Anna’s reflective mapping (October, 22<sup>nd</sup> 2016) of her documentational trajectory**

Each collective contributes in different ways to her documentation work. However, they are entangled in a way that it is difficult to attribute a single function to each of them. The interviews with Anna help us to distinguish some structuring features of Anna’s documentation work: elaborating her resources for teaching algebra; elaborating activities for teaching mathematical concepts and interpreting curriculum materials; elaborating resources for developing and evaluating students’ competencies; creating lessons and curricular scripts for her class; reflecting about using digital resources; creating new resources according to pedagogical changes in the school, supporting her participation in other collectives outside of school, writing papers, and teacher training.

These functions are not supported by all collectives, but all of them are exploited in Sésames, where Anna and Cindy used to work together. In addition, SESAMES gives Anna new possibilities for participating in new collectives and establishing new partnerships. Figure 2 shows how SESAMES resources nourish the resources of other collectives. Develop a critical thinking on their practice. When she was invited to join SESAMES, Anna hesitated “*that was a change, anyway. I accepted, finally, to join ... to join SESAMES. [...] It was a real challenge...*”.

<sup>1</sup> In spite of the likeness of the acronyms, Sésamath, a mathematics teacher association designing resources at a large scale, is totally different of SESAMES, a small team gathering researchers and teachers for re-thinking algebra education.

SESAMES<sup>2</sup> had a big impact on Anna's collective work. We can see (Figure 1) that she joined Assist me, M@gistère and Léa as a consequence of her engagement in SESAMES. It gave the opportunity for a new partnership with Camille. It helped her understand the competencies emphasized in the new French curriculum, leading to the design of a teacher training path at IREM, resulting in a chance to join this institute.

**Figure 2. Inferred mapping about the collectives and resource system impact**

SESAMES has two sets of *principles* guiding Anna's documentation work (cf. the SESAMES website, Pégame: <http://pegame.ens-lyon.fr/>), mirroring the thought style of SESAMES. The first set is composed of three principles for teaching algebra: justifying computation throughout algebraic rules; proposing proof activities and exploiting formulas to introduce the concept of a function. The second set is composed of four principles for teaching mathematics: providing students with sufficiently rich and open problems; giving them a chance to explore; giving them a chance to speculate; giving concrete meaning to concepts taught.

These principles gave birth to resources emblematic of SESAMES thought style, guiding then the whole process of collaborative resource design in this group. It's exactly the characteristic of the metaresources we have already introduced in this paper. One of them is *Mise en train*, and we will analyze in the following section its impact on Anna's documentation work.

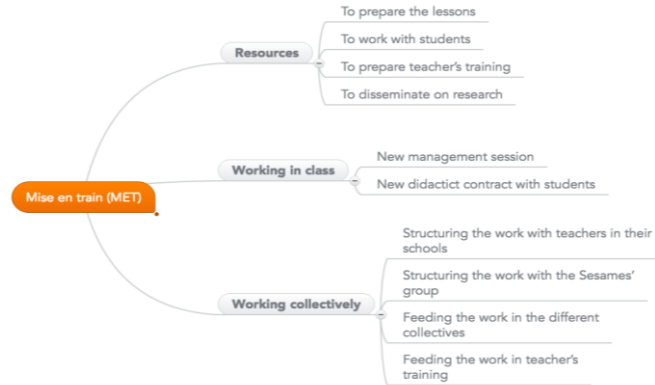

### The structuring role of a metaresource on Anna's individual and collective documentation

The *Mise en train* (MET) corresponds to a specific activity format: it aims to organize teacher's work at the beginning (around 15 minutes) of each class. The expression *Mise en train* has three meanings: the direct one is *warming up* (like for an athlete at the beginning of his training); the second one derives from a literal translation, "*put on a train*", meaning 'cutting a mathematics subject in short successive parts (allowing to store them in the successive wagons of a train)'; the third meaning derives from an acronym (created by Anna): Travail de Recherche ou d'Approfondissement avec prise d'Initiative (Research and Deepening Work with Initiative Taken). The global meaning of *Mise en Train* has to be understood as the compilation of these three interpretations. In the following, we have chosen to keep this acronym MET, incorporating this global meaning. This global meaning evidences some features of MET resources' design. MET is exactly a metaresource, as it gives a way to produce new resources and stimulates teacher's reflection on their documentation work and its effect on students' activity.

<sup>2</sup> Science Education: Modeling Activities, Assessment, Simulation (SESAMES, Situations d'Enseignement Scientifique : Activités de Modélisation, d'Evaluation, de Simulation).

MET appears as emerging, in SESAMES, from the documentation work of Anna and her colleagues. Anna explains factors leading them to create this metaresource: the loss of time at the beginning of each class (teacher being mobilized by administrative tasks); the good experience with the short sections of reflecting calculations; and her exchange with English teachers dividing students' activity in short articulated moments for a more dynamic activity format.

Once created, MET deeply changed Anna's documentation work (cf. Figure 4). It affects all five structuring features of classroom practice. The working environment changed, e.g. students entering class late did not disturb class activity. The activity format is also altered, because the class is divided into two moments: MET vs. main class.

**Figure 3. The impact of MET on Anna's documentation work**

The *curriculum script* is modified, including new goals and activities. Anna has then three possibilities for developing a lesson: MET then the regular course; the regular course, then MET; or beginning with MET... and going on with MET, for giving more responsibility to students for the advancement of the knowledge in the classroom. Regarding Anna's *resource system*, new resources are created (new curriculum script, new notebooks for students, new lesson plans with MET activities, slides that contains MET activities linked to a given notion, new articles (APMEP, IREM, Pégame website) for disseminating SESAMES resources. Last, but not least, the *time economy* changed, for example, Anna removed the initial "call to students" at the beginning of each lesson.

MET also affects Anna's work in other collectives: in her school, the new curricular script is shared by all teachers, as Cindy and Anna explain the principles of MET, and present their interest from their practice; outside of her school, Anna disseminates this metaresource in SESAMES training, IREM group, and training, APMEP group and training. Finally, this metaresource, initially constructed in SESAMES group to teach algebra, was extended to other mathematical topics. For us, the metaresource *MET* is a point of convergence between Anna's need and SESAMES' interest.

## Final considerations and perspectives

Our original question was: *What are the effects of a teacher's collective work on their documental trajectory?* Our initial analysis of Anna's documentation work gives us some clues. Our exploration of Anna's documentation work in collectives allows us to understand her resource system better. We saw a diversity of collectives that she participates or participated in, and how her different roles contributed to her work. Among them, SESAMES appears as an important collective, having a strong impact on Anna's documental trajectory. It contributes to developing new collective work, resources and thought styles. In this collective, she contributes to create a metaresource that structures her documentation work afterwards: this metaresource is exploited in various collectives and structures her way to create resources.

We proposed the concept of documentational trajectory for modelling a teacher's history with resources. In this modeling, the reflective and inferred mapping of the documentational trajectory allows us to evidence some critical aspects of this history. It should be noted that these maps constitute a picture at a given moment, and in a given context. This temporal aspect is linked to the fact that Anna's documentation work is still ongoing. The context aspect is also linked to the relationships the researcher can build with the teacher.

The combination of the *Structuring Features of Classroom Practice* and the *Documentary Approach to Didactics* helps us to analyze teachers' documentational trajectory, demonstrating the structuring role of SESAMES and a metaresource associated to a thought collective. Finally, we retain from this analysis that the development of the concept of documentational trajectory was relevant for analyzing interactions between resources, collective work and teacher's practice.

# Designing for responsibility and authority in experiment based instruction in mathematics: The case of reasoning with uncertainty

Abdel Seidouvy<sup>1</sup> and Andreas Eckert<sup>2</sup>

<sup>1</sup>Örebro University, Sweden; [abdel.seidou@oru.se](mailto:abdel.seidou@oru.se)

<sup>2</sup>Linnaeus University, Sweden; [andreas.eckert@lnu.se](mailto:andreas.eckert@lnu.se)

*Abstract: This study examines principles of task design concerning the concept of uncertainty in the area of statistics. A purpose is to promote and support students reasoning competency involving the aspects authority and responsibility. By using inferential role semantics as a background theory, we examine students' reasoning by means of how they show authority and responsibility for statements in the reasoning process. Statistical tasks where students generate and analyze their own data formed the basis for this pilot study conducted with seventh grade students in Sweden. The students were able to reflect on how their actions and consequences of their actions influence their reasoning with uncertainty. The study describes the findings, and presents principles to inform the design of innovative learning environments that promote authority and responsibility in reasoning in the domain of uncertainty.*

*Keywords: Design principles, uncertainty, responsibility, authority.*

## Introduction

Designing lessons and tasks has been an important part of developing theories of instruction in mathematics for over a century (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003) and emerging from this practice is the design-research methodology. Plomp (2013) speaks of a twofold yield in design research-projects, both producing an intervention that offers a solution to a problem in the practice and what he calls re-usable design principles. In the present study, we are aiming for the latter. Design principles are to be seen as heuristics as they do not guarantee success. The principles rather suggest design elements that could support the development of a prototype design of a task (Plomp, 2013). Design principles are guides that answer questions like “What should the lesson look like?” or “How should the lesson be developed?” (Van den Akker, 1999). They should connect task design with both a practical and theoretical understanding of the topic and inform the teaching practice as well as the research practice.

This paper begins in the idea of developing tasks for experiment based instruction in mathematics and the special case of stochastic. Groth (2013), amongst others, argues that stochastic education should be researched in particular since the nature of mathematical reasoning is largely deterministic whereas that of stochastic is with uncertainty. Our task design principles are therefore not focused on the creation of new knowledge but on eliciting stochastic reasoning and developing students' understanding. In the present study, we examine design principles in relation to how meaning making is described in the semantic theory of inferentialism (Brandom, 1994). Our guiding research question is:

- What are the design principles that trigger students' authority and responsibility in reasoning with stochastic uncertainty?

Plomp (2013) stresses the importance of reviewing similar examples when articulating design principles for the first time. Hence, the following section will elaborate on previous examples of experimentation-oriented tasks for stochastic education in the research literature to create a deeper understanding of design principles in stochastic education. Furthermore, the theoretical background of inferentialism gives the tools to see authority and responsibility in student's reasoning connected to the design of the task.

## **Related works**

In the Dutch tradition of RME, three principles inform task design: guided reinvention, didactical phenomenology, and emerging modelling (Freudenthal, 1973; Gravemeijer, 1994). According to the principle of guided reinvention, mathematical tasks should offer students opportunities to experience a process similar to that linked to the invention of a specific topic. On the didactical phenomenological account, task designers should consider how mathematical “thought objects” will be used by the students to structure and organize phenomena in reality. Emerging modelling emphasizes the process on progressive abstraction, from a model of a situation (experimentally real for the student) to a more general mathematical model (Gravemeijer, 1994). Overall, in RME, mathematical tasks are often rooted in Freudenthal's vision of “mathematics as a human activity”, and are designed to resemble realistic problems in context. Another school of thought close to RME is authentic teaching and learning in mathematics. The design principles of an authentic practice are used to perform certain actions and procedures, and knowledge as a tool to perform and achieve particular goals (Dierdorp, Bakker, Eijkelhof & van Maanen, 2011). The underlying conjecture in authentic mathematics is that students will be motivated and engaged in rich discussions if authentic practices are used as a source of inspiration in designing mathematical tasks. Ainley, Pratt and Hansen (2006) used *purpose and utility* as design principles in mathematical tasks. According to Ainley, Pratt and Hansen (2006), purpose means that a meaningful outcome of a task is crucial for student learning. Utility refers to acknowledging the power of mathematics ideas. Chance-maker microworld (Pratt, 2000) is an example of a learning environment in which purpose and utility are implemented. The chance-maker is a microworld program with a series of gadgets, simulations of everyday random generators such as spinner, coins and dice. The students are challenged to find the gadgets that according to them do not work (The students were told that the gadgets were programmed) and mend them. The purposeful activity, for the students, of mending the gadgets led to the understanding of the utility of representations (connection between probability and data distribution), and the importance of the law of large number. The students are supposed to discover the relevance of mathematical ideas through realistic situations created in classrooms, real life (Ainley, Pratt and Hansen, 2006) or in the microworld (Pratt, 2000).

Our hypothesis is that a mathematical task that can trigger students' authority and responsibility increases student awareness on the data generation process and, has the potential to develop students' reasoning with uncertainty.

## **Theoretical framework: The Game of Giving and Asking for Reasons – GoGAR**

The framework of our research is the game of giving and asking for reasons (GoGAR); it is a metaphor used by Brandom (1994, 2000) to describe the linguistic practices in inferentialism, which

is the background theory of this study. An inferentialist view on knowledge entails giving priority to inference in reasoning in account of what it is to grasp a concept:

To grasp or understand [...] a concept is to have practical mastery over the inferences it is involved in – to know, in the practical sense of being able to distinguish, what follows from the applicability of a concept, and what it follows from. (Brandom, 2000, p. 48)

It corresponds to the practical mastery of concept and, to the increasing awareness that reasoning is central to statistics and statistics education (Bakker & Derry, 2011). “The game of giving and asking for reasons is an essentially social practice” (Brandom, 2000, p.163), and the purpose of GoGAR is to make explicit reasons that are implicit in our linguistic practice (Brandom, 2000; Bransen, 2002). According to Brandom (1994, 2000), one way of understanding how reasons are made explicit in talk is in terms of interaction of inferentially articulated authority and responsibility. Authority of a claim is a process, capturing the influence of a claim in the GoGAR. However, “Authority is not found in nature” (Brandom, 1994, p.51) but is gained in taking responsibility by providing evidence for one’s claims. Students are expected to make claims that are related in a certain way, justify and explain their claims. Responsibility can be defined as a quest for authority, and it also expresses the quality of requirement for performing and maintaining authority (Hansson, 2010). By using GoGAR we aim to show how, independently of the quality of the reasoning, elements of task design eliciting authority and responsibility influences how students reason in the domain of uncertainty.

## Method

The present paper focuses on reaching an understanding of the data generation process connected to a mathematical task (Cobb et al., 2003). The data generation process involves clarifying the significance of the phenomenon under investigation, delineating key aspects of the phenomenon that should be measured, and considering how they might be measured (Cobb and McClain, 2004, p.386).

The analytical process of this paper is that of an abductive approach (Alvesson & Sköldbberg, 2009). The aim of this approach is to create an initial analytical lens to view the data through, and then allow for the emerging design principles to influence the initial theorization. The specific analytical tool is retrospective analysis by the use of constant comparisons (Gravemeijer & Cobb, 2013). Instances of data are compared to find similarities and differences related to authority and responsibility in the data.

The data set used in this analysis are transcripts of video recorded lessons in a pilot study. The purpose of the study was to document our starting point (Cobb & Gravemeijer, 2003) prior to an initial cycle of a design experiment (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003). The design experiment utilizes the idea of engaging students in actual data generation and asking them to reason about the results. Our aim is that the task would trigger students to develop authority and responsibility due to

their active involvement in the data generation. The empirical study was performed with a class of 20 students in grade 7 (aged 12/13) in Sweden using an experiment based task focusing on statistics. The “helicopter task” (figure 1) is a modified version of a task that originates from Ainley, Pratt and Nardi (2001). It involves constructing an auto-rotating helicopter out of paper and measuring five flight times per rotor length. The class dealt with the helicopter problem in

Your class has been chosen to help a company to build a helicopter. You work at the department that is responsible to make the rotor to the helicopters. It is known since before that the length of the rotor should be between 3-14 centimeters. It is of great importance that the rotor carries the helicopter as long as possible. Therefore, you should investigate which rotor blade length get the best flying time. The mission for your class is to help the company to find the best rotor length

### Helicopter Task

Answer to the following questions after your investigation

1. Which one do you think is the absolute best rotor length? Explain!
2. How sure are you about it?
3. Is there another way to decide the absolute best rotor length?

**Figure 1** Instruction for the helicopter task translated from Swedish to English

two lessons. In the *first lesson*, the students were involved in the data generation by e.g. testing paper-helicopters of varying rotor lengths (3cm to 14cm) and measuring flight times. In the *second lesson*, the class interpreted and evaluated the data in groups, guided by questions provided by the teacher. This was followed by a whole class discussion. The transcripts used here are meant to illustrate the ideas developed in the paper and are chosen because they portray typical student reasoning elicited by the task while using a relatively small amount of space in the paper. The reader is then invited to evaluate the plausibility of our interpretations and thereby assess the trustworthiness of our claims as an alternative to reliability and validity more suitable for this type of research (Lincoln & Guba, 1985)

## Results

The transcript elaborated on below is used to shed light on aspects of how responsibility and authority, embedded in the task, elicit reasoning with uncertainty. It is part of a whole class discussion in the second lesson where one of the groups presents their findings. The questions from the helicopter task in focus here are: *Which is the best rotor length? How sure are you?* (...) means that portions are inaudible and [...] means that we omitted a segment because of space limitation that we feel does not add to the reader’s understanding of our analysis. Table 1 contains the students’ results.

[1] Teacher: Before we move on, may I ask how you noticed that it was a failure with the rotors

[2] Gabriel: Because sometimes were like three, and then some were only 1 second

[...]

- [3] James: We aren't so sure because the experiment is done in a small scale therefore we don't have enough data on the functioning of the helicopter, which makes it hard to know which length is the best.
- [4] Eric: it also depends on the angle of the rotors (...), it depends on the height differences.
- [5] Eric: (...) some might be 4 seconds and others might be 1.48.
- [6] Jennie: It also depends on how you drop the rotors, wait, this? (...) You could've calculated it with the median which we should have done.
- [7] Maria: But we remembered that afterwards.
- [8] Jennie: But we did it with the mean which made it take longer time.
- [9] Teacher: why should you have measured the mean then?
- [10] Jennie: Because the differences were so big, and the times (...)
- [11] Teacher: would the results have been better if you used the median?
- [12] James: Yes
- [13] Teacher: Why do you think so?
- [14] Jennie: Because the differences were so big and the times
- [15] Teacher: okay, why did it become such big differences? Was it the failure or?
- [16] Maria: Because maybe you drop it from the exact same spot, maybe you drop it further down one time and another time further up.

### **Responsibility in justifying uncertainty**

If we compare instances [2], [4], [6] and [16] there are similarities and differences. All four instances are parts of GoGAR about the level of uncertainty. There are differences as well, for instance how their claims are accepted in the GoGAR and how they situate the responsibility for their claims. In [2], Gabriel reasons that the failure of the rotors becomes apparent in his data, but the reasoning is underdeveloped and no one else acknowledges his authority in the following discussion. In the following lines, not included because of space limitation, instead focus is put on the definition of margin used earlier. Eric's reasoning in [4] on the other hand situates responsibility explicitly in the activity of data generation. He draws on the experience of having been a part of the data generation and claims that both the angle of the wings and the drop height could be sources of uncertainty. Jennie acknowledges Eric's authority on line [6] by referring to the action of releasing the helicopter. We call this *Responsibility in justifying uncertainty*. Both students and teacher recognize that there is a measure of uncertainty in the results and use various informal concepts to indicate it, for example "hard to know" on line [3] and "differences are so big" on line [10]. Both Eric's and Jennie's giving and asking for reasons for the level of uncertainty situate responsibility in the act of data generation. Maria acknowledges that Eric's and Jennie's claims still have authority in the GoGAR on line [16] by relating the mathematical discussion of mean, median and uncertainty to the act of data generation.

### **Exercising authority by making claims**

From our analysis, it appears that students in this study exercise their authority through two types of claims: terminology related claims and context related claims. While the terminology claims are related to students' previous formal knowledge, context related claims are from observations through perception. *Terminology related claim*: We noted that all the students in the group were given the opportunity to express themselves. As whole, the group took the chance and made a considerable number of claims in a limited time period. As mentioned earlier, making claims is one way of

exercising authority. In [2], Gabriel answers to the teacher's question in [1]. A close look at Gabriel's utterance, indicates that Gabriel's authority is grounded in comparing one second to three seconds. In other words, formal logic is what lies behind his authority. In [5], Eric acknowledges Gabriel's claim [2] and undertakes it. We, therefore conclude that "Gabriel lends his authority to Eric". The same line of reasoning is observed in [10] and confirmed in [14]. Other students in their reasoning about uncertainty in GoGAR can use these claims. In [7] and [10], concepts such as mean and median are brought to the discussion. The students' involvement in data generation creates conditions in which students can make use of their previous formal knowledge. In this case the consequence of their actions in generating data, and the uncertainty that follows activates the use of mean and median while talking about uncertainty. *Context related claims:* it is evident that Eric's claim in [4], "it depends on high difference", is also accepted by the class. Hence [4] is based on observations during the data generation. One argument that supports our interpretation is that (here and otherwise in the data) the whole class has reported that it was almost impossible to drop the helicopter from the same height. Eric's claim is licensed by a context. The same observation is made by Jennie in [6]. Further, Eric points out that the angle of the rotor is reason for variation and uncertainty. This observation was specific to Eric's group. However, we believe the rest of the group will use it as a premise in their reasoning with uncertainty if needed. The context created by the data generation enables students to make claims that can be used in reasoning with uncertainty.

## Discussion

We organize the discussion around three questions connected to the design that seem to trigger authority and responsibility.

*Which different opportunities in the task are given by the students to accept responsibility for their claims?* The students reason naturally with uncertainty since they have the practical experience of manually generating data in the task to situate their responsibility. In contrast, Pratt (1998) found that many students in his study based on the chance-maker microworld software had to convince themselves that the gadgets in the game were indeed random and that the mode of reasoning should be with uncertainty rather than a deterministic reasoning. As long as the students had the opportunity to influence, for example, the strength of a simulated dice throw, they were more prone to accept that it was random. One explanation could be that the students working with the chance-maker had to situate responsibility inside a black box, being the software, which led them to believe that the results were predetermined. Our analysis in [2] and [4] show how the task provides opportunity for the students to situate the responsibility of the failure in the measurement. The cause-effect opportunities created by the task initiate fruitful GoGARs in the domain of uncertainty, which also seems to fit with Pratt's (1998) findings.

*Which different opportunities in the task give the students the ability to create authority for their claims?* From Roth's (1996) study, we know that students show difficulties in analyzing data when they have not been actively involved in the data generation. This view is supported by Noss, Pozzi & Hoyles (1999). Our analysis showed in [2] [3] and [4] that the task enabled the students to act as experts. The students were able to connect data analysis and inferences to data generation while reasoning with uncertainty. The experiment based instruction, which entails manual data generation, opens up for students to take control over the process. Leaving the data generation process to students, triggers their authority and responsibility and, students are more motivated than if they would just be

limited to data collection and get “the right data” (Cobb & McClain, 2004). Getting students to reflect on how their own actions influence the results is the first step in acting with authority and responsibility.

*Which different opportunities in the task are given to the students to shift responsibility and authority between different domains?* Designing tasks with manual data generation based on principles of authority and responsibility is not the general solution to improve statistics education. In fact, creating large data sets, suggested by Pratt (1998) as being a corner stone in statistics instruction, becomes almost impossible with this focus on manual data generation during lessons. We merely suggest that there are merits to these design principles in statistics education as it naturally elicits GoGARs in the domain of uncertainty and empowers students to take responsibility and use mathematics to back up their claims. In [6] and [8] our analysis in [6] and [8] show how the task provides opportunity for the students’ quest of authority as they shift responsibility between the empirical and theoretical domain. We show that designing tasks with manual data generation elicit fruitful situations for shifting authority and responsibility between context and concept levels. Thus the students used their previous concepts to act upon the context, and also looked for evidence in the context to strengthen their authority and responsibility. In sum, creating a learning environment where students can exercise authority by using their previous formal knowledge and most importantly “our imperfect perception” can promote a fruitful GoGAR in the area of uncertainty, and in mathematics in general.

# Promoting prospective elementary teachers' knowledge about the role of assumptions in mathematical activity

Andreas J. Stylianides<sup>1</sup> and Gabriel J. Stylianides<sup>2</sup>

<sup>1</sup>University of Cambridge, Faculty of Education, UK; [as899@cam.ac.uk](mailto:as899@cam.ac.uk)

<sup>2</sup>University of Oxford, Department of Education, UK; [gabriel.stylianides@education.ox.ac.uk](mailto:gabriel.stylianides@education.ox.ac.uk)

*Although the notion of assumptions is important in the discipline of mathematics and permeates (often tacitly) mathematical activity in school classrooms, instruction in the elementary school pays little attention to it. This situation is unlikely to change unless elementary teachers have a good understanding of the role of assumptions in mathematical activity and an appreciation of the pedagogical implications of that role. In this paper, we investigate how teacher education can promote this dual goal by illustrating a promising, task-based approach to supporting prospective elementary teachers to develop pedagogically functional mathematical knowledge about the role of assumptions in mathematical activity. We developed the approach in a 4-year design experiment we conducted in a mathematics course for prospective elementary teachers in the United States.*

*Keywords: Assumptions, elementary grades, prospective teachers, task design, teacher knowledge.*

## Introduction

Assumptions denote the statements doers of mathematics use or accept (often implicitly) and on which their claims are based (Fawcett, 1938) and, thus, assumptions are fundamental to any mathematical activity at all levels. In school mathematics, however, assumptions often receive little explicit attention, especially at the elementary school level. The notion of assumptions has received also relatively little explicit attention in the mathematics education literature.

A small number of studies addressed the role of assumptions in the particular area of proving at the secondary school (Fawcett, 1938; Jahnke & Wambach, 2013) and elementary school (Stylianides, 2016) levels. However, there is a scarcity of relevant research at the teacher education level. This is problematic: unless teachers are supported to develop a good understanding of the role of assumptions in mathematical activity and an appreciation of its pedagogical implications, it is unlikely that teachers will offer to their students productive learning opportunities in the area of assumptions.

In this paper, we investigate how teacher education can promote prospective elementary teachers' knowledge about the role of assumptions in mathematical activity. We focus on the design and implementation of tasks that can support *Mathematical Knowledge for Teaching (MKfT)*.

## Research background

The notion of MKfT (Ball et al., 2008) denotes the kind of “pedagogically functional mathematical knowledge” (Ball & Bass, 2000, p. 95) that teachers need to have to be able to manage the mathematical demands of their practice. It has been noted that “there is a specificity to the mathematics that teachers need to know and know how to use” (Adler & Davis, 2006, p. 271) and that teacher education should aim to create learning opportunities for prospective teachers (PTs) that would enable them “not only to know, but to learn to use what they know in the varied contexts of

[their] practice (Ball & Bass, 2000, p. 95). Thus mathematics courses for PTs cannot lose sight of the domain of application of the targeted knowledge (i.e., the domain of mathematics teaching).

We consider next what might be essential elements of MKfT about the role of assumptions in mathematical activity. We begin by describing two elements we identified based on consideration of the role of assumptions in the discipline of mathematics (e.g., Fawcett, 1938; Kitcher, 1984) and mathematical analysis of classroom practice where the notion of assumptions received explicit instructional treatment (Fawcett, 1938; Jahnke & Wambach, 2013; Stylianides, 2016).

- *Element 1:* Understanding that a conclusion is dependent on the assumptions on which the argument that led to it was based.
- *Element 2:* Understanding that different legitimate assumptions can lead to different conclusions that, although on the surface may appear to be contradictory to each other, may nevertheless both be valid within the set of their underpinning assumptions.

These interrelated elements are central to mathematical work. The different sets of axioms in Euclidean and non-Euclidean geometries, including associated results, offer an illustration of both of these elements in the discipline of mathematics or in the upper secondary school (Fawcett, 1938). Similar ideas are central also to the elementary school (Stylianides, 2016) and are consistent with recommendations in curriculum frameworks (e.g., NGA & CCSSO, 2010, p. 6). Furthermore, the two elements are essential for mathematical knowledge that is also pedagogically functional. For example, they can allow a teacher to recognize that, when two students offer inconsistent answers to a task, this does not necessarily mean that one of them is wrong; both students may have applied sound reasoning based on different assumptions about the conditions of the task. We capture this kind of pedagogical functionality of elements 1 and 2 under a third element of MKfT:

- *Element 3:* Ability to recognize possible ways in which elements 1 and 2 might apply in mathematics teaching.

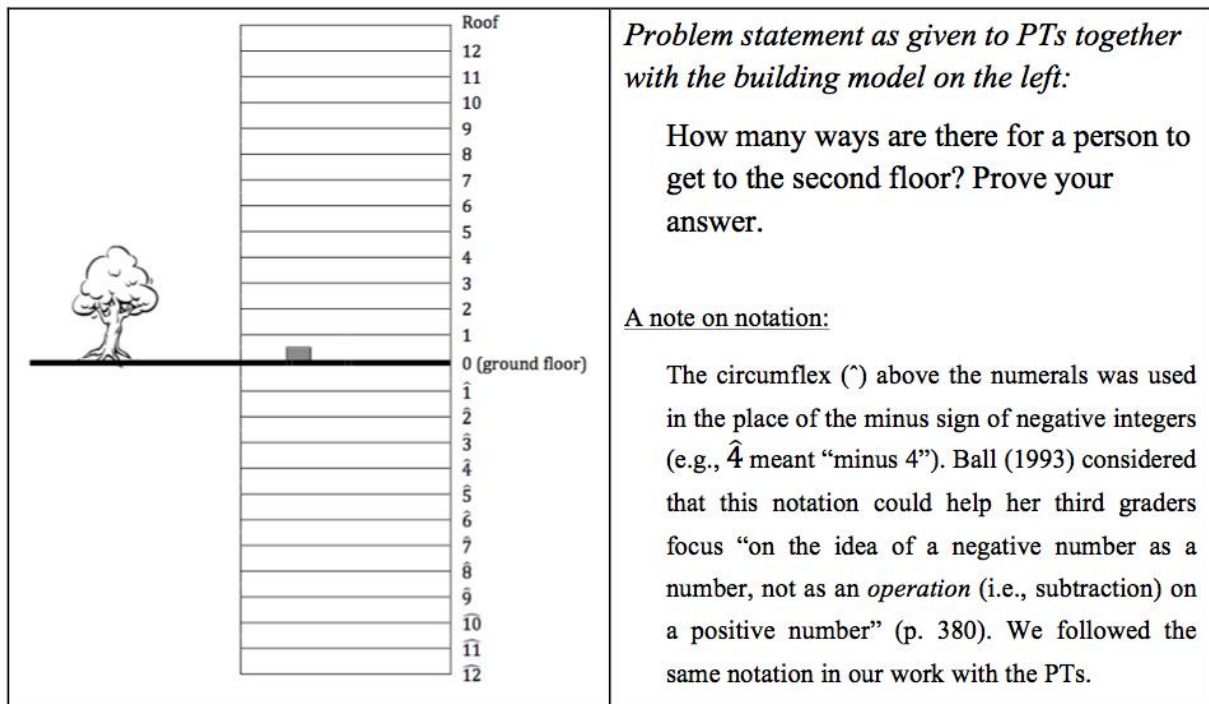

Regarding how to promote PTs' MKfT, in Stylianides and Stylianides (2014) we discussed and illustrated a special kind of *mathematics* tasks that we called *pedagogy-related mathematics tasks*. These tasks have two major features: (1) A mathematical focus, which relates to mathematical ideas that are important for teachers to know; and (2) A substantial pedagogical context, which is an integral part of the task and essential for its solution. Notwithstanding the importance of pedagogy-related mathematics tasks, there is also a need for the use of other kinds of tasks in mathematics courses for teachers. In this paper, we focus on a task sequence that illustrates another approach we followed to promote MKfT. Unlike pedagogy-related mathematics tasks where mathematics and pedagogy are intertwined in the same task, this task sequence illustrates an approach to promoting MKfT in which (1) initial work on a non-contextualized mathematics task can create a productive space for pedagogical reflection and (2) follow-up instruction can foster the intertwining between mathematics and pedagogy. We elaborate on the task sequence in the Method section.

To conclude, in this paper we address the following research question: What task sequence can offer a productive learning environment for prospective elementary teachers to develop the three elements of MKfT that we described earlier about the role of assumptions in mathematical activity?

## Method

### Research context

This research derived from the last cycle of a 4-year *design experiment* (e.g., Cobb et al., 2003) in a semester-long mathematics course (3hrs per week) for prospective elementary teachers in the United States. The design experiment comprised five research cycles of implementation, analysis, and refinement of task sequences and associated implementation plans that aimed to promote PTs' MKfT. The students were undergraduates who majored in different fields and were taking the course as a prerequisite for admission to the master's level elementary teacher education program. The task sequence we focus on was implemented toward the end of the semester and was the only one that explicitly targeted PTs' MKfT about the role of assumptions in mathematical activity. We introduced the task sequence in cycle 4 because we felt an explicit intervention was needed to adequately promote PTs' MKfT of elements 1–3. Analysis of how the task sequence played out in cycle 4, alongside our developing understanding of how things “worked,” led to modifications of the task sequence, culminating in the form described below which took place in cycle 5.

**Figure 1: The “Floors Problem” (derived from Ball, 1993) in part A of the task sequence**

### The task sequence

The task sequence comprised three parts. In part A we used the “Floors Problem” (Ball, 1993) in Figure 1. Two task features made it suitable for our goals to promote elements 1 and 2 of MKfT. First, the task conditions were ambiguous and thus subject to different legitimate assumptions; a major ambiguity concerned whether or not the person in the task had to travel directly to the second floor. Second, different assumptions about the task conditions could support different arguments for answers to the task that might appear to be contradictory but might actually be correct given their underpinning assumptions. In addition to promoting elements 1 and 2 of MKfT, we hypothesized

that PTs' mathematical experience with the task in part A could offer a productive context for pedagogical reflection (cf. element 3). We capitalized on this potential of the task in parts B and C.

In part B we used two *conceptual awareness pillars* (or simply *pillars*; Stylianides & Stylianides, 2009) to which the PTs responded individually and in writing. (There was a third pillar whose discussion we omit due to space limitations and a lack of direct relevance to our focus.) The pillars are presented in the first column of Table 1 (see next section). With them we aimed to amplify PTs' mathematical learning (see pillar 1 in relation to elements 1 and 2 of MKfT) and its intertwinement with pedagogical reflection (see pillar 2 in relation to element 3). As per the definition of pillars (Stylianides & Stylianides, 2009), the non-directive prompts in them could increase PTs' awareness of key realizations they might have developed (possibly in tacit form) during their work on the task.

Finally, in part C we engaged PTs in small-group and whole-class discussion around the three prompts in Figure 2 that aimed to further support PTs' reflective insights from part B and help them consider the applicability of those insights beyond the particular task. The prompts raised issues relating to elements 1–3 of MKfT. For example, in prompt 1 the first question related to elements 1 and 2, while the second question related to element 3. Each small group was asked to collectively produce a written response to each prompt prior to a whole-class discussion. Due to space constraints we report only findings from our analysis of the small groups' written responses.

1. "Conclusions are 'true' only within the limits of the assumptions on which they are based." How do you understand this statement? Do you think it is important for elementary school students to develop a sense of the role of assumptions in mathematics? Explain.
2. "Teachers should always make sure that the mathematical tasks they give to their students have unambiguous conditions." What do you think about this statement? Explain.
3. There may be situations where teachers do not realize that a mathematical task they give to their students has ambiguous conditions. What might happen in these situations and how might teachers handle the situations?

**Figure 2: Discussion prompts used in part C of the task sequence**

### **Data and analysis**

The task sequence in research cycle 5 was implemented in two parallel (independent) classes of the course that were both taught by the second author. At this stage of our analysis we are using data from only one of the classes: videos and transcripts of the implementation of the task sequence in this class with 16 PTs attending on that day; these PTs' written work including their individual responses to part B and their group responses to part C; and field notes from a research assistant documenting the work of one small group. Our data analysis was guided by elements 1–3 of MKfT that we aimed to promote. Specifically, we conducted qualitative content analysis of the transcripts and field notes in part A to examine whether and how the PTs developed understandings relating to elements 1 and 2, and also of PTs' responses to parts B and C to identify themes in their responses and examine whether and how these themes corresponded to elements 1–3 of MKfT.

## Implementation of the task sequence and discussion

### Part A: implementation of the Floors Problem

Stylianides showed the problem statement and the building model, and explained the notation for negative numbers. He also established a common notation with the class about representing trips. After that, he asked the PTs to work on the problem first individually and then in groups of four. He also said he would not answer any clarifying questions about the problem, an intentional aspect of our instructional design. The discussion in the small group where the research assistant was taking field notes is indicative of the way the PTs engaged with the problem (all names are pseudonyms):

Amanda: So... can you pass the second floor and then go back to it? Or do you have to stop, because you've technically gotten there? So... you just have to look at how to get *directly* there? If not, it's going to be infinity!

Beth: That's what I did...the direct. I just counted how many up and how many down...

Monica: But that doesn't say that you have to come in the entrance... So you can start anywhere?

At this point Stylianides passed by the small group and Monica asked him whether the trips had to start from the ground floor. Stylianides reminded her that he would rather not respond to clarifying questions and he moved on to a different group. The small group discussion continued as follows:

Victor: So... the solution of this problem depends on our assumption.

Amanda: Well, fine then. I say 15... because I'm assuming that you start on the ground floor and can't pass [floor] 2 and can't change direction more than once.

Victor: I say 25 because... [He was interrupted by the start of the whole-class discussion.]

As illustrated by this exchange, the decision not to respond to clarifying questions allowed for the notion of assumptions to emerge naturally in the discussion: had the instructor specified an interpretation, the PTs would not have considered alternative interpretations. The whole class discussion started with the small groups explaining their answers to the problem: 25, infinity, 15, and 51. Sherrill explained the answer of 25 by noting how each floor could constitute a separate starting point for a direct trip to the second floor. Sophie then tried to explain infinity as an answer:

Sophie: Well, we picked infinity because [...] if you're saying you can go up and down and up and down as many times as you wanted before you reach the second floor, I think that the question isn't specific enough. Like they [Sherrill's group] assumed you can only go up or down one time. [...]

Stylianides: So you say [referring to Sophie] if we don't assume that [what Sherrill's group assumed] and [we assume] you're allowed to travel up and down as many times as you want, then the answer would be infinity? [To the class:] What do you think about that? Is one of them wrong? Are both of them right? [...]

Lindsey: I think [...] they just made different rules, and like, thought processes. [...] You could have a direct route and that's it, no going back and forth... like, you *could*, when you were talking about going up and down and up and down and that's not

really a direct route... So really, you could do anything that you wanted to, but it just depends on what the person... what the problem is looking for, I guess.

Sherrill: It's up to the interpretation of the reader... Like I read it and I just assumed that it had to be a direct route, but it clearly doesn't state that... [...]

Infinity as an answer was discussed again later, after the class had considered also 15 and 51 as possible answers. Overall, the whole-class discussion mirrored the previous small-group discussion. Sophie, Lindsey, and Sherrill's comments show an increased understanding of elements 1 and 2: the PTs acknowledged that the task allowed for different legitimate interpretations of its conditions and that their conclusions depended on their assumptions (element 1), while realizing that the different answers they came up with were all correct based on their underpinning assumptions (element 2).

### Part B: PTs' responses to the pillars

Analysis of PTs' responses to the two pillars gave rise to the themes summarized in Table 1. Each response could receive multiple codes. The frequencies are offered to show how prominent each theme was among PTs' responses, not for generalizability. Regarding pillar 1, PTs' responses under themes 1–4 related to both elements 1 and 2 of MKfT. The responses below illustrate all themes:

Sherrill: I was surprised at the multiple assumptions made. I had not even considered the fact that answers other than 25 existed because of the way people interpreted the problem. I now realize how greatly making assumptions can alter mathematics. (themes 2, 4)

Lorri: [A]ll of our groups had different interpretations of how many ways there were [...] Some of the other groups' answers [...] I could understand their rationales as to why their answer was correct. Our answers were not wrong under this ambiguous problem. (themes 1, 3)

Pillars	Themes and frequencies (in parentheses)
<i>Pillar 1:</i> Is there anything that particularly stood out to you from our work on the "Floors Problem"?	1. Multiple legitimate interpretations (8) 2. Multiple assumptions (5) 3. Multiple correct answers (4) 4. Importance of assumptions (4) 5. Other (2)
<i>Pillar 2:</i> The "Floors Problem" was purposefully designed to be ambiguous. Why might a teacher use a problem like that in his/her classroom?	a. To encourage sensitivity to language (7) b. To increase awareness of the role of assumptions (6) c. To enhance appreciation of different possible interpretations of the same (ambiguous) text (6) d. To enhance appreciation of the interdependency between different assumptions/interpretations and different answers and solution paths (5) e. To encourage discussion, explanation, or proof (5) f. Other (3)

**Table 1: Summary of results from PTs' responses to the pillars in part B of the task sequence ( $n=16$ )**

Regarding pillar 2, PTs' responses under themes a–e showed ability to recognize how their mathematical insights from the problem could apply in teaching. Thus the responses offered evidence related to element 3 of MKfT. We offer two responses that illustrate some of the themes:

Lorri: A teacher could use this ambiguous problem to get their students to understand that sometimes their answers are not wrong and that there may be other answers to a problem. Students will be able to explore their different ways of interpretation and must be open to others' interpretations [...] They will understand that there will be different [...] answers that will depend on the information given in the problem, which may be ambiguous. (themes a, c, d)

Helen: To learn about assumptions and understand not only the importance of specifics [...] but also the freedom for one to think along the terms of their own assumptions. (themes a, b, c)

### **Part C: responses of small groups to the discussion prompts**

Overall the PTs' responses to part C were pedagogically sound and were informed by the powerful impact the Floors Problem had on their mathematical learning. Also, one can see parallels between PTs' responses in part C and the part B pillars; these were supported by our instructional design.

*Prompt 1:* An illustrative explanation of the first question in prompt 1 was: "You have to start with a base and then make assumptions from that. So your conclusion can only be based on those assumptions. Therefore your conclusion can be only true or false for those assumptions." Regarding the second question in prompt 1, all groups noted the importance of helping students develop a sense of the role of assumptions in mathematics. The groups justified their response with reference to the following: the importance of assumptions in the discipline; knowledge of assumptions can help students understand that different legitimate interpretations of a problem can lead to different valid conclusions; and knowledge of assumptions can highlight the need for students to explain their thinking. These justifications relate to element 3 and are underpinned by the understanding of elements 1 and 2 that was evidenced in PTs' responses to the first question in prompt 1.

*Prompt 2:* All groups disagreed with the statement and highlighted, in a similar manner, that the phrasing of a task should align with the teacher's goals. Here is an illustrative response: "If a teacher is giving a math test, or graded evaluation where they are looking for a specific answer then yes, the tasks should be unambiguous. However, if the teacher is trying to prove a point about assumptions or different approaches to the same problem, an ambiguous task may be beneficial."

*Prompt 3:* Two major points emerged from the responses to prompt 3. The first point related to teachers being able to recognize that some students' approaches to a task that appear as "faulty" may be in fact mathematically sound based on unforeseen (to the teacher) legitimate assumptions. The second point related to teachers asking students to explain their thinking to see whether the students indeed operated on different assumptions rather than just focus on the final answer. Again, these justifications relate to element 3 but are also based on understanding of elements 1 and 2.

### **Conclusion**

In this paper we investigated how teacher education can promote prospective elementary teachers' knowledge about the role of assumptions in mathematical activity, with attention to the design and implementation of a task sequence that aimed to support three elements of MKfT. We illustrated a task-based approach to promoting MKfT whereby a mathematics task, although not embedded in a

pedagogical context, can nevertheless create a productive space for pedagogical reflection through the creation of a powerful mathematical experience for PTs. Analysis of data from the fifth research cycle of a design experiment in a mathematics course for PTs provided evidence for the promise of this approach and highlighted the important role of the teacher educator in implementing deliberate (pre-planned) instructional moves to help amplify PTs' mathematical learning and enhance the pedagogical functionality of their acquired knowledge. Future research can investigate whether and how the rich insights (both mathematical and pedagogical) that PTs may develop through the task sequence about the role of assumptions in mathematical activity can inform their practice.

# Asymptotes and asymptotic behaviour in graphing functions and curves: An analysis of the Croatian upper secondary education within the anthropological theory of the didactics

Aleksandra Čižmešija<sup>1</sup>, Ana Katalenić<sup>2</sup> and Željka Milin Šipuš<sup>3</sup>

<sup>1</sup>University of Zagreb, Faculty of Science, Zagreb, Croatia; [cizmesij@math.hr](mailto:cizmesij@math.hr)

<sup>3</sup>University of Zagreb, Faculty of Science, Zagreb, Croatia; [mlin@math.hr](mailto:mlin@math.hr)

*Keywords: Asymptote, asymptotic behaviour, anthropological theory of didactics (ATD).*

## Introduction and methodology

Asymptotes and asymptotic behaviour play an important role in many traditional and modern mathematical disciplines and are supported by a rich and well-established abstract theory. Some basic aspects of these concepts can be utilized already in elementary mathematics as powerful tools in graphing and analyzing behaviour of elementary functions at infinity and near singularities and in graphing simple plane curves such as hyperbola. Therefore, this body of knowledge is a common part of upper secondary mathematics curricula worldwide. Here, we investigate its didactical transposition to the Croatian general upper secondary education. The survey is conducted within the theoretical framework of the Anthropological theory of the didactics (ATD), developed by Y. Chevallard (Chevallard, 1981, 2007). The main idea of the ATD is to determine a relation  $R_I(p, O)$  between a body of knowledge  $O$  and a person that occupies a position  $p$  in an institution  $I$ . Accordingly, mathematical knowledge and activities are described in terms of a *praxeology*  $[T, \tau, \theta, \Theta]$ , where its practical component, *praxis*, is represented with a *task*  $T$  and a *technique*  $\tau$  and its discursive or theoretical component, *logos*, with a *theory*  $\Theta$  and a *technology*  $\theta$ . Research within the ATD should include relevant data about the relation  $R_I(p, O)$  for all institutions  $I$  involved in the educational process i.e. the process of didactic transposition (Bosch, Chevallard & Gascón, 2005). Questioning and understanding *conditions* and *constraints* on the relation  $R_I(p, O)$  is necessary for setting up attainable, justified and significant educational interventions (Barbé, Bosch, Espinoza, & Gascón, 2005). Hence, as relevant for our setting, we analyzed and compared the relations  $R_B(p, O)$  and  $R_S(p, O)$ , where  $O$  is a graphical representation of an elementary function and a hyperbola in a square coordinate system, together with corresponding techniques regarding asymptotes, while institutions considered are two actual Croatian mathematical gymnasium textbooks  $B$  and the cohort of 40 the final, fifth year mathematics education students  $S$  at the largest mathematical department in Croatia.

This is a part of a more comprehensive study regarding asymptotes and asymptotic behaviour in the Croatian pre-university education which also included the institution of academic mathematicians. The methodology included a praxeological analysis of the textbooks as representatives of the *knowledge to be taught* and three questionnaires with open-ended questions for the prospective mathematics teachers to provide an insight in related *knowledge available* to students as a potential *taught knowledge*. Based on this, a reference epistemological model (REM) is proposed and then verified and improved with scholarly knowledge gained from semi-structured interviews with two

academics. Here, we focus on textbook topics, tasks, techniques and discourses related to  $O$  and on three particular tasks from the questionnaires administered: graphing and describing a simple rational function and a shifted exponential function from a real world problem, given by formulas, and graphing a hyperbola and its asymptotes.

## Results and conclusions

The results of the textbook analysis show that graphing a function  $f$  pointwise, that is, by plotting some corresponding points  $(x, f(x))$  and connecting them by a smooth curve dominates all other available techniques for graphing functions given by formulae. A technique of graphing a function or a curve regarding its properties recognized from a corresponding algebraic expression (formula or equation) occurs only in relation to the tangent and cotangent function and to a hyperbola, while the tasks on graphing polynomials and rational functions appear only as common practical activities of utilizing derivatives (calculus). Finally, a technique of transforming a prototype graph of an elementary function to get a graph of its composition with a linear function (by translations and dilations) is rarely implemented. Although textbook praxeologies of graphing functions often elaborate function properties and flow, discursive accents are set on establishing a function's domain, monotonicity and symmetry of its graph, neglecting its asymptotic behaviour. Asymptotes are seen relevant only for tangent and cotangent functions. Results of the questionnaire analysis completely reflect those of the textbooks. The students applied techniques and provided discourse to the same extent as it is given in the praxeological organization of the textbooks. Namely, their dominant techniques are drawing curves through their points and drawing graphs regarding function properties determined by using calculus, their chosen techniques are not the most efficient for the task in question, and asymptotic behaviour is available to them but not fully utilized in praxeologies relevant to graphing functions or curves. Considering this, it is our suggestion for the teaching practice and for an ongoing curricular reform in Croatia that: all relevant function properties should be emphasized when describing its behaviour; common properties of a function should be more related to its algebraic representation and utilized for its graphing; functions should be graphed by graph transformations, whenever fitted; and asymptotic behaviour should be more emphasized, adequately graphically represented and described by formal and informal mathematical discourse.

# Using variation theory to explore the reteaching phase of Lesson Study

Thérèse Dooley and Tugba Aysel

Institute of Education, Dublin City University; [therese.dooley@dcu.ie](mailto:therese.dooley@dcu.ie)

*Keywords: Variation theory, Lesson Study, task design, fractions.*

Japanese Lesson Study is now internationally accepted as a powerful form of professional development, particularly in the field of mathematics. It involves a cycle in which teachers collaborate to plan, observe, analyze and refine actual classroom lessons (Lewis, Perry and Murata, 2006). Frequently the lesson is retaught, although rarely by the same teacher to the same students (Fernandez and Yoshida, 2004). Reteaching of a lesson allows teachers to see how small variations in, say, the presentation of a task can deepen learners' understanding of mathematical concepts. This suggests that variation theory might be a useful lens for exploration of this phase of the Lesson Study cycle. From this theoretical perspective, learning is defined as "a change in the way something is seen, experienced or understood" (Runesson, 2005, p.70). Thus small changes in the design of a task can result in changes in what it is that students discern or notice. Watson and Mason (2006) refer to *dimensions of possible variation* (what is possible to vary) and a *range of permissible change* (perceived constraints on the extent and nature of change in any of the dimensions of variation): "Teachers can ... aim to constrain the number and nature of the differences they present to learners and thus increase the likelihood that attention will be focused on mathematically crucial variables." (p.102)

In this paper we report on a research project in which one primary and three post-primary teachers participated in Lesson Study in order to examine transition issues in mathematics. In particular, there is reference to the mathematical written work of two different groups of students who engaged with a similar task. The teachers had identified the topic of fractions as one that poses both teaching and learning challenges at primary and post-primary levels. They developed a research lesson and taught it first to a junior post-primary class (students aged 12-13 years) and later to senior primary class (students aged 11-12 years). The goals for both lessons were the same and centred around students'

1. development of confidence in comparison of fractions;
2. utilization of their own approaches to solve the problem;
3. discussion of their own ideas and opinions with each other; and
4. motivation to engage in further such mathematical tasks.

The particular task they chose (sourced from [nrich.maths.org](http://nrich.maths.org)) concerns the identification of the greatest amount of chocolate in a room where there are three bars on one table, two on another and one on the last table. It is assumed that an unknown number of people will enter a room in turn and that each will decide which might be the best table at which to sit 'at that moment'. Thus the first person should choose the table at which there are three bars. The comparison faced by the seventh person is mathematically more complex than that encountered by the first six people as, up to this point, comparison is between whole numbers and fractional amounts less than 1. For example, a choice that might have to be made by Person 6 is  $\frac{1}{2}$  or  $\frac{2}{3}$  or 1 bar of chocolate. However assuming

that Person 6 opts for the table at which there is one bar, the choice for Person 7 is  $\frac{1}{2}$  or  $\frac{2}{3}$  or  $\frac{3}{4}$ . While much planning time was spent anticipating such complexities and how pupils might deal with them, the teachers did not foresee that poor organisation of work by students would impinge on their solution processes. A change introduced in the second iteration of this lesson was that students would be encouraged to present their solutions in tabular form, and, in fact, on inspection of their written artifacts, most did so. However, while the use of this table facilitated fraction comparison (Goal 1), it did not encourage the exploration of various approaches (Goal 2) to the same extent. It appeared that this small variation in the task had considerable impact on students' focus of attention.

## Conclusions

A broader *range of permissible change* appears to have been conveyed in the post-primary than in the primary class due to the introduction of the tabular format in the second lesson. However, students perceived a narrower dimension of variation than was suggested by either teacher, evident in the frequency of use of decimals for recording in the post-primary class and use of fractions/tabular format for recording in the primary class. This may have been influenced by the teacher's representation of the task on the whiteboard in each lesson and might be explained by its endurance (and thus propensity to be noticed) over the course of each lesson. Such representations seem to have a considerable impact on the (enacted) object of learning and deserve focused attention in the design and analysis of mathematical tasks. More generally, while other theories have explanatory power in the consideration of the different outcomes of two similar lessons, variation theory has a significant role to play.

## Acknowledgment

This project was supported by 3U partnership (Greater Dublin Universities) that combines the complementary strengths of Dublin City University, Maynooth University and Royal College of Surgeons in Ireland.

# Changes in the images and arguing from the mathematics textbooks for the secondary school in Argentina along 67 years

Viviana Carolina Llanos and María Rita Otero

Universidad Nacional del Centro de la Provincia de Buenos Aires (UNICEN). Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina; [vcllanos@exa.unicen.edu.ar](mailto:vcllanos@exa.unicen.edu.ar)  
[rotero@exa.unicen.edu.ar](mailto:rotero@exa.unicen.edu.ar)

*This work analyses the changes in the relationship between arguing and images from the mathematics textbooks for the secondary school in Argentina along 67 years. The textbooks have been published in the period 1940 thru 2007. The analysis is done by (N=137) textbooks based on three meta-categories in an inductive way. A factorial analysis of multiple correspondences was performed to find the main similarities and differences between the textbooks and to make a cluster analysis and one possible classification.*

*Keywords: Textbooks, mathematics education, secondary school.*

## Introduction and conception of arguing

In 1994 an educational reform was performed in Argentina. The syllabus was changed and the scholar textbooks were adapted to the new educational system. The main modifications were realized in the properties of the images more than in the content. The characteristics of the text books, the ideas about argumentation and the characteristics of the images in the books are analysed. This research adopts an idea of arguing that emphasizes the relevance of the divergences between different points of view and the epistemological function of arguing, proposed by Leitão (2007). Different from other theories as Schwarz, Hershkowitz & Prusak (2010), Driver, Newton & Osborne (2000); Leitão proposes that arguing has to be analysed based on three elements: “*argument, argument against and response*” in order to generate confrontation between *argument* and *argument against*, to achieve construction of knowledge and transformation of perspectives in the subject (*response*). These processes occur into face to face situations, or in negotiations of the different points of view with ourselves, in this case, when we are reading a textbook.

## Methodology, categories of analysis and some results

A set of (N=137) mathematics textbooks is selected by means of purposive sampling techniques. The analysis was performed starting from a previous qualitative inductive categorization based on three meta-categories:

**A- Characteristics of arguing.** A1- *Commencement of arguing*: *Questions* or situation, which will be answered later; *Definition*, using to introduce knowledge; and *Examples* to formulate knowledge. A2- *Type of arguing*: *Deductive formal*, used deductive mathematics argument (definition, theorem, hypothesis, theory, demonstration, etc.); *Deductive informal*, they do not reach the formalism of the demonstrations; and *Inductive* that generalize knowledge from a single case. **A3- Degree of arguing**, cognitive conflict promoted by the text is analysed in three levels: *High*, books that generate explicitly confrontations, without solution in the text; *Low*, textbooks generate explicitly a cognitive conflict, solved later; and *Absent*, textbooks that inform without questioning.

**B- Relationship between the images and arguing** (Otero, Moreira and Greca, 2002): **B1- Use of the image: Ornamental**, images used with a decorative aim, not related to the content; and **Argument**, used as source of information, knowledge can be derivative. **B2- Type of image: Mathematical representations**, use mathematical systems of representation; and **Non-mathematical representations**, images not related with mathematical content. **B3- Grammatical style of the images: Conceptual**, represent relations and fixed characteristics between the represented elements; and **Narrative**, identify actions between objects that can represent a relation between them in the image. **B4- Relationship with the “real world”**: **Naturalist**, images referring to the empirical world, detailed and complex; and **Abstract**, not referring to the world that we experience.

**C- Characteristics of the textbooks: C1-Date of publishing: Period 1**, 1940 thru 1973, **Period 2** 1974 thru 1994 and **Period 3**, after the reform, until the year 2007. **C2- Educational level**: refers to the educational level the textbooks. **Level 1**, students between 12 and 14 years old; **Level 2**, students between 15 to 17 years old; and **Level 3**, older than 18 years old. **C3- Mathematical traditions** (Klimovsky & Boido, 2005): **Computational**, emphasis in the resolution of problems and calculation with numbers; **Axiomatic**, present the mathematics demonstrations steps; and **Structuralist**: books that search of regularities that meet the same conditions.

Using this categorization, a qualitative description is made, which originated a first analysis. Then, the categorization is transformed in a group of nominal variables and modalities using Exploratory Data Analysis (Lebart, Morineau, 2000). A Factorial Analysis of Multiple Correspondences allowed the selection of one possible classification in three classes. In addition, a test of randomness to analyse the reliability of the sample was performed using the statistical software SPAD.

The analysis explains changes in the images and arguing, given by: books that propose questions, or only definitions and examples, by the way to conceive and validate to mathematical knowledge, and mainly by the changes in the images and the relation between images and knowledge. The goal of most books seems to be informative. This explains the absence of questioning and discussing about several points of view, and the low level of arguing and conflict found within them.

# Teacher's pedagogical design capacity and mobilization of textbook

Ljerka Jukić Matić

Department of Mathematics, University of Osijek, [ljukic@mathos.hr](mailto:ljukic@mathos.hr)

*Keywords: Textbook mobilization, pedagogical design capacity, mathematics teacher.*

To investigate, understand and explain the relationship between teachers and curriculum resources, in our context a textbook, Remillard (2009) derived a model of the teacher-curriculum relationship, from earlier Brown's (2009) Design for Capacity Enactment Framework. The center of the model represents the participatory teacher–curriculum relationship designating what the teacher and the curriculum bring to the teacher-curriculum interactions. In this model, teacher resources include concepts of pedagogical design capacity, human and social capital, and agency and status. Curriculum resources include several components: mathematical topics and tasks that are structured in deliberate ways, embedded supports for the teacher to guide pedagogical decision-making and presence of a pedagogical orientation or emphasis embedded in instructional strategies and lesson structures. In domain of teacher resources, an interesting and important characteristic is the pedagogical design capacity (PDC). PDC describes the capacity of teachers to perceive and mobilize existing resources to create productive instructional episodes (Brown 2009), which to some extent, depends on the used resource and on the ways of working with that resource (Gueudet, Pepin & Trouche, 2013).

In this study, we wanted to examine the relationship between the mathematics teacher and the textbook in the classroom. Therefore, we formed the following research questions: What characterizes the nature of the teacher–textbook relationship and why? What is the level of the teacher's pedagogical design capacity?

Remillard (2009) suggested that individual PDC can be measured by examining dimensions of human and social capital, therefore in this study, two measures are used to examine the teacher's level of PDC; the one proposed by Remillard (2009) and the one described by Leshota (2015). Leshota (2015) proposed that one possible way for measuring teacher's PDC is examining whether teachers make injections of mathematical content into the lesson, omissions of mathematical content from the textbook and mathematical errors. Using those criteria one could determine whether teacher has low or high PDC.

We observed four lessons in Mrs. D's classroom and conducted an interview with the teacher. In terms of textbook content, Mrs. D offloaded, adapted and improvised in the lessons, but not to the same extent in every lesson. Those types of textbook mobilization were dynamically interchanging within a lesson. Mrs D. made several injections of content that are not in the curricular outlines or in the textbook for this grade level. She had no critical omissions in the lessons.

It seems that the teacher regards the textbook as a vital resource for the students' learning, but not crucial for her teaching. The established relationship between the teacher and the textbook could be regarded as a two way process in which both participants communicate. The outcome of that process is a product that fits the students' needs and the teacher's goals. The teacher positioned herself as having instructional authority in the classroom, regardless of what her colleagues in the school do or think. Recognizing the textbook's affordances and constraints allowed her to place

herself as an authority over the textbook. Mrs D. showed a high level of PDC in her teaching. She omitted content from the textbook, like activities or worked examples which were not crucial for learning mathematics. She injected content that is not usually introduced until the following grade because it was applicable to the topic being taught.

From our perspective, the term PDC seems to be more efficient when examining teaching expertise than Shulman's pedagogical content knowledge (PCK). In a way, PDC has more dynamic nature than PCK. Therefore, from the perspective of the textbook utilization, teachers' development of PDC is an important and critical part of their interactions with the textbook. Our study showed that interplay between curricular knowledge, professional development, mathematical knowledge, knowledge of the textbook's characteristics are important aspects in ability to craft pedagogical beneficial lessons. More studies on teachers' PDC would be beneficial for new and inexperienced teachers.

# How to design educational material for inclusive classes

Anna Noll, Jürgen Roth and Markus Scholz

University of Koblenz-Landau, Germany; [noll@uni-landau.de](mailto:noll@uni-landau.de)

*Keywords: Inclusion, symbols, easy-to-read, fractions.*

Inclusion is based on international legitimate developments like the Salamanca statement, which emphasizes the right of education for all (UNESCO, 1994). Furthermore, several studies showed that coeducation can have a positive effect on the development of performance of pupils with and without special educational needs (Markussen, 2004). But to include all students regardless of their physical, intellectual, social or other abilities the educational framework conditions need to be adopted at first. One important step into this direction consists in providing all pupils access to the assignments by enhancing their readability.

## Theoretical background

Readability can be enhanced by linguistic simplifications like the application of the *easy-to-read guidelines* (Netzwerk Leichte Sprache, 2006). Easy-to-read language has been established to facilitate understanding in everyday life for people with disabilities. It is, for example, used for the simplification of manifestos in order to support participation in society. So far, these guidelines are not verified scientifically, but show several similarities to empirically based linguistic simplification rules, like the *Hamburger Modell* (Langer, Schulz von Thun, & Tausch, 2011). The authors state, among others, that only one statement should be made per sentence. Another possibility to facilitate the comprehension of assignments is the use of symbols. A symbol can be defined as a graphical image conveying a single idea or concept (Detheridge & Detheridge, 2002). Little empirical data about the use of symbols to foster the readability of texts exists (Jones, Long & Finley, 2007; Poncelas & Murphy, 2007). Nevertheless, a positive influence can be assumed, e.g. because of the multimedia principle (Mayer, 2009). It indicates that people learn better from words and pictures than from words alone. An explanation is given by the cognitive theory of multimedia learning (ibid.) which assumes that pictorial and verbal information are processed in two different channels in our brain. When words and pictures are presented, both channels are used and the cognitive load on the limited capacity of the working memory is reduced.

## Methodology

Does the use of easy-to-read language and/or enriching text with symbols facilitate students' performance in mathematical tasks? This research question shall be answered with the following methodology. The tasks of this study deal with introducing fractions. These are taught in activity-oriented manner with hands-on material. The tasks are divided into two complexes. The first complex aims at the conduction of more basic actions like counting. Then, the pupils receive an input about fractions by watching a video. The pupils use the information of the video for more complex mathematical considerations which are necessary in the second task complex. Thus, the pupils' conceptualization of fractions is fostered, e.g. by the naming and comparison of fractions. In November and December 2016, a pre-study was conducted with 30 students in grade 5, 6 and 7. The sample consisted of pupils with learning difficulties and students without special educational needs. The students worked on the tasks individually and participated in a subsequent interview. Data was

also collected by use of eye tracking and thinking aloud. A first result of the pre-study is that the symbols are used by the students without explanation. This result can be exemplified by the following excerpt of the interview and the corresponding eye-tracking data. The different colors of the heatmap represent different durations of the fixations:

**Figure 1: Primary data insights**

Deeper qualitative analyses, which focus on how the symbols are used by the students as well as on the linguistic comprehensibility of the tasks, will follow. For the main study a posttest-only design, which includes two experimental as well as one control group, is planned. While experimental group 1 receives a linguistically and pictorially simplified version of the tasks, experimental group 2 works with a variation which is linguistically simplified only. The control group receives a not simplified version. After working with the exercises, the students' knowledge about fractions will be measured. The participants' reading ability and their IQ will be elevated beforehand. These control variables shall help to build comparable groups.

# **The application of the Universal Design for Learning framework to task design in order to support lower attaining children in the primary school mathematics classroom**

Caitríona Wynne<sup>1</sup> and Lorraine Harbison<sup>2</sup>

<sup>1</sup>Church of Ireland College of Education (a college of Dublin City University), Ireland;  
[caitronawy@gmail.com](mailto:caitronawy@gmail.com)

<sup>2</sup>CASTeL, Institute of Education, Dublin City University, Ireland; [lorraine.harbison@dcu.ie](mailto:lorraine.harbison@dcu.ie)

*Keywords: Universal task design, mathematics education, inclusion of lower attaining children.*

## **Background to the study**

It is a requirement that all schools in Ireland administer standardized attainment tests in mathematics when children are in 2<sup>nd</sup> Class (aged 7 – 8). On the basis of these results, children who are deemed to have underperformed nationally (Standard Score <90), are usually offered additional support by means of withdrawal from their mainstream classroom for mathematics lessons to work on a complementary program with the learning support teacher. Although it is argued that such provision is offered to less able children as they tend to simply ‘give up’ in classrooms in which they find the mathematical tasks too challenging, the concern is that that these children will fall further and further behind. It is the contention of the authors, that it is not the tasks per se that are too challenging for the children but rather the nature of the tasks, which all too often tend to emphasize traditional practices of rote procedure and drill.

In this study, the researcher, who was working as the learning support teacher, and the class teacher planned together to integrate children back into their classroom by co-designing mathematically rich tasks. Over a four week period, three children who had formerly been withdrawn from the classroom were put to the fore in the planning of the tasks. Particular consideration was given to their learning styles. The mathematical tasks were inspired by the three key principles of the educational framework, Universal Design for Learning (UDL), which constitute Multiple Means of Representation; Multiple Means of Action and Expression; and Multiple Means of Engagement (Rose & Meyer, 2000). The term ‘universal’ is particularly pertinent in the design of the tasks as they were developed in line with specific mathematical learning goals for ‘all’ learners from the beginning rather than implementing a standard ‘one size fits all’ set of tasks and differentiating the tasks to cater for the marginalized, less able children, at a later stage.

Therefore, in order to create learning tasks that will engage all children by design, this research sought to ascertain:

1. How can the principles of UDL be used to design mathematically rich tasks?
2. Do UDL informed tasks engage and support children of low-ability in mathematics?

## **Methodology**

This case study took place over four weeks with one class of 32 children for 45 minutes per day.

The children were aged between eight and nine years old.

It was a detailed body of work comprising collaborative universal lesson design on the topic of 'Measurement', implementation of lessons, critical analysis of tasks and peer review. Each lesson was assessed using an adapted scoring rubric developed by Spooner, Baker, Harris, Ahlgrim-Dezell and Browder (2007). Frequencies of different events were tabulated. Formal observational instruments were developed to recognize and discern certain types of behaviors such as children's degrees of engagement. Observations were supplemented by photographs. Teachers' daily reflections were analyzed using the analytic technique of pattern matching. A matrix of categories was developed and evidence placed within each classification. Information was put in chronological order. A follow up interview was held with the host teacher at the end of the intervention.

## Results

The 14 lessons scored 82 points out of a maximum of 84 points on the adapted scoring rubric (Spooner et al., 2007) implying that a very high level of the UDL approach was used in the task design and implementation. Diversity was the starting point in planning the tasks, with lower ability children being accommodated within and enriching the regular class. The development of positive learning profiles for the three target children, such as, 'needs assigned role during group tasks', or, 'needs to have basic equipment available such as a pencil and a ruler prior to task allocation', helped to remove barriers to and enable participation in learning. UDL tasks offered the children various ways of acquiring information and knowledge; provided alternatives for demonstrating what they knew; tapped into children's interests, gave appropriate challenges, and increased motivation. Multiple means of representation, action and expression, and engagement were used in task design. Video clips were used on five occasions, concrete materials on eight occasions, ICT (PowerPoints, images, interactive stylus and interactive tools) were used during eight lessons, a parallel ICT mathematics program was set as homework for the children on each of the 14 days and the local environment was used on seven occasions. ICT was also found to be a key component that engaged children who were previously observed to be challenged by mathematics.

## Discussion and conclusion

This research revealed that tasks which take into consideration UDL instructional goals, assessments, methods and materials are usable and accessible from the outset rather than having to retrofit the tasks to children's needs as an afterthought. Crucially, results from this study found that by intentionally creating flexible learning opportunities, less able children were engaged and understood difficult mathematical ideas when they were provided with UDL informed tasks.

*In this introduction, we briefly present selected theoretical constructs relevant for the Thematic Working Group 23 (TWG23). We first address the topic of “implementation research” by looking into other research fields and domains where this topic is well-developed. Drawing on a taxonomy of so-called “implementation science” in health-care, we attempt to categorize the papers and posters of TWG23 according to their “implementation research aim” (Nilsen, 2015). Using this taxonomy, we elaborate on future perspectives for the TWG by relating to ongoing discussions in mathematics education research.*

*Keywords: Research findings, research results, theory to practice, implementation research.*

### A need for creating a new CERME Thematic Working Group

With almost five decades of accumulated knowledge, research findings, theoretical frameworks and experiences, the field of mathematics education research now has quite a bit to offer to the ongoing teaching and learning of mathematics in primary, secondary and tertiary education. Regardless of the well-known long and winding “journey” that research results must travel before finding an actual foothold within practice, results from mathematics education research nowadays seem to be present to a much larger extent in practice than ever before – not to say that there is anything strange in this, but rather it is probably only natural given that the field has matured and become successively more and more established over the years.

Indeed, as researchers in mathematics education, we are frequently involved in putting previous empirical results and findings as well as theoretical constructs based on these to good use in mathematics classrooms, mathematics programs, mathematics teacher education, in-service teacher training, etc. In several countries there are ongoing developmental projects that rely heavily on previously documented research results. However, as researchers we often find ourselves in a peculiar situation when wanting to report on these activities, since such accounts do not necessarily fall under the usual paradigm of “research in mathematics education” and do not in a clear-cut manner qualify as either “empirical” or “theoretical research”. To assist in closing this “gap” the purpose of creating a new thematic working group focusing on aspects and issues related to the implementation of research results and findings, is to provide a venue for discussing, collecting and advance the “implementation research” aspects of our activities.

## Implementation research and its aims

In relation to research on actual implementations, mathematics education may profit from other disciplines or areas, where research on implementations is further ahead. Healthcare is one such area, where since 2006 an entire journal has been devoted to “implementation science” (the name of the journal as well). Although the journal of course publishes several empirical studies related to various aspects of implementations, it occasionally also offers theoretical studies focusing on “implementation research” itself. One such theoretical contribution is the study by Nilsen (2015), who proposes a taxonomy consisting of five categories of theoretical approaches in order to make “sense of implementation theories, models and frameworks” (p. 1). Nilsen describes implementation science as “the scientific study of methods to promote the systematic uptake of research findings and other EBPs [evidence-based practices] into routine practice to improve the quality and effectiveness” (p. 2). Although Nilsen focuses on the case of health care, the definition seems adaptable and applicable also to the field of teaching and learning of mathematics. As part of the background for the taxonomy, Nilsen states that “Implementation science has progressed towards increased use of theoretical approaches to provide better understanding and explanation of how and why implementation succeeds or fails” (p. 1). According to Nilsen, the theoretical approaches used in implementation science have three overarching aims:

1. describing and/or guiding the process of translating research into practice (*process models*);
2. understanding and/or explaining what influences implementation outcomes (*determinant frameworks, classic theories, implementation theories*); and
3. evaluating implementation (*evaluation frameworks*).

The five categories of theoretical approaches consist of those provided in parentheses following the aims above. For aim 1, *process models* serve the purpose of breaking down the translation process into smaller steps, stages or phases. For aim 3, *evaluation frameworks* serve the purpose of assisting in evaluating the success – or lack thereof – of a given implementation. More interestingly, perhaps, are the theoretical approaches associated with aim 2. *Determinant frameworks* specify types of determinants that act as barriers and enablers that influence implementation outcomes, or even specify relationships between types of determinants. *Classic theories* are defined as those originating from fields external to implementation science, e.g. psychology, sociology or organizational theory that can be applied to understand or explain aspects of implementation. Finally, *implementation theories* are defined as those which have been developed from scratch within the field of implementation science.

## Implementation research aims of the papers and posters in TWG23

TWG23 received 16 papers prior to the congress. At the congress 14 papers and 1 poster were presented. In the light of Nilsen’s three aims of implementation research (or science), most of the studies presented in TWG23 at CERME 10 in Dublin concerned aim 1, addressing aspects of how to adapt research results and findings to practices in schools or other learning situations. A few of the presented studies touch upon aim 3, i.e. evaluation frameworks. Although it is seldom the main focus of the studies presented, aspects related to aim 2 occasionally surface. We shall return to

potential reasons for this distribution, but first we will use Nilsen's framework to categorize and briefly discuss the papers and posters in TWG23 presented at CERME 10.

In line with Nilsen's aim 1 to guide the process of translating research into practice, **Ärleböck** describes and discusses the framing of, and experiences from, a project that combines research, practice, and teachers' professional development based on the tenets of the "Models and Modeling Perspective" on teaching and learning. Besides providing a general description of the methodological considerations in the project design, the paper describes how the accumulated results and experiences in the research literature on so-called model eliciting activities are used to inform the design, implementation and evaluation of activities aiming at introducing functions to grade 8 students. The focus of the paper is on the implementation, and aims to show how the teacher in question realized the offered perspective and tools in practice. The work presented by **Aguilar, Castañeda and González-Polo** aligns with aim 1 as it illustrates how research results generated in the field of mathematics education can be implemented in the design of mathematics textbook tasks. In particular, it is shown how research findings related to representation registers and to the conceptualization of the concept of function as a process are used in the design of textbook tasks for upper secondary level. The poster by **Chandia and Montes** matches with aim 1, since they report a professional development strategy for teachers focused on improving students' and teachers' problem solving skills. The professional development strategy by Chandia and Montes incorporates research results related to the creation of professional development systems in mathematics. **Bulien** presents theoretical and methodological arguments for the design and implementation of a research based course for pre-service teachers aimed at clarifying and strengthen the connection between didactical and mathematical theories to in-school teaching activities. Drawing on a design experiment methodology and the theory of communities of practice, Bulien elaborates on a "Mathematics Didactics Planning Tool" for teaching in different classroom situations. Thus, this study also relates more closely to Nilsen's aim 1. **Jankvist and Niss** deal with the research-based design and implementation aspects of a so-called "detection test" in relation to upper secondary school students' difficulties with mathematical conventions, concepts and concept formation, in particular those related to equation solving. In a similar manner, **Ahl** addresses the design of a detection test related to students' difficulties with proportional reasoning. Hence, both these studies deal with Nilsen's first aim, that is, translating carefully selected research results from mathematics education into suitable test items. Based on the answers of 405 Year 1 upper secondary school students, Jankvist and Niss also address aspects of evaluation (aim 3). Another research report that corresponds to aim 1 is the one by **Kjeldsen and Blomhøj**. In their work, research findings on students' concept formation and the digital tutorial genre are brought to use in the teaching of a first year calculus course. They present and discuss a theory-based design and its implementation for students' productions of video tutorials aimed at supporting their understanding of the limit concept. It could be said that this work is also related to the aim 3 delineated by Nilsen, since the study examines whether the designed learning environment supports the students' formation of key concepts in calculus or not.

The paper by **Valenta and Wæge** touches on both aim 1 and aim 2 of Nilsen's taxonomy. The paper describes a course aimed at supporting in-service teachers' learning of ambitious mathematics teaching. The design of the course is based on a project called "Learning in, from, and for Teaching Practice Teacher Education Project" (aim 1). In addition, the particular question addressed in the

paper is coupled to aim 2, since it focuses on the learning potential in the interactions between in-service teachers and course instructors during the public rehearsals that are the key innovative feature of the designed course and manifested through cycles of enactment and investigation. The theoretical paper by **Nilsson, Ryve and Larsson** align with Nilsen's second aim (understanding and/or explaining what influences implementation outcomes). They draw upon a systematic literature review on productive classroom practice to construct a framework for categorizing theories aiming at supporting teachers' actions in mathematical classroom practices. They do so by relating to theories and literature on educational policy research, professional development research and implementation research. Related to a larger scale early intervention program, **Lindenskov and KIRSTED** touch upon aspects of Nilsen's aim 2. More precisely, they discuss teachers' perception of "theory" and barriers these may lead to, when implementing research results in practice. In addition, they also address aspects of the translation of theoretical constructs to the teachers as well as the suitability of these constructs provided a given context of practice. The study reported by **Tamborg, Allsopp, Foug and Misfeldt** clearly falls with Nilsen's category of studies related to developing determinant frameworks (aim 2), since it investigates the role of the local supervisor (enabler) in the implementation of a mathematics teacher training program.

**Amit and Portnov-Neeman's** work can be related to the aims 1 and 3 proposed by Nilsen. They report on the implementation of a methodology used to teach reading and mathematics called "Explicit Teaching Method" focused on teaching students the "working backwards strategy" for solving non-routine mathematical problems; on the other hand, the effect of using the explicit teaching method as a means to learn the working backwards strategy is evaluated. **Koichu and Keller** position their paper as so-called design-based implementation research (DBIR) (see later). They present an evaluation framework (aim 3) to analyze and theorize their attempts in creating and sustaining online exploratory problem-solving discussion forums using the conceptual tools provided by Rogers' "Theory of Diffusion of Innovation". **Ejersbo and Misfeldt** report on a design-based research (DBR) project related to developing numeracy in grades K-3. This study too focuses specifically on evaluation aspects (aim 3), not least in terms of improving the design being implemented as well as the future of the project at the local school. **Kuzle's** work somehow touches all three aims outlined by Nilsen. She reports on a collaborative project between educational researchers and practitioners with the goal of developing a problem-solving curriculum for grade 6 students using DBR. The curriculum was developed and implemented based on problem solving research and theory, and through the evaluation of its implementation objective and subjective factors that inhibited the full-implementation of the curriculum were identified.

## Implementation of research findings in mathematics education

As seen above, a few aspects of aim 2 were touched upon in the papers and posters of TWG23, and some papers also considered aim 3. Still, aim 1 appears to be the dominant one among the reported studies. This, however, is not so strange since actual "implementation research" within the field of mathematics education must be regarded as a relatively new trend. This is of course due to the field of mathematics education itself not being much older than fifty years, but at the same time it is mature enough to have produced a sound basis of research results to actually be implemented into the practice of teaching and learning mathematics. Engaged in such implementation-oriented endeavors, researchers in mathematics education work systematically at different levels to establish

evidence-based solutions to the problems and challenges faced by practitioners and learners. Whether the research carried out is empirical or theoretical in nature, *implementation* of research findings and results is at the core of the research activities, either in the form of evaluating and furthering actual practices or materials etc., or to deepen our theoretical understanding to facilitate, guide and support various future implementations. Hence, and as already illustrated by the papers of TWG23, implementation of research findings and results in mathematics education can take many forms and expressions. Further examples from the literature are: in the design of experiments (e.g. Cobb, Confrey, diSessa, Lehrer & Schauble, 2003) and mathematical tasks (e.g. Margolinas, 2013); as tools for professional development of in-service and pre-service mathematics teachers (e.g. Tsamir, 2008; Sánchez, 2011). The research findings and results that are implemented as part of systematic research are typically empirical results, theoretical results in terms of frameworks of different kinds, or some mixture of the two. Still, such findings and results usually fall within Nilsen's first and third aims, whereas results directly concerning aim 2 are scarcely touched upon.

As seen from the presented research studies of TWG23, implementation of research findings may have connections with research areas already existing in the field of mathematics education. One such example, although not reported in TWG23 at CERME 10, is that of *lesson study*. In the lesson study approach, lessons are designed and analyzed as a means to improve mathematics teaching in the classroom, but also as a means for professional development of mathematics teachers. Another existing research area, represented in TWG23, is that of task design. Hence, from the presented papers, it is clear that "implementation research" encompasses different kinds and formats (textbooks, apps, software, etc.) of didactical designs and products, stretching from task design, over teaching modules, courses, to entire programs – on all educational levels. Yet an example is that of design-based research (DBR), where results might take the form of a teaching module that successively and iteratively have been envisioned, designed, applied, analyzed and redesigned. The result is the final design as well as measures of how successful the design has proven to be. However, to focus on the implementation aspect of DBR means to not only focus on the end product and its success in achieving what was set out to do, but also to seriously take into account the "design phase" of the design research cycle. That is, the phase where the researcher identifies a learning problem and then uses available research results to design a (preliminary) product or tool that can help students in overcoming this learning problem. A primary concern then becomes to focus precisely on the way research knowledge is applied to generate some type of educational product. Elements of these concerns are addressed by Fishman and colleagues (2013), who forefront the implementation aspects of DBR in a research approach they call design-based implementation research (DBIR) – a framework also used in a few of the papers presented in TWG23. In short, DBIR has:

"(1) a focus on persistent problems of practice from multiple stakeholders' perspectives; (2) a commitment to iterative, collaborative design; (3) a concern with developing theory and knowledge related to both classroom learning and implementation through systematic inquiry; and (4) a concern with developing capacity for sustaining change in systems." (Fishman and colleagues, 2013, pp. 136-137)

More generally, an important aspect when implementing research findings and results into practice is to focus on what Burton (2005) has called the *methodology* of the research conducted. Burton

argues that researchers in mathematics education in general pay little or no attention to explaining and motivating the rationale for the actual research design they apply to be able to draw the conclusions they report when writing up their research. This “craft knowledge” of the researcher is in a way silent. In Burton’s opinion, accounts of research is full of descriptions of how results were obtained (i.e. what the explicit methods applied were), whereas elaborations on *why* choices were made and decisions taken in order to arrive at conclusions are rarely found. The *how*-question concerns the *methods* used by the researcher to undertake his or her research, while the *why*-question focuses on the rationale for the research design, i.e. the *methodology*. That more emphasis should be put explicitly on the methodology has also been put forward by for example Wellington (2000), who describes methodology as “the activity or business of choosing, reflecting upon, evaluating and justifying the methods you use” (p. 22). He further argues that it is necessary to know the methodology of a piece of research to be able to impartially judge and assess it. TWG23 provides a venue and forum for researchers to discuss *how* to best put research results to use in practice alongside the accompanying rationale for *why*. In this sense, TWG23 has as one of its primary foci *methodologies* for initiating and institutionalizing *research-based implementation designs*. Over time, the activities of such a group could also make us wiser on the actual usefulness of our various research results, constructs, and frameworks.

## Perspectives for the TWG at future CERMEs

Although the main focus of TWG23 seems currently to be on Nilsen’s first aim, and to some extent the third aim, in time the TWG may potentially contribute much more to the second aim: in identifying determinants across various countries; in identifying relevant classical theories external to mathematics education, which may help to understand or explain implementations; and last but not least in developing homegrown *implementation theories of mathematics education*. This was also reflected in the evaluation of the TWG, where the question was asked: What shall be TWG23’s contribution of knowledge to the field of mathematics education? The participants of the TWG collectively phrased the following “vision” for the group:

“We want to explore a wide variety of ‘good examples’ of implementing research findings and results (back) into practice in order to improve the teaching and learning of mathematics at all educational levels on a research-based foundation. Over time we may begin to look into the aspects of research on implementations, potential requirements for these to function, etc.”

Hence, for the future of TWG23, it may be envisioned that the TWG could come to consist of a core of researchers interested in these aspects (Nilsen’s second aim). But at the same time, a group like TWG23 is also a place for mathematics education researchers to go when wanting to report and discuss on any “intermediate” activities of either designing new research projects or developmental work, before the activities may result in more traditional research to be reported in other TWGs. In this sense, TWG23 also provides a forum for mathematics educators at CERME to “come and go” from one congress to another.

To put it a bit boldly, it is our hope that this TWG can assist in filling the “gap” of where to report on implementation activities in our research community, while at the same time act as a “bridge” between research and practice.

*The aim of this paper is to illustrate how the research results generated in the field of mathematics education could be implemented in the design of mathematics textbooks tasks. First we present research findings related to the concept of function, particularly findings related to representation registers and to the conceptualization of function as a process. Next we illustrate with examples obtained from a high school textbook, how these research findings can be implemented in the design of mathematical tasks. We close the manuscript with a reflection on the implications for research that this kind of implementation may have.*

*Keywords: Textbook development, functions, task design, implementation of research findings.*

## Introduction

As noted in the call for papers for the Thematic Working Group 23, *implementation research* can encompass a wide range of different kinds of didactical designs on a broad range of formats. In this work we focus on the use of research findings in the design of mathematics textbooks. More particularly, we will address research findings related to the learning of the mathematical concept of function and its implementation in the design of tasks included in a mathematics textbook for upper secondary level.

Textbooks play an important role in the teaching and learning of mathematics. For example, textbooks can affect teaching strategies by conveying pedagogical messages to mathematics teachers (Fan & Kaeley, 2000); also, mathematics textbooks can contribute to the creation and strengthening of students' misconceptions (Kajander & Lovric, 2009), and even the content selection and presentation of materials in a textbook appear to influence learners' participation and success in mathematics (Macintyre & Hamilton, 2010). Due to the huge influence that textbooks can exert in the dynamics of the mathematics classroom, over time there has been a growing interest in developing new and high-quality textbooks, however as pointed out by Li, Zhang & Ma (2014), "there are a very limited number of studies available that examine and discuss textbook design and the process of textbook development" (p. 306). Even more rare are the studies considering the implementation of research results in the design and development of mathematics textbooks, which it is the main focus of this manuscript.

The aim of this paper is to illustrate how research results produced in the field of mathematics education can be implemented in the design and development of tasks for mathematics textbooks. To achieve this we identify some research findings related to the concept of function and illustrate how they were used in the development of tasks for a high school mathematics textbook that is currently in use in the Mexican education system.

## On the concept of function and research findings associated with it

We have focused our attention on the concept of function because it is a fundamental concept in the mathematical knowledge and as such plays a major role in mathematics textbooks (Mesa, 2000), particularly in those of middle and upper level. Because of its status and importance in the corpus of mathematical knowledge, educational research around this concept has been developed for several years and its results could be useful in the process of designing textbooks. In the next section we mention some research findings associated with this concept that we ourselves have implemented in the design of mathematical tasks included in upper secondary level Mexican textbooks.

### What do we mean by «research findings»?

The products or results generated by research in mathematics education can be varied and fluctuate in a range that goes from tangible products (such as textbooks, educational activities, software) to more abstract products (such as constructs and theories). When we use the term «research findings» in this work we refer to information that has been obtained or discovered through empirical research and that can be expressed through observations, identification of obstacles and students' modes of thinking, didactical suggestions, etc.

We argue that this type of information may be applicable in designing mathematical tasks included in textbooks. Next we present some examples of research findings connected to the learning of the concept of function, whose implementation will be illustrated below.

### What research says about the learning of the concept of function?

*Different representations of the concept should be encouraged.* Some students' difficulties connected with the concept of function can be attributed to the procedural emphasis with which this concept is taught, and also to the lack of variety in the representation contexts in which this concept is illustrated and manipulated.

Research has shown that many students possess prototypical visions of the concept of function. For instance, they tend to assume that functions are linear or quadratic in cases where this assumption is unwarranted, so for example they tend to think that “u-shaped” graphs are parabolas (Schwarz & Hershkowitz, 1999); Carlson & Oehrtman (2005) suggest that this difficulty may be related to the fact that many teachers introduce the concept of function through prototypical examples, which often are linear or quadratic. Thus, they suggest that the concept of function instruction should include more opportunities to experience different types of functions emphasizing different contexts of representation.

This is in line with the observations of Duval (2000). He claims that the conceptual understanding of a mathematical object becomes more robust when there is coordination between representation registers. Each register highlights certain characteristics and properties of the mathematical object, and the interaction between these registers allows for a broader conceptual understanding, so it is important to promote tasks that favor the transit between such representation registers, particularly the transit in directions that are not usually addressed in school, such as transit from the graphical register towards the algebraic one.

*A dynamic vision of function as a process should be promoted.* A common practice in the teaching of mathematics is to represent functions as static objects, however it has been suggested that

students must possess dynamic interpretations of this concept in order to favor a conceptualization of function as a process (Carlson, Oehrtman & Engelke, 2010). For instance, Figure 1 represents the area under a curve defined by a function  $f(x)$ , and it does not promote a dynamic conceptualization of the area function; to achieve such dynamic conceptualization the student should imagine that point  $b$  moves and in doing so the shaded area  $S$  increase or decrease its size.

**Figure 1: «Static» representation of an area under a curve**

This type of static conceptualizations is closely related to an *action view of functions* (Dubinsky & Harel, 1992):

An *action* conception of function would involve the ability to plug numbers into an algebraic expression and calculate. It is a static conception in that the subject will tend to think about it one step at a time (e.g., one evaluation of an expression). (p. 85)

However, an action view of functions may result in an impoverished conceptualization of the concept; for instance, students with an action view often think of a function graph as being only a curve, a fixed object in the plane, they do not think the graph as defining a general rule where a set of input values are mapped to a set of output values (Carlson & Oehrtman, 2005). It is desirable to move students from an *action view of functions* to a *process view of functions*:

A process conception of function involves a dynamic transformation of quantities according to some repeatable means that, given the same original quantity, will always produce the same transformed quantity. The subject is able to think about the transformation as a complete activity beginning with objects of some kind, doing something to these objects, and obtaining new objects as a result of what was done. (Dubinsky & Harel, 1992, p. 85)

Is difficult to achieve this transition from static to a dynamic view of functions, however it has been suggested that technological tools can help in this transition. For example Borba & Confrey (1996) have suggested an approach to the study of functions based on visualization and the use of software; the approach focuses on the relationship between graphs and tabular values, and on the relationship between graphs and algebraic representations. For instance students could be asked to use the software to graph and explore how the coefficients of a quadratic function relate to translations, stretches and reflections of its graph.

## Examples of implementation of research findings in the design of mathematics textbooks tasks

As we have claimed before, we believe that research findings as those previously presented can be implemented in the design of tasks for mathematics textbooks. We are aware that there may be different types of «implementation of research findings»; although it is not our intention to discuss such distinction here, we do want to clarify that in this work the «implementation of research findings» is interpreted as taking results or suggestions produced through research, and to use them as a source of inspiration for the design of mathematical tasks. To illustrate this point, next we present examples of tasks that were designed taking into consideration the research findings previously discussed. These tasks are included in the text González-Polo & Castañeda (2014), which was developed by the second and the third authors of this article. This is a textbook for high school level that is currently in use in the Mexican educational system; high school in Mexico traditionally consists of three years of education divided into six semesters, and this book is used in the fourth semester. Its print run for 2015 was 10,000 copies. The tasks proposed in the textbook are unpublished, but some of them have been inspired by tasks used as tools in the development of research in mathematics education.

### Tasks to study functions in different representation registers

As mentioned before, research suggests that the concept of function should be studied and manipulated in different representation registers, but also should be promoted the transit between such representation registers, especially in directions that are not habitually addressed in school.

To implement this research-based suggestion, we have designed activities that require the student to transit from a graphical representation register to an algebraic register, when the usual is to ask students to start from an algebraic expression to generate a table of values, and from this table trace the graph of the function. Figure 2 shows an example of this kind of task.

**Figure 2: Task that requires the student to transit from a graphical register to an algebraic register**

The English translation of the task instruction is as follows: «The graph in figure 1.66 belongs to a first degree polynomial function. Determine the new function obtained by rotating the graph  $90^\circ$  to the right leaving the coordinate  $(0, 0)$  as a fixed point». In this task the student must start working on a graphical register—rotating the graph  $90^\circ$  clockwise—and then determine the algebraic expression that defines the new function, which in this case would be  $f(x) = -x$ .

Another example is shown in Figure 3. This is an activity in which the study of the concept of constant function in different representation registers is promoted, although contrary to usual, the student is required to transit from a numerical register—a table of values—to an algebraic register.

1. Una boya en el Océano Pacífico mide la salinidad del agua (cantidad de NaCl, cloruro de sodio). Sus registros cada hora son enviados vía satélite a una base meteorológica para su análisis. La tabla 3.4 muestra la información obtenida en un intervalo de 14 horas.

a) Ubica las coordenadas sobre el plano y traza la gráfica resultante.  
b) Escribe una función que mejor se adapte a los datos graficados.  
c) Describe verbalmente la tendencia de la gráfica, es decir, ¿cómo se comportarán los datos en las siguientes horas?

¿Qué operación debes aplicar para trasladar verticalmente la gráfica de la función constante?

**Ejercicios**

1. Traza la gráfica de las siguientes funciones:

a)  $f(x) = \frac{1}{2}$       b)  $f(x) = \sqrt{2}$       c)  $f(x) = \pi$

2. Determina la función constante que pasa por el punto  $(-2, 1.7)$  y traza su gráfica.

3. Sea  $f(x) = 2$ , para cada inciso escribe la función resultante, y obtén la gráfica.

a)  $2[f(x)]$       b)  $\frac{f(x)}{f(x)}$   
c)  $f(x) + 2$       d)  $f(x) \cdot f(x)$

**A2**

Hora	Gramos por litro
1	35.01
2	35.02
3	35.01
4	35.01
5	35.01
6	35.01
7	35.03
8	35.02
9	35.02
10	35.01
11	35.01
12	35.01
13	35.02
14	35.01

Tabla 3.4

**Figure 3: Task that requires the student to transit from a numerical register to an algebraic register**

The English translation of the task instruction is the following:

«A buoy in the Pacific Ocean measures salinity (the amount of NaCl, sodium chloride). The measures are sent every hour via satellite to a meteorological database for analysis. Table 3.4 shows the information obtained during an interval of 14 hours.

- a) Locate the coordinates on the plane and trace the resulting graph
- b) Write the function that best fits the data graphed
- c) Describe verbally the trend of the graph, i.e., how the data will behave in the next few hours?»

The interpolation requested in paragraphs b) is somewhat facilitated because the function that best fits the data provided is a constant function, which in this case could be the function  $f(x) = 35$ . It is important to note that the activity is complemented by the question: «What operation should you apply to vertically translate the graph of the constant function?». This question attempts to engage the student in a dynamic conceptualization of the constant function, that is, to be able to understand that the graph of a constant function  $f(x) = k$  will move vertically by adding another constant  $c$  obtaining thus the graph of the function  $f(x) = k + c$ .

### Tasks to promote a process view of functions

Inspired by the approach proposed by Borba & Confrey (1996) in which functions are studied with a strong emphasis on the visualization of their graphs, we have included tasks where students are asked to explore the graphical behavior of functions using software. It is assumed that these kinds of activities promote a dynamic conceptualization of functions where the graph is not interpreted as a fixed or static entity. An example of this type of task is shown in Figure 4.

A2

1. A partir de la forma general  $f(x) = a^x$  se puede:

Multiplicar la función por una constante	$f_1(x) = k \cdot a^x$
Multiplicar el exponente por una constante	$f_2(x) = a^{kx}$
Sumar al exponente una constante	$f_3(x) = a^{k+x}$
Sumar una constante a la función	$f_4(x) = a^x + k$

a) Utiliza un graficador para obtener las gráficas de las siguientes funciones.

• $k = 2$	$f_1(x) = 2 \cdot 2^x$	$f_2(x) = 2^{2x}$	$f_3(x) = 2^{2+x}$	$f_4(x) = 2^x + 2$
• $k = 3$	$g_1(x) = 3 \cdot 2^x$	$g_2(x) = 2^{3x}$	$g_3(x) = 2^{3+x}$	$g_4(x) = 2^x + 3$
• $k = 5$	$h_1(x) = 5 \cdot 2^x$	$h_2(x) = 2^{5x}$	$h_3(x) = 2^{5+x}$	$h_4(x) = 2^x + 5$

b) Analiza el comportamiento de cada grupo de gráficas y explica cuál es el efecto en la gráfica al variar la constante  $k$ .

**Figure 4: Task requesting the student to use graphing software to explore the effect of parameters on the graph of a function**

The task takes as its starting point the function  $f(x) = a^x$  and the constant  $k$ . Then the student is asked to use software to explore the effects that different integer values of the parameter  $k$  produces in the graph of the following functions:

$$f_1(x) = k \cdot a^x$$

$$f_2(x) = a^{k \cdot x}$$

$$f_3(x) = a^{k+x}$$

$$f_4(x) = a^x + k$$

## Discussion

In this article we have tried to illustrate how some research findings related to the learning of the concept of function can be implemented in the design of tasks for mathematics textbooks. If one of our aims as mathematics educators is to bring products that are generated in our discipline closer to the school society (teachers, students, administrators, parents, etc.), then the textbooks are a privileged outlet for this purpose since it allows to bring research findings into the heart of formal mathematics instruction: the mathematics classroom.

Our enthusiasm as authors of textbooks and as researchers in mathematics education incline us to think that these tasks with a research-based design can be productive and beneficial for students' mathematical learning, but what evidence is there to support these enthusiast assumptions? It would be necessary to develop studies from different perspectives that could allow us to understand how the textbook mathematical tasks are enacted in the classroom, and the type of conceptions and perspectives that they produce on students.

Regarding the actual design of the tasks, in her reflections on textbook design, Yerushalmy (2015) has suggested that the tasks appearing in textbooks—or more precisely the mathematical concepts involved in such tasks—can be organized around objects and operations that can mathematically and pedagogically support a variety of progressions and sequences. For example, in the case of functions, it can be considered an organizational map that clarifies the type of mathematical object involved in the task (like linear or quadratic functions), but also the type of operations required in the task such as represent, modify, transform, analyze, operate or compare), where each operation can take place in symbolic, graphic, or numeric representations (see figure 5).

Symbolic/ Graphic/ Numeric						
Operation Objects	Represent	Modify	Transform	Analyze (function change)	Operate (with 2)	Compare
Generic						
Linear						
Quadratic						

**Figure 5: Example of an organizational map for the tasks included in a textbook. Taken from Yerushalmy (2015, p. 243)**

This type of organizational maps can make the design of tasks more transparent, that is, to render explicit the mathematical objects involved in the tasks as well as the operations that are performed on them. These maps can work as a framework that helps both textbook designers and users to identify gaps in the presentation of concepts, and produce a sequencing of tasks that addresses the largest possible number of operations and contexts of representation with the intention to provide students with a richer picture of the mathematical objects studied.

Finally, it is important to note that in addition to the textbook González-Polo & Castañeda (2014), there is a teacher's guide explaining in more detail the theoretical background on which the design of the tasks is based, as well as their purpose. This kind of guide represents a fundamental support to achieve a classroom implementation of mathematical tasks that is faithful to the intentions of the task designers.

# Designing a research-based test for eliciting students' prior understanding on proportional reasoning

Linda Marie Ahl

Kriminalvården, Section for adult education, Sweden; [linda.ahl2@kriminalvarden.se](mailto:linda.ahl2@kriminalvarden.se)

*Mathematics education in the Swedish prison education program is struggling with a high rate of students that fail to pass the basic mathematics courses. One of the main issues seems to be the challenge for the teachers to elicit students' widespread prior mathematical knowledge. The consequence of this is that the teachers cannot meet the students' educational needs with meaningful teaching activities. Focusing on the most pervasive mathematical idea in these courses, proportional reasoning, a test was designed that aimed to elicit students' mathematical reasoning. This paper illustrates that by making use of accumulated and selected research results and findings, we can gain valuable information on students' proportional reasoning competency. This information may be used as an access point for individualized instruction.*

*Keywords: Adults, individualized instruction, proportional reasoning, prison education.*

## Introduction

In the Swedish prison education program, only two out of ten students finish and pass their mathematics courses<sup>1</sup>. This is disturbing in itself, but particularly so given the resources available. The teachers are university trained upper secondary school mathematics teachers, and the students sign up voluntarily and typically are highly motivated. Moreover, all courses are individually designed for each student, which should ensure good teaching and learning conditions. However, a challenge is that the student group shows significant variation in age, ethnicity, socioeconomic background, school background and life experience in general. For the basic mathematics, the mathematics in compulsory school and the first course in upper secondary school, there exists no such thing as one course design that suits all students' different backgrounds. In 2015 the Swedish prison education program in mathematics had 728 students enrolled, spread across 47 prisons, and 80% of these were found in the basic mathematics courses

A plausible reason for the low pass rate in the basic courses is that the teachers fail to make proper use of the individualization possibilities. A prerequisite for actual individualization is that teachers have the opportunity to find out students' prior mathematical understanding and adapt the teaching accordingly. Realizing that this opportunity hinges on the teachers' competencies, e.g., they need to put their didactic and pedagogical *teaching competency* to play (Niss & Højgaard, 2011). But teachers' possibilities to individualize instruction might also depend on various forms of support. Inspired by Jankvist and Niss (2015), I report on a research-based effort to develop such support: a test for identifying beginner students' prior mathematical understanding. The test needs to provide information on students prior understanding in two ways: vertically, in relation to progression throughout school years, and horizontally, throughout taught topics in compulsory school. Hence, a major design decision was to focus the content on proportional reasoning. As will be argued below, proportional reasoning permeates the basic mathematics courses in a systematic way, which means that probing students' competencies in this area gives a good access point for individualized teaching. The foundation for the test is the accumulated and selected research results and findings related to proportional reasoning, since proportionality may be the most important, pervasive and powerful idea in elementary school mathematics (Behr, Harel, Post, & Lesh, 1992; Lamon, 2007).

Constructing such a test involves several design decisions involving the content and form of the test, as well as constructing, collecting and adapting test items that realize these design decisions. The

main question elaborated on in this paper is: *How can research findings inform the development of a test that elicits students' prior understanding on proportional reasoning so as to provide teachers with an access point for designing individualized teaching?*

## Theoretical underpinnings for the development of the test

Mathematical reasoning is one of eight competencies for identifying and analyzing students' mathematical understanding, described in the Danish KOM-project (Niss & Højgaard, 2011). "The *mathematical reasoning competency* consists, first, of the ability to follow and assess mathematical reasoning, i.e., a chain of arguments put forward – orally or in writing – in support of a claim." (Jankvist & Niss, 2015, p. 264). The kind of mathematical reasoning called proportional reasoning is a prerequisite for successful further studies in mathematics and science, since multiplicative relations underpin almost all number-related concepts studied in elementary school (Behr et al., 1992; Lamon, 2007). A proportion is defined as a statement of equity of two ratios  $a/b = c/d$ . Proportion can also be defined as a function with the isomorphic properties  $f(x+y) = f(x) + f(y)$  and  $f(ax) = af(x)$  (Vergnaud, 2009). A function,  $A(x,y)$ , can also be linear with respect to several variables, (n-linear) functions. For example the area functions for a rectangle with sides  $x$  and  $y$  is bilinear (2-linear) since  $A(x,y) = xy$  and it is easy to check that this function is linear with respect to each of its variables when the other is considered constant.

Proportionality is a key concept in mathematics and science education from elementary school to university (Lamon, 2007). Despite the pervasive nature of proportional reasoning throughout the school years it is well known that children around the world have considerable difficulty in developing the mathematical competency to reason about fractions, percentages, ratio, proportion, scaling, rates, similarity, trigonometry, and rates of change (Behr, Harel, Post, & Lesh, 1992; Lamon, 2007). Typically, proportional reasoning problems come in the shape of a missing value problems or comparison problems (Lamon, 2007). In the former, a multiplicative relation is present where three elements are provided and the fourth is to be found. The latter asks the student to compare which ratio is the bigger or smaller.

From accumulated research, some *key points* for the developing of proportional reasoning and the building of multiplicative structures can be identified (c.f. Behr, Harel, Post, & Lesh, 1992; Fernández et al., 2012; Lamon, 2007; Shield & Dole, 2013; Van Dooren, De Bock, Vleugels, & Verschaffel, 2010; Vergnaud, 1983). Students need to:

1. Be able to distinguish additive from multiplicative reasoning and recognize when a multiplicative relation is present;
2. Be able to draw connections to the algebraic rules for fractions when working with part/part ratios, part/whole fractions and proportions,  $a:b = c:d$ ;
3. Recognize and use a range of concrete representations for proportions, e.g., tables, graphs, formulas and drawing pictures;
4. Acknowledge the properties of geometrical objects in two- and three dimensions for calculation of scaling and similarity.

*Key point 1.* Research studies and findings show that the ability to distinguish additive from multiplicative comparisons constitute a major stumbling block for students (Van Dooren et al., 2005). Students need to be able to recognize that a proportional situation exists when the comparison is multiplicative (Shield & Dole, 2013). In Sweden, students get acquainted with additive strategies for reasoning about quantities in grades 4 to 6. For example, an increase in price by 10% can be calculated in two steps. First, calculate how much 10% is and then add this to the original price. A transition from an additive to multiplicative thinking approach is introduced in grades 7 to 9. The new price can now be approached in one multiplicative step: the original price multiplied by the factor 1.1, to find

the new price. Far from all students embrace this new idea of approaching percentage change. The additive approach works well for calculating a single increase or decrease, while they may lack motivation to change strategy.

Fernández et al. (2012) found that the error of using additive strategies on proportional situations increased during primary school and decreased during secondary school. A desirable development in students' reasoning would be that they, after being introduced to multiplicative reasoning, still hold on to their ability to use additive strategies when appropriate. However, research findings show that once students have been introduced to multiplicative strategies they tend to overuse this approach on everything that resembles a proportional situation (Van Dooren et al., 2005). Further, non-integer ratios cause more errors than integer ratios (Fernandez et al., 2012; Gläser & Riegler, 2015), while the non-integer situations can be considered to require a more developed understanding of rational numbers.

*Key point 2.* Many situations require that students can relate to part/part ratios and part/whole fractions (Vergnaud, 1983). For example, if a company employs 11 women and 31 men, the part/whole fractions  $11/42$  and  $31/42$  represent the relation of women and men related to the whole. If asked to determine the company's gender distribution, it is instead the part/part ratio 11:31 between women and men that is relevant. When a ratio connects two parts of the same whole, students may not adequately recognize the difference between part/part and part/whole relationships (Clark, Berenson, & Cavey, 2003). It is not easy for students to approach situations that require shifting from part/part to part/whole situations. Moreover, students need to connect mathematical ideas. Since ratios can be written in fraction form, they obey the same mathematical laws as fractions (Shield & Dole, 2002).

*Key point 3.* Another stumbling block for students is that they tend to apply linear proportional reasoning on scaling, without considering the nature of the item. Van Dooren et al. (2010) found that students tend to use linear proportional reasoning even when it is inappropriate e.g., in word problems where a real word context is required to solve the problem. For example: *Farmer Gus needs 8 hours to fertilize a square pasture with sides of 200 meters. Approximately how much time will he need to fertilize a square pasture with sides of 600 meters?* Recognizing this as a missing value problem i.e., three values given and one unknown, this problem will trigger a cross-multiplication type solution which gives the wrong answer of 24 hours. Since scale is one of the major themes that span mathematics, chemistry, physics, earth/space science and biology it is crucial for students to gain understanding of the concept of scale. Scale in one, two, and three dimensions is a central unifying concept that crosses the science domains, crucial for understanding science phenomena (Taylor & Jones, 2009).

*Key point 4.* Proportionalities can be represented in different ways, e.g., with words, pictures, algebraically, with graphs or tables. Shield and Dole (2013) enhance the use of a range of representations to promote students' learning. If students are given the opportunity to work with graphs, tables and other diagrams that illustrate the proportional situation present in the mathematical task, their conceptual understanding is promoted (Vergnaud, 2009). Further, their ability to see connections between problems that are based on the same mathematical idea is enhanced, e.g. to see that missing value problems on similarity, proportional functions and speed problems can be illustrated with different representations but approached with the same mathematical idea.

Several concepts are in play when students reason with proportional quantities. The intertwined concepts required for the development of proportional reasoning makes up a *conceptual field* (Vergnaud, 2009). A conceptual field is a set of situations and concepts tied together. As the theory of conceptual fields show, together with other well-known theoretical frameworks for conceptual understanding, the meaning of a single concept does not come from one situation only (Sfard, 1991; Tall & Vinner, 1981; Vergnaud, 2009) but from a variety of situations demanding mathematical reasoning related to the concept in question. The conceptual field of intertwined concepts in play in

proportional reasoning cover at the least “linear and n-linear functions, vector spaces, dimensional analysis, fraction, ratio, rate, rational number, and multiplication and division” (Vergnaud, 1983, p. 141). It is the complexity of the concepts in play together with the pervasive nature of proportional reasoning from elementary school to university that makes proportional reasoning suitable for the design of the test.

## Design of the test on proportional reasoning

An important design choice for the test was to use a multiple-choice design. Even though open response tests are a powerful method to elicit students’ understanding, the advantages of multiple-choice tests were in this case considered to be the best option. An open response test can be a negative experience for students with low prior understanding, since they may be unable to supply any answers. Since the students often have bad experiences from school mathematics, we want to avoid negative experiences in the beginning of a mathematics course. A multiple-choice test, on the other hand, is easy to take for the students. Even when they do not have the mathematical competencies to reason and solve an item, they can still provide an answer by intuition or chance. The test is designed to be followed up with student interviews. This is an important step since many students do not have Swedish as their mother tongue, which of course may cloud their interpretation of the items. Many of the students also have concentration difficulties, so a written test may not give a satisfactory picture of students’ prior understanding.

A downside of multiple-choice is the possibility to choose the right answer by chance. For this reason, a two-tier design was chosen (see examples below) yielding only 0.125 probability to pick both the right *true* or *false* value and the right claim. A pilot version of the test, consisting of 22 items, was tried out in April 2016. Feedback from the participants informed me that the test was too long and that some of the items were difficult to interpret. After revision and further testing, the resulting test consists of 16 proportional reasoning items. The final version of the test takes about 20 to 40 minutes to complete, without any time pressure.

The items in the test were chosen from published research papers, with the intention to draw on knowledge from the research field on proportional reasoning. The rationale for my choices is as follows: a) the items have already been proved to work well for giving information on students’ understanding, and b) extensive background information of the nature of the mathematical reasoning in play are provided as well as analyzes of students results. Referring to the *key points* presented in the theory section, the potential reasoning related to each item involves several concepts and abilities, yet the items can still be categorized as referring mainly to one or two of the four presented key points:

*Key point 1.* Students’ ability to distinguish additive from multiplicative reasoning and recognize when a multiplicative relation is present, and is always required for carrying out proportional reasoning, however mainly tested by items 1, 5, 6, 7, 11 and 16.

*Key point 2.* Students’ ability to draw connections to the algebraic rules for fractions when working on part/part ratios, part/whole fractions and proportions,  $a:b = c:d$ , is mainly tested by items 2, 4, 12, and 13.

*Key point 3.* Students’ ability to recognize and use a range of concrete representations for proportions, e.g., tables, graphs, formulas and drawing pictures is mainly tested by items 3, 8, 9 and 15.

*Key point 4.* Students’ ability to acknowledge the properties of geometrical objects in two- and three dimensions for calculation of scaling and similarity is mainly tested by items 8, 10, 13 and 14.

Several errors on items referring to the same *key point* indicate a lack of understanding that should be investigated further in the following student interview. The test items are also adapted to mirror the progression throughout the basic course. Items 1 and 4 refer to content taught in part two of the basic

course. Items 2, 3, 6 and 10 deal with content from part three and part four is reflected in items 7, 8, 9 and 11-16.

Key points <hr/> Basic course	Distinguish additive from multiplicative reasoning	Draw connections to the algebraic rules for fractions	Recognize and use a range of concrete representations	Acknowledge the properties of geometrical objects
Part 2	Item 1	Item 4		
Part 3	Item 5 Item 6	Item 2	Item 3	Item 10
Part4	Item 7 Item 11 Item 15 Item 16	Item 12 Item 13 Item 16	Item 8 Item 9 Item 15	Item 8 Item 13 Item 14

Table 1. Schema over items in relation to key points and progression in the basic courses

The sources for the test items are: Hilton, Hilton, Dole, and Goos (2013); Fernadéz et al. (2012); Niss and Jankvist (2013a; 2013b); and Gläser and Riegler (2015). The items from Hilton et al. were already designed as two tier multiple test items. The other items were adapted from their original design to a multiple-choice design, using erroneous answer alternatives either reported in the original studies or answer alternatives recalled from my experience from teaching.

## Examples of test items

In what follows, I will exemplify how research results on common difficulties on proportional reasoning are guiding the choice of the test items. To illustrate, items included to elicit students' difficulties to discriminate *additive* from *multiplicative* situations and difficulties with *scaling* are displayed below.

Consider this item, adapted from Fernadez et al. (2012):

Loading boxes: Petra and Tina are loading boxes in a truck. They started together but Tina loads faster. When Petra has loaded 40 boxes, Tina has loaded 160 boxes. ***When Petra has loaded 80 boxes, Tina has loaded 200 boxes.***

**True or False** because (choose the best reason)

- a) Tina will always be 120 boxes ahead of Petra.
- b) Petra loads faster than Tina.
- c) Tina loads 4 times faster than Petra.
- d) Tina loads with double speed.

This is a proportional situation where Tina is loading 4 times faster than Petra, so the claim “***When Petra has loaded 80 boxes, Tina has loaded 200 boxes.***” is false. Students should consider whether it is appropriate to use additive reasoning, that is, if Tina has still loaded 120 boxes more than Petra. If the students answer *a) Tina is always 120 boxes ahead of Petra*; further investigation of their reasoning strategies is required, though the answer indicates that there may be a lack of transition from additive to multiplicative thinking. This suspicion is further strengthened if the student is successful in items requiring additive reasoning, like in the item below, from Hilton, et al. (2013):

Running laps: Sara and Johan runs equally fast around a track. Johan starts first. When Johan has run 4 laps, Sara has run 2 laps. **When Sara has completed 6 laps, Johan has run 12 laps.**

**True or False** because (choose the best reason)

- a) The further they run; the further Johan will get ahead Sara.
- b) Johan is always 2 laps ahead of Sara.
- c) Johan completes double the laps of Sara.
- d) Sara has run 3 lots of 2 laps to make a total of 6 laps, so Johan must have run 3 lots of 4 laps to make a total of 12 laps.

This is an additive situation where Sara and Johan run at the same speed. Students should consider whether it is appropriate to use multiplicative reasoning, that is, if Johan runs 3 times faster than Sara. If the students answer d) *Sara has run 3 lots of 2 laps to make a total of 6 laps, so Johan must have run 3 lots of 4 laps to make a total of 12 laps*, further investigation of their reasoning strategies is required though the answer indicates that a difficulty to discriminate multiplicative from additive situations exists.

The two examples above illustrate how research findings on proportional reasoning have been used in the design of the test. By including items requiring multiplicative reasoning as well as items requiring additive reasoning you may elicit the students' ability to discern when a multiplicative situation is present.

The Dice- and the Circle item below are adapted from Niss and Jankvist (2013b), The Dice item is originally phrased: *A cube of wood with all edges 2 cm weighs 4.8 grams. What weighs a cube of wood, where all edges are 4 cm? Justify your answer.* [En terning af træ med alle kanter lik 2 cm vejer 4.8 gram. Hvad vejer en terning af træ, hvor alle kanterne er 4 cm? Begrund dit svar.] I added the claim: **“A wooden dice where all edges are 4 cm weight 19.2 g.”**, and the response alternatives.

Dice: A wooden dice where all edges are 2 cm weighs 4.8 g. **A wooden dice where all edges are 4 cm weight 19.2 g.**

**True or False** because (choose the best reason)

- a) The weight increases 4 times if the edge doubles.
- b) The weight increases 6 times if the edge doubles.
- c) The weight increases 8 times if the edge doubles.
- d) The weight doubles if the edge doubles.

Circle: **Simon says that if you draw a new circle with half the diameter of another circle, the new circle will have half the perimeter and half the area of the other circle.**

**True or False** because (choose the best reason)

- e) If the diameter is halved, the perimeter and area is halved.
- f) The area will be  $\frac{1}{4}$  and the perimeter  $\frac{1}{2}$  of the original.
- g) You cannot know without knowing the length of the diameter in the new circle.
- h) You cannot know without knowing the length of the diameter in the original circle.

Students may fail to interpret the effects on volume from a doubling of the edges, while further investigation on the students' conceptualization of geometrical objects needs to be undertaken. To reason about the circle item, the students need to consider the conjunction that both the perimeter and the area are halved. Since  $(\text{area scale}) = (\text{length scale})^2$ ; a halving of diameter will result in a  $\frac{1}{4}$  size of area while the perimeter halves. An error on these items may indicate difficulties to acknowledge the properties of geometrical objects in two- and three dimensions for calculation of scaling and similarity.

## Reflection

There are many reasons why educational research tends to be isolated from practice. Research results and findings need to undergo a number of transformations from theory to practice, before they can be adapted to teaching practice, as illustrated in the design of the discussed in this paper. The test was designed with considerations to a special prison context and early results from using the test shows that it provides valuable support for the teacher when eliciting students' prior understanding of mathematics. Although, the test focuses on the *mathematical reasoning competency* it also informs us of students' *mathematical thinking competency*, *problem-handling competency* and *modeling competency* since these competencies are intertwined and overlapping. Together these four competencies create one out of two overall competences associated with mathematics: *The ability to ask and answer questions in and with mathematics* (Niss & Højgaard, 2011). The other overall competence: *The ability to deal with mathematical language and tools*, covers the intertwined competencies *representing competency*, *symbol and formalism competency*, *communication competency* and *aids and tools competency*. The scope of the test does not cover *the ability to deal with mathematical language and tools*. These competencies are left to be tackled within the course design, as well as the further development of the students' *ability to ask and answer questions in and with mathematics*.

A fundamental idea of educational research is that research findings should be put in play in teaching practice to help students to succeed with their studies in mathematics. I have discussed the design of a test for supporting teachers when pursuing the goal of finding an access point for individualized instruction. Through making use of accumulated and selected research results in the area of proportional reasoning in the design of the test, we gain a more thoughtful idea of the students' prior understanding.

# **‘Explicit teaching’ as an effective method of acquiring problem solving strategies - the case of ‘working backwards’**

Miriam Amit and Yelena Portnov-Neeman

Ben- Gurion University, Department of Science and Technology Education, Israel;

[amit@bgu.ac.il](mailto:amit@bgu.ac.il) ; [yelenapo@post.bgu.ac.il](mailto:yelenapo@post.bgu.ac.il)

*It has been shown that children who control strategies are better able to direct their own learning and knowledge. Seeking for an effective teaching method to achieve this goal, we experimented with the Explicit Teaching method vs. a traditional school one, using both to teach the Working Backwards Strategy. The study was conducted amongst 57 mathematically talented students participating in a unique mathematics program called Kidumatica. A mixed method analysis showed that Explicit Teaching produced better results regarding students' ability to use the strategy, though it did not affect the students' ability to recognize the strategy. This indicates that young students can understand when to use this powerful tool and, with further guidance, can also master their ability to use it.*

**Keywords:** *Explicit teaching, strategy, working backwards strategy*

## **Introduction**

Since Polya (1957), who claimed that students who control many strategies will become more effective and intelligent problem solvers, other researchers have advocated integrating problem solving strategies into school mathematics (English, 1993; Steiner, 2007), especially for talented students (Lee, 2014). The development and use of strategies is definitely not intuitive, and students need proper instruction, guidance and encouragement in order to systematically implement strategies in different domains - especially in problem solving (Tishmen, Perkins & Jay, 1996). Unfortunately, teachers face immense difficulties when it comes to teaching strategies in an effective way (Zbiek & Larson, 2015). This fact led us to look for an effective method to teach (talented) students some basic problem solving strategies. Based on interviews and talks with “professional mathematicians,” we decided on four such strategies: Trial and Error, Proof by Contradiction, Working Backwards, and Recursion, which were taught to students using the “Explicit Teaching method.” In this paper we focus on just one example, showing how Explicit Teaching can be used to teach students the “Working Backwards Strategy” for solving non-routine mathematical problems.

## **Explicit teaching method**

Explicit Teaching is a systematic methodology that is currently used primarily to teach reading and mathematics. This method is described as “highly organized and structured, teacher-directed, and task-oriented” (Archer & Hughes, 2011). All stages of the learning process include mediation between the teacher and the learner, in which the teacher transmits an external understanding of certain information to the learner, who then processes that pre-determined understanding (Olson, 2003). Nevertheless, using Explicit Teaching does not predetermine or confine learners’ thinking; on the contrary, it can help them become more active solvers and foster independent thinking (Portnov-Neeman & Amit, 2015). The methodology consists of a five step model (Figure 1). The steps described below are performed sequentially by the instructor in order to efficiently pass on specific information to the learner with as little ambiguity and room for error as possible (Rosenshine, 1986).

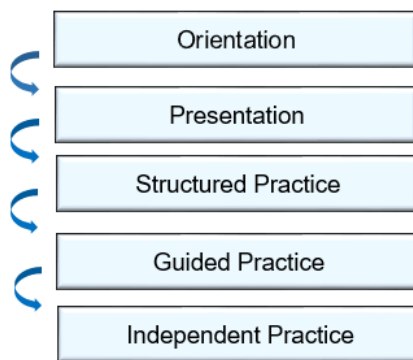

*Orientation:* Each lesson begins with a clear instruction about the purpose of the lesson. Learners need to understand what they going to learn and how it connects to previous lessons.

*Presentation:* The lesson material is divided into small units that fit the learners' cognitive abilities. The teacher uses a model or schema to guide them through their problem solving process.

*Structured Practice:* The instructor gives a direct and detailed explanation of the problem solving using the model or schema that was presented in the previous step. During this phase, it is critical that the instructor asks learners questions and encourages class discussion in order to check and assess their understanding of the material and clarify any confusion.

*Guided Practice:* In this practice the instructor addresses individuals' questions and misconceptions one-on-one, and tailors responses to meet the individual needs of each learner. Students can work in small groups in order to develop their ideas together and help each other with the new material.

*Independent Practice:* In this step, learners are asked to complete an assignment on their own and without assistance. They are not expected to have a flawless understanding of the lesson, but they must understand the steps involved in the process. This step should continue until learners gain full independent proficiency with the materials.

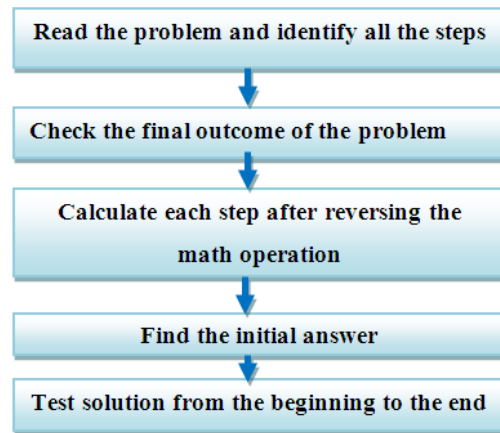

**Figure 1: Model of Explicit Teaching**

### **‘Working Backwards’**

‘Working Backwards’ is a useful and efficient strategy for solving problems in many aspects of our lives, in which an achievable outcome is known, but we have not yet determined the path towards achieving it (Newell & Simons, 1972; Portnov-Neeman & Amit, 2015). When dealing with word problems, for example, the information given in the problem can appear like a complex list of facts, so it is sometimes helpful to begin with the last detail given (Wright, 2010). The Working Backward strategy is illustrated in Figure 2 and explained step by step in detail below:

- 1) Read the problem from beginning to end and identify all its components and steps.
- 2) Check the final outcome of the problem.
- 3) From the final outcome, start reversing each mathematical operation in each step until you reach the beginning of the problem. For example, reverse the adding operation and replace with a subtraction operation.

- 4) After reversing every step, resolve the initial state of the problem.
- 5) Check the answer by starting from the initial state and working through the steps to see if the final outcome is achieved (Amit, Heifets & Samovol, 2007).

**Figure 2: Model of the Working Backwards strategy (Amit, Heifets & Samovol, 2007)**

## Methodology

The study presented here examined the effect of using the Explicit Teaching method to learn a new strategy, specifically the Working Backwards Strategy for mathematical problem solving. The research questions are: To what extent does Explicit Teaching affect:

- a) The ability to recognize when the Working Backwards Strategy is needed for problem solving?
- b) The ability to use and implement the Working Backwards Strategy?

## Context

The study was conducted in the framework of "Kidumatica". Kidumatica - the math club for excellence and creativity - is an after school program for talented students in the 5th to 11th grades who are interested in mathematics, but require further tools to reach their full potential (Amit, 2009). Fifty-seven ( $N=57$ ) 6<sup>th</sup> grade students were divided in two groups: an Experimental Group (EG = 30 students) and a control group (CG = 27 students). Over a period of six months, these students learned different mathematical strategies, including the Working Backwards Strategy. The EG learned through the Explicit Teaching method, while the CG was taught using the traditional school one. None of the students in this study had been research subjects in previous studies involving the Working Backward Strategy, and none had learned the strategy before.

### **The ‘Explicit Teaching’ Group (Experimental Group)**

Students in this group studied all the strategies by means of the Explicit Teaching method. Each strategy, including the Working Backwards Strategy, was taught for four weeks by one of the researchers, according to the model illustrated in Figure 1. The teacher had an integral part in the lessons. She clearly and explicitly outlined what the learning goals are for the student, and offered clear, unambiguous explanations of the skills, information and the problem solving process. As the lessons progressed, the teacher’s role reduced, until students were able to solve problems independently. It was like riding a bicycle, where the instructor gradually releases his hold of the bike and the child rides off by herself. The first lesson started with an explanation of the strategy, including its importance as well as where and how it should be implemented. The teacher showed the students the model of the strategy and explained the role of each step in the solution process. The following lessons were dedicated to structural, guided and independent practices. During the structured practice the teacher gave a direct and detailed explanation of the problem solution using the Working Backwards model (Figure 2). The teacher encouraged discourse between the students and asked questions to assess their understanding and clarify any confusion. In the guided practice, students worked in smaller groups or by themselves on different working backwards problems. The teacher walked around the students and addressed individuals’ questions. When the teacher felt confident enough of a student’s abilities, that student was allowed to start working individually and begin the independent practice step. At the independent practice stage, students were asked to complete several assignments using the working Backwards Strategy, and to solve complex problems on their own.

### **Traditional teaching control group**

The control group studied the Working Backwards Strategy for the same period of time as the EG, but they studied the strategy in the traditional school method. This group differed from the EG in the following ways:

1. Lessons were mainly dedicated to students’ work. The teacher’s part was smaller than in the EG. Her role was to give short explanations about the lesson activities. She did not use the word “strategy” in her explanations, or explain that a special approach is needed for solving working backwards problems. Most of the lesson was dedicated to independent time, so that students would develop their own strategy toward those problems. It was important that students draw their own conclusions, create their own conceptual structures, and assimilate the information in the way that makes the most sense to them.
2. The teacher did not show the model of the strategy and did not name the strategy explicitly. Instead, students could develop their own model and meaningful name based on the teacher’s examples and their own experience.
3. The practice process in the CG was mainly independent, in contrast to the three levels of practice used in the EG. That led to less room for discussion and collaborative work between the students, unlike the EG, where time was allotted for these during the structured and guided practice.

## Data collection and analysis

Data was collected via pre- and post-tests, students' products, short interviews during and after the lessons, and teacher's notes. The pre/post-tests were administered to both groups before and after the learning program. Both tests included working backwards problems. This paper will discuss two problems from the pretest (problems 1 and 2 below), and two from the posttest (problems 3 and 4).

**1. Card Problem:** *"Yael, Danny and Michael played cards. At the beginning of the game each one had a different amount of cards. Yael gave Danny 12 cards. Danny gave Michael 10 cards and Michael passed Yael 4 cards. At the end each one of them had 20 cards. How many cards did Yael, Danny and Michael have in the beginning?"*

**2. Mangoes Problem:** *"One night the King couldn't sleep, so he went down into the royal kitchen, where he found a bowl full of mangoes. Being hungry, he took  $\frac{1}{6}$  of the mangoes. Later that night, the Queen was hungry and couldn't sleep. She too found the mangoes and took  $\frac{1}{5}$  of what the King had left. Still later, the first Prince awoke, went to the kitchen, and ate  $\frac{1}{4}$  of the remaining mangoes. Even later, his brother, the second Prince, ate  $\frac{1}{3}$  of what was then left. Finally, the third Prince ate  $\frac{1}{2}$  of what was left, leaving only three mangoes for the servants. How many mangoes were originally in the bowl?"*

**3. Weight Problem:** *"Four students in the class weighed themselves. Cobi was 15 kilograms lighter than Adi. Gaby was twice as heavy as Cobi and Jenya was seven kilograms heavier than Gaby. If Jenya weighed 71 kilograms what was Adi's weight?"*

**4. Baseball Problem:** *"The Wolverines baseball team opened a new box of baseballs for today's game. They sent  $\frac{1}{3}$  of their baseballs to be rubbed with special mud to take the gloss off. They gave 15 baseballs to their star outfielder to autograph. The batboy took 20 baseballs for batting practice. They had only 15 baseballs left. How many baseballs were in the box at the start?"*

At the end of each test, students were asked to write what method they had used to solve the problems. The purpose of the pre-test was to determine the homogeneity of the two groups. The post-test examined the effect of the teaching methods at the end of the learning process. A five point scale was used to rank students' answers (5 points = full and correct answer, 0 points = no answer). For example, if students identified all the steps, calculated each one by doing the opposite mathematical calculation and wrote the final answer correctly, they received 5 points. Figure 3, for example, shows a five point solution for the "Weight Problem." The problem has three steps: (1) Jenya was seven kilograms heavier than Gaby; (2) Gaby was twice as heavy as Cobi; (3) Cobi was 15 kilograms lighter than Adi. The student calculated the weight of each person by working backward through every step of the problem. Figure 4 shows an example of a 2 point solution. The student started with the last detail given and calculated Gaby's weight correctly. However in the next two steps he did not reverse the mathematical operations and got an incorrect answer.

	Final phase	Operation	
Adi	47	Cobi was 15 kilograms lighter than Adi	$32+15=47$
Cobi	32	Gaby was twice as heavy as Cobi	$64:2=32$
Gabi	64	Jenya was seven kilograms heavier than Gaby	$71-7=64$
Jenya	71	Jenya weighed 71	

Answer: Adi weights 47 kilograms.

Handwritten student work for Figure 3. It shows a table with names and weights, and calculations for each person's weight based on the problem conditions. The calculations are:  $32+15=47$  for Adi,  $64:2=32$  for Cobi, and  $71-7=64$  for Gabi. The final answer is 47 kg for Adi.

**Figure 3: Example of a five point answer to the weight problem**

Jenya	Cobi	Adi	Gabi	Categories
1	2	4	3	Weight
71	$64 \times 2 = 128$	$64 + 15 = 79$	$71 - 7 = 64$	
71	128	79	64	Answer

Adi weight 79 kg

Handwritten student work for Figure 4. It shows a table with names and weights, and calculations for each person's weight based on the problem conditions. The calculations are:  $64 \times 2 = 128$  for Cobi,  $64 + 15 = 79$  for Adi, and  $71 - 7 = 64$  for Gabi. The final answer is 79 kg for Adi.

**Figure 4: Example of a two point answer to the weight problem**

## Findings

Findings from the pre-test showed that in both problems, there was no significant difference between the groups, which indicates that both groups had the same level of homogeneity. After six months of learning strategies, the average scores in the post-test for both problems were higher among the EG than the CG. In Table 1 we can see a significant difference in the post-test between the two groups in both problems. Figure 5 indicates that students' ability to recognize the strategy improved after the learning process, but that both groups had similar results in the pre and post-test.

**Table 1: Results from pre- and post-test in the EG and the CG**

Test	Problem	Group	N	Mean	SD	Sig
Pre test	Card Problem	EG	30	3.50	1.676	$P = 0.68$
		CG	27	3.30	2.035	
	Mango Problem	EG	30	1.77	1.977	$P = 0.96$
		CG	27	1.74	2.141	
Post-test	Weight Problem	EG	30	4.97	.183	$P = 0.00^*$
		CG	27	3.56	1.987	
	Baseball Problem	EG	30	3.77	1.547	$P = 0.03^*$
		CG	27	2.89	1.553	

\* $P < 0.05$

**Figure 5: Amount of students from the EG and CG that recognized the Working Backwards Strategy in pre- and post-tests**

Our qualitative analysis of students' solutions revealed that the EG students reversed the mathematical operations much better and more easily than those in the CG, and were thus able to solve the problem correctly. Moreover, while the EG explicitly stated the name of the strategy they had used when asked, the CG students were very creative in naming the strategy, coining names such as, “going in through the back door”, “reverse manual” etc. Finally, the EG students used the model of Working Backwards Strategy in a very efficient way, sometimes adjusting the model to make it easier to use.

## Discussion

Strategies are undoubtedly an important tool for goal-directed procedures in problem solving. Introducing them at a younger age can improve learners' mathematical ability (Polya, 1957) as well as their understanding and thinking skills (English, 1993). To achieve this goal, it is important to use a specific teaching method (Tishmen, Perkins & Jay, 1996). In this study, that method is the Explicit Teaching method, through which we introduced the Working Backwards Strategy. The study examined the effect of this method on students' ability to recognize and solve working backwards problems. Fifty-seven sixth graders were divided into two groups, an experiment group (EG) that studied with the Explicit Teaching method and a control group (CG) that studied with a traditional school one. The strategy was unfamiliar to both groups and the findings from the pre-test showed that both groups had a similar starting point. At the end of the learning process, the group that studied explicitly showed higher results than the control group. The structured steps of the Explicit Teaching helped the students to have a better, clearer understanding of the strategy (Anhalt & Cortez, 2015). Qualitative analysis revealed that students who studied explicitly were more much resourceful in their solutions. They understood how the strategy works, adopted it and changed it to make it easier to solve. We believe that this ability developed due to the discourse and the collaborative work in the structured and guided practice. We saw how students' understanding of the strategy and its use improved over time. They asked more questions, listened to other students' answers and learned how to avoid misconceptions. In addition, the integral role of the teacher in this method helped students gradually to build their confidence. Thus, these students were more prepared to work on working backwards problems by themselves. Our previous study showed that teaching explicitly can help students become active learners and foster their independent thinking (Portnov-Neeman & Amit, 2015). The current study supports this conclusion, showing that Explicit Teaching did not limit students' thinking by fixing it on a particular process. On the contrary, students understood the core principle of the Working Backwards Strategy and then applied it creatively in whatever way seemed

best to them. Both groups showed improvement over time in their ability to recognize when and why the Working Backward Strategy is needed. The percentage of students that recognized the strategy before and after the learning process was similar. This is very encouraging, since it may indicate that the teaching method does not affect students' ability to recognize strategies. We can assume that with additional practice, all of the students could potentially master strategies and develop their understanding and their strategic approach to problem solving, but this has to be tested and researched. In this study, we experimented in 'laboratory conditions' with talented students, and found that the method works. Further research is needed to confirm its effectiveness outside of the Kidumatica Mathematics Club, in the 'real world' of education.

## Conclusion

Mathematical strategies are complex concepts to learn and understand, and we as educators must search for the most effective way to teach them. In this study, we used a systematic and structured methodology called Explicit Teaching, and found that students who studied with this method had higher scores than students who studied with a traditional school method. Introducing strategies like these to students is important, since they can help students evolve into better thinkers and develop their ability to solve problems. We believe that strategies can and should be introduced from a younger age so they can be developed over time. We have found that younger children are capable of acquiring the basic tools. Given time, they will be able to develop their tool kit of strategies further, and eventually master them all. It is our obligation as educators to teach our students how to use strategies correctly, and the sooner we do so the better.

# Using a Models and Modeling Perspective (MMP) to frame and combine research, practice- and teachers' professional development

Jonas Bergman Ärleback<sup>1</sup>

<sup>1</sup>Linköping University, Department of Mathematics, Sweden; [jonas.bergman.arleback@liu.se](mailto:jonas.bergman.arleback@liu.se)

*This paper describes and discusses the framing of, and experiences from, a project that combine research, practice- and teachers' professional development based on the tenets of the Models and Modeling Perspective on teaching and learning (MMP). Besides providing a general description of the methodological considerations in the project design, the paper describes how the accumulated results and experiences in the research literature on so-called model eliciting activities are used to inform the design, implementation and evaluation of activities aiming at introducing functions to grade 8 students. The focus of the paper is on the implantation and aim to showcase how the teacher in question realized the offered perspective and tools in practice.*

*Keywords: Practice development, teachers' professional development, models and modeling perspective, model eliciting activities.*

## Introduction

Clarke, Keitel and Shimizu (2006) have shown that much of the teaching and learning of mathematics in many counties are centered around, and dominated by, a traditional use of textbooks. This practice seems to strengthen as the students progress through the educational system, as does the fact that many students lose their interest in, and motivation for, learning mathematics with increasing age. TIMSS 2007 for example shows that the attitudes towards mathematics in Sweden expressed by grade 4 students generally are much more positive compared to the attitudes among grade 8 students (Skolverket, 2008). This situation in combination with the declining results of Swedish students on the international assessments PISA and TIMSS, are reflected and frequent in the public debate as well as in many of the ongoing drives, projects and programmes trying to realize changes in schools. Learning mathematics is complex (Niss, 1999), and now more than ever is the role teachers play stressed for what mathematical understanding and knowledge the students develop in schools (Hattie, 2009; 2012).

However, the challenges that teachers meet in their everyday mathematics teaching are numerous and of various kind and nature. Students' lack of interest in combination with too monotonous (and "traditional") forms of teaching seems to be part of the reasons for the Swedish students' declining performances as well as interest in mathematics. Often, a proposed strategy to reverse these trends is to try to change the prevailing norms in the classroom (Yackel & Cobb, 1996) by increasing student interaction and the overall student activity. Teachers are encouraged to try to vary their teaching, increase students' activity levels and strive to make students 'talk more mathematics'. But how is this going to work in practice in everyday teaching? How do we get students to 'talk more math' and to be more engaged and (inter-)active in the mathematics classrooms?

The concerns mentioned above are part of the motivation for the installment for a joint collaborative initiative between two municipalities and a university, from which this paper will discuss some aspects. The overarching question for the initiative is: *How can we organize the mathematics*

*teaching so that students are given the opportunity to develop their conceptual, procedural/ methodology and reasoning abilities in, for the students, interesting and engaging ways?*

## **A project combining research, practice- and teachers' professional development**

As a response to the situation and challenges briefly outlined above, a collaboration between two municipalities and a university was initiated with the aim to establishing a long term and sustainable collaboration as well as to seek for ways to counterbalance the current trends. The initiative rest one three strands, namely to simultaneously (1) combine and produce research with (2) the development of teaching practices in schools and (3) to serve as professional development for the teachers in the municipalities. The project involves two researchers focusing on different grade levels: grades F to 6 (6- to 12-year-olds) and grades 7 to 12 (13- to 18-year-olds). The two researchers have autonomy in how they define, plan and conduct the work within the given boundaries defined by the university and the municipalities.

The project focusing on grades 7 to 12 runs a series of semi-parallel 1-year projects where the researcher in each project works together with 4-6 teachers from different schools and grades as *partners* (c.f. Jaworski, 1999) in, what ideally could be described as, a *co-learning agreement* (Wagner, 1997). Each project departs from the practices of the participating teachers and the possibilities and challenges they see in their everyday teaching. Based on the teachers' experiences a discussion leads to the formulation, planning and implementation of a 1-year long project with specified aims and goals. The research carried out in the projects is centered around the participating teachers own everyday teaching, and their engagement in research and developing their own practices constitute the professional development for the teachers. Within the context of the initiative two key questions then become: *How to coordinate the experiences and result from the individual projects?* and *How to communicate then?* Note that these questions also are at the heart of mathematics education more generally (aka the accumulation of research and the dissemination of knowledge; a main topic for CERME 10's TWG23). For the 1-year project discussed in this paper, the studied question was: *How can we create and work with joint classroom activities that challenge all students regardless of their levels of mathematical understanding and capabilities?*

## **The models and modeling perspective on teaching and learning**

The *models and modeling perspective on teaching and learning* (Lesh & Doerr, 2003), MMP for short, sometimes given as an example of a so-called *contextual perspective* in the discussion on modeling (Kaiser & Sriraman, 2006), draws on and traces its lineages back to Vygotsky, Piaget and Dienes as well as influences from the American pragmatists' tradition represented by Mead, Peirce and Dewey (Kaiser & Sriraman, 2006; Mousoulides, Sriraman, & Christou, 2007). The central notion in this perspective is that of *models*, which are conceptual systems used to make sense of situations and phenomena. Models are considered to be human constructs which are fundamentally social in nature and can be described as systems consisting of elements, relationships, operations, and rules that can be used to predict, explain or describe the behavior of some other system. In the MMP learning is equated with model development, in which the role of modeling activities is to support this development by engaging the students in purposefully developing, understanding, modifying, and using their models to make sense of different situations and contexts (Lesh & Doerr, 2003).

The adaptation of the MMP at the macro level for all grade 7-12 projects establishes a common perspective and vocabulary that facilitate communication within as well as between different projects and levels of stakeholders in the initiative. The inherent recursive complexity of the MMP (researchers developing models of teachers' models for teaching and supporting students developing their models) connects the work and results from the different projects and levels. The inclusive and accessible notions models and model development (understood in a more mundane way) facilitates communication with teachers, high municipality officials and policymakers.

### **Model eliciting activities**

*Model eliciting activities* (MEAs) are purposefully designed activities where students need to develop a model that can be used to describe, explain or predict the behavior of, for the students, meaningful contexts, phenomena and situations. Traditionally, much work within the MMP have been centered around so-called *model eliciting activities* (MEAs) developed by Lesh and colleagues (Lesh, Hoover, Hole, Kelly, & Post, 2000). Although originating in mathematics, MEAs have in the last 15 year been used to support and investigate the development of students' models (conceptual systems) in a range of disciplines and contexts (Diefes-Dux, Hjalmarson, Zawojewski, & Bowman, 2006; Iversen & Larson, 2006; Yildirim, Shuman, & Besterfield-Sacre, 2010; Yoon, Dreyfus, & Thomas, 2010).

The research involving MEAs have resulted in six design principles for MEAs, which also to some extent capture the essence of the MMP: (a) *the reality principle* – the MEA connects to students' previous experiences and is meaningful; (b) *the model construction principle* – the MEA induces a need for the students to develop a meaningful model; (c) *the self-evaluation principle* – the MEA permits the students to assess their work and models; (d) *the model documentation principle* – the situation and context in the MEA requires the students to externally express their thinking (models); (e) *the model generalization and sharable principle* – the elicited model in the MEA is sharable, generalizable and applicable to similar situations; and (f) *the simplicity principle* – the situation in, and formulation of, the MEA is as simple as possible (Lesh et al., 2000; Lesh & Doerr, 2003).

Teacher working with MEAs have proven to provide rich opportunities for professional change and development. Schorr and Lesh (2003) found that teachers working with MEAs in their classrooms

- (a) changed their perception regarding the most important behaviors to observe when students engaged in problem activities; (b) changed their views on what they considered to be strengths and weaknesses of student responses; (c) changed their views on how to help students reflect on, and assess their own work; and (d) reconsidered their notions regarding the user of the assessment information gathers from these activities. (Schorr & Lesh, 2003, p. 157)

These experiences and results suggest that MEAs might provide a productive tool to address the question about how to create mathematics teaching that is challenging for all students. The teachers in the project found this a promising approach and especially expressed the following aspects of MEAs appealing: MEAs build on and respect what the students bring to the classroom in terms of prior knowledge in a fundamental way; MEAs focus on the students' sense making of meaningful situations, representations and connections between representations; working with MEAs naturally includes a range of classroom organizations (working one-by-one, in pair, group or different whole class interactions); MEAs have the students work on explicitly formulating and expressing their

thinking using mathematics. In addition, the six design principles for MEAs come to play a few different roles: tools for design; tools for analyzing tasks; evaluative tools for students work in class; and tools for thinking about one's own view of mathematics, teaching and learning.

## **The MEA and its' implementation**

We now end the paper by showcasing the result of one teacher's implementation of an MEA given as an introduction to linear function in grade 8.

### **The context and the design of the MEA *Candy time!***

The teacher wanted to use an MEA to introduce linear functions in grade 8. Functions, and different representations of functions, are something that the students have been exposed to more or less consciously in different forms during the majority of their mathematical schooling. In other word, students already have ideas and models for what graphs and tables are and how and when to use them. So, rather than systematically treat these concepts in a traditional manner, the teacher wanted to challenge the students to use their previous experiences and to see and explore the connections between tables, graphs and diagrams by engaging in a more exploratory activity (aka an MEA).

The context of the problem was chosen by the teacher to be about buying candy. In Sweden, there is a often practiced tradition, that the children on Saturday do their weekly candy shopping, called *lördagsgodis* – “Saturday's Candy.” Not seldom, the candy is bought in candy stores where you pick 'n' mix candy after your own preferences and liking, and pay by the hectogram (100 grams) or the based on the actual number of pieces of candy you picked.

In the design of the MEA the teacher stressed four of the guiding principles as especially important for this particular purpose: (a) *the reality principle*: the choice of context and situations (the candy store) was made in order to be familiar to the students in that it should facilitate the students in making connections and interpretations between different representations; (b) *the model construction principle*: the intention with the activity *Candy time!* is for the students to build on their previous experiences and knowledge in order to connect and coordinate them further; (d) *the model documentation principle*: to facilitate for the students to document their work, a in that they make their models visible and objects for discussion, a worksheet was developed with easy-to-read instructions, questions and diagram as well as generously with space for writing answers and comments; (e) *the model generalization and sharable principle*: to promote that students share ideas as a means for furthering their models, the MEA was designed to have the students working along as well as in pairs or small groups, and engaged in whole class discussions. Note that the four principles not are independent, and that they contribute to make the students' previous experience and knowledge the basis for the activity, to make students' ideas and thoughts (models) visibility, and to facilitate that the students' models are confronted with other students' models so that they through discussion can refine and develop their ways of thinking.

### **Implementation**

After the teacher started the lesson and introduced the first part of the activity, the students began to work individually on the first part of the task about the three stores A, B and C; see Figure 1 below. However, it only took seconds until the students spontaneously started discussing with each other about which store would given them the most candy for their money, and they spontaneous formed

pairs and small groups. The teacher observed the students' work and listen to the students' discussions while walking around in the classroom and making sure all students understood the task, but otherwise intentionally kept a low profile.

### Candy time!

It's Saturday and you're thinking about which of the three stores A, B and C you'll go to and spend 2,50 € so that you'll get as much candy as possible. Compare all three stores and motivate your choice.

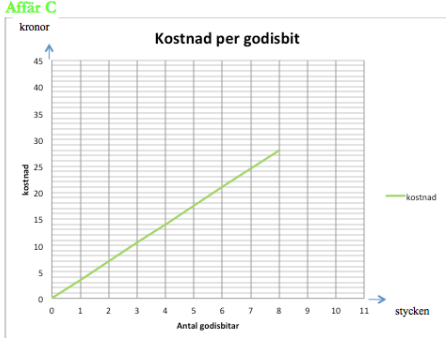

#### Store A

You'll pay 1 € for a bag of 32 pieces of candy.

#### Store B

Pieces candy (#)	Price (€)
5	1,5
10	
15	

#### Store C

**Figure 1: Part one of the activity *Candy time!***

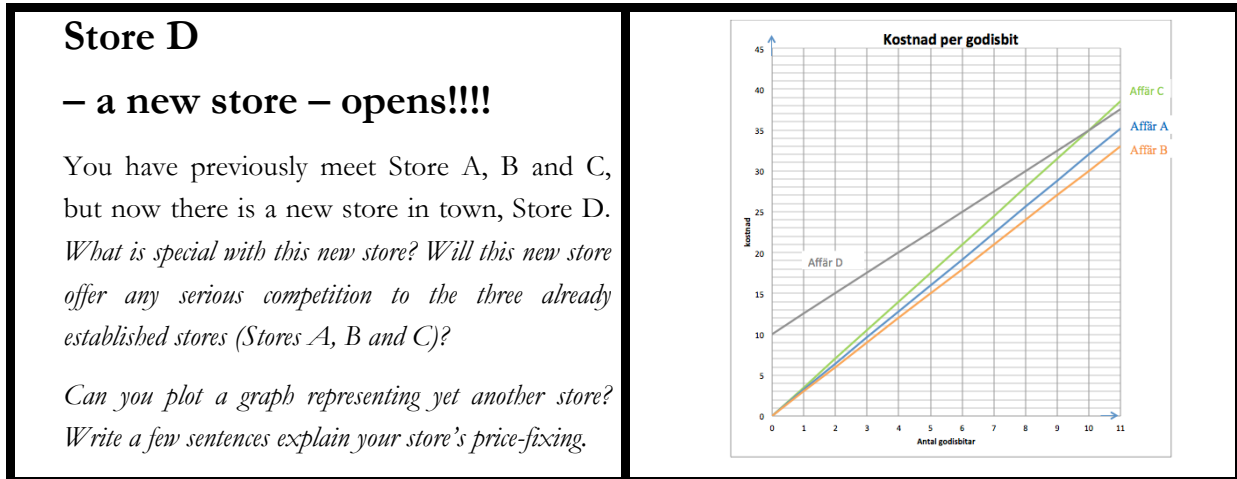

The idea was that the students' should use an experimental approach and try different ways and strategies to approach the problem. If the teacher noticed that some of the student got stuck she approached the student with encouragements like "Try to fill out the table for Store B!", "What would it look like if one plotted the table-values for Store B in the same diagram displaying Store C's pricing?", or "What would Store A 'look like' in the Store C diagram?" When the majority of the students had decided in which Store to do their shopping of Saturday's candy, the teacher focused and pulled the class together by asking "What would the graphs for Store A and Store B look like if you plotted them in the same diagram as the graph for Store C?".

When all the students had decided on which store gave them the most value for their money, the teacher, based on her observations in the classroom, chose a few of the students to orally present their solution for the whole class. The selected students showed, motivated and explained what method they used to approach and solve the problem. In the whole class discussion that followed the students' presentations, the teacher, based on continuous inputs of the students, showed what the graphs for the different stores would look like if they were plotted in the same diagram.

The discussion continued in smaller groups where the students were engaged in thinking about and explaining: *What use does one have of graphs and tables? What are the differences and similarities between the three stores? What factors other than the price can affect where one choose to buy one's candy?* Looking at the students' answers, there is a tendency to consider graphs as suitable tools for comparing things ("when you want to compare something", "you can see the differences in prices") or to illustrate how something develops over time ("when you wanna show something along a timeline"). Tables on the other hand the students put forward as good tools for presenting different kinds of compiled data or results ("as for example results from sports", "to present one's findings", "sport results, lengths, weight, sizes, ages, sexes, opinions").

Regarding the differences and similarities between the stores the students mostly commented on directly observable features like “*all are selling candy*”, “*the price goes up with the number [of pieces of candy you buy]*”, “*all have different pricing*”. The selection of available candy in the different stores, both with respect to and quality and quantity, as well as to the geographical location of the store, were factors the students identified as things influencing where one buy one’s candy.

After the students had discussed and compared their answers for a couple of minutes, the teacher introduced part two of the *Candy time!* activity; see Figure 2 below:

**Figure 2: Part two of the activity *Candy time!***

While working on the second question in the second part of the activity, *Will this new store [the Store D] offer any serious competition to the three already established stores (Stores A, B and C)?*, the students concluded “*well, it depends on how much you buy!*”. Many of the students argued that Store D not would be any competition to the other stores if you as in the first part of the activity, only spent 2,50€. However, if you were spending a greater amount of money, then Store D should be the preferable choice. (“*No, this [Store D] is more expensive than the others [Stores A-C]. But this [Store D] becomes more affordable if you buy a larger and larger amount*”). The fact that the graph for Store D intersect the y-axis at  $y=10$  some of the students interpreted as “*you have to pay 1€ to enter the store, like an entrance fee*” or that you pay for the box or bag you put the picked candy in: “*Surely it’s some kind of fancy candy store where you have to pay for the boxing. That’s is probably one of the reasoning people will come [and shop in the store] – that it’s a fancy shop that is*”.

The last task in the activity set lose the students’ creativity, drawing graphs describing other imaginary store’s pricing (see Figure 3). Most of the students draw in multiple stores and the most commonly pricing was a model giving the price proportional to the number of pieces of candy bought, as exemplified by Store H: “*Every single piece of candy costs 0,10 € each*”. One of the students wrote “*In this store the only sell giant pieces of candy*” (Store E) to explain the steepness of her graph. Store G was described by another student as “*I’ve made a cheaper store - one where you’ll get one piece of candy for free!*”, explaining the meaning of the graph intersecting the x-axis at  $x=1$ . Although the diagram only display the price for between zero and 11 pieces of candy, some of the students physically prolonged the lines representing the cost in Stores A – D and concluded that if you buy a large enough amount of candy, then Store D is the most price-worthy store. The

students also constructed stores that had price-fixing represented by a line with negative slope (“*The price decreases, and after 11 pieces the candy becomes free*”, Store I), and stores with a flat rate price-fixing (“*Take as much candy you want for 2,80 € ☺*”, Store F). After the lesson the teacher noticed and expressed her surprised over how much the students own examples of stores’ pricing showed and reveled about the students’ creativity and proficiency to interpret linear functions  $y = kx + m$  with positive ( $k > 0$ ), negative ( $k < 0$ ) slope as well as zero slope ( $k = 0$ ) in the given context of the activity.

**Figure 3: The students’ own stores (Stores E – I)**

The students’ worked on the second part of the activity till the lesson ended. The teacher then collected all the students’ written work, and followed up the activity the following lesson, after having read and summarized the students’ explanations, with a whole class discussion about the students’ conclusions, interpretations and price-fixing of their own stores. The teacher was surprised over the interest and engagement the students showed when working on the activity as well as over the wide range of solutions and explanations the students offered. The fact that the activity allowed for a variety of solutions resulted in almost all students wanting to share their solution and thinking at the whiteboard in the whole class discussion. In a few instances the students asked for how to name certain concepts such as *origin* and *intersection point* to be able explain their thinking more precise and clear to their peers. In other word, the students wanted to express themselves mathematically correct.

# Providing a tool for lesson planning in pre-service teacher's education

Tone Bulien

University of Stavanger, Faculty of Arts and Education, Norway; [tone.bulien@uis.no](mailto:tone.bulien@uis.no)

*This paper discusses the theoretical and methodical arguments for the design and implementation of a research based course for pre-service teachers. The course program was carried out five times matching the methodology of design experiment and the theory of communities of practice. Students' assignments in the course were designed to focus on planning teaching and to give the pre-service teachers experiences of how to use and connect didactical and mathematical theories to practical situations, and hence provide them with a tool for teaching in different classroom situations.*

*Keywords: Pre-service teacher education, implementation, design experiment, lesson planning, mathematics teaching and learning.*

## Introduction

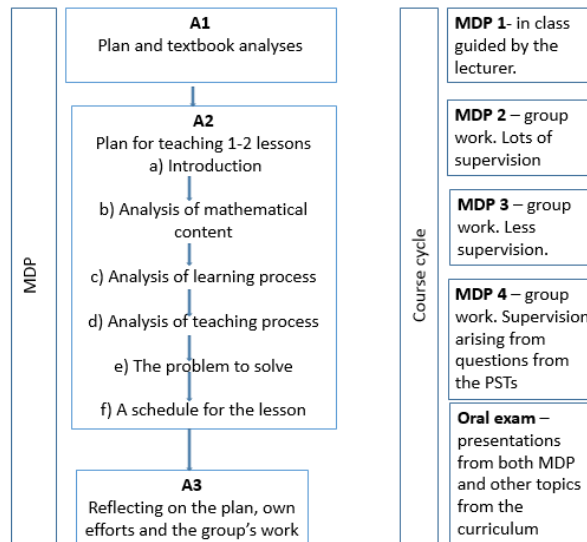

The implantation of a new teacher-training program in Norway (Kunnskapsdepartementet, 2010) presented an opportunity to think about new ways of teaching a pre-service teacher course in mathematics within the program at a Norwegian university. Previous to this reform the corresponding course was organized more traditionally entailing plenary lectures, workshops and various student assignments in which the pre-service teacher students (PST) actively had to participate. However, feedback from the PSTs showed that they found it difficult to see the connection between the course work at the university and the in-school teaching practicing activities, especially with respect to the implementation of didactical theories in the everyday mathematics classroom practice (Bulien, 2008; Solstad, 2010). Therefore, the design and implementation of a revised course focused on and included activities that aimed to enhance and make the connection between theories of teaching and learning and the actual practice of teaching clear and explicit for the students. This paper discusses the central idea used to realize this connection in the redesign of the course, namely, to focus on lesson planning by adapting and introducing the so-called *Mathematics Didactic Planning tool* (MDP).

Besides presenting the MDP, the aim of this paper is to describe the research design and the theoretical background for the educational design experiment in which the MDP was developed, implemented and evaluated.

## Introducing the MDP, the setting and background

The course that was subjected for redesign is a 30 credit compulsory course in the teaching and learning of mathematics given within a full time teacher education program for grades 1–7 (6–12 years old). The students take multiple courses simultaneously and the course in teaching and learning mathematics spans over a period of 2 years (7,5 credits each semester). Even though the program is a full time program, most of the students are not at campus all the time. Rather, the students travel and are physically present at joint seminars at the university for three separate weeks each semester. In each week, the students studied mathematics for 7 hours spread out over two days. The rest of the semester, the PSTs and teachers communicate via different media over the Internet.

In the first two semesters (credits 1-15) of the course in teaching and learning mathematics, the students focus on theories and frameworks related to the role of a mathematics teacher, teaching and learning mathematics, numeracy and early training of algebra (pre-algebra). This experience of different theoretical approaches to teaching and learning mathematics provided an advantage when they were introduced to the MDP in the third and fourth semester of their teacher-training program. During the second year of the course (credits 16-30) the PSTs worked through three MDPs, each organized in three different parts or phases named A1, A2 and A3, see Figure 1 (left).

**Figure 1: MDP model (left) and the course cycle of PST implementing MDP (right)**

Phase A1 is about analysing textbooks and making a brief plan for teaching mathematics covering a whole school year. In phase A2, a much more detailed plan for teaching a lesson given a particular content is worked out. The last phase, A3, time is spent on reflecting back on the previous phases. The assignment students are obliged in phases A1 and A2 are written assignments carried out as group work, whereas the assignment in phase A3 is individual reflecting text.

In this second part of the compulsory course (semester three and four), the structure of the MDP was used as a frame to organize of both lectures and students' assignments, and during the year the PSTs worked through three MDPs focusing on different mathematical topics as well as on different grades (1–7). The mathematical topics were geometry, measurement, statistics, probability and functions.

The introduction to the MDP model was given in the first seminar in the third semester at campus where the teacher and the PSTs together planned a fictitious lesson for teaching using the MDP framework. The following three MDPs were mainly supervised using Google Disk (GD) and through Internet seminars, but also in face-to-face seminars with the teacher when the students met at campus. Additionally didactical and mathematical theories were provided to the students through lectures, both at campus and in online video lessons made and hosted by the teacher. Having the PSTs iteratively working through three MDPs made it possible for the PSTs to familiarize themselves with the framework, and hence their need for support and guidance successively declined, aiming at the PSTs to be more and more independent. In other words, writing the assignments (A1, A2 and A3), the supervision in GD was more active during the first MDP, less in the second and only by questions from the PSTs in the third (Bulien, 2013).

## Methodology

The methodology of the project to implement the revised course on teaching and learning mathematics based on this new tool for teaching (the MDP) was founded on experiences from previous teaching similar courses; research about PSTs' education experiences (e.g. Bulien, 2008; Solstad, 2010); and, students' feedback on the content in similar and previous courses. Based on these, special emphasis in the revised course became the application of theory in practical teaching situations. In short, the aim of the project was to present a more visible connection between the theoretical work at campus and the practice at schools.

During the four-year teacher education program, the PSTs experience rather short periods of actually practicing teaching in schools, and each time they must focus on three or four different subjects which makes it difficult to go into depth on each subject during their practice time in the classroom (Solstad, 2010). Solstad (2010) found that PSTs' ability to connect theory with practice increase the longer they attended the education program, but the students still wanted more supervision in implementing theory into their teaching practice. This increasing theoretical understanding might be a result of engaging in multiple cycles of supervised practice at schools and evaluated written assignments at the university, which suggests that a similar iterative learning model would be the preferred teaching and learning environment for the new course. However, closer collaboration and involvement with the actual teaching practices done in schools by the students was not feasible. Instead, a more active collaboration between the PST and the teacher in the spirit of communities of practice (Wenger, 1998) was integrated in the design of the course.

To guide and structure the overall re-design, implementation and evaluation of the new course, something that can be considered to be a classroom design experiment (Cobb, Confrey, diSessa, Lehrer, & Schauble, 2003), a *design experiment* (Cobb et al., 2003) methodology was adapted.

Most classroom design experiments are conceptualized as cases of the process of supporting groups of students' learning in a particular content domain. The theoretical intent, therefore, is to identify and account for successive patterns in student thinking by relating these patterns to the means by which their development was supported an organized. However, different classroom design experiments may set their focus on different constellations of issues (Cobb et al., 2003, p.11)

The theoretical intent of implementing the MDP was to focus on the PSTs' development in lesson planning using didactical theories and mathematical knowledge, which could be evaluated in the assignments of each MDP and the PSTs' reflection notes. The teaching and learning process involved in the implementation of the course was continually evaluated through out the five years based on the PSTs' work and reflection as well as the teachers reflections notes and written logs. The course was modified and adjustments were made both during the semester and when before starting a new course for a new group of PSTs.

In the design and development of the MDP and the new course, Cobb et al. (2003) five crosscutting features of design experiments were used to structure and guide the work during the five-year period of this project.

First, design experiment involves both the *goal* and the *process* (Cobb et al., 2003). The goal was to educate prospective mathematics teachers so they could give their students a grounded mathematical

education based on mathematical knowledge and research about how to teach mathematics. The process, which should facilitate the goal, had two different parts. Initially the process was about developing a class of theories that supported the ideas of using the MDP as an artefact for the PSTs' studies, and to get an overview of the implementation of the new ideas in the course. Next it was the process of defining the roles of the PSTs and of the teacher, in which the theory of communities of practice (Wenger, 1998) was introduced.

Since the collaboration between the PSTs and the teacher was supposed to be less like the usual teaching situation and more like an ongoing working together process, communities of practice was a suitable framing since "... the property of a kind of community created over time by the sustained pursuit of a shared enterprise" (Wenger, 1998, p.45). Further, Wenger claims that in educational design "Learners must be able to invest themselves in communities of practice in the process of approaching a subject matter" (Wenger, 1998, p.270). In this project the subject matter was the MDP that could be seen as a reification of a teaching and learning situation in the sense of "... giving form to our experience by producing objects that congeal this experience into "thingness"" (Wenger, 1998, p.58). For the MDP, the process was to present a learning trajectory to the PSTs that realized the possibility to adapt theoretical perspectives of teaching to classroom situations. A corollary to this involved a change in the teacher's role from less lecturing to more supervising, which supports Wenger's idea of self-investment.

Second, design experiment is about being *innovative*, and there should be a *discontinuity* between tradition and new ideas to test (Cobb et al., 2003). Expecting a more active contribution from the students and more supervision from the teacher changed the traditional lectures to seminars. In between seminars at campus, the supervision was implemented online using Google Disk (GD) and short video-films made by the university teacher. The focus for the supervision was to encourage the PSTs to evaluate didactical theories and mathematical knowledge and decide how to use them in teaching and learning situations.

Third, design experiment should involve both *prospective* and *reflective* situations (Cobb et al., 2003). In this project, the prospective aspect was manifested in the hypothesis or conjectures developed in terms of lesson plans in the written assignments in phases A1 and A2 of the MDP. In Phase A3 provided the possibility for reflection based on reflective knowledge and building on experience and research. Here, the MDP and the change of teaching and learning situations, build on previous teaching courses in mathematics and new ideas about learning, especially focused on social constructivism and the community of practice.

Fourth, design experiments include an *iterative* design. In this project, there are two levels of iteration (Cobb et al., 2003). A first is that the PSTs repeat the MDP three or four times during the course period, whereas the other is that the course itself was repeated five times with different students. The PSTs repeating the task hopefully provides better learning and the teacher had the possibility to adjust teaching according to the students' needs for supervision. The iteration of the course focused on the design of both the MDP and the teaching on a meta-level.

Fifth, design experiment involves *analysing* and *evaluating* the course to search for potential new theories (Cobb et al., 2003). Each year the PSTs were asked to evaluate the course and their responses together with the exam results and logs written by the teachers during the year, were used to adjust

the plan for the course for the following year. Although analyses took place during the five years, a retrospective analysis is yet to be fulfilled. Since then the designed course with the MDP has been repeated five times, and it has additionally been used in other courses, might give broader information about the ability of the use of MDPs. This adoption into other courses and continued use lead one to assume that the analyses made after each year have given positive results, but there is still need for more thorough analyses to quantify the effects of the implementation of the MDPs and the changes in teaching. A retrospective analysis of all available written material collected during the five years is necessary and is currently in progress.

### Theoretical discussion of the MDP

The Danish textbook for teacher education, Delta (Skott, Jess, & Hansen, 2008), was part of the syllabus for the course and in this book there is a presentation of Gomez cycle of didactic analysis (Gomez, 2002). Based on this work of Gomez an artefact for lesson planning named *The Mathematics Didactic planning tool* (MDP) was constructed by changing the original model to fit a Norwegian teaching and learning context informed by the work of Ball, Thames & Phelps (2008) and Niss and Højgaard (2011). Hence, the content of the MDP considered both mathematical, didactical and methodological theories that was based on the curriculum of the course, but focusing on different mathematical subjects for each assignment aiming at a (fictitious) classroom situation.

Gomez' (2002) model for didactical analysis was inspired by the *teaching trajectory* of Simon (1995), which is a cyclic planning tool for mathematics teaching, and Shulman's (1986) work on pedagogical content knowledge which later informed the development of *Mathematical content Knowledge for Teaching* (MKT) (Ball et al., 2008). MKT is divided into different theoretical issues like areas of *knowledge of content and curriculum*, *content and students*, *content and teaching*, *common content knowledge*, *specialized content knowledge*, and *horizon content knowledge* (Ball et al., 2008, p.403). In the various parts of the MDP (Figure 1) these areas was conceptualized in terms of *the mathematical tasks for teaching* from Ball et al. (2008, p.400), such as for instance *using mathematical notation and language*, *asking productive mathematical questions*, and *finding an example to make a specific mathematical point*. Another theoretical framework used were the didactical and pedagogical competencies with specific regards to mathematics from the KOM-project (Niss & Højgaard, 2011). These are the eight mathematical competencies concerning mathematics as a discipline (chapter 4 and 5), and the six forms of specific competencies which a mathematics teacher should possess (chapter 6 and 7). The areas of knowledge concerns the students' *competences of representing*, *symbol and formalism*, *communicating*, *aids and tools*, *mathematical thinking*, *problem-tackling*, *modelling*, and *reasoning*, and the teachers' *competences of curriculum*, *teaching*, *revealing learning*, and *assessment* (Niss & Højgaard, 2011). In the following text these theoretical notions will briefly be discussed how to be used in the design of the different phases of the MDP; see Figure 1 for the presentation of the model.

A1 introduces and presents topic, grade and focus points from the National curriculum's perspective. This provides the background for the PST choosing two or three textbooks, which the PST should analyse according to the mathematics topic and the focus points in the national curriculum. After which, they should make a short plan for teaching mathematics over a school year focusing on how to structure and organize given topics and argue for their choices. For instance, it would be wise to have worked with fractions and multiplication before an introduction to probability. A1 focus mainly

on theoretical aspects from *knowledge of content and curriculum* (Ball et al., 2008) and *the teacher competency of curriculum* (Niss & Højgaard, 2011).

A2 is the main part of the MDP where the PSTs work with their understanding of both knowledge about mathematics and didactical theories. It is important for the student to notice that the different parts of the plan (again see Figure 1) are meant to be understood and worked through in a hierarchical way. The theoretical aspects mainly focus on the MKT (Ball et al., 2008) and the competencies of teaching and learning (Niss & Højgaard, 2011), but of course additional theory is added when relevant.

The aim for this part is to formulate a plan for teaching the subject given, e.g. geometry, over a period of two to five lessons. In the first part (A2a), they present focus points and quality frameworks from the national curriculum to illustrate the frames and goals for the teaching and learning. Since the PSTs had no real class to teach, they had to make assumptions based on the information given in the national plans and other relevant sources such as e.g. textbooks. Analysis of mathematical content (A2b) illustrates “all” the mathematics that the PSTs knew about the subject given, including symbols, algorithms, different representations, modelling, etc. The goal of this part is to provoke the students to go deep into their own mathematical knowledge and analyse different aspects of mathematics without thinking about teaching or learning. In these analyses of mathematical content, the PSTs’ theoretical framework is knowledge about *representing competency*, *symbol and formalism competency*, *communicating competency* and *aids and tools competency* (Niss & Højgaard, 2011), which also illustrates *general and special subject matter knowledge* and *horizon content knowledge* (Ball et al., 2008).

Analysis of learning process (A2c) is about the students’ learning process *in the specific subject given*, e.g. geometry, not about general pedagogical learning theories. This part focuses on *knowledge of content and students* (Ball et al., 2008) for instance illustrated by knowledge about misconceptions, what could be difficult to understand and why, or how to support the learners that needed an extra challenge building on the mathematical issues discussed in A2b. Some of the same issues were the basis for the analysis of teaching (A2d), but this time the focus is teaching and to predicate how they can meet different situations that probably occur in teaching the mathematics subject given were, such as *asking productive mathematical questions* (Ball et al., 2008). This part is illustrating *knowledge of content and teaching* (Ball et al., 2008), and the teacher competencies about *teaching*, *revealing learning*, and *assessment* (Niss & Højgaard, 2011). Since the A2 is hierarchical built, the three analyses should be written in the way they are presented, the next building on the information given in the previous. A final and important task in A2 is to construct an open mathematics problem (A2e) with different levels of cognitive demands (Stein & Hiebert, 2009) which is based on knowledge gained from the three analyses. All the work is summed up in a schedule for the lesson(s) (A2f).

A3 is an individual written reflection assignment where the PSTs reflect on the decisions and analysis made in A1 and A2. Since A1 and A2 are carried out as group work, the final reflection gives each student the possibility to add his or her own perspectives on the process and the result of phases A1 and A2. The last phase, A3, has been a valuable resource for the on-going and continuing development and implementation of the MDP in the new course.

## Final comments

Using different theoretical perspectives from previous research about teaching (Ball et al., 2008; Niss & Højgaard, 2011; Stein & Hiebert, 2009), the research design method for planning new teaching models (Cobb et al., 2003), and research-based models of lesson planning (Gomez, 2002), have been useful in designing and developing the new course in which the MDP serves as a backbone.

Although the PSTs' practice in schools could not be integrated within the course, it could be argued that focusing on lesson planning by working with the MDP had a close connection to the practice of teaching mathematics, which was one intention of using lesson planning as a focal idea. Another was to elucidate the importance of theoretical argumentation when planning (and teaching) mathematics lessons and the intention of repeating the MDP several times became an important choice of performance since especially the complexity of A2 needed to be exercised several times. A profit of all the work was that all the MDPs together with the teachers' comments were shared on a learning management system to be available for all the PSTs attending the course. When the PSTs finished the course, the students thus had a number of lesson plans ready to use (with adjustments) in their future career.

The empirical material available for analysing different aspects of the project is teachers' logs, planning documents, students' reflective papers from the course, students' papers on didactical and mathematical analysis, and electronic records showing supervising dialogue during the writing of papers. The preliminary analysis of all the empirical material available, five years of teaching experience, and reading some of the PSTs' final reflection notes indicates that the majority found the MDP challenging but educational, and that they experienced writing MDPs' assignments to be valuable. Many argued that it would be too much work for planning lessons when working as a teacher, but that the experience of having done so during their education will influence their work as teachers.

There were a couple of practical changes made during the five years of study, such as to change the number of group members from groups up to 6, to working in pairs, and lowering the number of MDPs the students should work through from four in the first year to three the years following. Since the students only were on campus for a short time, much of the contact had to be via the Internet and became the common form of communication. Supervising the process of writing papers in this way had clear implications on the process. This is documented in several reflection notes where the PSTs explicitly wrote that they would not have gone so deep into the material if they had not been pushed by the supervisor.

In summing up, it seems like the MDP can be a good mediator for MKT and competencies. Further and more rigorous analysis of the empirical material will be valuable in documenting the proof of this indicative claim, and it should additionally provide more information and suggestions on how to enhance the MDP and the role of the supervisor.

# From theory to praxis

Lisser Rye Ejersbo<sup>1</sup> and Morten Misfeldt<sup>2</sup>

<sup>1</sup> Aarhus University, DPU, Copenhagen, Denmark; [lre@edu.au.dk](mailto:lre@edu.au.dk)

<sup>2</sup> Aalborg University, Copenhagen, Denmark; [Misfeldt@learning.aau.dk](mailto:Misfeldt@learning.aau.dk)

*This article is a description and discussion of a design research project in which we introduced a research idea about the influence of language on number concepts development into praxis on a school in grades K-3. Danish children have difficulties remembering the Danish number names because the Danish language resembles a primitive number concept in mathematical thinking. In the project, we renamed the numbers between 11- 99 after the base-10 system. Our hypothesis was that this system would help Danish students to get a more secure concept about the base-10 system. The project lasted for three years ending in spring 2016. Our results were so convincing that the school decided to continue using the mathematical number names, and other schools that heard about the project seem to be interested in using the system as well. In other words, the project goes from being a top-down project to a bottom-up project.*

*Keywords: Design research, base-10 system, grades K-2, top-down and bottom-up project.*

## Introduction

In this article, we describe a design research project, which took place in a public school in the primary grades K-3. We started with a hypothesis, and then it moved on to a design and then contact with a public school. We ran the project for three years and then worked with the school on its continuation. The main concern of our paper is that of existing and anchoring projects that have proven successful and engaged (part of) the organization with which we have collaborated.

Our research idea was provoked by the fact that the Danish number names (Ejersbo & Misfeldt 2011; 2015) have an etymology and wording that are both peculiar and impractical. For example, in Danish, the number 73 is *treoghalvfjerds* (three and half-four), the number 32 is *toogtredivte* (two and thirty), and the number 16 is *seksten* (sixteen). These old roots are unknown to most students. Furthermore, the number names are abbreviated. In Danish, the number 70 or *halvfjerds* (half-four) was once named half-four-times-twenty (in Danish *halvfjerdsindstyve*), but the *times-twenty* (in Danish *sindstyve*) has been lost in the counting numbers but retained in the ordinal numbers (for further explanation, see Ejersbo and Misfeldt, 2011). Another concern is the irregularity of the number names between 10 and 20, where 11 and 12 have unique names while 13 to 19 each end with a ten. Also, the two-digit numbers from 13 to 99 have an inversion property (the ones are said before the tens), and the tens have names inspired by a 20-base system.

Even though Danish number names are particularly irregular, most European languages break away from the clear regularity of the base-10 place value system. So understanding the effects of such irregularities on mathematics teaching and learning is interesting. With that motivation, we developed a hypothesis of how speaking about numbers with specific regular words that resemble the base-10 system would be beneficial for learning about the numbers in an easier way. This hypothesis has been tested with a three-year long intervention at a school in the Copenhagen area.

The project has ended, and the intervention was to a large extent successful. The data about student learning confirms that the classes where the new words for numbers system was successfully implemented have very strong performances in the areas related to number sense and arithmetic. Therefore, some of the teachers and the school organization would like to continue the work. We consequently discuss the question of how to exit intervention projects while anchoring relevant practices from the intervention into the organization.

In the paper we explore how this initial hypothesis has been activated as a way of using language as a didactical tool in a design research project. We will describe the state of the art that allowed us to develop the project idea, and how the project proceeded. Then we will briefly state our results in terms of a more well developed and tested set of hypotheses. Finally, we will describe our *exit strategy* for leaving a better practice at the school and reaching out to other schools and teachers.

### **Number concepts, base-10 and number names**

We know from the research literature that there are major differences in the kind of system and regularities a language uses to describe numbers. Most European countries have an irregular naming system for numbers between 11 and 20; both the German and Dutch systems feature an inversion property of the numbers between 13 and 99, similar to the Danish one. These inversion effects were studied by Moeller, Pixner, Zuber, Kaufman, and Nuerk (2011) for two-digit numbers, showing how inversion-related difficulties predict later arithmetic performance (for an overview, see Ejersbo and Misfeldt, 2011, 2015).

Different studies (Miura & Okamoto, 1989; Miura, Okamoto, Chungsoon, Steere, & Fayol, 1993; Miura, Okamoto, Vlahovic-Stetic, Kim, & Han, 1999) compared Japanese, Chinese, Korean, and English-speaking American first graders' (6–7 years old on average) cognitive representations and understanding of place value. The findings confirmed that the Asian-language speakers showed a preference for using base-10 representations to construct numbers, whereas English speakers favored using a collection of units. Note that a significant difference between American and Asian number names appears between the numbers 11 and 19, exactly when the base-10 system starts to use two digits. In Miura and Okamoto's (1989) study, children were asked to construct the numbers 11, 13, 28, 30, and 42 from sets of ten and unit wooden blocks. The results showed that 91% of the American first graders used unit blocks to represent the numbers on their first attempt. In contrast, about 80% of the Asian children used sets of ten blocks when representing the numbers on their initial attempt. These differences in cognitive representation were mainly ascribed to language (Miura et al., 1993).

Learning to count and understand the base-10 system are cognitive challenges involving many small steps. We have chosen to focus on oral counting, the cardinal principle of combining a name with a cardinal value, and the combination of words for a number, its cardinal value, and the digit sign.

Children typically learn the names of numbers as a long list of words and demonstrate knowledge of the stable order principle by almost always saying number words in a constant order while emphasizing the last number (Goswami, 2008). The names are developed as sounds connected to the number of objects in the sets.

The developmental shift to understanding the number name as a cardinal value requires a qualitative shift in children's representation of numbers. The cardinal principle requires comprehension of the logic behind counting (Goswami, 2008) and the ability to judge the size of a set. It relies on a representation of quantitative information in which the coding of smaller quantities is different from that of larger quantities (Goswami, 2008). Children's conceptual understanding of numeration depends on their ability to make a connection between a number name and its cardinal value, which they learn to do by grouping and quantifying sets of objects (Thomas, Mulligan, & Goldin, 2002).

Learning how to connect the number name, its cardinal value, and the digit sign is another challenge. As discussed, two different systems must be combined with different representations. Becoming an expert at combining these two systems means developing rapid access to an automatic use of written numbers and simultaneously being able to multitask to solve other problems in parallel. If the two systems are iconic and support each other, the child encounters less difficulty in learning this skill, as is the case for Japanese-speaking children. If the two systems are irregular and therefore conflict with each other, it is more problematic for the child to understand and remember the connection among the name, the cardinal value, and the sign. Duval (2006) described this situation as a conversion between registers and observed that the congruent conversions seem the easiest for students, meaning that the representation in the starting register is transparent to the target register. One obvious solution is, therefore, to use a fully regular approach to saying the names of the numbers, which means saying "one-ten and four" instead of fourteen and so on. It is possible and easy to *create* such a logical system for naming the numbers in Danish, and thus this became our main project idea.

This reasoning helped to form the project idea of using such logical number names as a didactical tool.

## **The design of a research idea**

Occupied by these issues of why and how different languages influence number concepts and perhaps even the ability to learn simple arithmetic, we designed a three-year project to take place at a Danish public school in the suburbs of Copenhagen.

Using design research (Cobb & Gravemeijer, 2008), we formulated our hypotheses for empirical investigation. The hypotheses were grounded in our initial understanding of the difficulties that Danish children experience with the Danish number names. The research builds on the following two hypotheses:

1. Number names function as cognitive artifacts; hence, a concordance between spoken and written language is sensible.
2. Language constitutes concepts, which is why clear terminology seems effective in developing lucid concepts.

## **Project intervention**

To address the question of the influence of number names on number concepts, we contacted a Danish public school that could be interested to run the project together with us. We already knew the school, which made the access easier. We were invited to a meeting with the leading team of the

school, including the headmaster, together with a small group of teachers from the school. We presented our project, and the participants accepted it for one year as a start. An evaluation would decide if it should continue additionally for two more years. We decided to involve all 10 classes—three grade 2, three grade 1, four kindergarten classes—and 9 teachers in the primary section of the school. The project combined the renaming of numbers with supporting the teachers in instructing the students. In each class, 20–35% was children who had migrated from other countries, but all the children spoke Danish, and all the teaching was in Danish. The entire research project was planned to last for three years. The data consists of students' performance in classroom observations, a number understanding test, teachers' portfolios, interviews with teachers and students, and notes from collaboration with teachers. At the end of the projects, we used the national test for evaluating the students' competencies in Algebra and Numbers.

### **The first year**

The cooperation with the teachers and the classes were only possible because of the positive attitude from the headmaster of the school. She left it to us, the researchers and the teachers, to run the project. But she and the leading team was helpful and showed interest the whole time.

An in-service course for the involved teachers was the first thing to arrange and run. At this course many questions came up and were discussed. Should the teachers always rename both the names of the numbers? How should the fractions be named? Would the student get to know the normal Danish number names? We made a lot of decisions that day and agreed that the teachers should write a log with further questions that we as researchers should answer, either by discussion or by recording answers in the log.

The participants were now ready to start the next school year with the mathematical numbers.

**Kindergarten:** The Kindergarten (K) teachers were used to cooperating with each other and continued this work with the mathematical numbers. We observed the classrooms regularly and had follow-up meetings. The K teachers used both the mathematical number names and the normal number names when they named a number, or the students read a number. They also arranged joint counting for all using mathematical numbers, and they made materials for student use that helped the students to be aware of the base-10 position system, and the students became very familiar with the mathematical numbers. The parents were informed at a meeting with the kindergarten teachers only; all in all, they implemented the mathematical numbers very easily.

**Grade 1:** The project proceeded differently in the first-grade classrooms. All these classes had new teachers, which is normal for students in the first grade in Denmark. We were in a real-world situation with all the mess that exists there. The three first-grade classes had three different teachers who did not work together very often, and none of them continued the work done by the K class teachers. So the routines disappeared. The big difference in practice between first grade and the K class caused some chaos during the first two months. Furthermore, some of the first-grade teachers left the school or their classes during that period. But new teachers came, and during November and December the classes also worked regularly with the mathematical numbers. We were lucky that one of the newcomers believed in the project idea and was very involved with it. He became a teacher in two of the three first-grade classes, and his presence was a great benefit for the project.

**Grade 2:** We never observed any of these classes, but met with the teachers and discussed how they could implement the mathematical numbers in the best way. These students had already been in school for two years, and we decided that while we could not expect that they would naturally use the mathematical numbers, they should know them.

**Evaluation:** In the first year we were very busy collecting data, observing the seven classes, and trying to find the best ways to implement the mathematical numbers. The teachers' log idea never caught on, so we solved any problems during our meetings with the teachers. At the end of the year, we tested all the students. The outcome of the test showed us that the student used both names for the numbers quite naturally. There was a slight tendency that the students were more secure from the spoken mathematical numbers to written numbers than from the spoken normal numbers to written numbers. In the K classes, we noticed that the students were much more secure in correctly recognizing and naming numbers between 10 and 20 than was normal for these classes.

During the year, we used the design research method as a way to evaluate the actual lesson related to how the whole project was running. We exchanged good ideas and noticed the progress and difficulties. We solved the difficulties in different ways and changed some of our means; but not our goal. We made a report of the first year with our results and data. It was positively received by the leading team, who decided to let the project continue for the next two years.

In our plan for the second year we decided not to observe in the K classes, but only meet with the K teachers. We would do a brief orientation for the new mathematics teachers in the four new first grades, and we would follow the second grades more intensively.

### **The second year**

For each year, we expanded our research with new K classes and with that also thirds grades. The K teachers could more or less develop and repeat with their new students what they had done first year. The newcomers in the K teacher group were taught by especially one of the K teachers taking the major responsibility for informing the new teachers. As we discussed in our meetings with the teachers, the work in the K classes went very smoothly.

The four new first grades had new teachers, luckily only two teachers with two classes each. They did not know anything about the project before they chose to teach first-grade mathematics, but cooperated from the start. We met with them and introduced them to the project, and visited their classrooms several times during the year.

The three second grades were the most interesting, because the students were in their second year of the project. Their teachers were very engaged and consistent in the use of the mathematical numbers. Each time we observed the classroom we talked with the students and asked how they felt using two different names for one number. The answers were surprising:

- Student 1: It is fun, and we like to use the mathematical number names, because then we always are able to remember the names.
- Student 2: We also know the cardinal at once.
- Student 3: It is a help to remember the names of the normal number as well.

We were a little overwhelmed but agreed with the students that they should explain to their parents why we used the mathematical number names. We decided that no one could do it better than them.

At the end of the year, we used the same test we had used in the first year but only with the first and second grade. We noticed again that the students' understanding of numbers was very good, both for the use of normal number names and for the mathematical number names

Due to the time we had to do the project, and how it developed in the school, we decided to minimize the observation to only the three third-grade classes, but we still met with the teachers from second grade. We did not observe the first grades or meet with their teachers. We continued with the K teachers' meetings.

### **The third year**

We mostly concentrated our research on grade three and the kindergarten classes. The use of the mathematical number names seemed very natural for the students together with the normal number names, and they were bilingual in the numbers from 10–99. In third grade, the students were so familiar with the base-10 value system that they could transfer the knowledge to the decimal numbers, which meant that they easily answered questions correctly when asked to compare numbers like 0.4 and 0.25. In May 2016, the three classes had the national test in mathematics for third grade. Compared to the average of all the third graders in Denmark, one of the third-grade classes—the one that was observed most frequently—had an average score in Numbers and Algebra that was far above average. The other third-grade classes also showed a better result in Numbers and Algebra than the average third-graders.

The conclusion we draw was that the students using the new system showed a better understanding of the base-10 system. We saw these competencies, and met our goals, in all the classes which used the mathematical numbers. And because the national test investigates additional competencies in Numbers and Algebra, we dared to conclude that the students gained from using two names for the numbers.

During the following year, the school had a new headmaster and a new leading board, but because of the results, she decided to continue with the mathematical number names even though the research project stopped.

### **From Top-down to Bottom-up**

With the decision that the school wanted to continue using the mathematical number names after our exit, we needed to design a plan for how it could be possible. Inspired by the research (Jarvis, 1999; Nielsen, 2001) we suggested the following plan:

1. All the teachers at the school should know that the project stopped as a research project, but that the project would continue as an intervention project with the teachers as the drivers.
2. One K teacher should be responsible for introducing the methods in the K classes for incoming teacher and for ideas to be exchanged among the K teachers.

3. A mathematics teacher should be responsible for orientation of the mathematics teachers in first grade each year and arrange a course at the beginning of the new school year, which everybody could join in.
4. There will still be access to the researchers for questions and other things; we are interested in the continuing process.

This plan was first discussed with the involved teachers who agreed to the work they should do, and then it was presented to the headmaster. She also agreed and was willing to find time for the teacher support.

We started the process with a course for mathematics teachers in the K-3 classes in August 2016. There were about 15 people at the course, which was organized and run by a K teacher, a mathematics teacher, and one of the researchers. At this course, we made a quick run through the ideas behind the project and how it had run in the previous three years. The teachers who had previously taught classes and been involved in the project exchanged ideas and views of the learning processes with the mathematical numbers. The K teacher told how she was at an in-service course for K teachers in the Copenhagen region and told about the project and how she and the math supervisor at the school videotaped how she used the mathematical number names in the K classes. The other participants at the in-service course showed a big interest in the project. A similar course will be held again, and the math supervisor has told us that there is already a big interest in this in-service course.

## Discussion

This article is less concerned with the actual results of the investigations that we conducted in the school and more concerned with the transition from an intervention driven by research curiosity to an ongoing project driven by the school itself.

The project was large with many classes involved, and we must admit that it was a little too big for only two researchers on a very low budget. We shared the work, so at times only one of us made the observations, conducted the interviews, and participated in the meetings with the teachers. Everything was documented with taping, pictures, and materials that we analyzed together; we still have data waiting for deeper analysis.

In spite of the low budget and the few researchers, or maybe because of these limitations, we saw some teachers taking over the project in an especially engaged way. One teacher, in particular, took a lot of responsibility and during a period when other teachers were out sick, he taught all the three classes in third grade. Without him, we are not sure the project would have had the success it had. It would neither be possible to run such a project without the support and interest we had from the leading team including the head master, who played an important role.

## Perspectives

As it looks now, we hope that the use of mathematics number names will spread to other schools and continue to develop. Even though we officially stopped the project at a meeting with all the

teachers at the school, we will continue with some kind of support if necessary. We will also stay in touch for our own sake.

### Acknowledgment

We would like to thank Husum Skole, Copenhagen, for financial support together with the teachers, who worked for the project.

# The notion and role of “detection tests” in the Danish upper secondary “maths counsellor” programme

Uffe Thomas Jankvist<sup>1</sup> and Mogens Niss<sup>2</sup>

<sup>1</sup>Aarhus University, Danish School of Education, Denmark; [utj@edu.au.dk](mailto:utj@edu.au.dk)

<sup>2</sup>Roskilde University, IMFUFA, Denmark; [mn@ruc.dk](mailto:mn@ruc.dk)

*This paper presents and discusses a specific aspect of the Danish “maths counsellor” programme for upper secondary school, namely that of detection tests. More precisely, the purpose and design of a detection test is presented, as is the prospective counsellors’ use of the test. In the description, emphasis is placed on the ways in which detection tests assist in informing the maths counsellors in their work with students experiencing learning difficulties in mathematics.*

*Keywords: Detection test, “maths counsellor”, learning difficulties.*

## Introduction

The words “test” and “testing” are omnipresent in educational research and practice in general and in mathematics education in particular. However, the actual notions covered by these terms are very diverse, as are their roles and uses. Basically, the terms mean “critical examination of a person’s or a thing’s qualities”. There is an abundance of different purposes, goals and objects of testing, as well as a multitude of different approaches to and instruments for testing. Without attempting to outline a comprehensive theory of test and testing, one distinction is worth introducing in the context of mathematics education, a distinction between direct and indirect testing. In *direct* testing, the test object directly epitomises the very purpose and goal of the testing. If your purpose is to find out whether a given person can actually drive a car, a direct test consists of taking the person to trial in real car driving. In *indirect* testing, the test object is devised as an indirect indicator of – a probe into – something that is not identical to the test object itself, because this “something” is either inaccessible in direct terms or too large or too complex to be fully represented by the test object. So the test object becomes a proxy for – a representative of – the underlying, but necessarily indirect, object of testing. Mathematical learning, understanding, reasoning, modelling, and problem solving are just a few examples of such underlying objects of testing, for which a wide variety of test objects are only more or less well-chosen proxies. Mathematics education research and practice make extensive use of indirect testing, alongside direct testing.

The key issue concerning indirect testing is what relationships can be established between respondents’ responses to the test object and the real underlying object of testing. The generic question is: What do responses to the test object tell us about the respondent’s qualities in relation to the real underlying object of testing. Since, in indirect testing, these objects are not identical it requires a non-trivial amount of clarification of concepts, of interpretation and analysis, and oftentimes of independent empirical research to account for the inferences that can be justifiedly drawn from responses to the test object onto the underlying object of testing. The “detection tests” in focus in this paper are instruments for indirect testing. So, the above-mentioned generic question has to be specified for our context. Our *research question* then is: *In what respects and to what*

*extent does the detection test presented below allow for the detection of students with mathematics specific learning difficulties regarding mathematical concepts and concept formation?*

Due to space limitations we are not able to fully answer this question here and to fully corroborate the answer. Instead, we confine ourselves to providing some key points in an answer, that is by describing the context in which the detection tests are used; by providing an overall description of what a detection test is; and finally by means of an illustrative and authentic example. It should be noted that although the actual content of the detection tests is based on research findings and issues considered in the mathematics education literature, the notion and role of “detection test” in the sense presented here have been introduced by us and thus have not been described previously.

## **The “maths counsellor” programme**

This section is based on (Jankvist & Niss, 2016). The maths counsellor in-service teacher programme at Roskilde University (Jankvist & Niss, 2015) runs part time over three semesters (in total 30 ECTS – European Credit Transfer and Accumulation System), during which the upper secondary teachers – ideally – have a reduced teaching load at their schools. Each semester has an overarching theme: (1) concepts and concept formation in mathematics; (2) reasoning, proofs and proving; (3) models and modelling. These themes were chosen both because they are significant to upper secondary mathematics education in Denmark, as is spelled out in the national curriculum documents, and because they epitomise key aspects of the eight mathematical competencies in the Danish KOM-project (Niss & Højgaard, 2011), which constitutes the theoretical foundation of the maths counsellor programme. The teachers’ work in each semester is structured in terms of three different phases: (1) to *identify* (i.e., detect and select) students with genuine learning difficulties in mathematics; (2) to *diagnose* the learning difficulties of the student(s) identified; and finally (3) undertaking *intervention* according to the diagnosis arrived at with respect to the individual student.

At the very beginning of each semester, the teachers are equipped with a theme-specific *detection test*, consisting of questions and tasks for the students in relevant classes at their schools. As will be exemplified below, these tests are developed by us and are informed by research literature regarding the specific theme. The purpose of the test is to assist the teachers in detecting students with potential learning difficulties in mathematics. Usually, each teacher detects several such students, some of whom are selected for being offered maths counselling with the aim of rectifying or reducing the observed difficulties during the semester. This typically leads to the *identification* of 1-4 students per class in need of, and also interested in, receiving counselling. When speaking of mathematics specific learning difficulties, we rely on our previous definition given in (Jankvist & Niss, 2015, p. 260), i.e. “those seemingly unsurmountable obstacles and impediments – stumbling blocks – which some students encounter in their attempt to learn the subject. These stumbling blocks include, but are not limited to, a wide range of misconceptions, misinterpretations, misguided procedures, inadequate beliefs etc. with regard to established notions of mathematics. We do not include general learning disabilities, cognitive or affective disorders and the like.” The purpose of the counselling is not to motivate unmotivated students, but to assist those who work hard in mathematics on a daily basis but do not succeed.

In the diagnosing phase, the participating teachers – strongly assisted by the research literature they read as part of the programme (see Jankvist & Niss, 2015) – employ self-constructed tasks,

interviews, etc., to come to grips with the nature and origin of the students' mathematics specific learning difficulties. Taking the diagnosis as the point of departure and with support from the research literature and supervision by us, the teachers design and implement an intervention scheme for the students selected. The intervention scheme also includes steps which enable the counsellors to "measure" in what respects and to what extent the intervention has worked as anticipated for the selected students. For each semester, groups of 2-3 teachers write up a report. After the completion of the third semester, all three reports are combined into one, along with an introductory chapter. This final report forms the basis for a final oral exam at the university. The teachers who pass receive a diploma as certified maths counsellor.

### **What is a detection test – and what is it not?**

A *detection test*, as designed for the Danish "maths counsellor" programme, is a set of maths questions to be answered by upper secondary student classes (grades 10-12) within a time frame of 60-90 minutes without time pressure. The questions are short, both in their formulation and in the sense that they neither require lengthy procedures or computations nor longwinded explanations. Moreover, the questions do not involve conceptually complex or technically involved mathematics beyond standard upper secondary school mathematics. However, the questions are usually not routine questions either. On the contrary, many of them are deliberately posed in such a way that they break the "didactical contract" of upper secondary mathematics and require students to think and act independently. Danish upper secondary school takes three years and students usually enter at the age of 16 after having completed ten years of mandatory comprehensive primary and lower secondary schooling. Upper secondary students can choose to have mathematics for one, two or three years; three years being the advanced level. Danish upper secondary school covers three streams: general, technical, and business.

The primary purpose of a detection test is to be one among several instruments for *detecting students* possessing genuine learning difficulties in mathematics, within the relevant theme of the programme. So, the focus is not primarily on detecting the difficulties themselves – even though the tests do have something to offer to that end as well, because the questions in a detection test are composed such that wrong answers, individually or in combination with others, may suggest the potential presence of particular kinds of learning difficulties with a student giving these responses. As mentioned, a detection test is not meant to stand alone. When it comes to detecting students with learning difficulties, other sources of information, e.g. the teacher's prior knowledge of the students have to be taken into account as well. More precisely, a detection test may be seen as having three different roles. Firstly, in cases when the test, within a certain area or theme, points out students who by the teacher/counsellor were already suspected to have difficulties within that area, the role of the detection test is to *strengthen* the teacher's observations. Secondly, in cases when the test singles out students who were not already detected by the teacher, the test serves to amplify and sharpen the teacher's attention and to supplement his or her own observations of the students. Thirdly, it is also a purpose of the detection test to provide an initial support in pointing out the *specific sub-domains* within the test's theme, in which a detected student displays difficulties. Of course, students' test responses may not only indicate difficulties within particular mathematical topics; students' response patterns may also suggest overarching difficulties of a more principal or

general nature. Thus, this third role of a detection test then typically is to provide inspiration for the following “diagnosis” (cf. later sections).

It is important to keep in mind that a detection test is *not* meant to be a fair test of the students’ attainment levels in the subject of mathematics, neither when it comes to content knowledge, skills, and proficiency, nor when it comes to mathematical competence at large or to inventiveness or special mathematical talent. Due to the fact that detection tests are designed with a different purpose in mind, several important aspects of the usual handling of mathematics – e.g. familiarity with concepts and facts, computational skills, or proficiency in solving standard routine tasks – are not in focus of the tests. Similarly, the test cannot be used as a *screening test* in the usual sense, attempting to chart students’ possession of various mathematical competencies. However, employed on a larger population of students, e.g. a year group in a given school, the test may of course be used as a screening test for the potential presence of mathematics specific *learning difficulties pertaining the theme of the test*, within this population, but the test is still much more focused than a general screening test for attainment level or competencies.

Even though the test contributes to singling out students with potential learning difficulties, it *cannot determine*, in itself, whether a given student actually possesses such difficulties. It is certainly possible to encounter poorly performing students whose erroneous answers are not due to mathematics specific difficulties, but to ill-will and shoddy job, lack of accept of the didactical contract with or in the test (e.g. because the test is not supposed to influence teachers’ marks, or because the questions are of a different nature than usually encountered by the students), a bad day on the time of testing, or maybe to much more general learning difficulties (or disabilities) that manifest themselves in several subjects, not only in mathematics. To determine whether a student detected by the test actually possesses mathematics specific difficulties, supplementary means must be applied as well, not least the teacher’s knowledge of the student.

Beside the fact that the test, for a student who has been “detected” by it, may provide important indications for a subsequent diagnosis of mathematics specific difficulties, the test is *not a diagnostic test*. It requires an independent diagnostic process to uncover the specific nature of observed learning difficulties as well as the sources actually responsible for them. Oftentimes, preliminary hypotheses concerning the nature of the difficulties, and what may have caused them, must be supplemented with – or even replaced by – other hypotheses as the diagnosis proceeds. This may be due to much more deeply rooted difficulties than the ones observed at first, e.g. regarding more fundamental mathematical conceptions and beliefs than those in focus of the detection test.

## **An illustrative example of algebraic equations and equation solving**

As mentioned above, in each semester of the programme the maths counsellors are equipped with a detection test related to the theme of the semester. Hence, *detection test 1* concerns mathematical concepts and concept formation (we intent to discuss detection tests 2 and 3 in subsequent publications). This test consists of some 57 questions (and sub-questions) on selected topics relevant for Danish upper secondary school. These include: concepts of number (including fractions, decimals, negative numbers, irrational numbers); percent; algebraic expressions and transformations; equations (first and second degree, with different types of numbers as coefficients and solutions, and with the unknown on both sides of the equal sign); simple functions and aspects

of the coordinate system; and finally a selection of mathematical conventions such as: different symbolic notations for fractions; the equal sign; the inequality sign; minus and negative numbers. Out of the 57 questions (with sub-questions) around ten questions concern equations and equation solving. In the following we shall focus on examples of this.

As suggested by various researchers (see e.g. Kieran, 2007), students' difficulties in solving algebraic equations are of two rather distinct kinds. The first kind is related to transformation of equations – and algebraic expressions – by means of permissible operations, eventually leading to solutions. This not only involves knowing and understanding the scope and legality of the operations at issue, it is also to do with the nature and structure of the number domains implicated, the meaning of the equal sign, and the arithmetic operations involved, etc. The second kind of difficulty is to do with what an equation actually is, and what it means for an object to be a solution to an equation. Detection test 1 includes the following questions, among others: [17] Are there any values of  $a$  such that  $a^2 = 2a$ ? [18] Are there any values of  $b$  such that  $4b = 4 + b$ ? [20] What is the solution(s) to the equation:  $3x - x = 2x$ ? [25] Is  $x = 0$  a solution to the equation:  $3x - x = 2x$ ? [35a] Solve the equation:  $3x + 20 = x + 64$ . [36a] Solve the equation:  $-6x = 24$ . [37] For what  $x$  do we have  $38x + 72 = 38x$ ? Our purpose here is to illustrate two things: what the maths counsellor may learn from using the test on a larger population of students; and what the maths counsellor may learn about a single student from his or her answers to the test questions.

When a maths counsellor gives the detection test to a group of students, perhaps a larger cohort of students – say a class or a year group – certain patterns are likely to reveal themselves. For example questions 17 and 18 may tell us something about the students' algebraic understanding, e.g. the students' perception of how variables may and may not be denoted (anything other than  $x$  is often rejected as a variable). Questions 35a and 36a address the first kind of difficulty of solving algebraic equations, namely the operational aspect in relation to the number domains involved. Question 35a is an example of what Filloy and Rojano (1989) call a “non-arithmetical equation”, referring to the fact that the unknown appears on both sides of the equal sign. Question 36a may give rise to difficulties due to the appearance of the negative coefficient and division by a negative number, but also the situation of having to accept a negative number as a solution. On the one hand, questions 17, 20, and 25 may tell us about the second kind of difficulty mentioned above, i.e. knowing what a solution to an equation means, as well as about the consequences of the fact that an equation may have infinitely many solutions. On the other hand, they may also tell us something about the students' conception of equality in relation to equations and equation solving. From extensive experience, we know that Danish students have difficulties with equations that have either no solutions or any number as a solution. Question 37 addresses another aspect of the second kind of difficulty. Despite the fact that the vast majority of students are not able to correctly answer question 20, a large number of students will say that 0 is indeed a solution to the same equation in question 25. More interesting, perhaps, are those students who are able to answer that all numbers satisfy the equation  $3x - x = 2x$ , but still answer “no” to 0 being a solution. This may have to do with a belief that solutions are positive integers or be an aspect of more fundamental difficulties with 0.

To illustrate what an overview of a large student population may reveal, we provide table 1, which displays a binary (“correct-incorrect”) coding of 676 Danish upper secondary students' responses from 2012 and 2013 (from all three levels and streams). For the 405 1<sup>st</sup> year students participating in

the study we may confirm that questions 20 and 37 are indeed difficult ones, since 92.8% and 85.4%, respectively, cannot answer them correctly.

As an illustration of two maths counsellors' use of the test in regard to equations and equation solving, we present the story of student Å (Christensen, 2016). Student Å followed the mathematics programme at intermediate level at a general upper secondary school. The two maths counsellors spotted student Å at the beginning of Year 1, and then worked with her for three consecutive semesters, while they themselves were enrolled in the maths counsellor programme. In relation to the above questions on equations, student Å answered incorrectly on both questions 17 and 18 (“no”), she left question 20 unanswered but answered question 25 incorrectly (“no”), and left questions 35, 36, and 37 unanswered. The two maths counsellors initially interpreted this as if she had difficulties with the transformation of algebraic equations and with algebraic expressions in general, since she also gave incorrect answers to: [6] What is  $(a/b) \cdot (b/a)$ ? (Where neither  $a$  nor  $b$  is 0.) (Å: “ $a^2/b^2$ .”) and [50] If  $a = b$  is then  $b = a$ ? (Å: “no.”).

**Table 1: Binary coding of 676 student answers to selected questions from detection test 1 (coding by Morten Elkjær Hansen as part of his master's thesis at Aarhus University, 2016)**

Based on interviews which confirmed that student Å most certainly had difficulties in solving algebraic equations, and handling algebraic expressions in general, the two maths counsellors designed a series of small interventions focusing on solving various equations, arithmetic as well as algebraic ones, etc. (Filloy & Rojano, 1989). Soon, however, the maths counsellors began to suspect that Å's difficulties had indeed deeper roots. Student Å found that negative numbers as well as fractions were “ugly”, and on one occasion she uttered “0 that's not a number!” Sometimes student Å had difficulty at distinguishing the operations of addition and multiplication. When trying to find the difference between two numbers, she counted on her fingers. When having to find how many times 8 divides 24, she answered “four” by counting “8, 12, 16, 24”, and even double checked the result by repeating the same count. Having to perform the division  $24/6$ , she eventually gave up and replied “I don't know when the numbers are so big.” It turned out that student Å had fundamental difficulties with the concept of number, including understanding of numbers, number domains and handling of numbers. She appeared only to be on safe ground when operating with small natural numbers, where calculations can be performed on her fingers. Student Å's difficulties extended to her (in)ability to correctly apply basic mathematical terms. Thus, on a later occasion she used the term “diameter” (of a pizza) as just another unit along with centimeter and millimeter.

Upon revealing the depth of student Å's difficulties and acknowledging these to be the cause of her symptomatic difficulties with equation solving, the obvious question becomes whether the detection test might have provided us with some indications of this. In hindsight, even if there were several questions that Å left unanswered, the ones she answered erroneously do seem to corroborate her subsequently revealed learning difficulties: [7] Is the number  $-a$  positive or negative or is it not possible to decide this? (Å: "negative"). [13] Which number is larger:  $13/3$  or  $13/4$ ? (Å: " $13/4$ "). [15a] What is  $x + 0$ ? (Å: " $0x$ "). [26] Round off  $148.72 + 51.351$  to an integer. (Å: " $149 + 51 = 191$ "). [27] Which of the following fractions are equal:  $1/4$ ,  $4/16$ ,  $4/12$ ,  $2/8$ ? (Å: " $4/12$  and  $2/8$ "). [52] If  $a < b$  is  $b > a$ ? (Å: "no"). [53] Is  $(a - 1) / (b + 1) = (a / b) - 1$ ? (Å: "yes"). 55. Is  $(a + 3) / (a + 4) = 3/4$ ? (Å: "yes"). 56. Is  $(a - 1) / (b - 1) = a / b$ ? (Å: "yes"). In total, the occurrence of the above erroneous answers, together with the responses to the previous questions on equations, indicates the presence of a manifest learning difficulty syndrome with student Å.

### The revelation of mathematics specific learning difficulty “syndromes”

We now return to our research question, i.e. in what respect and to what extent do detection tests allow for the detection of students with mathematics specific learning difficulties – here exemplified by concepts and concept formation regarding equations and equation solving? As we saw in the case of student Å, she most certainly was *detected* to possess the potential learning difficulties as suggested by the test. Clearly, the counsellors' first hypothesis concerning Å's difficulties regarding concepts and concept formation was insufficient. However, we should keep in mind that this was the first time ever that these counsellors used the instrument of an indirect detection test. Once the maths counsellors become accustomed to the instrument and skilled in using it, they tell us that they are able to make much more accurate initial hypotheses – or even preliminary “diagnoses”. Indeed, having experienced a case like student Å, our two maths counsellors are able to make much more qualified initial hypotheses concerning students' difficulties. Seeing the answers to the questions above on numbers, conventions, etc., these maths counsellors will no longer suspect a student “merely” to have difficulties with solving first degree equations; they will see this as a likely symptom of more deeply rooted and fundamental difficulties.

Indirect tests, such as the detection test outlined above, may mislead the interpreter of test outcomes in several ways. In the case of student Å we saw that the maths counsellors at first mistook the student's apparent difficulties for her real, more fundamental difficulties. Another example, which we have also seen time and again, is where students are perfectly able to solve algebraic equations in an instrumental manner, but do not understand the relational aspects of the operations they perform or the very meaning of the solutions they arrive at (for references, see Jankvist & Niss, 2015). This is to say that if the aim is to “train monkeys” to find solutions to equations, then this is certainly possible. Our aim with the indirect detection test is to go deeper, since “our” object of learning is more complex than to mechanically obtain a solution. Our aim is to pave the way for drawing conclusions that are much broader than what the test questions ask, taken at face value, e.g. we insert “spot probes” into aspects of students' mastery of numbers and algebraic expressions and attempt to come up with hypotheses concerning their concept of number in general: if a student comes up with this and that erroneous answer, (s)he most likely possesses such and such learning difficulties; or if, on the contrary, the student can give correct answers on this particular set of

questions, then it is fair to assume that (s)he has actually grasped, in a relational manner, something significant about the entities involved.

As illustrated above, an indirect test such as a detection test may function both on an individual student level and on larger populations. For example, in the case of student Å we noticed that she answered incorrectly to question 15 and question 50 (cf. above). This we interpret as an indication of student Å not believing 0 to be a number and possibly possessing misconceptions of equality. But how special are these misconceptions for a 1<sup>st</sup> year student like Å? The coding among the 405 1<sup>st</sup> year students displayed in table 1 revealed an error rate of 18.3 for question 15 and 13.6 for question 50. In addition, question 14, asking what  $0 \cdot x$  is, which student Å answered correctly, has an error rate of 18.8 among the 405 1<sup>st</sup> year students. This is to say that if questions 14 and 15 are taken as markers of difficulties with the number 0, and if the population of the 405 students is representative, then it might be expected that more than one sixth of the students in a class at the beginning of Year 1 will have the number 0 as a “stumbling block” in some sense. The indirect detection test may suggest the presence of syndromes, on an individual level as well as on the level of populations.

## Introduction and research questions

The many papers in the literature of mathematics education devoted to calculus signify the difficulties with the teaching and learning of calculus with the limit concept as one of the fundamental challenges (Rasmussen & Borba, 2014). In this paper we present and discuss a theory based design and its implementation for students' productions of tutorials aimed at supporting the students' learning of the limit concept. The research was related to a teaching experiment in a first year calculus course at Roskilde University, where the students produced tutorials with the app *Explain Everything* or similar apps<sup>1</sup>. Building on theories explaining general learning difficulties with mathematical concepts such as the notion of students' concepts images (Vinner & Dreyfus, 1989) and Sfard's (1991) model for formation of mathematical concepts and the importance of communication in the learning of mathematics (Sfard, 2008) a didactic tutorial activity was designed. The purpose was to get the students to express their images of key mathematical concepts in dialogues with their fellow students and to support their concept formation process in particularly with respect to their use of symbolic representations and their reification of key concepts such as the derivative, integral and limit concepts as mathematical objects. The activity was designed and implemented as an assignment; namely to produce in small groups video tutorials explaining the group's solution to selected exercises and the mathematical basis hereof, see figure 1. In the assignment specific requirements for the workflow of the students' production were given in order to support the didactic purpose. The tutorials were used as a resource by the students at the course and in preparing for the final.

In the design and implementation of the experiment the basic idea was to use the digital tutorial genre to create a theory directed learning environment that encouraged the students to communicate with each other about mathematical theory, concepts and techniques. The tutorial genre mediated

---

<sup>1</sup> The pedagogical set up was developed in collaboration with Maja Bødtker-Hansen, University of Copenhagen.

student-student interactions and hereby supported students' reflections on key mathematical concepts. The didactical assumption was that by focusing the students' attention on the production of tutorials, aimed at supporting their fellow students' learning, it would be possible to create situations where small groups of collaborating students would activate and express their own understandings and images of the mathematical concepts in focus. In addition, the digital tutorials could be (and was) used by students for their own retention of the problem solving techniques and their mathematical foundation – particular in preparing for the final. Furthermore, re-viewing and discussing the tutorials could support the students' reflections on their conceptual learning or be used as a basis for common reflections.

With respect to the scope and focus of the working group *Implementation of Research Findings in Mathematics Education* (see the introduction to TWG23), the implementation aspect of this paper and further related work is the design and organization in the classroom of the digital tutorial in creating a learning environment in which research findings on students' concept formation and the importance of communication are brought to use in the teaching of a first year calculus course. We are developing our practice of mathematics teaching through interplay with research – and in this process we are also engaged with research, so in the present paper, implementation of research results and research are intertwined.

We audio recorded the students' reflections during their work with the tutorials. The transcripts of these records, the tutorials, the students' performance at the course and observations during the course form the empirical basis for addressing our three didactical research questions (RQ):

1. In what sense and degree can a learning environment focusing on the students' productions of tutorials and other digital products with subject matter content support the students' formation of key concepts in calculus?
2. Which learning difficulties related to the key concepts in calculus can be revealed and theoretical explained through analyses of such student activities and products?
3. How can the findings from such analyses be used to further develop the learning environment and the way in which the students' products are used in the calculus course?

In this paper we address the three RQs focusing on the limit concept.

## **The context of the experiment**

The experiment was performed at the calculus course in the natural science bachelor program at Roskilde University. There were 32 first year students in the course, which was taught in English using a typical American calculus textbook (Adams & Essex, 2013). During the previous few years, it had become evident that the students' had problems explaining and applying the concepts and methods of calculus in their subsequent courses. One possible explanation for the increasing difficulties for the students in developing their conceptual learning in the calculus course could be changes in their prerequisites concerning key mathematical methods and concepts from high school, which are fundamental for calculus such as algebra, variable, function and the limit concept. CAS and graphing software for calculators and computers are used intensively in mathematics teaching at high school in Denmark and students learn instrumented techniques to solve standard problems by means of such tools. Similar experiences are reported in other educational systems. Barbé et al.

(2005) have analyzed the situation in Spanish high schools, in particular the incoherence in the mathematical organizations of the theory of limits at high school level. Similar incoherencies have been found with other key elements of upper secondary level calculus in Denmark and American textbooks for first year calculus courses at the university level, due to the elimination of the topological parts of mathematical analysis (Winsløw 2015, pp. 200-203). In general, the extended use of it-instrumented techniques, in particular CAS-based techniques, poses challenges for the teaching of calculus in high school and at introductory courses at university entrance level. Gücler (2014, p.4) addresses the role of the teacher in students' learning of the limit concept in such a teaching practice and pinpoints the importance of the teacher in challenging the students to consider limits both from a process and an object perspective in different mathematical contexts. In particular, the students need to communicate their conceptual understanding in order to really experience both of these perspectives and typically they will need specific support in order to grasp the idea of the limit of a function as a mathematical object.

Our approach to this challenge is to experiment with the learning environment so as to make the students produce and publish their own mathematical products in the form of tutorials in the digital genre through the use of various app's and video-recordings with tablets. The students' products combined oral and written explanations and presentations of their mathematical task and its content matter with visual and dynamical elements.

### **Implementation of the experiment: mediatized presentations and assessment**

The students' fabrications of the mediatized tutorials were connected to their usual homework of sets of traditional problems and exercises. During the course, the students handed in three sets of homework that each consisted of between 10 to 21 standard problems and exercises from the text book. The students were allowed to discuss the solutions to the exercises with each other, but they handed in an individual presentation of solutions to the exercises. In order to participate in the final, a student had to have all three homework sets approved by the teacher. After the deadline for handing in a homework set, the exercises of the set were distributed between the students who in small groups produced a video tutorial of a solution to one of the exercises using the app *Explain Everything* or by other means. The video assignments were accompanied by a set of requirements for the product and a specific work flow which the students had to follow. The instructions given to the students can be seen in figure 1.

Each student also participated in a project work in which the students worked in groups with different subjects from the text book that were not covered in class. Each group wrote a technical report of two pages, which was supplemented by various video and/or other visual and oral digital products.

Finally, the assessment criteria were changed. The written test towards the end of the course was replaced by an oral test. The oral examination consisted of two elements: (1) a 12-15 minutes group presentation of the group's project work. Every student was required to participate actively in the presentation of his/hers project work; (2) an individual examination of 8-10 minutes following the group presentation. After the presentation of the project work, the group left the examination room and hereafter each student was called back in for the individual examination. Each student drew by chance one of the three homework sets of exercises, and made a 5-6 minutes presentation of

selected parts of the subject matter covered by the exercises in the set. The presentation by the student was followed by 4-5 minutes of questioning in the remaining parts of the course and/or homework sets.

#### Video Assignment for portfolio

You must prepare a tutorial for the exercise you have been asked to work with.

A tutorial is a visual, instructive guide with added speak. The genre is used primarily for technical explanations on the internet and 'Walk Troughs' to computer games. Here we use it to communicate mathematics, both to understand the content and partly to train oral communication with and about mathematics (and as preparation for the final).

Your tutorial must be prepared in the app: "explain everything" (download in the app store). You can see a tutorial (!) to the program's most basic functions here: <https://www.youtube.com/watch?v=9yvA4bzfrI4>. See it before you come to class on Thursday the 23. of October, so you can skip most of the technical problems.

The assignment corresponds to the individual part of the final, where you draw a portfolio set and have to characterize it in relation to the syllabus and then focus on specific, representative exercises that illustrate the concepts, techniques and issues. Taken together, all your video tutorials constitute a 'bank' of small videos for each portfolio set.

#### Product requirements for the video:

The video may last 3-5 minutes. All group members must play an active role in the preparation. The video must contain the following:

1. Introduction  
An introduction to your tutorial (we are xxx, this tutorial is aimed at xxx)  
An introduction to the topic (e.g. xxx)  
What kind of math is involved?  
What do you calculate / use it for / describe?
2. Problem Solving  
A demonstration of how to solve the exercise  
In your demonstration you must explain and highlight every step both verbally and visually
3. The "bottom line"  
Finish the video with a short summary  
Reference to the introduction (e.g. we now have an example of ....)

#### Workflow:

Before you begin, you should all have downloaded "explain everything" and seen the accompanying tutorial (link above).

1. Formulate an introduction to the exercise. You may write it out completely in prose, so the text can be read aloud.
2. Write down the solution to the whole exercise  
Divide the solution process into clear 'steps' - preferably with a number.  
Elaborate on each 'step' with the speaking that needs to be added in the video.
3. Formulate "the bottom line" - remember to refer to the introduction
4. Check with Tim
5. Make a small test movie where you test the sound and get familiar with how to draw and write in the program.
6. Record the movie.
7. Upload the video to Moodle with the file name: "exercise ?? in chapter ?? "or" review exercise ?? in chapter ?? " according to which kind of exercise you have worked with.

**Figure 1: Assignment, product requirement and workflow for video production. 'Tim' in step 4 of the work flow refers to the teaching assistant. The students were requested to perform a quality test through his approval before they continued to step 5**

The alignment of the requirements for the students' work during the course and the final was an important aspect of the design of the new learning environment. The oral communication skills which were needed for the final were trained through the student-student interactions in the design phase of the video productions as well as in the actual fabrication of the videos of the homework exercises and the mediatized parts of the project work. The mediatized products of the project report were directly aligned with the first part of the final, and the video tutorials were directly aligned with the second part of the final. The bank of video tutorials of the total amount of exercises in the portfolio sets that were produced by the students during the course helped the students prepare for the second part of the oral examination. The students carefully designed tutorials that explained

clearly and in depth how to solve the exercises, because they were to be used by their fellow students in their preparation for the final.

### Analyzing the students' reflections on the limit concept

The students' tutorials were examined during the course in order to identify those which were rich enough to be analyzed for answering RQ 2 with respect to the limit concept. Among them, a few were selected for discussions with the students in the classroom. Later, the material might be used for analyses that focus on other key concepts. Here, we illustrate with one case how we have analysed the students' work with the tutorials for answering RQ 2 focusing on the limit concept. Guided by the theories, we looked for indicators of students' image concept, of students revealing a conceptual understanding, and of students using a process oriented conception when we analysed the data. The data is transcripts of the audio recordings of one group of students while they produced their first tutorial of an exercise from the first homework set. The students' video is also included in our analysis.

The students' objective was to explain the limit concept using the exercise of finding the limit:

$$\lim_{x \rightarrow 3} \frac{x^2 - 6x + 9}{x^2 - 9}$$

To begin with, the students observed that the limit cannot be found simply by inserting  $x=3$  in the expression, since the denominator is zero for  $x=3$ . They mentioned the technique of factorization in order to handle this challenge. This technique is used in several examples in the text book. During their work, the students had software for graphical and CAS analysis at their disposal. However, before implementing this technique they began to reflect on the meaning of the limit concept. The students realized that the video should be aimed at "all the students that are struggling with calculus", as student 2 phrased it. Accordingly, they took on the challenge of explaining the limit concept in their tutorial. Their dialogue went as follows:

- S1: Wait a second and now I think I'm lost a little bit. What is this limit thing actually doing?
- S2: We have to watch the limit, so we have to watch the value that our function is approaching, when it's, when the axis approach ...[S2 draws a graph of the function on the computer.]
- S1: Ah, yeah so we can see here, that's true. Okay trace, so we can see here, so we take  $x$  value 3, eeh.. to here, so it's pretty close to 0.!
- S1: Makes a lot of sense. We can also zoom in!
- S1: I think you just say that a limit is a number that is (inaudible) by. We have a value that is approaching a number ... right?
- S2: A variable that is approaching a number?
- S1: We have a function. We have variables in a function that is getting approached by a number. .. It's like we're getting infinitely close, we're getting infinitely close to a number in the function without reaching it. That's a limit.

Here we see that there is a close interplay between, on the one hand, the students' understanding of the particular problem in hand and their ideas and images for the limit concept in general, and on the

other hand, the challenge of producing an explanatory tutorial for their fellow students. The situation forces the students to activate and verbalize their images of the limit concept. It becomes clear for the students that their understanding is not sufficiently developed for explaining the limit concept clearly in their own words in the tutorial. In the process of writing the manuscript for their tutorial the students consulted the text book of the definition of the limit concept. The dialogue continued as follows:

- S1:            yeah, okay, but let's first answer the first one. ... What's an introduction to the topic. I think an introduction would just be like "A limit is an..."!
- S2:            value that
- S1:            it's actually like...
- S2:            a value or number, maybe a number. It's a number that...
- S1:            yeah it is a number that is getting approached, but is never reached!
- S2:            it can be reached, it can be reached. I just. You don't have to say if it's reached or defined or undefined, you just say that it's a number that the function approaches as  $x$  approaches. As  $x$  gets closer and closer to the  $c$ . [Referring to the notation in the textbook]
- S1:            but I mean it doesn't reach the limit, that's the idea.
- S2:            it has... it could. It can because you can write, because that's only the...
- S1:            it's still the number it's going towards but...
- S2:            you can, you can say limit of  $x$  when  $x$  approaches 2, it's (over) the limit.
- S1:            yeah okay, but the limit is numbered, but it never reaches that number, that's not the idea. The limit is just taking it to the limit.
- S2:            okay!

The students are getting into a deep discussion of how to understand the limit concept. Student 1 is quite persistent in his process-based thinking of a limit, and he has difficulties with accepting that the limit of a function can actually be reached. Student 2, however, switches to a more object-based thinking in their discussion of how they should introduce the limit concept in their tutorial. In some of her utterances she is getting close to formulating the definition of a limit in her own words, and she seems to be aware of the fact that the value of the function can be forced arbitrary close to its limit in a certain point  $x=c$  by choosing  $x$  to be sufficiently close – but not equal – to  $c$ .

After a while student 1 begins to switch into a more object-based thinking of limits. He says:

- S1:            a limit is a number that is being. A limit is a value, you have (on there), the  $y$  axis, when you're approaching a number on the  $x$  axis.... But is it mathematically correct to say that? It's like if you have a function, and you go towards the number.

In their tutorial the students explain in detail doing the algebraic manipulation by hand how to get to the identity:  $\frac{x^2 - 6x + 9}{x^2 - 9} = \frac{(x-3)^2}{(x+3)(x-3)}$ , which for  $x \neq 3$  is equal to  $\frac{(x-3)}{(x+3)}$ .

They explain in the tutorial how the limit of the given expression can be evaluated by substituting 3 for  $x$  in "the redefined function" and that this yields the result 0. The students also explain that the

given function is not continuous for  $x$  equal to 3: “It has a hole in its graph for  $x$  equal to 3, while the redefined function is continuous in this point and has the value 0”.

However, the crucial mathematical argument is not stated or explained explicitly in their tutorial; namely that since the two expressions are equivalent for all real value of  $x \neq 3$ , then

$$\lim_{x \rightarrow 3} \frac{x^2 - 6x + 9}{x^2 - 9} = \lim_{x \rightarrow 3} \frac{x - 3}{x + 3}$$

## Discussion and some initial conclusions

Focusing on the limit concept, our findings in relation to the three RQs are:

Ad (1): The learning environment encourages the students to articulate and communicate their understanding of key concepts such as the limit concept in various situations and forms of representations. As illustrated in the analysis presented, in the process of producing the tutorial, the students engaged in dialogues about the limit concept using their own language. In their tutorial they used oral, written and visual forms of expressions in communicating their conceptual understanding and the techniques they used in solving their problem. The crucial didactical feature of the learning environment is the focus on the students’ productions of the tutorials aimed at their fellow students. Together with the prescribed work flow and the requirements specified in figure 1, the focus on the productions of the tutorials, encouraged and enabled the students to express and reflect on their own conceptual understanding. In general, from analyzing the students’ dialogues during their production of their tutorial it is evident that only when the students began to work on the video production they became fully aware of what their task really was about, how the technique they used could be explained, and why their results were correct.

Ad (2): From the analysis it is clear that the students found it very difficult to really understand and use the formal definition of the concept of a limit of a function from the text. Especially student 1 insisted on understanding the limit concept as a process or actually as two connected processes. He did not focus on the quality of the limit of a function, and he emphasized wrongly that the limit is a number which will not be reached by the function. This phenomenon can be understood by means of the concept of students’ concepts images (Vinner & Dreyfus, 1989). Their research explains and evidences that formal concept definition only become meaningful to students to the extent in which they are unfolded and concretized by personal experiences. The phenomenon can be further analyzed by means of the process – object duality of mathematical concepts (Sfard, 1991).

In the tutorial, the students explain how to use the technique of factorization to find the limit of the given function. They reached a new expression for the function, which is equivalent to the given expression for all real values of the independent variable  $x$  except for  $x=3$ . Only the new expression is defined for  $x=3$  and can therefore be evaluated in  $x=3$ , which yields 0. However, in the tutorial, the students did not really explain why the limit for  $x \rightarrow 3$  have to be the same for the two expressions since they are equal for all values of  $x$  except for  $x=3$ . Güçler (2013, 2014) found and analyzed similar difficulties in students’ learning of the limit concept.

Ad (3): In general, analyses of the students’ productions of the tutorials and the tutorials themselves allow pinpointing learning difficulties related to key concepts in calculus such as the limit concept, which are theoretically explainable. The analyses can provide ideas for variation of problems to be

dealt with in the tutorials in order to invoke and challenge the students' different concept images of the key concepts in calculus. Such analyses can inform the development of the learning environment in order for the theories to be used in the practice of teaching for identifying and help overcoming students' learning difficulties. Moreover, anchored to the students' experiences with the tutorial, theories can help students develop a sound meta-learning related to the formation of mathematical concepts.

Also, the tutorials can be used in whole class teaching as a point of departure for discussing the relations between the techniques used to solve the different types of problems addressed and the mathematical theory explaining them and hereby contribute to the development of the mathematical organization in the calculus course.

# Implementation enterprise through the lens of a theory of diffusion of innovations: A case of online problem-solving forums

Boris Koichu<sup>1</sup> and Nelly Keller<sup>2</sup>

<sup>1</sup>Weizmann Institute of Science, [boris.koichu@weizmann.ac.il](mailto:boris.koichu@weizmann.ac.il)

<sup>2</sup>Technion – Israel Institute of Technology, [nellyk@tx.technion.ac.il](mailto:nellyk@tx.technion.ac.il)

*The goal of this article is to present and theorize our more successful and less successful attempts to create and sustain problem-solving forums, in which exploratory discourse takes place. The main argument is that many implementation-related phenomena that we have encountered when working with seven high-school classes for one or two school years can be characterized and explained with the aid of conceptual tools provided by Rogers' Theory of Diffusion of Innovation. The most successful process of forming an online forum in one of the classes is presented in some detail, and the parallel processes in the rest of the classes are presented in the form of an aggregated summary. Implications for future design-based implementation research are drawn.*

**Keywords:** Problem solving, online forums in social networks, diffusion of innovations.

## Introduction

This article presents an implementation aspect of a research project entitled “Heuristic and engagement aspects of learning through long-term collaborative mathematical problem solving”<sup>1</sup>. The main research goal of the project (on-going until September 2017) is to produce a model of learning through mathematical problem solving, which would be attentive to cognitive, socio-affective and contextual aspects of this activity. In particular, the model is supposed to attend to interactions between variations in heuristic behaviors (Koichu, Berman & Moore, 2006; Koichu, 2010) and socio-affective engagement structures (Goldin et al., 2011) activated when high-school students collaboratively cope with challenging mathematics problems for relatively long time.

An implementation aspect of the project consists of designing and sustaining a special learning environment, in which long-term problem solving might be investigated. The intended environment comprised of a particular combination of problem-solving lessons in a classroom and out-of-classroom work supported by online asynchronous discussion forums. Its design was strongly informed by past research on affordances of online learning environments. Past research tells us that students in online environments can actively participate in solving complex problems for 2-3 weeks almost without teacher interventions (Moss & Beatty, 2006) and that some of those students who tend to be silent in a classroom can actively participate in online discussions (Schwarz & Asterhan, 2011). In addition, there is evidence that online discussions enable students to meaningfully use their mathematical knowledge, enhance self-regulation skills and support knowledge construction (Nason & Woodruff, 2003; Tarja-Ritta & Järvelä, 2005; Stahl, 2009).

Schwarz and Asterhan (2011) attribute the benefits of online discussions to their unique traits, such as: fostering divergent rather than linear interactions, enabling flexible time schedules of

---

<sup>1</sup> Selected findings of the project are reported in Lachmy & Koichu (2014), Koichu (2015ab), Keller and Koichu (in press).

participation in the discussions over relatively long periods of time, encouraging explicit and accurate expression of the ideas in writing. Koichu (2015ab) argues that many affordances of an online problem-solving forum stem from its fundamental characteristics of being a *choice-affluent environment*, that is, an environment, in which the students are empowered to make informed choices of: a challenge to be dealt with, a way of dealing with the challenge, a mode of interaction, an extent of collaboration, and an agent to learn from. In brief, past research on online collaborative problem solving presents many evidence-based cases of successfully working online forums.

However, little is known from the professional literature about how to put the forums into work and sustain them. Our experience in the aforementioned project taught us that this enterprise is truly challenging. The goal of this article is to make sense and theorize our more successful and less successful attempts to create and sustain problem-solving forums, in which exploratory rather than expository problem-solving discourse (this distinction is due to Stahl, 2009) takes place. The main argument is that many implementation-related phenomena that we have encountered when working with seven high-school classes (grades 10 and 11) can be characterized and explained with the aid of conceptual tools provided by Roger's (2003) Theory of Diffusion of Innovation.

## Conceptual framework

### Approach: Design-Based Implementation Research (DBIR)

Werner (2004) refers to *implementation research* as the systematic study of the implementation of innovations. Fishman, Penuel, Allen, Cheng and Sabelli (2013) point out that this type of research encompasses studies of fidelity, of variations in implementations as well as studies of conditions under which programs can be implemented effectively. They further refer to implementation research and to design-based research as antecedents of a new, emerging research model, which they name Design-Based Implementation Research (DBIR). The core principles of DBIR are as follows:

- (1) a focus on persistent problems of practice from multiple stakeholders' perspectives; (2) a commitment to iterative, collaborative design; (3) a concern with developing theory and knowledge related to both classroom learning and implementation through systematic inquiry; and (4) a concern with developing capacity for sustaining change in systems. (Fishman, Penuel, Allen, Cheng and Sabelli, 2013, pp. 136-137)

In addition, DBIR calls for breaking down barriers that isolate those who design and study innovations and those who study the diffusion of innovations. We find the DBIR concept and principles well-adjusted to the needs of our project.

### Vocabulary: Selected elements of the theory of diffusion of innovations

The notion *innovation* is frequently used in the literature on implementation research as a self-explanatory one (Fishman et al., 2013). However, there exists a branch of the professional literature that explicitly focuses on innovations and the processes of their diffusion. In particular, Rodgers (2003) defines *innovation* as "an idea, practice, or object that is perceived as new by an individual or other unit of adoption. It matters little, so far as human behavior is concerned, whether or not an idea is 'objectively' new as measured by the lapse of time since its first use or discovery" (p. 11). In our case, the idea of stretching the boundaries of a classroom by means of an online problem-solving forum was an innovation because it was new to the students and the teachers.

Rodger's (2003) theory of diffusion of innovations meticulously characterizes the *innovation-decision process*, in which individuals (or other decision-making units) decide whether to accept an innovation or not. In particular, Rodgers distinguishes five stages of the process: *knowledge*, *persuasion*, *decision*, *implementation* and *confirmation*. The stages are briefly presented below.

At the *knowledge* stage, potential innovation adopters are exposed to the innovation's existence and obtain some information about how it functions. Sometimes individuals become aware of an innovation by accident, and sometimes they actively look for it in order to fulfill particular needs. It is also possible that the needs are formed as a result of one's exposure to an innovation.

At the *persuasion* stage, an individual forms a favorable or unfavorable attitude towards an innovation. This stage presumes affective involvement with the innovation. In particular, the individuals may mentally apply the new idea to their present or anticipated future situation. They seek to answer such questions as "what are the innovation's advantages and disadvantages in my situation?", and seek the answer mostly from their near-peers, whose opinions based on their personal engagement with an innovation, are the most convincing. There is a discrepancy between forming a favorable attitude towards an innovation and an actual decision to adopt it. Adoption of an innovation can be influenced by a *cue-to-action*, an event that crystallizes an attitude into overt behavioral change.

At the *decision* stage, an individual adopts (i.e., makes full use) or rejects an innovation. Any decision is not final however. The rejection can occur even after a prior decision to adopt; in Rodgers' terms, this phenomenon is called *discontinuance*. The theory distinguishes between *active* and *passive rejection*. The former type of rejection consists of considering adoption of the innovation and then deciding not to adopt it. The latter one consists of never "really" considering the use of the innovation. The decision stage frequently includes a small-scope trial. The actual sequencing of the three stages presented so far can alter. Namely, both *knowledge–persuasion–decision* and *knowledge–decision–persuasion* sequences are possible.

At the *implementation* stage, an individual puts an innovation into systematic use. Even though the decision has been made, the adopters may still feel a certain degree of uncertainty about the consequences of the innovation. In addition, problems of how exactly to use the innovation may emerge. Sometimes the adopters change or modify (in Rodgers' terms, *re-invent*) the innovation at this stage. The implementation stage can be lengthy, but it ends when the idea that has once been innovative becomes institutionalized and regularized in the adopters' normal functioning.

Finally, at the *confirmation* stage, an individual constantly seeks reinforcement for the decision to adopt or reject an innovation that has already been made. As a result of positive or negative messages about the innovation, the decision can be reversed. Rodgers points out that the *change agents* (i.e., those who influenced one's decision to adopt an innovation) have responsibility of providing supportive messages to the individuals who have previously adopted the innovation.

## **Methodological aspects of the project**

### **Participants and the project's activity**

Two experienced mathematics teachers and two of their 10<sup>th</sup> grade classes took part in the first year of the project (2013-2014); five more teachers and their corresponding five classes joined the

project during its second year (2014-2015). Each participating teacher acted in the project as a member of the research group and took part in the meetings of the group. In addition, each teacher worked in contact with an additional member of the group who was responsible for the technological support and documentation of the activity. Mathematics in all participating classes was studied for five hours a week, in accordance with the Israeli high-level curriculum (see Leikin & Berman, 2016, for details). For the concerns of this article, it is enough to mention that geometry was studied two hours a week and that its study included systematic work on proving tasks.

We planned that each participating in the project class would be engaged, at least three times during a school year, in the following activity. The students cope with a series of preparatory tasks during a 90-minute lesson and are offered an especially challenging geometry problem at the end of the lesson. They then engage, for 5-10 days, in solving the problem from home in a closed (that is, available only to the students of a participating class and the members of the research group) online forum. Different technological platforms, including Google+ and WhatsApp, were tried in different classes. When the problem is solved or, alternatively, when the students give up, a 90-minute lesson is conducted in the classroom in order to get closure. The lesson consists of whole-class and small-group discussions, during which the students share their experiences with the problem.

### **Documentation of the project**

Forty-two meetings of the research group were audiotaped (about 100 hours) and, in addition, documented in the protocols of the meetings (more than 100 pages). The documents produced by the group and all relevant email exchange were stored. Every member of the group was required to keep a diary. The diaries were for writing anything their authors deemed important for the project, including their thoughts and feelings in relation to the project's events. The diaries were stored in shared Google Drive of the group and were available for reading and commenting by the members. In addition, 14 lessons were videotaped, the content of the forums was stored (more than 3000 posts), interviews with students and teachers were conducted (about 15 interviews), and the students' written feedback on different aspects of the project was collected.

The story of NK's class, which is presented below in some detail, is produced using *narrative inquiry methodological tradition*. As Clandinin and Caine (2008) explain, "Narrative inquiry is marked by its emphasis on relational engagement between researcher and research participants" (p. 542). This approach was chosen because we (hereafter, BK and NK) had been active members of the processes under exploration; in particular, NK was a mathematics teacher of the class. An aggregated summary of the stories in the rest of the classes is produced using a *general inductive approach* (Thomas, 2006), which enables researchers "to condense extensive and varied raw text data into a brief summary format" (p. 238).

## **Findings**

### **A (success) story of NK's class**

The main events at the *knowledge* phase of the project in NK's class consisted of: (1) a conversation between NK and BK following BK's observation of one of NK's lessons; (2) a conversation between NK and her students. Because of the first conversation, NK decided to take part in the project mainly because the idea to stretch the boundaries of a classroom by means of an online forum resonated well with NK's constant need to enrich her teaching repertoire in order to create

valuable learning opportunities for her students. In Rodgers' terms, NK acted as a *venturesome innovator* who is able to cope with high degree of uncertainty about an innovation, and BK acted as a *change agent*. In her conversation with the students, NK acted as a *change agent*, and the students were potential innovation-adopters to be *persuaded*. NK argued that developing problem-solving skills was a strong benefit of participating in the project, and appealed to the students' curiosity to try something new and be a part of an interesting initiative. The students' reaction to the information about the project was favorable, though not exactly for the reasons that NK had presented.

The first mathematical problem of the project is presented in Figure 1. It is representative of most of the problems of the project. In particular, it looked similar to geometry problems the students were familiar with from classwork and homework. As such, the problem "invited" the students to approach it by means of mathematical ideas that worked well in the past. For instance, the students might think of including the angles, whose equality is to be proved, in a pair of triangles and attempt proving their congruence by finding some equal elements. However, such a general plan was insufficient; something else (e.g., a clever auxiliary construction) should have been invented.

Nine-Square Problem: There is a net of nine congruent squares (see the drawing). Prove that the two angles denoted in the drawing are equal.

**Figure 1: The first problem of the project**

When the problem was uploaded to the Google+ forum, three students worked on it. Their three-hour-long brainstorming session was unsuccessful. As a result, the forum was non-active during the next two days. The following day NK met the students at school and asked: "Why did you stop solving the problem? It is not too difficult". The students showed NK their hand-made drafts as evidence that they had tried. NK asked the students to upload their drafts to the forum and continue solving the problem together. That evening eight students entered the forum, cooperated and eventually solved the problem. Two solutions to the problem by the active participants of the forum and an additional solution by a student who was a silent observer were presented at the mathematics lesson following the forum. The students' voluntarily expressed their suggestions as to how to further run and improve the forum by the end of the lesson,

In Rodgers' terms, the first three students acted as *venturesome innovators*. Rodgers points out that this category of adopters is important for launching a new idea, but they have little influence on other individuals' decision to adopt or reject the idea. The conversation between NK and the students in school was crucially important as a *cue-to-action* for eight students, who acted as *early adopters*. Rodgers characterized this category of individuals as *respectable*, that is, well-integrated members of a local community whose opinion about the innovation matters for the potential adopters. The mathematics lesson, in which these eight students shared their positive experience at the forum with the rest of the class, was another crucially important *cue-to-action*.

The next two problems of the project were approached on the forum by about the same group of students. The students learned to share their half-baked ideas, and even developed some rules related to publishing the full solutions at the forum. In brief, they agreed that a student who obtained

the full solution should not publish it early, in order to not “spoil the fun” for others. The forum was indeed exploratory rather expository in nature. Three months later, collaborative problem solving at the forum became a well-established practice for six students; most of their classmates joined the forum occasionally and constituted the *early majority*. It seems that each student has *decided* how and to which extend to use the forum. The *implementation* stage (three to eight month from the beginning of the project) was characterized by gradual two-directional diffusion of social and socio-mathematical norms developed in the forum and in the lessons. In particular, there were several forum-like lessons initiated by the students (see Keller & Koichu, in press, for details).

The evidence of *confirmation* of the students’ decision to adopt the innovation came from the following sequence of events. As mentioned, the Google+ forum flourished for several months, but it we have not yet mentioned that then it was deserted. NK inquired with the students about this fact and discovered that the activity moved from the Google+ to WhatsApp, a popular social network in Israel since about 2014. The students granted NK access to their WhatsApp forum, and we were happy to find there many autonomous problem-solving discussions of exploratory nature. The WhatsApp forum flourished in NK’s classroom until the students’ graduation in 2016.

### An aggregated summary of seven stories

An aggregated summary of the conduct of the project in all participating classes, by Rodgers’ phases, is presented in Table 1.

	NK class	AP class	AH class	ES class	RN class	OG class	LA class
<i>Knowledge</i>	++	++	++	++	++	++	++
<i>Persuasion</i>	++	++	++	++	++	-	+
<i>Decision</i>	Accept	Passive R	Accept	Passive R	Accept		Active R
<i>Implementation</i>	++	+	++	+	+		
<i>Confirmation</i>	++						

**Table 1: The implemented stages of the project in seven classes**

The sign “++” in the table means that the stage is fully realized; “+” means that the stage is partially realized (e.g., the forum was active only as a trial or only few students were active); “-” means that there were no conditions for realizing the stage; “Active R” and “Passive R” stand for active and passive rejection, respectively. An empty cell means that the project did not arrive at that stage.

As Table 1 tells us, only NK’s class went through all five stages, up to the point when using the online forums for problem solving stopped being an innovation and became a routine. Implementation of the project’s idea at the scope comparative to NK’ class occurred in one other class, and partial implementation – in three classes. In two classes the project did not reach the implementation stage, despite of much effort made by the teachers and the research team.

### Concluding remarks

Recalling Tolstoy’s seminal assertion, *happy families are all alike; every unhappy family is unhappy in its own way*, we can argue that there is a unique story behind each cell of Table 1.

Unfortunately, we cannot tell these stories here due to the space constraints. In brief, sometimes school conditions or classroom norms were inappropriate for realizing the project's idea, sometimes a particular *cue-to-action* event did not happen at the right time or was not appropriately designed, and sometimes our decisions and actions as a research group were far from being optimal. We have also observed, more than once, the phenomena of *discontinuance* and of *passive rejection* for which we do not have convincing explanations, despite the extended data set in our possession.

We intend to continue the aforementioned project, and one of the lessons learned so far is that the DBIR concept and theories like the Rodgers' theory of diffusion of innovation should be taken seriously. Either detailed or aggregative analysis of implementation of the project idea is helpful for us as a tool for refining the roadmap of the project. In addition, we now better understand that creating conditions for implementation of an innovative pedagogical idea in a school reality should be given full attention prior to delving into a pursuit for "traditional" research questions, such as questions on cognition and affect in mathematical problem solving that have been the main *research* questions of the project. Based on the accumulated experience, we call for reporting and analysing not only those cases where an innovative idea is being fully implemented, but also those case where the implementation was partial or did not occur as planned. We conclude by suggesting that systematic attention to implementation issues, by means of DBIR, may have not only practical, but also fundamental theoretical significance in mathematics education.

### Acknowledgment

The research project is partially supported by the Israel Science Foundation (Grant No. 1593/13; PI Koichu). We are grateful to all the participants in the project, and especially to the teachers who cooperated with us and devoted much time, thought and effort to making the project work.

# From theory through collaboration into practice: Designing a problem- solving curriculum for grade 6 students

Ana Kuzle

University of Potsdam, Germany; [kuzle@uni-potsdam.de](mailto:kuzle@uni-potsdam.de)

*Teachers are continuously confronted with instructional endorsements, such as the inclusion of problem solving in school mathematics. However, adoption of problem solving is still not a reality. One reason for it is the lack of practical teaching materials based on research findings to achieve the goals stated in the standards. In the context of this reform agenda, collaborative work between educational researchers and practitioners in a real setting working on issues of everyday practice is crucial in order to overcome the gap between theory and practice. In this paper, I focus on such theory based problem solving curriculum for grade 6 students that was developed using design-based research. At the end, I discuss factors inhibiting the implementation of the curriculum.*

*Keywords: Word problems, material development, mathematics activities, problem solving.*

## Introduction

The (inter-)national educational standards (e.g., KMK, 2003; NCTM, 2000) have strongly endorsed the inclusion of problem solving in school mathematics. Empirical studies, however, portray a different picture. Students are often unable to solve problem tasks (e.g., Schoenfeld, 1985). In addition, quality analyses in the German school system contend to a poor problem solving culture. As reported in Kuzle and Gebel (2016), problem solving tasks got rarely introduced. When this was the case, they were primarily done by the teachers; mostly routine tasks dominated the lessons, and problem solving strategies were explicitly applied in one third of examples only. The biggest problem reported by the school's teachers was the lack of practical teaching resources to achieve the goals stated in the standards (Kuzle & Gebel, 2016). In the context of this reform agenda, the development of materials for students and teachers is of great importance for overcoming the gap between theory and practice (Jahn, 2014). One urban school recognized this deficit and set as a goal promoting problem solving instruction centered around curriculum material, developed through collaborative work between educational researchers and practitioners.

Here I report on a small part of SymPa<sup>1</sup>-project (Systematical and material based development of problem solving competence) focusing on collaboration between practitioners and researchers with the goal of developing a problem solving curriculum for grade 6 students using design-based research (DBR). The guiding question is: What factors inhibit implementation of research-based problem solving curriculum in practice? In the following sections I outline relevant theoretical and methodological underpinnings used to design a problem solving curriculum, before showing how these got implemented, and report on its evaluation (initial DBR-cycle). As a result of evaluation, I discuss the curricular redesign that might allow more effective implementation in practice.

---

<sup>1</sup> SymPa stands for „**S**ystematischer und **m**aterialgestützter **P**roblemlösekompetenz**a**ufbau“. Inga Gebel (researcher) and Christian Conradi (practitioner) initiated and participated in the project likewise.

## Theoretical foundation guiding the design process

Plethora of research on problem solving undergoing since the 1970s identified several pivotal areas for a problem solving curriculum. I outline here only a small portion of this research that was crucial for the project based on German standards' conception of problem solving (KMK, 2003).

### Problem solving competence

Problem solving competence relates to *cognitive* (here heuristic), *motivational* and *volitional* knowledge, skills and actions of an individual required for independent and effective dealing with mathematical problems (Bruder, 2002; Kuzle & Gebel, 2016). Accordingly, students should a) learn approaches (heuristics) for solving mathematical problems and how to apply them appropriately in a given situation, b) develop reflectivity for own actions, and c) develop willingness to work hard (cf. Bruder, 2002; KMK, 2003). As problem solving competence encompasses so many different facets, problem solving curriculum should account for the following research areas: (a) teaching approaches and concepts on problem solving, (b) theories of self-regulated learning and self-regulation in problem solving, and (c) theories of motivation which are outlined below.

### Teaching approaches and concepts on problem solving in combination with self-regulation

There are at least seven practices for problem solving curriculum that researchers (e.g., Kilpatrick, 1985; Pólya, 1945/1973; Schoenfeld, 1985) have claimed to be important for helping students grow in their problem solving ability: (1) osmosis (give lots of problems), (2) give “good” problems, (3) memorization (teach specific or general heuristic strategies (heuristics)), (4) imitation (model problem solving), (5) cooperation (limit teacher input by having students work in small groups), (6) reflection (promote metacognition by asking metacognitive questions or encouraging students to be reflective), and (7) highlight multiple solutions. In the recent years, Bruder (2002) developed a problem solving teaching concept focusing around Lompscher's (1975) idea of “flexibility of thought”. *Flexibility of thought* is expressed by one's ability to

1. reduce a problem to its essentials or to visualize it by using visual and structuring aids, such as informative figures, tables, solution graphs or equations (*reduction*).
2. reverse trains of thought or reproduce these in reverse, such as by working backwards (*reversibility*).
3. simultaneously mind several aspects of a given problem or to easily recognize any dependences and vary them in a targeted manner (e.g., by composing and decomposing geometric figures and objects, by working systematically) (*minding of aspects*).
4. change assumptions, criteria or aspects in order to find a solution, such as by working forwards and backwards simultaneously or by analyzing different cases. Such ability prevents “getting stuck” and allows new approaches and insights (*change of aspects*).
5. transfer an acquired procedure into another context or into a very different one by using analogies for instance (*transferring*).

These typical manifestations of mental agility can be related to analyses of heuristic approaches by Pólya (1945/1973). Untrained problem solvers, however, are often unable to access the above outlined flexibility qualities consciously. Moreover, not only the knowledge of different heuristics (flexibility of thought) is needed when problem solving, but also self-regulatory abilities which evolve gradually through a 5-phase model (Zimmerman, 2002). Problem solving can be trained by

learning heuristics corresponding to these aspects of *intellectual flexibility* in combination with *self-regulation*, which according to Bruder (2002) and Bruder and Collet (2011) develops through the following five-phase concept:

1. *Intuitive familiarization*: This phase builds on Pólya's (1945/1973) model, in which a teacher serves as a role model when introducing a problem to students. Thus, the teacher moderates behaviors typical for the problem by engaging in self-questioning pertaining to different phases of the problem solving process (before, during, and after). For example questions such as, "What is the problem asking for?" "What information am I given?" "Is there anything I don't understand?" "Am I headed in the right direction?" may help guide the students (Kuzle & Bruder, 2016). At this point the heurism in focus is not specified.
2. *Explicit strategy acquisition*: During this phase the students get explicitly introduced to the heurism in focus on the basis of a reflection from the first phase. Here the particularities of the heurism get discussed and it gets a name (exemplification). Here prototypical problems get used for introducing a heurism in focus, so that the students can more easily recognize its main ideas and more easily remember their specific steps for future problem solving.
3. *Productive practice phase*: During this phase the students practice solving the problems using the heurism in focus. Here is important that the problems do not reproduce type problems, but rather expand the possibilities from the first two phases. In addition, differentiation should be a guiding concept during this phase, so that students can choose at what cognitive level they want to work and adapt the observed learning behavior.
4. *Context expansion*: In this phase the students should practice the use of heurism in focus independent of a mathematical context. In that way, the students learn to flexibly, unconsciously and independently of a context use the heurism in focus.
5. *Awareness of own problem solving model*: The aim of the teaching concept is that the problem solving model of the students gets expanded, so that they are in a position to solve problems better using different heurisms. Awareness of own problem solving model can be induced by having students reflect on and document their problem solving process.

Lastly, students' willingness to work hard is a major factor for the successful problem solving process. Without an effort from the learners, there will be no successful learning. For that reason, the criteria such as, understandable and clear problem, age-appropriate choice of context, and visible competence growth (Bruder, 2002) are crucial when designing problem solving curriculum.

To summarize: the problem solving curriculum was developed around the operationalization of the terminology "problem solving competence". This included the teaching concept of problem solving by Bruder (2002) in combination with Zimmerman's (2002) self-regulation model taking into consideration the criteria for motivating tasks (Bruder, 2002).

### **Curriculum development**

The problem solving curriculum was developed in collaboration between the two researchers (author and young researcher) and one practitioner (teacher from the project school). More concretely, the researcher team developed the curriculum based on the outlined theories and school's contextual factors (see below), which were discussed up-front. Curriculum materials (e.g., problems, textual parts, figures, colors) were either separately developed by the researcher team and

discussed afterwards with the teacher or the entire team met together and developed them. The final decision about the problem solving curriculum (e.g., content, problems) was met by the teacher.

## Enactment

For the design of curriculum contextual factors played a great role, in which theoretical ideas had to be operationalized. Students of 6<sup>th</sup> grade were chosen to participate in the project lasting one school quarter (ca. 16 lessons, 1 lesson = 45 min). The implementation of the curriculum took place during two parallel phases (see Table 1). During the first DBR-cycle 13 students participated. Teacher A initiated the project, had previous experience in problem solving (e.g., attended professional development courses on problem solving, read literature on it, and implemented problem solving tasks occasionally in his teaching practices). The second DBR-cycle started parallel to the first DBR-cycle, and was led by another mathematics teacher. In total 12 students participated. Teacher B had practically no experience with problem solving or teaching problem solving.

1 <sup>st</sup> DBR-cycle	2 <sup>nd</sup> DBR-cycle
every 14 days (8 meetings), Fridays, double period, teacher A	weekly (17 meetings), Mondays and Tuesdays, single periods, teacher B

**Table 1: Parallel enactment cycles**

With respect to heuristics, focus laid on those heuristics prescribed by the school's own curriculum, namely heuristic auxiliary tools (informative figure, table, solution graph), heuristic strategies (working systematically, working forwards, working backwards), and heuristic principles (composing and decomposing). Thus, all flexibility qualities were addressed. With respect to mathematical content, problems covered the content areas of 5<sup>th</sup> and 6<sup>th</sup> grade mathematics (operations with natural numbers and fractions, combinatorics, geometric and numeric patterns, measurement pertaining to 2- and 3-dimensional figures). Based on the project time frame, each heuristic was covered within two lessons, but followed the above underlined problem solving concept. For one exemplarily operationalization with references to theoretical base see Figure 1.

During the implementation phase data collection took place on three different levels: student level, teacher level and classroom level. With respect to the student level, data from student textbooks (intermediate reflections, final reflection) and their workbooks (student productions) was collected. With respect to the teacher level, data from continuous communication with the teachers (e-mail, telephone calls), teacher textbook and semi-structured interview at the end of the project was collected. Concretely, continuous communication allowed the researcher team to support the teachers during the implementation phase with respect to pedagogical and/or methodological questions (e.g., discussion of different solutions, cooperative methods), by answering questions of content nature (e.g., questions about particular heuristic), and through flexible and stepwise redesign of the curriculum after each lesson. Lastly, with respect to the classroom level, observations allowed for analysis of student-teacher interaction, and students' interaction with the curriculum.

## Curriculum on the heuristic auxiliary tool of table

## Theoretical foundation

**2.2 Table**

**2.2.1 Coin Problem**

Probi wants to buy a bar of chocolate for 27 cents. He has only 10-, 5-, and 2-cent coins. In how many different ways can Probi buy the chocolate?

Mmmh chocolate! How can I combine my coins, so that I don't get any change?

**What is a table?**

Tables are useful heuristic auxiliary tools when trying to structure, reduce and focus the information in problem tasks. They are well suited for documenting different approaches or different possible solutions, and record all possible cases of a solution without losing track.

**Example**

Probi, here I want to show you that problems can be solved with different heuristic auxiliary tools. For example, I solved here the Age Problem "2.1.3" using a table.

Probi's age	Promi's age	Prof's age	Sum of their ages	Promi's exact age
5	more than 10	15	more than 30	56-5-15=36 (older than Probi)
6	more than 12	18	more than 36	56-6-18=32 (older than Probi)
10	more than 20	30	more than 60	The sum of the ages is too high.
9	more than 18	27	more than 54	56-9-27=20 (it works)

**2.2.2 Usage of a table**

Profi, I still don't understand how you approached the problem in the example.

Write a letter to Probi, in which you explain him how you have solved the problem using the table.

**2.2.3 Choice for outfits**

Probi was invited to Probi's garden party. He is standing in front of his wardrobe, and doesn't know what he should wear.

I wanna wear my favorite jeans in any case.

I am missing then only a T-shirt, a hat, and a pair of shoes.

Uiii, I have not too possibilities for my outfit.

a) How many different possibilities does Probi have for his outfit? List them all.

b) How can a table be helpful when solving the above problem?

**2.2.4 Table instead of informative figure**

I solved now the "Sliding Task" using a table. Probi, how did I do it?

Hmmm...

Explain Probi how you solved the problem. Which approach do you prefer? Why?

In the phase of intuitive familiarization, students solve a representative problem for the heurism in focus together with the teacher, who serves as a moderator. Here the imitation of teachers' behavior takes place through self-questioning. The problem represents the students' first encounter with the heurism in focus.

In the phase of explicit strategy acquisition, the heurism in focus gets formally introduced through a short student-centered information text and an example.

In what follows, at least three problems of different cognitive level are presented that serve as a productive practice phase. This allows for differentiation, where each student can solve as many problems as he or she can. In addition, problems from different mathematical content areas are covered, to allow for transfer (context expansion phase), which pertains to the fourth phase of the teaching concept.

In addition, the heurisms are interrelated, so it is important that the students comprehend this. The last task allows students to make this connection by comparing the two heurisms and reflect on it.

**Figure 1: A sample page from the problem solving curriculum on the heuristic auxiliary tool of table**

The problems focused on contexts that are motivating and appropriate for young students. In addition two figures were introduced to support students' willingness to work hard; they could identify with Probi (shape of a question), who asks questions and gets stuck. Profi (shape of an exclamation mark) offers then support to students, who illustrates a professional problem solver.

## Evaluation

Qualitative-content analysis was used to analyze the collected qualitative data as outlined in Patton (2002). This method is particularly suitable for research activities, in which the knowledge is low and a study has more of an exploratory character. Thereby, the aim was to systematically analyze the

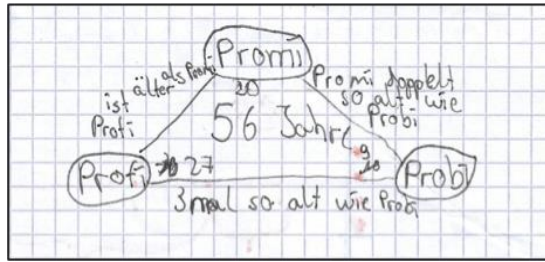

qualitative data and produce a category system by focusing on factors inhibiting the implementation of the curriculum. The deductive analysis was performed based on the theoretical foundation, which was then refined in the inductive analysis by emerging issues and additional codes. The situations were interpreted as inhibiting when they allowed for a limited implementation of the curriculum only as reported explicitly by teachers and students and/or was observed by reviewing the collected data. As a result four categories were produced (see Table 2, for more detail see Kuzle & Gebel, 2016). The category system was then used to interpret the results of the study with respect to the research question. All data got analyzed by the two researchers independently.

Category	Description	Subcategory
Language	All language-based comments that influenced the understanding of the problem were assigned to the language category.	Problem solving terminology Figure names Problem enumeration
Level of performance	Barriers influencing the level of performance during problem solving process (e.g., content barriers, subjective barriers) were assigned to the level of performance category.	Motivation and differentiation Curricular difficulties Increased level of performance
Learning pedagogies	The evaluations of the curriculum in terms of the didactic ideas about learning how to solve problems are listed in the learning pedagogies category.	Communication ability Reflective ability
School and personal influences	Any feedback that aimed at external factors influencing the implementation was assigned to the school and personal influences category.	Teacher attitude Professionalism Organization

**Table 2: Four content categories inhibiting implementation of the problem solving curriculum**

Table 2 shows that also school and personal influences, which were not part of the design process, influence the extent to which the curriculum gets implemented. Thus, teachers also inhibit successful implementation of the curriculum, despite being part of the design process. I focus on this category by giving different subcategory examples since this factor was most surprising.

Figure 2 shows student's work solving one problem where the heuristic auxiliary tool of informative figure was to be used. Instead of representing a graphical illustration of the situation to be resolved from which the solution can be "read" (informative figure), it represents a sorting of information. Hence, the student work is a reflection of teacher's B lack of knowledge of problem solving, despite this problem being discussed in the teacher manual, which she glanced only once (professionalism). This was seen in all students' notes. Moreover, the analysis of students' workbooks revealed that teacher B avoided introducing problem solving terminology and allowed students to solve problems as they wished (teacher attitude). She explained that she did not want to burden them with formal terminology and constraint their problem solving process.

**Figure 2: Teacher's professionalism reflected in a sample page from one student's workbook**

Also teacher B criticized heavily the name of the figures in the curriculum (Profi, Probi), which was reflected in students' final reflection, where they urged for the change of figure names. Thus, teacher's negative attitude about a design element transferred negatively onto the students. Such behavior was not observed with the students led by teacher A, who questioned the chosen names, but never criticized them during his instruction. Teacher B in comparison to teacher A was not part of the design team, but was assigned to implement the curriculum due to organizational school context. The case of teacher B shows that negative attitude and lack of professional behavior inhibited successful implementation of the curriculum. Hence, teacher as an inhibiting factor should not be neglected during the design and implementation process.

## Conclusion

Problem solving must gain more importance in school mathematics. Although several teaching concepts and practices are known (e.g., Bruder, 2002; Kilpatrick, 1985; Pólya, 1945/1973; Schoenfeld, 1985), these get rarely implemented. Moreover, curriculum based on existing and empirically tested problem solving pedagogies is non-existent. To overcome this gap SymPa-project was grounded. Teachers participating in the project reported improvement in students' problem solving competences with respect to deliberate and mindful use of different heuristics when problem solving. In addition, the teachers not participating in the project, reported students using these heuristics in regular mathematics classes. Hence, it was possible to develop curriculum that met the local demands with the aim of supporting a systematical development of problem solving competence. However, different objective and subjective factors inhibited full-implementation of the curriculum. With respect to the former (language, level of performance, learning pedagogies), changes done in the re-design phase of the DBR-cycle will shed light to which extent these were enough for successful implementation in the upcoming phases of enactment. With respect to the latter (school and personal influences), it became clear that the curriculum alone does not guarantee the implementation of the teaching concept. Substantial knowledge base of the content and pedagogical ideas seem necessary to teach in accordance with the theoretical foundation. Confidence and experience in teaching problem solving played a crucial role likewise. Likewise school organizational factors should not be ignored. Since the teachers were assigned to teach the problem solving lessons and received no compensation for the participating in the project, a lack of motivation may develop, which influences the willingness to teach, the lesson quality and with it the students' acceptance of the curriculum.

In this paper I demonstrated that DBR-paradigm allows creating novel teaching environments in which theory and practice were not detached from one another, but rather complemented each other. Here the efforts were made to design, use and do research on problem solving curriculum in a real

setting. This promoted adoption of the innovation – problem solving curriculum – which became an official part of that school’s curriculum. Moreover, close collaboration during the design and enactment phase, and the re-design of the materials by the researchers as a result of teachers’ feedback allowed them to develop a sense of ownership for the designed curriculum. Future work should use similar methodologies to ensure implementation of research into practice, adoption of research into practice, which would then allow research on implementation projects. These components may build a fundamental step to overcome the gap between theory and practice.

# **Theoretical constructs for early intervention programs in mathematics: Who cares? – A Danish example**

Lena Lindenskov & Katrine Kirsted

Aarhus University, Danish School of Education (DPU), Denmark

[lenali@edu.au.dk](mailto:lenali@edu.au.dk), [kaki@edu.au.dk](mailto:kaki@edu.au.dk)

*“There is nothing so practical as a good theory”. The statement from Kurt Lewin is frequently cited, also in mathematics education. The statement invites for and requires close cooperation between different agents, whatever their specific relation to practice and theory is. It is not a straightforward endeavour. One reason is that the term theory as well as the term practice may very well be given different meanings by different agents. This variation is, in our view, to be considered in “implementation research” and Lewin’s statement ought to be qualified by two questions: “Who cares about a good theory?” and “What makes a good theory good for whom?”*

*This paper explores the variation of how theory is perceived by mathematics teachers and by mathematics researchers involved in a developmental project on early intervention in mathematics education in Denmark. The paper exemplifies how agents’ different work conditions and work requirements seem to constitute qualitatively different needs for theoretical constructs, despite some common interests.*

*Keywords: Early intervention programs, teaching principles, theoretical constructs.*

## **Background for the early mathematics intervention project**

We noticed a long tradition of integrating early mathematics intervention programs into compulsory education practice like, e.g. Mathematics Recovery (MR) (Wright, 2006; Wright et al, 2007) and Extending Mathematical Understanding Intervention Program (EMU) (Gervasoni, 2016), in Australia, Ireland, the UK and the USA. A similar tradition exists in Denmark for early reading intervention programs, as such programs are implemented at a regular basis in all schools in Denmark. Either as part of a municipal policy or a matter of choice, schools launched early (from the first grade) intervention processes in reading to support individual children, who show signs of reading difficulties.

At the ministry level in Denmark concerns were raised about pupils failing at mathematics in the National Official Guidelines in the 2003 National Mathematics Curriculum from the Ministry of Education (UVM, 2003). In 2004 the need to support failing pupils in mathematics in the first school years was emphasised (Mortimore et al.) and the national official guidelines to the revised 2009 national curriculum (UVM, 2009) described, for the first time, the issues in detail. Still, no intentions of integrating programs for early mathematics intervention into compulsory education practice were seen in Denmark until recently (Lindenskov, 2007).

In 2009 the material Early Intervention in Mathematics [Danish: Tidlig Indsats i Matematik, TIM], written to primary school mathematics teachers was published and used in some places. Just before, in 2007 local politicians and school authorities in the municipality of Frederiksberg in the capital area, decided to give priority to mathematics teaching and learning in their 9 public schools in the period 2007-2013. Priority was given to a development project on early mathematics intervention

for their 9 schools in collaboration with the researchers Lena Lindenskov and Peter Weng. It soon became clear that the existing intervention framework and written materials solely focused on numbers and arithmetic, which were insufficient to comply with the Danish Mathematics Education Philosophy and Curriculum. Also, approaches in the existing intervention framework and written materials were insufficiently inquiry and problem based to correspond with the curriculum. Finally, teachers' freedom and responsibility to adapt materials to their own students were too limited in the existing frameworks and materials.

With this background a research-based developmental project with four design cycles was prepared in order to develop a Danish program for early intervention in mathematics that would fit into the Danish Mathematics Education Philosophy and Curriculum. The private Danish fund Egmont showed interest in a Danish early mathematics intervention program (personal communication), and together Egmont, Frederiksberg Municipality and Aarhus University assured the budget for this project. The project was named Early Mathematics Intervention at Frederiksberg with the Danish abbreviation TMF [Danish: Tidlig Matematikindsats Frederiksberg].

### **Perceptions of what is good theory – by mathematics school teachers**

Our research question is, *what is a good theory for whom - teachers as well as for researchers?* Our analyses draw on our communication with the 18 teachers involved in the design cycles of the project. In the following these teachers are called pilot teachers. All pilot teachers were chosen by their school principal as among the most qualified and motivated mathematics teachers at the school. Some also were 'Mathematics Counsellors' with a one-year diploma course.

It is the use of theoretical constructs in the four cycles, which is analysed in the following. We analyse interactions between teachers and researchers. The data come from written materials and recorded minutes and notes from seminars<sup>1</sup>, training sessions, coaching sessions and e-mails

Generally, Danish teachers have a relatively high self-confidence and a strong wish to influence. It is shown, for instance, that Danish teachers, more than British teachers, prioritise their students' personal development and see their students' mathematical development as a means for personal development (Kelly, Pratt, Dorf & Hohmann, 2013). Because of the way the 18 pilot teachers were chosen by their principals, we anticipated that the teachers would be involved, to a high degree, in the project's four design cycles. The specific choice of mathematical and other aspects for the framework and written materials for the early intervention was actually made in dialectic processes involving the researchers and the 18 pilot teachers. Further descriptions of the cycles are found in Lindenskov & Weng (2014).

---

<sup>1</sup> Mathematics Recovery Programme (MR) is a source of inspiration for the developmental project, see Wright et al., 2007. This is why we included a teacher seminar with Ms. Noreen O'Loughlin from Mary Immaculate College, University of Limerick focusing both on some hypotheses and issues in MR and on specific concerns at Frederiksberg.

## **The framework and materials developed through four design cycles**

(1) From January 2009 to September 2009, Weng and Lindenskov developed the first draft material, based on theory, empirical results and their knowledge about mathematics in life and in primary and lower secondary schools in Denmark. They initially doubted whether the teachers would find it relevant to study the rationales and theory behind the choice of mathematical areas, materials and evaluating and teaching principles. That is why only a few theoretical constructs and justifications were in the first draft communicated to the teachers.

*But*, as the structure and each part of the draft material were critically explored and discussed during the teacher training sessions from 14 - 18 September 2009, this expectation of the teachers' perceptions of their needs for theory was wrong. The teachers endorsed the underlying ideas, but actually asked for further explanation of rationales and theoretical constructs. The teachers also asked for an extensive introduction to the program as such. The time teachers were expected to use in the development processes did not include reading articles, so the researchers presented articles orally and provided printed extracts or copies of some articles as handouts. The main printed materials were newly developed diagnostic test materials and the problem solving materials to be used with their students, plus general introduction and justification for the choice of mathematical areas and instruction approach.

At the end of the week, the teachers suggested that measurement as a mathematical area and the use of measurements in other mathematical areas should be expanded in the next draft.

(2) Lindenskov and Weng developed a second draft of material based on the pilot teacher feedback and feedback from the research assistant. This meant that for more mathematics areas further justification for and explanation of rationales and theoretical constructs were included. The second draft was sent to each school October 2009 for experimenting. Each pilot teacher tried out specific parts of the material in the fall of 2009. The distribution of the parts to each school was decided through discussions among all pilot teachers. Each pilot teacher was requested to try out two or three activities with as many pupils as possible. The age of the pupils was not important. If possible, more material was to be attempted. The pilot teachers were given a specific task in order to evaluate the materials: they were asked to document in as much detail as possible - by writing in premade tables - how each mathematics task and each mathematics and attitude question led to pupil-teacher conversations which could indicate the pupil's thinking. The experiments were concluded with a seminar on 3 December 2009, where each pilot teacher presented results. Anything that had particularly surprised the teachers was also presented and some common concerns were then discussed. It was put forward that the pages with descriptions of justifications and theoretical constructs were helpful, 'or else we do not know why the chosen mathematical areas, concepts and competences are important to focus on.'

(3) Based on these results Weng and Lindenskov developed the third draft material and introduced it at a seminar on 28 January 2010. Justifications and theory were included for all mathematical areas. In the following months, each pilot teacher tried out parts of the material with a number of pupils. This time all the pupils were in the second grade. The aim was to allow the pilot teacher to experience the structure of the material and to practice pupil-teacher conversation. Peter Weng

visited and coached every teacher once and the teachers were invited to contact the researchers at any time during the pilot study.

At a midway seminar on 9 March 2010, the teachers described their general impression as positive and generally considered the material adequate. Several pilot teachers said they found it motivating to work with the material together with the pupils and that they had heard from the pupils' ordinary mathematics teachers that the intervention seemed to have a positive impact on the pupils' learning process.

The individual schools' prioritization of subjects was also discussed: how to decide between pupils' participation in a class excursion or a TMF session?

At the seminar a representative from the Egmont Foundation was present, as the Foundation had decided to fund the project. In the developmental project, the choice of pupils was left to the schools and the criteria differed between schools. The Egmont representative was particularly interested in the discussions on ethical issues: Whether pupils with very weak home support should be chosen over pupils with better support from home, who would probably benefit more? It is well known from research that socioeconomic factors are important for pupils' learning and development. Maybe particular pupils need this intervention the most, but are they really the ones chosen?

Issues regarding the scope and range of the material were discussed, for instance how to prioritise between presentations of many mathematical aspects or assuring success in fewer mathematical areas. The risk that the material put severe strain on teachers, especially when they were unfamiliar with it, was also discussed. To illustrate this discussion, we have listed three pilot teacher transcripts and one researcher transcript below:

Teacher 1: I feel pinned down by the material. I feel like, 'Now I must do this, then I must do that,' and you have to look for concrete material yourself. It is very restraining. While I look for extra material, I give the pupils small tasks on the computer to work with, OK.

Teacher 2: The material could be constraining. But the material is important as a database of ideas. The material gives me ideas. It supports my own inspiration process and it helps me to include everything in my practice.

Teacher 3: The material is useful, when I prepare the intervention sessions.

Researcher Weng:

Try to think about the material as something that provides you with opportunities and inspiration. We invite you to a flexible adaptation to specific pupils.

(According to the minutes, authors' translation)

The final seminar on 27 May 2010 discussed organisational and psychological issues in detail. The teachers wanted organisational and psychological aspects of individual pupils' learning and instruction to be emphasised as equally as the mathematical aspects.

Also the teachers again asked for more geometry and measurement in future versions, as well as a compiled list of recommended materials, but they did not mention any further need for justification and theory. (According to the minutes, authors' translation)

(4) The fourth draft was developed by 12 August 2010 and was to be used from 2010 onwards in the regular TMF for individual second grade pupils in all of Frederiksberg's public schools. The research assistant, Tina Kjær, examined the material and ensured that the teachers' suggestions were taken into account. Strongly supported by the pilot teachers' feedback, organisational and psychological aspects of individual pupils' learning and instruction were included as just as important as mathematical aspects.

### **Example of how researchers' theoretical understanding is communicated to teachers**

As an example of how the researchers communicated their theoretical understanding underpinning the developmental project to the pilot teachers, we have chosen the mathematics area "Basic Strategies for Numbers in Addition and Subtraction". The table below shows in the left column four of the theoretical constructs chosen by the researchers to underpin the project. The right column shows how the constructs were being communicated and discussed between researchers and teachers. The right column consists of citations from the final written materials, which was published in 2013 and meant to be studied and discussed among teachers involved in intervention projects.

<b>Researchers' choice of theoretical constructs and justifications</b>	<b>Citations from the published intervention materials (Lindenskov &amp; Weng, 2013)</b>
Relational understanding (RU) and instrumental understanding (IU): Although IU in its own context is often easier to understand and gives correct answers with less knowledge involved, RU is more adaptable to new tasks and easier to remember. (Skemp, 1976/2006).	When the pupil experiences a productive development in his/her basic strategies in addition and subtraction, it opens the pupil's possibilities of becoming capable in doing relevant addition and subtraction and to use it in many contexts. Also, potentially this experience will contribute to another highly relevant math competence: good estimating skills for big numbers.
Constructivist teachers' primary activity is communicating with students. In the constructivist view, teachers should continually make a conscious attempt to "see" both their own and the children's actions from the children's points of view. (Cobb & Steffe, 1983).	Some teachers might, for the last decades, have misunderstood the core of constructivism. Some teachers might have been inclined not to interfere when the pupils calculated and developed their calculation skills and strategies. Some teachers might have believed that the pupils by themselves would develop at the pace that was most optimal for them individually. But we know, it is a risky affair.

<p>Pupils who engage in strategy development decisively perform better in the long run than pupils who do not.</p> <p>(Ostad, 2008).</p>	<p>Pupils, who from an early age, start developing his/her strategies, tend to continuously improve existing strategies and increase the number of strategies. In contrast, pupils, who stick to their strategies, tend not to start improving them until later on. It is shown that pupils, who stop developing their strategies, will toil hard and will still lag behind.</p>
<p>Strategies, strategy development and teaching strategies should be the core of fundamental mathematics instruction and learning.</p> <p>(Ostad, 2013).</p>	<p>Do not just present materials for the students to acquire new further learning. Let the pupil use materials and activities in order to consolidate what is almost or recently learnt as a means to improve the pupil's self-confidence and realistic self-perception of addition and subtraction skills. We recommend that the teacher talk with the pupil about his/her strategies, i.e. by regularly asking how long this strategy has been used, if the strategy leads to the right results, if the pupil uses other strategies, too, or thinks other strategies could be used. Appropriate further learning may well be about strategy development.</p>

## Conclusion

This paper has shed light on what is a good theory for whom - teachers as well as researchers, how to explain theory and justifications to the pilot teachers in a meaningful way and how to develop material in collaboration between researchers and teachers? During the four development phases the pilot teachers endorsed the underlying ideas of the intervention project and asked for the rationale behind every included aspect to be explicitly communicated. They encouraged more extensive introduction and to expand the included measurement aspects into two measurement aspects.

The teachers explicitly endorsed the theoretical construct and justifications in the material, as they said it helped them to acknowledge many opportunities to help the pupils and to identify pupils' potentials and motivation while exploring and developing their mathematical needs. The teachers appreciated that the material gave a firm frame and at the same time invited and inspired the teachers to adapt and further expand the materials to the specific learning situations with the pupils. The teachers recommended the material to be expanded with more mathematical concepts and competences, which are considered relevant in the Nordic contexts (Dalvang & Lunde, 2006; Niss & Højgaard, 2011) and by the teachers as potentially troublesome for the weaker pupils, and to expand the materials on measurements and part-whole.

The teachers asked for further ideas and materials which could be used as they were or could be adapted in order to fit their own pupils' needs and motivations. The teachers did not suggest more clarified theoretical constructs and justifications underpinning the program than were communicated to them already.

For the educational researcher the task was to find and select theoretical constructs to underpin the intervention and communicate these to the teachers, as it is further described in Lindenskov et al (2016). It could not be communicated as in scientific journals, but as justified practical advices. Both theorists and practitioners care for theory, but in very different ways.

*In this paper we draw upon examples from a recently published systematic literature review (Ryve et al., 2015) on productive classroom practice to contribute to the research on the nature of theories for action in mathematics education. By relating the results from the review to theories and literature on educational policy research, professional development research and implementation research we construct a framework for categorizing theories aiming at supporting teachers' actions in mathematical classroom practices.*

*Keywords: Theoretical frameworks, theories for actions, mathematical classroom practice.*

## Introduction

The development of frameworks and theories<sup>1</sup> that aim at guiding the actions of teachers have rendered much recent attention in educational research (e.g., McKenney & Reeves, 2012; Ruthven, Laborde, Leach, & Tiberghien, 2009). Within research areas such as curriculum material (Davis & Krajcik, 2005), planning and implementing whole-class discussions of cognitively demanding tasks (Smith & Stein, 2011), professional developments programs (Borko, 2004; Desimone, 2009), and improvement of mathematical instructions at scale (Cobb & Jackson, 2012) cumulative work has been conducted to establish theories for action. Further, frameworks for supporting teachers' actions and thinking such as curriculum materials, theories and models have been put forward as essential components of effective professional development (Cobb & Jackson, 2012) and for establishing productive mathematical classroom practices (Franke, Kazemi, & Battey, 2007). However, we need to know more about how theories should be designed to facilitate implementation; to be used and do real work in supporting and constructing teachers' actions (McKenney & Reeves, 2012). In this paper we relate result from a recently published systematic literature review (Ryve et al., 2015) on productive classroom practice to literature on educational policy, professional development and implementation research in order to construct a framework for understanding and facilitating the implementation of theories and research results aiming at supporting teachers' mathematical classroom practices.

## Relevant research

The approach of the present study is based on the assumption that 'theory matters' for teachers, to enhance their ability to develop rich mathematical classroom practice (Charalambous & Hill, 2012).

---

<sup>1</sup> There are many ways to denote theories serving the purpose of guiding actions and this is further discussed below.

For instance, by adopting and making use of theoretical tools teachers are supposed to enhance their ability to establish productive routines in their classroom practice (Franke et al., 2007), develop and continuously adjust a learning trajectory and the means to support that trajectory (Cobb, Confrey, Lehrer, & Schauble, 2003), become more sensitive to notice instructional opportunities in the moment and be methodical without being mechanical. However, Burkhardt and Schoenfeld (2003) argue that most theories that have been applied to education are quite broad, lacking the specificity that helps teachers to guide and understand the design and analysis of learning activities. Cobb et al. (2003) adhere to this view, claiming “General philosophical orientations to educational matters – such as constructivism – are important to educational practice, but they often fail to provide detailed guidance in organizing instruction” (p. 10). So, there is this dilemma; theoretical constructs are supposed to enhance teachers’ capacity to teach but, to do such work, theories need to be of a certain kind.

### Perspectives on theories

diSessa and Cobb (2004) detail the nature of different theories relevant for research in mathematics education. They distinguish between grand theories, orienting frameworks, frameworks for action, domain-specific instructional theories and ontological innovations. Skinner’s behaviourist theory provides an example of a grand theory. Even if grand theories have a prominent position in educational research, they appear to be too general to provide guidance for explaining and supporting the learning of mathematics. Orienting frameworks, such as constructivism (Von Glasersfeld, 1995) or communities of practice (Lave & Wenger, 1991), provide general support for specifying issues of learning, teaching and instructional design whereas frameworks for actions concern analytical constructs of a more or less general *prescriptive* character (diSessa & Cobb, 2004). Domain-specific instructional theories are also of a prescriptive nature as they are typically specific to a domain or even learning trajectory of certain content and the means by which this trajectory can be supported. An ontological innovation is descriptive in nature. It is about developing analytical categories by which aspect of a phenomenon can be discerned. The framework of Socio-mathematical norms (Yackel & Cobb, 1996) exemplifies an ontological innovation.

diSessa and Cobb’s (2004) categorization not only labels the nature of different frameworks, it also points to the *descriptive*, *explanatory*, *predictive* and *prescriptive* purposes of different theories. **Firstly**, theories could be used to describe the world and many theories and frameworks within mathematics education serve such a purpose. The contribution to research in engaging in describing or characterizing objects or processes as certain phenomena could be understood in terms of new or unconventional lenses for viewing the world. **Secondly**, a further purpose of theories is to explain relations between phenomena and as mentioned above this purpose is often stressed as absolutely central for theories. A prerequisite for explaining those relations is to explicitly characterize each phenomenon. Therefore, theories used for explanatory purposes build upon or encompasses descriptive theoretical contributions. **Thirdly**, in a similar vein predictive theories necessitate explanations and clear descriptions of phenomena. Predictions include foreseeing effects of certain actions under certain conditions. **Finally**, prescriptive theories are used to identify and articulate productive ways to make decisions and performing actions. This kind of theory integrates descriptive, explanatory and predictive knowledge to guide actors in constructing and establishing

interventions. Within design research prescriptive theories are often denoted design principles but neither the term nor the nature of those design principles are settled (Ruthven et al., 2009).

### Theories for action

In this paper we are particularly interested in theories for actions and what McKenney and Reeves (2012) denote the prescriptive role of theories. Both the characteristics of theories of actions and prescriptive theories and ways of denoting them are not settled in educational research as indicated above (cf. McKenney & Reeves, 2012). As becomes apparent in (Ruthven et al., 2009), the relation between the terms used to denote theories for action is not just connected to neutral ways of denoting the same phenomenon but instead accentuates particular features and characteristics of such prescriptive theories. For instance, Ruthven et al. (2009) shortly muse about the relation between the design tools they introduce and design principles. They suggest that the conceptual set up of grand theories, intermediate frameworks and design tools introduced in Ruthven et al. (2009) stresses *theoretical* underpinnings for *sensitizing* researchers to critical issues while design principles from US often *prescribe* certain course of actions and are typically more loosely anchored in theoretical perspectives. One may ask, should theories for actions prescribe and sensitize teacher? In general, the development and understanding of design principles is weakly developed and in summarizing the most urgent issues for educational design research McKenney and Reeves (2012) suggest “a worthy challenge facing educational design researchers is to further the development of predictive and prescriptive theories” (p. 212). We want to add to this research.

### Method

The design was framed by a ten-step process for systematic literature reviews (Gough, Oliver, & Thomas, 2013): (1) Need, (2) Review questions, (3) Scope, (4) Search, (5) Screen, (6) Code, (7) Map, (8) Appraise, (9) Synthesize, and (10) Communicate. In the project we engaged in processes 1-7 and 10. Our *review questions* were: (a) What characterizes research on classroom teaching practices, teaching approaches and teaching methods in mathematics? (b) What characterizes research on teachers’ instructional strategies used to establish classroom practices in mathematics? and (c) What does research tell about teaching for the learning of mathematical competencies?

We *searched* in title, keywords and abstract in Web of Science<sup>2</sup>. Search strings<sup>3</sup> were iteratively developed while reading some abstracts. In total, we had 622 hits that we *screened* for relevance according to our *scope* defined by our inclusion criteria<sup>4</sup>. The screening was made in two steps based on: (1) title, keywords, and journal name, and (2) abstracts. Uncertain cases were discussed and decided upon collectively among the three researchers. After the two screening steps, 242 articles remained potentially relevant for the scope of the review. Simultaneously as the screening of

---

<sup>2</sup> We searched Web of Science Core Collection as a way to focus on high-quality journal articles. We limited our search to the year span 2008-2014 and to the document types “article” and “review”.

<sup>3</sup> See Appendix A in Ryve et al. (2015) for the exact search strings.

<sup>4</sup> For an article to be included in the review, the article must be: (1) about mathematics teaching/learning/education, (2) related to compulsory school (grade 1-9), and (3) about the teacher’s role.

abstracts, the articles that remained relevant were *coded* on Object of study, Method, Number of participants, Context, Results, and Implications for practice. When needed, we also read other parts of the articles apart from the abstract. 201 articles remained relevant for the review based on the inclusion criteria. The next step of the *mapping* was to structure and characterize trends and interests within the discourse of research in mathematics education that focus on teaching methods, classroom practice and teacher's role in classroom practice. Therefore, we looked closer at the abstracts of the 201 articles, categorizing them in relation to object of study. See Ryve et al. (2015) for detailed descriptions of steps and rationales in the processes.

## Results

	Student knowledge		Student attributes (SA)	Practice (P) (Teaching approaches)
	Processes	Products		
Interactional strategies (IS)	3	10	4	11
Teaching approaches (TA)	9	42	8	
Learning material (LM)	5	14	2	7
Background variables (BV)	1	16	2	34
Characterization (Char) Total: 33				

**Figure 1. Categories and analytical relationships of the mapping**

Of the 201 articles, we found 168 to be structured according to an analytical relationship between an outcome variable and a design variable. In the remaining 33, the object of study did not follow such a structure. The design variables we distinguished are gathered in the left column of the matrix (Figure 1), while the outcome variables we found are categorized in the top row of the matrix. In elaborating on the mapping we intend not to go through the entire mapping. We highlight and provide examples on some specific findings, which we then follow up on in the discussion. In the discussion we construct a new framework, to be used for categorizing theories to be implemented in mathematics classroom practices. On this account, and due to space limitation, we are not backing up all claims and findings by references from the mapping.

### Elaborating on theories within the mapping

#### *Student knowledge*

Our review reveals a clear bias towards research that focuses students' product knowledge. Mathematical products relate to conventions, symbol systems, concepts and calculation techniques of mathematics. Looking at studies that emphasized a product view of mathematics and those emphasizing a process view we also notice a methodological difference. In the product view knowledge is expressed in the language of mathematical products and students understanding are profiled and ordered in accordance to the mathematics itself. Connected to such a conceptualization of knowledge, students' performances are often measured by standardized tests (Desimone, Smith,

& Phillips, 2013). In the process view, qualities and progressions are not explicitly elaborated on. These frameworks are descriptive in nature, specifying a set of analytical categories, which is used to sensitizing (Ruthven et al., 2009) the analyst on some certain characteristics of, for instance, students' ability to communicate and reason in and with mathematics.

### *Interactional strategies*

Studies belonging to this category explicitly refer to teachers' moves and actions. The teacher takes an active role in these studies; how he/she acts in interaction with the students, is central to the investigation. The focus is on how teachers communicate and engage with their students, and what role the communication and engagement play in students' learning of mathematics. It could be about, for instance, how a teacher uses gestures and questions (Shein, 2012) and follow up on students' ideas in order to develop the mathematical classroom practice (Akkus, 2013).

### *Teaching approaches*

Teaching approaches refer to studies taking a broad perspective on classroom teaching in mathematics. The teachers' actions and interactional behavior are not the main object of investigation. The teacher may be important, but it is the more general and overall structures of teaching that are the object of study. In our review we found different examples of teaching approaches, such as technology-based teaching, mathematical games, problem-based teaching, and contrasting ways of using textbooks in mathematics teaching.

### *Learning material (task design)*

Some studies focus on how a specific artifact or design principle can support or challenge students' learning in mathematics. In these studies, the teacher takes a passive role. Focus is on the students' interaction with the learning material and the role of the teacher is basically to execute the lesson. Studies belonging to this category may investigate the role of visualization or simulation in the learning of mathematics (David & Tomaz, 2012). In this group we also include issues of task design; types and sequences of tasks (Hattikudur & Alibali, 2010) and instructions for solving mathematics tasks (Orosco, 2014).

### *Background variables*

Several studies did not connect classroom practice and students' learning to any didactical design variable. These were studies giving accounts of personal attributes such as teachers' beliefs, attitudes and knowledge in order to explain classroom practice and students' performance.

### *Characterization*

In 33 articles of the articles, the object of study did not follow the structure of an analytical relationship between two didactical variables. In this group of studies, to describe a certain practice or teaching approach is the focus in itself. The goal is to provide *descriptive* accounts of analytical categories of a teaching/learning phenomenon, which can be used to sensitizing researchers and teachers to critical issues of the phenomenon in question (Ruthven et al., 2009). It may concern the characterization of curriculum material (Sherin & Drake, 2009), the orchestration of math-talk with interactive whiteboards (Beauchamp, Kennewell, Tanner, & Jones, 2010), mapping the mathematics in classroom discourse (Herbel-Eisenmann & Otten, 2011), or profiling students' understanding or strategies of specific subject matter content (Wagner & Davis, 2010).

## Discussion

By relating the results of our mapping to literature on educational policy, professional development and implementation research we construct a framework for understanding and facilitating the implementation of theories and research results aiming at supporting teachers' mathematical classroom practices.

In studying the papers it is apparent that teachers are ascribed different roles in different research studies. While quite a few studies within the category of learning material position teachers as administrators of tasks and computer programs other studies highlight the role of expert and orchestrator of classroom practices. Within the latter categories of articles, the role of teachers is central in asking questions, explaining content and acting formatively to support and challenge students' mathematical thinking. In understanding the implementation of theories and results aimed at improving classroom practices and students' mathematical learning it seems essential to consider how **theories construct the role of teachers in classrooms**.

Ruthven et al. (2009) notice the distinction between theories that prescribe teachers' actions and theories that aims at sensitizing teachers to essential aspects of classroom practices. In a similar vein, while some theories and studies in our review are clearly prescriptive towards teachers (e.g., theories belonging to Instructional strategies and Learning material) and what they should do in classroom practices, others aims at sensitizing and empowering teachers (theories belonging to the Characterization category). We are not normative about these different ways and suggest that both could be productive for different teachers in different context. Further, we hypothesize that these two strands are correlated with research methodologies in that many studies within mathematics education taking an educational design perspective aims at empowering teachers while studies taking a stricter experimental approach prescribe and praise clear prescriptive instructions. However, to what extent and in which ways **theories prescribe or sensitize teachers** seem relevant to consider for anybody collaborating with teachers.

Cobb and Jackson (2012) stress that tools and frameworks within educational policies play a prominent role. When it comes to designing and using tools Cobb and Jackson suggest that it is important that the tools can be used by agents immediately in that they are easy to access, but at the same time harmonize with the planned reorganization of the practices. In addition, in developing frameworks, theories and tools it is essential to consider the amount and type of learning that are required for teachers to develop in order to use them in an appropriate and reliable way. Of course, such using requires good mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008). However, there is also reason to believe that certain types of frameworks are easier then other to use and apply in a mathematical teaching practice. For instance, in our survey we notice how the product perspective dominates research focusing on student knowledge. That the product perspective has a long tradition in the field is probably the major reason for this. However, taking a closer look to the mapping we can also understand this dominance as if there is a higher degree of transparency in how to use product knowledge theories compared to process-knowledge theories. From this we learn that, in implementing theories to school practice, we need to consider how user-friendly, accessible and transparent different types of theories are to teachers. In other words, we need taking into account to **what extent and which kind of teacher learning is necessary** for productively implementing theories or frameworks to mathematical classroom practices?

Desimone's (2009) put forward *coherence* as a critical feature of professional development programs. The concept of coherence refers to the relation between the PDP and teachers' knowledge and beliefs. This raises questions about the extent to which theories should be coherent with teachers' knowledge and beliefs. In other words, should theories strengthen teachers' knowledge and beliefs or should it challenge their knowledge and beliefs? Should theories aim at strengthening classroom practice or should theories aim at reorganizing classroom practices (Cobb & Jackson, 2012)? The reorganization of practice could include working with new types of mathematical problems, new roles for students and teachers, and the establishment of new classrooms. Hence, in examining and choosing theories, frameworks and models, mathematics educational researchers working with teachers should consider whether the aim is to **strengthen or reorganize ongoing practices** and, consequently, consider how frameworks are supportive for such endeavors.

To conclude, as a complement to categorize theories for actions in terms of content areas we suggest it is productive for researchers working with teachers to consider theories in terms of: the positioning of teachers in classroom practices; the positioning of the teacher as a receiver of the theory; the amount and type of teachers' learning required; and if theories primarily function to strengthen or to reorganize practices.

*In this paper we investigate the role of the local supervisor when implementing a mathematics teacher training program based on Action Learning (Misfeldt et al. 2014, Plauborg et al. 2007). Using data from interviews of teachers, local supervisors and school managers we examine the arising expectations on the local supervisor and how these expectations influence the program's ability to support teachers in their professional development. We do so by using Clarke's (2009) Situational Analysis and Arcform notation (Allsopp 2013) to map the actors' relation to the supervisor. We see that the local supervisor is caught in a tension between expectations from the Action Learning method and the school managers. This hinders schools in anchoring Action Learning as a teacher training method and thereby benefitting its full potential.*

*Keywords: Teacher training, Action Learning, theory and practice, Arcform.*

## Implementing teacher capacity building through collaboration

A crucial aspect of a number of initiatives to improve mathematics education is the ability for teachers to collaboratively question and improve their own teaching (Stigler 1998), sometimes involving resource persons such as researchers or teacher educators. For such in-service training or capacity building to be efficient and scalable it is important that they are anchored in the school organization and not solely dependent on enthusiasts. Initiatives like Lesson Studies and development of own practice (alone or in collaboration with researchers), are examples that requires systemic and organizational attention (Lewis, Perry & Murata 2006). Systematic approaches often mean that teachers take on certain roles in relation to each other's practice in order to maintain initiatives. Such structures and roles that connect in-service training to practice and build directly on the school organization and culture are important. Research has found that it is very difficult to make sustainable changes with teacher training initiatives (Shear, Gallagher & Patell, 2011; Henriksen et. al 2011), and Maurer (2010) has estimated that 70% of teacher training projects fail in changing teachers' practices within the given time frame of the project. This is a major challenge to the mainstream implementation of research findings in mathematics education. According to research literature the difficulties with changing teacher practice through in service training are associated with a lack of connection between training programs and teachers' existing practices (Fixsen et. al. 2005) as well as with the fact that teacher training programs often lack a focus on establishing active, collegial relations among teachers, which are crucial in order to build sustainable development (Hargreaves 2000, Sølberg, Bundsgaard & Højgaard 2013). When trying to address these concerns certain employees often take on certain roles towards their colleagues in the sense that they advocate for, manage and nurture certain projects. In this paper we explore this challenge by investigating a case where the distance between training activities and day-to-day teaching is very small and where the collegial relations are supported in a direct fashion. We do so by describing an Action Learning case as it has been implemented in a Danish municipality.

## Context

In 2012 a municipality in Denmark launched a teachers training program aimed at developing teaching practices and enabling schools in the municipality to develop teacher competencies independently from external resources. The training program involved every school in the municipality and a total of 3500 participating teachers. The program consisted of a combination of a summer university in which teachers were given thematic lectures on a variety of subject-specific and pedagogical topics (implemented at 80% of the schools) and a method called Action Learning (implemented at approximately 20 % of the schools). Action Learning is a teacher-training program developed as an alternative to traditional course based in-service training. It draws on inspiration from Action Research in that it is based on an assumption that solutions to practical problems require practical understandings, which must be gained through iterative attempts to solve the actual problem (Plauborg et. al. 2007). The “action” in Action Learning refers to a pedagogical or didactical intervention that addresses *real* classroom issues as the individual teacher experiences them. While the “problem” is defined by the individual teacher the intervention is developed collaboratively by a group of teachers engaging in a so-called “team-conversation”. Local supervisors from each school were designated the responsibility to facilitate professional discussions among the teachers in the team conversations. The local supervisors were teachers from the school who had a mathematics supervisor education, and who provided didactical support on a daily basis. The local supervisors also had the responsibility of anchoring the collaborations among the teachers at the schools to enable their ongoing professional development. The characteristics of Action Learning therefore seem to counter many of the challenges identified in the research literature about teacher training programs; active collegial teams are established, the team conversations are facilitated by the local supervisor in order to maintain an academic focus in the conversations and the starting point is the teachers’ existing practices. In this context these initiatives however relied heavily on the local supervisors who were designated a key part in facilitating the team conversations and in anchoring team collaboration at the schools. In our research we therefore investigate the expectations arising to the local supervisors in the implementation of Action Learning and their possibilities meet these expectations (for further information about the program see the full evaluation report (Misfeldt et al. 2014).

## Method

Our research draws on interviews of key actors in the training program from two schools, namely the participating teachers, local supervisors and school managers. We interviewed 6 teachers, 2 local supervisors and 2 school leaders coming from 2 different schools. Our interviews explored the actors’ experiences of the training program and their understandings of the role of the local supervisor in the program. We also collected documents and literature that describes the Action Learning Method and documents from the municipality describing how Action Learning was to be carried out. All of these sources were considered with the goal of identifying how the role of the supervisor was perceived. We analyzed this data by using Clarke’s Situational Analysis (Clarke 2009). Situational Analysis is rooted in Grounded Theory, but modified according to postmodern assumptions that “boundaries are open and porous; negotiations are fluid and usually ongoing” (Clarke 2009). There is no a priori assumption that human actors are of greater importance than either non-human or discursive actors (Clarke 2009), which allows us to view the Action Learning

concept as an actor in itself. In Situational Analysis, Situational Maps provide a methodological approach to organize and visualize empirical data by foregrounding situations (Clarke 2009). We initially processed our data by using a sub type of Clarke's Situational Maps: Relational maps (den Outer 2013). Like other situational maps these aim at foregrounding situations rather than individual actors or their actions by mapping all actors (human as well as non-human and discursive) that occur in any situation, but go further than this by showing relations between actors. Relational maps use a type of network notation where actors are represented by labeled nodes and relations are represented by un-labeled lines drawn between the actors/nodes.

We drew our relational maps while reading our transcribed interviews and other relevant documents. We began by listing the relevant actors that appeared in our data and their relation to each other. We produced many versions of some maps, modifying them as some actors and relations grew in prominence in our analysis. The messy nature in our data was easily overviewed with the simple structure of relational maps and thus they played an important part in opening up our data and thereby prompted our analyses. However, beyond a certain point they seemed to counteract rather than support overview. Clarke stresses that though situational maps are useful tools for beginning analyses, they are not necessarily an appropriate end-product of analysis (Clarke 2003, 563). We experienced two related problems: Firstly, it was difficult to draw some types of relations between actors and secondly they became difficult to understand/interpret, especially when returning to the analyses after several weeks. To overcome this limitation of our relational maps, we chose to visualize the situations through Arcform notation (Allsopp 2013). Like relational maps, Arcform maps do not visualize our data, but rather the results of our ongoing analysis. Arcform maps differ from most relational maps, but resemble many network notations by supporting direction and labels on relations (arcs). Thus relations like “local supervisors coach teachers” are clearly visible as an arc labeled “coach” pointing from an actor node labeled “local supervisors” to another actor node labeled “teachers”. However, Arcform also differs from most other network notations by allowing arcs to point from or to other arcs. In this way more complex relations like “teachers see local supervisors as coaches” can be drawn as shown in Figure 2.

Figure 1. The sentence “Teachers see local supervisors as coaches” expressed in Arcform.

## Results

As our analysis progressed it became clear that the actors in our data articulated their relation to the local supervisor quite differently, and that they had different conceptions of the main job of the supervisors in the action learning project. Though these actors were all engaged in the same project at the same school, their ways of participating and their relation to the supervisor was rather different and seemed at first glance to be related to their role in the school outside the project. Besides being a part of a project, the actors were respectively also teachers, supervisors and school managers, and this fact seemed to be of importance. Our maps also revealed that this meant that the actors had different expectations on the supervisor and that these expectations could intersect with problematic consequences. In order to refine our analysis of these preliminary results we decided to use a notion of cultural logics developed by Nielsen (2012), which we will introduce below.

In a study on teachers' learning from collaboration in teams, Nielsen develops a view of teacher collaborations as having a dynamic stability (Nielsen 2012). It is dynamic because it involves numerous ongoing activities that are oriented towards one or more objectives. It is stable because it involves a perceived regularity in actors' actions suggesting a stable understanding underlying these activities. Such logics effect peoples' objectives and can be difficult for externals to change, because they reflect the every-day phenomena which are experienced as urgent by the actors involved. For example, although teachers most likely find the learning processes of students an important objective to orient their collaboration towards, so too may they find the practicalities that make a well-settled lesson (Nielsen 2012). In situations where there are multiple cultural logics we can expect actors sometimes to be caught in a tension between these logics.

The notion of cultural logics is highly useful in our context as the Action Learning training program is a project in which several actors', who occupy diverse positions, participate. Viewed this way the role of the supervisor is at risk of being caught in a tension between multiple cultural logics. As the local supervisor is a key actor in implementing and anchoring the Action Learning method, such tensions and their implications are of particular interest in this study. We identified three dominant logics. We refer to these as the workplace logic, the curriculum logic and the project logic. The cultural logics are characterized by situations in which certain aspects of the training program are foregrounded over others which translate into a set of expectations on the local supervisor. In brief the logics translate in to the following expectations:

- In the **workplace logic** the supervisors are expected to manage the project and to avoid delays in the project.
- In the **curriculum logic** the supervisors are expected to be willing and able to guide the teachers academically in their professional development.
- In the **project logic** the supervisors are expected to initiate and support the teachers' professional development in a coaching-manner where an equal relation between supervisor and teacher is crucial.

The map below illustrates how the role of the supervisor is formed by the different cultural logics.

*Figure 2. An Arcform map showing how two actors (school managers and teachers) see local supervisors as three different roles (project managers, academic beacons and (equal) coaches) with three different cultural logics (workplace logic, curriculum logic and project logic).*

The goal in the project logic are progress and development of the school, while the curriculum logic foregrounds the quality of teaching. Though these logics can be complementary, our mapping revealed that the supervisors are faced with a tension due to a collision between the project logic and the workplace logic. In the following two sections we will therefore further describe the dynamic stabilities of the two latter cultural logics and unfold the tension emerging from here.

### **The project logic**

The project logic concerns the cultural logic of the Action Learning training program as it occurs in documents describing the Action Learning concept and the expectations to the role of the supervisors emerging from it. In the Action Learning concept, the primary priority is the competence development of the teachers participating. In this, the supervisors are first and foremost expected to have the will to develop the school and the teachers and to do so as an equal coach rather than as a managerial authority. The supervisor is expected to initiate the Action Learning collaboration and to support the teachers in their development - not to lead/manage them. This is crucial as it is an acknowledgement that it is the teachers themselves who are experts on their own practices – the role of the local supervisor is therefore to facilitate conversations that creates the best setting for this knowledge to be shared (Plauborg et. al. 2007). The statement below from a local supervisor illustrates her view of the Action Learning project suggesting that she embraces the project logic and that she is capable of seeing the potentials in the method.

Local supervisor: (...) there were some 3<sup>rd</sup> grade teachers who said: “We have already tried this method. Why do we have to go through it again?” And my argument was that even though we have tried the method before, it is not implemented at our school. We don’t use it as a method as things are now.

The statement indicates that the supervisor views competence development as ongoing and Action Learning as a way to enable such ongoing developments. She therefore argues to her colleagues that Action Learning is not a syllabus which you only have to read once and then move on – rather, Action learning is a concept that involves specific ways of collaborating which are not implemented at the school. The statement thereby demonstrates a will to develop the school that resonates with the expectations embedded in the Action Learning concept. It also tells us that the supervisor has the skill needed to spot and to articulate that the crux is to integrate Action Learning as a way of collaborating.

### **The workplace logic**

The workplace logic concerns the main objective of the training program from the school managers' view and their expectations to the local supervisors' role in the project. From the interviews with school managers the training program appears as a project among many other projects in which the main priority is to safely navigate the school through it and to avoid any delays. Though the school managers presumably also have an interest in developing the competencies of their teacher staff, safely getting through the project appears as the dominant cultural logic. Interviews with school managers show that this logic translates into an expectation that the local supervisors will be managers of the project due to high trust of the professionalism of the supervisors. The statement below from a school manager illustrates how the supervisor is referred to through the workplace logic.

School manager: I highly trust my supervisor's skills. Our supervisor is very professional and she is currently going through a pre-leader course. (...) and I thought that she therefore was better qualified to manage the project than I was.

In what appear as an acknowledgement of a supervisor's skills, this supervisor is given the responsibility to manage the project. At this particular school a group of teachers refused to participate in the training program due to short notice and discomfort about having to be observed as a part of the project. As the school managers had distributed the responsibility to manage the project, this became an issue for the local supervisor to handle. Consequently, the supervisor was obliged to "persuade", as she puts it, another group of teachers to participate in the project.

Local Supervisor: I didn't lure them but... I just told them that it wasn't optional. They just had to do it, you know.

As the responsibility of managing the project was designated to the supervisor through the workplace logic, these project management issues become a task for the supervisor to handle. This implies that the supervisor is required to draw on a formal leadership mandate by reminding the teachers that participation in the project is mandatory. As the supervisor describes in the following excerpt, this incident resulted in an uncertainty among the teachers about the role of the supervisor:

Local Supervisor: I think that this made it very unclear for the teachers what my part in this project was. Am I here to check if they are doing a bad job? Will I go to my manager and say: "That teacher does a bad job. She is really bad at teaching math". Or whatever it might be.

The supervisor's task of managing the project is not necessarily problematic in itself. But as a group of teachers refuse to participate in the training program, this is an issue that becomes a task for the supervisor to handle. In order to handle this issue, the supervisor is obliged to find another group of

teachers that are willing to participate. As no other teachers were willing to participate in the project the local supervisor was obliged to emphasize to a specific group of teachers that they were obliged to participate as this was necessary for the Action Learning project to carry on.

### **Implementing research findings in practice – emerging problems and prospects**

Our analyses have identified three cultural logics, two of which we have unfolded above. Each of these cultural logics produces a certain set of expectation to the supervisor in terms of how he or she adequately should participate in the project. What becomes evident from our analyses is that the local supervisors are met by mutually exclusive expectations as a consequence of these logics; the project logic expects the supervisor to support the teachers as an equal peer whereas the workplace logic expects the supervisor to manage the project as a superior. This has at least two consequences. Firstly, the supervisor's delegated management role triggers an uncertainty among the teachers of the intentions of the supervisor and raises the questions of whose errands he or she is running. Is the supervisor's main task to support the teachers in their professional development or to monitor their work on behalf of the management? This uncertainty makes it difficult to draw on the supervisor as an equal facilitator. A key component in the Action Learning concept is the joint observations of each teacher's practice, which subsequently are meant to be the starting point for a conversation aiming to develop the teachers' understandings of their own practices. Such an uncertainty among the teachers in respect of the supervisor's role represents a substantial barrier in creating a safe environment in which the teachers can learn from their own practices. Secondly, the coexisting logics cause a tension on the supervisor as he or she is expected to fill many roles at the same time. Each of the cultural logics influence the actors' expectations to the role of the supervisor according to their own dynamic stability, thus tying the supervisor to different, incompatible priorities at the same time. As the potential for anchoring the Action Learning concept is closely connected to the role of the supervisor, there seem to be little chance that the supervisors are capable to do so under such difficult circumstances.

Our analysis also points to more general issues related to implementation of research findings in practice. Though Action Learning addresses what seem to be the main challenges in gaining long-term results from teacher training programs, the different expectations arising on the local supervisor complicates the implementation and the anchoring of the training program. The training program investigated in this paper exemplifies how many actors are at play in a school setting and that each participating actor may have different agendas in and around such projects. Though this perhaps is no surprise, our research suggests that difficulties in implementing research informed training programs can be the result of the differing actors' agendas outside the project. In Action Learning, as in many other training approaches, some actors are of immense importance in order to harvest the potential results of research informed approaches. The professional development of teachers involves and affects many others than the participating teachers and enters the professional lives of actors, which may have different priorities, agendas and available resources. A main problem about the issues identified in our research is that the co-existing cultural logics and the expectations arising to the supervisor thereof largely remain tacit. Though different agendas and the effects of such cannot be eliminated by simply making them explicit, an increased awareness and joint management of expectations would most likely be a step towards overcoming such hurdles.

# Rehearsals in work with in-service mathematics teachers

Anita Valenta<sup>1</sup> and Kjersti Wæge<sup>2</sup>

<sup>1</sup> Norwegian Centre for Mathematics Education, Norwegian University of Science and Technology (NTNU), Norway; [anita.valenta@matematikkssenteret.no](mailto:anita.valenta@matematikkssenteret.no)

<sup>2</sup> Norwegian Centre for Mathematics Education, Norwegian University of Science and Technology (NTNU), Norway; [kjersti.wage@matematikkssenteret.no](mailto:kjersti.wage@matematikkssenteret.no)

*An approach that has shown to give pre-service teachers rich opportunities for learning to teach mathematics is through a cycle of enactment and investigation. An important part of the cycle is rehearsal where novices rehearse their plans for enacting particular instructional activity in front of their peer pre-service teachers. The peers and the course instructor take part in the rehearsal as students, and every participant can stop the activity for discussion on different aspects in teaching. We build on the approach developed for pre-service teachers, and work on the adoption and development of the approach for work with in-service teachers in Norway. This paper reports from a pilot that was implemented with a group of in-service teachers. Our research question concerns interactions between in-service teachers and course instructors during the rehearsals and in-service teachers' opportunities for learning in rehearsals.*

*Keywords: Rehearsals, in-service teachers, ambitious teaching.*

## Introduction

The aim of mathematics instruction is development of broad mathematical proficiency characterized by conceptual understanding, procedural fluency, adaptive reasoning, strategic competence and productive disposition to mathematics (Kilpatrick, Swafford, & Findell, 2001). This ambitious goal leads to a more demanding, and thus ambitious, conception of mathematics teaching. In this paper we aim to add to the existing knowledge base about how teacher education can support in-service mathematics teachers to learn the work of ambitious mathematics teaching.

In the Mastering Ambitious Mathematics Teaching (MAM) project we develop a course for in-service mathematics teachers in Norway. In designing our intervention, we take our lead from the Learning in, from, and for Teaching Practice (LTP) teacher education project (see Kazemi & Hubbard, 2008; Kazemi, Lampert, & Franke, 2009; Lampert et al., 2010; Lampert et al., 2013; Kazemi & Wæge, 2015). Central in the LTP-practice based approach is work with specifically designed instructional activities (IAs) in a cycle of enactment and investigation. A key innovative feature of the design is the use of public rehearsals. In a rehearsal, the pre-service teacher is responsible for teaching an IA to a group of peer pre-service teachers acting as students, with the course instructor offering guidance.

This paper reports on our work on rehearsals with *in-service* teachers in a pilot study. We ask: What characterizes the interactions between in-service teachers and course instructors during the rehearsals in the study, and in what ways might rehearsals support in-service teacher's learning of ambitious teaching?

## Rehearsals within a cycle of enactment

Ambitious teaching entails mathematical meaning making, identity building and creating equitable learning experiences for children. It requires teachers to engage deeply with children's thinking - by eliciting, observing, interpreting and responding to student reasoning, language and arguments. Attending to students' experiences and designing instruction to enable each child to do rigorous academic work in school is also a central principle of the approach (Lampert et al., 2013).

In their work on ambitious mathematics teaching, Lampert et al. (2010) build on the study of Leinhardt and Steele (2005) who identified some routines skilled teachers used in leading instructional dialogues and argued that expressing the routines explicit make them teachable for course instructors. Lampert et al. (2010) use the notion "routines" to denote well-developed practices which have shown useful in teaching, which respect the complexity in mathematics, mathematics teaching and learning. They argue that focus on learning to use these routines/practices can provide novices an opportunity to hold something constant in a process of further learning to teach. The teaching practices that are central in ambitious teaching include aiming toward a mathematical goal, eliciting and responding to students' mathematical ideas, orienting students to each other's ideas, setting and maintaining expectations for student performance, positioning students competently, assessing students' understanding, and using mathematical representations (Kazemi et al., 2009; see also Hunter & Anthony, 2012). Teachers who are novices in teaching mathematics ambitiously need to learn to enact the practices in their teaching. They also need to develop the mathematical knowledge needed to teach ambitiously at a particular grade.

Grossmann, Hammerness and McDonald (2009) argue for incorporation of "pedagogies of enactment" and use of "approximations of practice" in teacher education in order to help pre-service teachers develop knowledge, skills and professional identities as teachers. As a type of approximation to practice, Grossmann, Compton et al. (2009) suggest use of rehearsals where novices rehearse a particular instructional activity in front of a group of peers. Kazemi, Lampert and Franke (2009) develop instructional activities (IAs) that are designed to be "containers" for the practices, principles and mathematical knowledge that novice teachers need to learn and be able to use in interaction with students (see Kazemi & Wæge (2015) for descriptions of the IAs). The structure of the IAs offers the novices a scaffold in eliciting and responding to student thinking and understanding. The novice teachers learn to teach IAs – through repeated investigation, discussion, rehearsal, enactment and observation. Each cycle of enactment and investigation consists of six stages (Lampert et al., 2013), as illustrated in Figure 1:

- 1) Observation of a teacher educator's enactment of a particular IA
- 2) Collective analysis of the observed enactment
- 3) Preparation to teach the IA to a group of students
- 4) Rehearsal of the IA by novice teachers
- 5) Enactment of the IA with a group of students
- 6) Guided collective analysis of the enactment

**Figure 1: Cycle of enactment and investigation**

In stage four of the cycle, selected novice teachers publicly rehearse their plans for enacting an IA in front of their peers and with feedback from the course instructor. During the rehearsal, the course instructor or a peer may stop action to ask questions or suggest possible alternative courses of action. The course instructor may also act as a student, by asking and answering questions or by making errors that students are likely to make (Lampert et al., 2013). Rehearsals within repeated cycles of enactments and investigation can be considered as an approximation of ambitious teaching.

Lampert et al. (2013) argue that a rehearsal is an important setting for building novices motivation and commitment to teach ambitiously (p. 239-240). They analyzed 90 rehearsals of IAs by pre-service teachers. The study revealed that rehearsals not only allow pre-service teachers to work on routine aspects of ambitious teaching, but also to attend to more complex aspects of it. The study also showed that rehearsals give the pre-service teachers an opportunity to learn the principles of ambitious teaching while the course instructor guide their progress.

## **Design of course**

The course consisted of seven sessions (each four hours in length) during a period of four months. The sessions were held in a fifth grade classroom of an elementary school<sup>1</sup>.

Session 1: The in-service teachers (ISTs) were introduced to the principles and practices central to ambitious teaching and the instructional activities they would work on during the course.

Session 2-6: In these sessions ISTs were divided into three teams of 4-5, and the teams worked together in planning, rehearsing, enacting, and debriefing course tasks: 1) Teams of ISTs came to class prepared to teach an IA; 2) Teams of ISTs rehearsed the IA under supervision of a course instructor (CI); 3) ISTs observed one of the CIs teach the subsequent session's focal IA to the whole group of fifth graders. This was part of the preparation for the following session; 4) One IST from each team taught a small group of fifth graders the IA that they had come to class prepared to teach. A CI also observed the enactments; 5) After a break, ISTs met in their teams to do a collective analysis of the day's enactment with their CI; 6) Each team debriefed what they had learned; 7) The CIs prepared the class for the following session's focal IA and, as part of that, shared some reflective comments on the whole group lesson that was taught.

Session 7: The last session was devoted to concluding discussions and try outs.

## **Method**

### **Participants and data**

There were 14 in-service mathematics teachers from three different elementary schools participating in the pilot study. The three schools are partner schools of the Norwegian Centre for Mathematics Education. Some of the ISTs in the study had only a few years of experience as mathematics teachers, while others were experienced teachers. A group of six course instructors (including both authors)

---

<sup>1</sup> Due to practical reasons we had to make some changes to the cycles of enactment and investigation proposed by Lampert et al. (2013) and illustrated in Figure 1.

from the Centre participated in the study. The course instructors had little experience in leading rehearsals.

Rehearsals were carried out in three teams at five of the sessions. All rehearsals were videotaped, but two of the recordings were damaged. Our data is therefore consisting of 13 recordings. Each recording is about 25 minutes.

### Coding and data analysis

A rehearsal consists of parts where an IST is teaching the activity, and parts where IST(s) and CI interact. We denote the interactions between IST(s) and CI during the rehearsal as *CI/IST exchanges*. To understand what characterizes the CI/IST exchanges during rehearsals, we take a CI/IST exchange as the unit of analysis and we analyze: 1) the substance of exchanges between CIs and ISTs, and 2) the structure of exchanges between teacher CIs and ISTs. In our analysis we used a priori codes adopted from Lampert et al. (2013). Table 1 shows a list of the substance codes and Table 2 shows a list of the structure codes that we built our analysis on. We used Studiocode video-analysis software which allowed for detailed coding of the rehearsals. For each rehearsal, we created a timeline for each video-recorded to capture the substance and structure of exchanges. Coding the video directly allowed for both verbal and visual cues to be considered, such as written representation, gesturing, and movements.

## Results

### Substance of CI/IST exchanges

In Table 1 we present an overview of frequency of the various substance codes in all CI/IST exchanges in the data<sup>2</sup>. The most frequent codes in our data are *representation*, *student thinking*, *content goals* and *elicit and respond*. These codes were also among the most frequent in the rehearsals by pre-service teachers analyzed by Lampert et. al (2013).

Substance codes	Description	% of all exchanges
assessing understand.	Assessing what a student knows and understands about the mathematics	16,1
attending to IA	Drawing attention to the structural aspects of the IA, particularly to help novice teachers' understanding the entire IA	23,1
body/voice use	Attending to how one uses body and voice while teaching	0
closing the IA	Bringing the IA to an end	3,5
content goals	Attending to the specific mathematical content goals of the lesson	31,5
elicit and respond	Eliciting, interpreting, responding to student mathematical work or talk	31,5
launching the IA	Introducing and beginning student engagement with the IA	5,6
manage space	Attending to issues of classroom space while engaging students	0,7
manage timing	Moving through the lesson in a way that manages timing and pacing	3,5

<sup>2</sup> Due to the complexity of CI/IST exchanges, an exchange can be coded by several substance codes. As a consequence, the percentages do not sum to 100%.

mathematics	Working on and understanding the mathematical content, particularly for IST learning	22,4
orienting students	Orienting students toward each other's mathematical ideas	7,0
process goals	Attending to the specific mathematical process goals of the lesson	16,1
representation	Representing mathematical ideas in writing and making connections between talk and representation	39,2
student engagement	Managing the intellectual and behavioral engagement of students	12,6
student error	Surfacing and responding to student errors	4,9
student thinking	Attending to the details of student mathematical thinking	32,9

**Table 1: Substance codes: description and frequency as percentage of all CI/IST exchanges in the data**

Many of the CI/IST exchanges involved more than one substance code, and the same combination of substance codes were frequently found together across different exchanges. For example, *student thinking*, *elicit and respond* and *representation* appear repeatedly in the same exchange. The combination of *content goal* and *representation* is also very common, in many cases together with *mathematics*. The frequency and the combination of the codes indicate that the main substance in CI/IST exchanges consist of

- 1) attending, representation, eliciting and responding to student thinking
- 2) content goals and representation of mathematical ideas in the activity

The following example is representative of the first category above:

Example 1. The IST who is teaching during the rehearsal shows the image of three groups of eight dots and asks the “students” how they see it. One of the other ISTs in the team suggest an answer.

IST2: I see eight times three. In the first group I saw four plus four, eight. I have eight three times.

IST: [Circles three groups of eight. See Figure 2.] So first you have one times eight, so one times eight, so one times eight. [Writes  $1 \times 8 + 1 \times 8 + 1 \times 8 = 3 \times 8$ .] Some other suggestions?

**Figure 2: Drawing on the whiteboard**

CI: Can we stop for a moment? Hmm, this is not so easy. The student presents her thinking rather imprecisely, and now we need to illustrate it on the image and also write it symbolically. We lose the part about seeing eight as four plus four in the way you represent her thinking. Can we try to represent her idea more accurately?

IST: I can circle four and four...

- IST3: But just in the first group. She said that she saw it in the first group and then just multiplied by three. And it is not clear whether she thinks eight times three or three times eight, she says both.<sup>3</sup>
- IST: Yes, right. I tried to make “eight times three or three times eight” clearer by leading to one times eight, and so on. Because it is three times eight.
- CI: Maybe you can ask the student how she would represent it? Or, if you find her explanation too vague, you can ask her to say more?

The IST2 (who plays the role of the student) says that she sees eight as four plus four and she says “eight times three”. Later she says “eight three times” which is more in accordance with the image and the convention. The IST takes no notice of the first parts of the utterance, and he grabs hold of the last part which is more in line with his goal. The CI’s first question is about *attending to* and *representation* of student thinking. The IST simplifies and changes the student’s contribution through the visual and symbolic representation. Further on, he asks for other suggestions and thus indicates that the discussion is finished. The CI’s second utterance explicitly addresses *eliciting and responding*.

The combination of *content goals* and *representation* of mathematical ideas in the activity appear also often within exchanges in our data, and the combination is illustrated in the following example:

Example 2. The IST’s goal is to use a string of problems to discuss multiplication by ten, hundred and thousand with the students. He starts by four times three, and asks the students for a story that would fit the arithmetic problem. A student (one of the ISTs) suggests four groups of three apples, and the IST draws the illustration as shown in Figure 3.

- CI: Are you planning to use money in the discussion? Your illustration reminds me of money.

Figure 3: Illustration on the blackboard

- IST: Yes, I have been thinking about it. Money can be useful here, when we discuss multiplication by ten, hundred. One can use tenths and talk about 12 tenths in the next step. Same with hundreds. But, another story came up.
- CI: As a teacher, you have decided what the content goal is, and you have been thinking about what representation would be appropriate. You can ask about a story *with* money from the start to get the representation you want in the discussion.

These kinds of exchanges, where *representation* and the *content goal* are combined, appear frequently in the data. In Example 2, the main substance discussed is the type of representation that could be appropriate for a given content goal and how to introduce it. In some other exchanges in the data that are coded with these two codes, the discussion is on ways to represent mathematical ideas so that the representation emphasizes the the relations that are targeted in the activity.

<sup>3</sup> In Norway, when the multiplication is interpreted as equivalent groups, the meaning of “eight times three” is eight groups of three.

## Structure of CI/IST Exchanges

The structure codes used in our analyses are the same as those used by Lampert et. al. (2013). Table 2 shows the description and frequency of the various codes in our data. Similarly as with substance codes, an exchange can be coded using several structure codes. For instance, In Example 2 above, the exchange starts by “CI facilitates discussion” and develops to “CI gives directive feedback”.

Structure-codes	Description	% of all exchanges
CI facilitates discussion	CI lead a discussion and reflection raised by CI or ISTs	50,4
CI gives directive feedback	CI suggests new move or think aloud about possible next move	35,7
CI gives evaluative feedback	CI make evaluative comment	7,7
CI scaffolds enactment	CI takes the role of teacher or student, scaffolding the enactment by either increasing or reducing the complexity	23,1

**Table 2: Structure codes: description and frequency as percentage of all CI/IST exchanges in the data**

Considering the structure of the rehearsals, the analysis shows that half of all CI/IST exchanges in our data can be characterized as *discussions facilitated by CI* (at least partly, in cases where several structure codes are used in the same exchange). In rehearsals analyzed by Lampert et. al. (2013), the code “CI facilitates discussion” is the least frequently appearing code, whereas “directive feedback” is the most frequent. This indicates that the structures of the rehearsals in the two studies are quite different. One reason can be that our study concerns in-service teachers while Lampert et al. (2013) report from their work with pre-service teachers. In-service teachers have more experience with teaching than pre-service teachers, and it is reasonable to expect that their skills in teaching and their identity as mathematics teachers are more developed. A consequence can be that both in-service teachers and course instructors working with them might feel more comfortable in discussions than with CI giving directive/evaluative feedback or scaffolding enactment.

## Discussion

Further work with in-service teachers and further data collection will take place in the coming year, and the results presented here are preliminary. However, the pilot study has already yielded a number of valuable insights. The study shows that the interactions between ISTs and CIs during rehearsals are mainly in form of discussions on some central principles and practices of ambitious mathematics teaching - using mathematical representations, aiming toward a mathematical goal, attending to student thinking and eliciting and responding to students’ mathematical ideas. More specifically, we have found that multiple substance and structure codes are present within individual rehearsal exchanges, indicating that rehearsals offer in-service teachers the environment and opportunity to work simultaneously on a variety of aspects of practice.

The study of Lampert et. al (2013) shows that rehearsals give opportunities for pre-service teachers to learn to enact principles, practices and knowledge entailed in ambitious teaching. The findings in our study indicate that rehearsals function as an approximation of ambitious teaching in work with in-service teachers too, even though the structure of rehearsals is different.

# Incorporating mathematical problem solving in the Chilean school curriculum

Eugenio Chandia<sup>1</sup> and Maria Luz Montes<sup>2</sup>

<sup>1</sup>Universidad de Chile, CIAE, Santiago, Chile; [eugenio.chandia@ciae.uchile.cl](mailto:eugenio.chandia@ciae.uchile.cl)

<sup>2</sup>SIP, Santiago, Chile; [lulu.monteslira@gmail.com](mailto:lulu.monteslira@gmail.com)

*Problem solving is one of the skills that is expected to develop in children who learn mathematics. To do this, school mathematics curriculum worldwide has incorporated this skill for teachers to promote it in classrooms. Though research results show what should be made, these have been parceled and make difficult an effective incorporation of the skill, its promotion and students' learning in schools. Therefore, the following work presents a professional development strategy that incorporate diverse research results related to the promotion of problem solving in math class. This allows to achieve a professional development complex system whose main axis is the school teacher.*

*Keywords: Problem solving, math curriculum, professional development.*

## Introduction

In Chile, the General Law of Education states that “students develop knowledge, skills and attitudes that allow them to understand and use basic mathematical concepts and procedures, related to numbers and geometric forms, in everyday problems solving, and to value the contribution of mathematics to understand and act in the world”, (article 29, section f). However, in the Curricular Study Programs of Chilean Mathematical Education there is no concrete proposal for teachers to promote such skills and attitudes in the classroom. Then, this poster shows one way to develop and include the problem solving in the Chilean Curriculum National of Math Education. To do this, is necessary to know what is needed for a successful curricular proposal implementation in math. The NCTM (2014) suggests the following points to implement a successful curricular development proposal: a) Teachers need to have a professional development of high quality to maximize the efficacy of the materials and activities they propose in the curriculum, since even the best textbooks and resources can be misinterpreted or misused. b) Collaboration among teachers throughout the school year may result in appropriate adjustments and activities adaptations for dosing topics to address the strengths and weaknesses of each student. For this reason, along with thinking about the curricular development proposal, a professional development proposal that supports teachers to incorporate in a better form the new requirements that are demanded need to be thought. On the other hand, Marrongelle, Sztajn and Smith (2013) indicate that the characteristics that make more effective a professional development program are: to be performed regularly and connected to practice; to be focused on students learning; to be directed to the teaching of a content; to be aligned with objectives of the school; and to build strong links among teachers. Considering the perspective mentioned above, in the following parts will be described the process for the implementation and the incorporation the PS in the curriculum.

## Methodology

The project aims to impact the: instructional practices of participant teachers related to the delivery of opportunities to develop skills in the students, focused in problem solving; teachers' skills to solve problems; teachers' skills to modify and adjust activities to promote the development of skills in their students; students' skills to solve problems; students' skills to represent, report, discuss, argue and explain mathematically. For this purpose, a proposal for curricular development that was adapted to the reality of the Chilean school system in Mathematics Education was designed. The project includes two main stages. In the first one a proposal for curricular development based on a literature review was designed, based on the Chilean curricular framework. The proposal included classroom activities for students, instructional methodologies for teachers and an annual curriculum integration plan for each participating school. In the second one, there was implemented a pedagogical technical support model in order to teachers appropriate the activities and methodology to be performed later in the classroom. The curricular development proposal will be implemented in 4 schools, which compromised their participation of teachers and students from 1st to 4th grade and the time necessary to do so. It had a population of 24 teachers and 600 students from 1st to 4th grade in total.

## Discussion and conclusions

The project is still being conducted, but there are preliminary results on its implementation. In the stage 1 of the proposal design was observed that while the curricular proposals from countries such as Singapore or Finland have among their curricular objectives to promotion of mathematical skills as the problems solving, the curricular resources available for teachers in those countries do not guarantee by their own, the skill promotion and not the acquisition of teachers' instructional practices. Again, research results corroborate the lack of professional development strategies that allow the skills acquisition by teachers (Bunyi, 2013). Given this lack and the need of the Chilean teachers in terms of mathematical knowledge, as well as in pedagogical skills to promote mathematical skills and attitudes towards it in classrooms, it is that the strategy of weekly and monthly support was crucial, both for the acquisition of pedagogical skills and mathematical knowledge.

# TWG24: Representations in mathematics teaching and learning

## Introduction to the papers of TWG24:

### Representations in mathematics teaching and learning

Elisabetta Robotti<sup>1</sup>, Anna Baccaglini-Frank<sup>2</sup>, Gérard Sensevy<sup>3</sup>, Torsten Fritzlar<sup>4</sup>

<sup>1</sup> University of Torino, Department of Philosophy and Science of Education,

<sup>2</sup> University of Pisa, Department of Mathematics

<sup>3</sup> University of Western Brittany, School of Education

<sup>4</sup> Martin Luther University Halle-Wittenberg, Faculty of Education

*TWG24 made its first appearance as a new Thematic Working Group at CERME10, focusing on representations of mathematical concepts or mathematical objects because of their constituting an “integral part of the doing of mathematics” (Presmeg, 2002) and thus an important part of teaching and learning mathematics. Indeed, representation has been a crucial topic in research, for instance, in PME groups, in a special issue of ESM, in a special issue of ZDM, in ICME 13 in 2016. In the group’s “Call for papers” the term representations referred to thinking tools for doing mathematics encompassing graphs, tables, diagrams, formulas, symbols, texts, concrete models, and, in a broader sense, even gestures, videos, sounds etc.*

*Keywords: Representation, visualization, imagine, visual-spatial abilities, visual-spatial image.*

### Introduction

This Thematic Working Group explicitly welcomed papers from a variety of different theoretical approaches and methodological frameworks addressing the role of representations of different types in teaching and learning processes, in particular those involving visualization (considered here as defined by Arcavi (2003)). In TWG24 there were 24 participants (authors, co-authors, and some other participants), from 13 countries (these included Chile, Denmark, Finland, France, Germany, Italy, Mexico, The Netherlands, Portugal, Sweden, Switzerland, Turkey, the UK) with 16 accepted papers and 2 accepted posters. The most part of the 16 papers, were empirical studies (related to primary and secondary school). The 2 posters reporting empirical studies conducted at the primary and secondary school levels. The poster concerning primary school described what students learn in mathematics lessons when different representations of fraction are used; and the poster concerning secondary school described how a variety of multi-sensory activities allowed 14 year old students to familiarise with some pivotal mathematical concepts such as prime and irrational numbers. The structure of the timeslots was designed in order to stimulate interaction and collaboration among participants: all participants were asked to read all papers, and prepare reaction-questions to two papers in particular that had been assigned ahead of time by the TWG leaders. After a 10-minute presentation by the presenting author, the prepared questions were posed and a general discussion was initiated and conducted for 25 minutes: first the authors of the paper would reply to the reaction-questions, then there was a discussion on issues related to the general list of questions designed for TWG24’s call for papers. Posters were also allocated a few minutes of presentation time within the working group, and a short follow-up discussion took place after each of them. The last session was completely devoted to summing up the main issues that had emerged from the

group discussions. One of these was that certain key words, present in the literature on representations and visualization in mathematics education, were not being used consistently by the participants. Therefore a list was put together with the suggestion for the upcoming CERME of making explicit the definitions used in each study. Among these (in alphabetical order): figure, gesture, mental imagery, metaphor, representation (including the distinction between internal and external), sign, symbol, visualization, visual-spatial abilities, visual-spatial image.

## **Gestures and representations**

The group agreed on the following: gestures can be considered as a way to create temporary external visualizations of internal imagery or structures, to explain or communicate thinking; movement involved in the gesture can connect physical properties and theoretical properties; different kinds of artifacts affording (or fostering) the use of gestures can be involved (such as the movement within dynamic geometry software). The importance of gestures in the context of representations in mathematics education was evident in TWG24, because many of the papers presented included a focus on gestures. Okumus and Hollebrands investigated how middle school students created 3-dimensional objects from 2-dimensional figures using an extrusion method, and they identified students' strategies for forming 3-dimensional objects with a focus on their gestural signs. The paper by Joffredo-Le Brun, Morellato, Sensevy, and Quilio focused on the relation between gestures and (other kinds of) representations (and metaphors), through the analysis of an extract from a lesson proposed in primary school during which the students work on the notion of difference, introduced with the help of several systems of representation. Ferrara and Ferrari also considered the relation between gestures and (other kinds of) representations, presenting the diagrammatic activity of secondary school students exploring motion through graphing technology, which captures a pair of space-time graphs on a single Cartesian plane. Indeed, the use of computers and technology was another transversal theme present in many papers and group discussions.

## **Technology and representations**

TWG24 discussed the issue of how technology can change the dynamics of teaching-learning by offering specific kinds of representations. The paper by Okumus and Hollebrands presented findings from a study conducted during a summer enrichment program, in which students used manipulatives and a dynamic geometry program (Cabri 3D). Miragliotta and Baccaglini-Frank presented analyses of excerpts from a set of activities designed and proposed within the context of a 2D dynamic geometry software (Geogebra) for a group of 9<sup>th</sup> grade students. Schreiber and Klose focused on the role of artifacts and different forms and modes of representation when learning mathematics at primary school level, through an interactive approach, in which mathematical audio-podcasts were produced. A perspective on teachers' competencies in the context of multimedia-based representations was presented by Ollesch, Grünig, Dörfler and Vogel. Their study described findings from a project in which they used video-vignettes in order to assess the competencies of mathematics teachers for multimedia use in mathematics lessons. Taking a closer look into how technology can change the dynamics of teaching-learning by offering specific kinds of representations, a study by Garcia Moreno-Esteva, White, Wood, and Black showed how eye movement can be tracked and used as a window to cognitive processes involved with use of representations in mathematical activities.

## Theoretical frameworks used in the papers and posters presented

Several different theoretical frameworks were referred to in the papers and posters presented: Arzarello's Semiotic Bundle theory (Bini; Robotti); Balacheff's theoretical notion of epistemological validity (Hoyos); Bartolini Bussi and Mariotti's Theory of Semiotic Mediation (Okumus and Hollebrands; Robotti; Schou; Schreiber and Klose); cognitive psychological approaches, applied in the problem solving context, such as Bayes' (Böcherer-Linder and Andreas Eichler); or Vergnaud's framework, (Serrazina and Rodrigues); Duval's registers of representation and theory of apprehension (Miragliotta and Baccaglini-Frank; Robotti; Hoyos, Bini); Enactivism (Ferrara and Ferrari; Soto-Andrade and Diaz-Rojas); Fischbein's Theory of Figural Concepts (Miragliotta and Baccaglini-Frank); Goldin's definition of representation (Sveider); the Joint Action Theory in Didactics (JATD) (Joffredo-Le Brun, Morellato, Sensevy and Quilio); Lakoff and Núñez's conceptual metaphors (Finesilver); Mishra & Koehler's Technological Pedagogical and Content Knowledge (TPACK) (Ollesch, Grünig, Dörfler and Vogel); psychological approaches such as Bruner's approach (Ott; Finesilver); or Ainsworth's approach (Böcherer-Linder and Eichler; Ollesch, Grünig, Dörfler and Vogel); Krutetskii's approach (Olgun and Ader); Tall and Vinner's Concept Image and Concept Definition (Schou);

According to these, the authors developed different kinds of empirical studies: intervention studies (short term and long term studies; with attention to the teacher's role or focused on learners); and observation studies (observing learners in different educational settings; observing teachers; observing classroom processes). In one case, a paper attempted to make some steps forward in elaborating a new theoretical framework emerging at the intersection between cognitive psychology and mathematics education (Miragliotta and Baccaglini-Frank). In another paper, Ferrara and Ferrari conceive mathematical thinking as a place of events instead of objects, and they bring forth inventive and speculative possibilities for learners to encounter and problematize spatio-temporal relationships, rather than seeing them as ways of being mistaken.

## Concluding remarks

We conclude this summary with the two questions, from the general list, that seemed to arise the greatest interest of the participants, and sketch out the main comments advanced by the Working Group.

*What aspects of the use of different types of representation, imagery and visualization are effective in mathematical problem solving at various levels?*

Participants of TWG24 suggested that a representation does not stand alone, and it cannot be separated from how it is used. Thus, it is important to take into account interaction between the individual and the representation (both its external as well as its internal – though difficult to access – component) and between representations and context in which they are used (Joffredo-Le Brun, Hoyos, Schou). Moreover, representations are used within a social context, partly (but not only), for communication of ideas; it is important to encourage learners to express themselves using their own representational strategies, and appreciate multiple representations of information and of their ideas (Finesilver; Olgun and Ader; Robotti; Okumus). Through a careful and appropriate use of representations it is possible to increase positive affect towards mathematics and inclusion (Soto-Andrade and Diaz-Rojas; Robotti). However, there is a tension between the advantages of flexible

representation (and specific useful reps) and pushing students to use representations, which do not come naturally to them (Finesilver).

*How can teachers help learners to make connections between visual and symbolic representations of the same mathematical notions (mathematical object)?*

In response to this question participants of TWG24 suggested that there are certain registers of signs that are considered conventional (by teachers), and others which are less conventional. Indeed, teachers may be less familiar with the various alternative ways of representing, and either not accept alternatives as legitimate (e.g. drawing), or not be conscious of how they are being used (e.g. gestures) (e.g.: Bini; Olgun and Ader; Ollesch, Gruenig, Doerfler and Vogel; Schou). Finally, in various occasions, the group discussed the issue of low achievers and use of representations both by them and by teachers involved in their education processes. These discussions were fueled especially by the papers by Finesilver and by Robotti. In her paper Finesilver drew on qualitative data from problem-solving interviews with very low-attaining secondary school students, focusing on the visuospatial organization of elements in four types of non-standard student-created and co-created representations. She discussed these four types of representations in terms of relationships between representation type, scenario, calculation success, and the students' developing understanding of multiplication and division concepts. On the other hand, Robotti presented a didactical sequence involving the use of various artifacts, introduced by the teacher, to solve tasks on fractions. She analyzed how the representations, fostered by the artifacts, produced by the students, and then picked up by the teacher, contributed to students' development of mathematical meanings around the notion of fraction.

<sup>3</sup> University of Education Heidelberg; [vogel@ph-heidelberg.de](mailto:vogel@ph-heidelberg.de)

*In this paper, we refer to the efficiency of different visualizations for mathematical problem solving. Particularly, we investigate how set relations that are potentially important in probability are made transparent by two different visualizations, i.e. the tree diagram and the unit square. In this paper, we use these two visualizations as representations of statistical information. First, we analyze theoretically the quality of visualizing set relations by tree diagrams and unit squares. Second, we briefly report a published study with students of mathematics education ( $n = 148$ ) where the unit square outperformed the tree diagram when the perception of subset relations was regarded. A main focus of this paper is a replication of the aforementioned study with  $n = 58$  undergraduate students. Finally, we discuss the significance of our results, specifically for the teaching and learning of conditional probabilities.*

*Keywords: Representation of statistical information, set relations, tree diagram, unit square.*

## Introduction

In mathematics education, it is widely accepted that representations and visualizations could have a considerable impact on students' learning. For example, Duval claims that visualizations of mathematical concepts are "at the core of understanding in mathematics" (Duval, 2002, p. 312). However, research in mathematics education and cognitive psychology gave evidence that visualization does not necessarily foster students' understanding. For this reason, a crucial question in research in mathematics education is to identify the one of potentially different visualizations that is most efficient referring to students' learning. We refer to this question concerning competing visualizations aiming to support students' learning in statistics and probability, but also in fractions. The transparency of set relations plays a crucial role in probability (Böcherer-Linder & Eichler, 2017), but is also important in many other domains of mathematics education, such as the teaching and learning of fractions.

## Theoretical framework

In the context of Bayesian reasoning, research in cognitive psychology has shown that the transparency of set relations in the visualization of statistical information impacts on the performance in tasks concerning the Bayes' rule: "any manipulation that increases the transparency of the nested-sets relation should increase correct responding" (Sloman, Over, Slovak, & Stibel, 2003, p. 302).

**Figure 1: Nested sets of the Bayesian situation of a medical diagnosis visualized by an Euler diagram (cf. Binder, Krauss & Bruckmaier, 2015).**

Proponents of this point of view, called *nested-sets account*, attribute the difficulties of Bayesian reasoning to the fact that some sets of events are nested (Lesage, Navarrete, & Neys, 2013; Sloman et al., 2003). For the example of a medical diagnosis, Figure 1 illustrates the nested-sets situation. “Transparency of set relations” means that it is easy to see, how many elements are in the sets and how the sets relate. The cognitive model into which the *nested-sets account* has been incorporated is the dual process theory (Barbey & Sloman, 2007): Representing the statistical information in a standard probability format (without visualization) obscures the nested-sets structure of the problem and, therefore, triggers the associative system which may lead to biases. Representing the statistical information with natural frequencies and / or appropriate visualizations in contrast trigger the rule-based system because nested sets relations are made transparent, enabling people to reason consciously and according to the logic of set inclusion (Barbey & Sloman, 2007). For the design of effective visualizations, proponents of the *nested-sets account* claim that visualizations are helpful to the extent that they make the nested set structure of the problem transparent (Barbey & Sloman, 2007; Sloman et al., 2003). There are different competing visualizations that claim to visualize efficiently set relations or situations that necessitates applying Bayes’ rule and it is an open question which visualizations are the most efficient and which properties explain these visualizations’ efficiencies.

In this paper, we investigate how set relations are made transparent by two competing different visualizations, i.e. the tree diagram and the unit square. We use these two visualizations as representations of statistical information (Venn diagrams are not considered in this paper because we focus on the visualization of statistical information and Venn diagrams are pure set representations but not representations of statistical information). First, we analyze theoretically the quality of visualizing set relations by tree diagrams and unit squares. Second, we briefly refer to a published study (Böcherer-Linder & Eichler, 2017;  $n = 148$  undergraduate students) where we investigate whether the tree diagram or the unit square is more efficient to support the perception of subset relations. Since we used a new approach to explain the effectiveness of visualizations of the Bayes’ rule, we conducted a replication study ( $n = 58$  undergraduate students) which results are in the main focus of this paper. Finally, we discuss the significance of our results, specifically for the teaching and learning of conditional probabilities.

## Visualizing set relations

“A flower girl is selling red and white roses and carnations.” We use this situation as an example to illustrate how the tree diagram and the unit square visualize set relations. In this situation, we have sets (for example the set of all roses) and subsets (for example the subset of all red roses) and subset relations (for example the red flowers among the roses). If we attribute some numerical values to the number of roses and carnations, the situation can be visualized by showing absolute numbers in the tree diagram and the unit square:

**Figure 2: Representing statistical information with the tree diagram and the unit square**

Both, the tree diagram and the unit square can be seen as nested-sets representations. In the tree diagram, the logical relations between sets and subsets are visualized by lines. The subsets are on a lower level than the sets in the tree and the branches connect the subsets with the sets. For example the subset “red roses” is on a lower level than the set “roses” and the branch connecting “red roses” and “roses” visualizes the relation between both sets. The tree implies a hierarchical structure which means that subsets are always on a lower level than sets. Therefore, only those subset relations that are in line with the hierarchy are salient. For example, the subset relation of “roses among the red flowers” where the “roses” are the subset and all the “red flowers” are the including set is not visualized by a branch in the tree and thus, is not transparent.

In the unit square, subset relations are visualized by areas being embedded in other areas. For example the subset of “white roses” is represented by a partial area of the rectangle that represents all roses. In contrast to the tree diagram, the unit square implies no hierarchy. That means that subset relations can be grasped vertically (e.g. “white roses among the roses”) as well as horizontally (e.g. “roses among the red flowers”). Therefore, all subset relations that are possible in this situation are transparent in the unit square.

Because of these differences in the properties of the two visualizations, we expected a difference between the tree diagram and the unit square when the perception of different subset relations is regarded. Therefore we hypothesized:

If the subset-relation is not in line with the hierarchy of the tree diagram, the unit square is more efficient to make the subset-relation transparent (*hypothesis 1*). If the subset-relation is in line with

the hierarchy of the tree diagram, there is no significant difference between the unit square and the tree diagram (*hypothesis 2*).

## Method

The method in our first study and the replication study was the same. In the first study, we administered a questionnaire to 148 students who were enrolled in a course of mathematics education. In the second study, the test was administered to 58 students who were also enrolled in a course of mathematics education. In both studies, we asked the students (among other questions concerning conditional probabilities) in one task that we indicate below to calculate proportions and to indicate the result in form of fractions:

$$proportion = \frac{\#subset}{\#set}$$

In this way, we could analyze if the right subsets and right sets have been grasped from the visualization. The questionnaire had two versions, one showing tree diagrams, the other showing unit squares to represent the statistical information. The rest of the test-items remained constant and the participants were randomly assigned to one of the two groups. Thus, any potential difference in the results could directly be attributed to the influence of the visualizations.

To assess the influence of representation on the perception of subset relations we designed test-items that each addressed structurally different subset relations. In Figure 3, we show the questions that were accompanied by either the tree diagram or the unit square shown above. Note that the item (d) addresses a subset relation that is not in line with the hierarchy of the tree diagram and therefore a higher performance for the unit square was expected. The items a, b, c and e address subset relations that are in line with the hierarchy of the tree diagram and therefore no significant difference between the tree diagram and the unit square was expected. We rated correct answers with 1 and incorrect answers with 0.

Flowers: A flower girl is selling red and white roses and carnations. Altogether, she has 120 flowers. Calculate the following proportions. Indicate the results in form of fractions.

The proportion of

- a) red carnations among all carnations.
- b) white roses among all flowers.
- c) white flowers among all flowers.
- d) carnations among the red flowers.
- e) roses among all flowers.

**Figure 3: Items to assess the perception of subset relations**

## Results

Figure 4 shows on the left side the results that we reported in Böcherer-Linder and Eichler (2017). As we hypothesized in this study, the unit square ( $M = 0.66$ ,  $SD = 0.44$ ) was more efficient than the tree diagram ( $M = 0.38$ ,  $SD = 0.48$ ) for the item (d) that addressed a subset relation that is not in line with the hierarchy of the tree diagram. The difference for the item (d) was significant ( $t(146) = 3.579$ ,

$p < .001$ ) with an effect size of  $d = .58$ . In the replication study there is again a significant difference referring the item (d) that addressed a subset relation that is not in line with the hierarchy of the tree diagram (unit square:  $M = 0.63$ ,  $SD = 0.43$ ; tree:  $M = 0.31$ ,  $SD = 0.39$ ;  $t(54) = 3.101$ ,  $p < 0.01$ ,  $d = .82$ ). Thus, we replicated our result referring hypothesis 1. Further, it is interesting that the ratios of correct answers are very similar in the original study and the replication study. However, there are also unexpected differences for the items (b) and (c).

Results of the first study,  $n = 148$ Results of the replication study,  $n = 58$ 

**Figure 4: Participants performance in the first study (left side) and in the replication study**

In our first study, we investigated also the differences in the other four items that addressed subset relations within the hierarchy of the tree diagram. For these items a t-test for the accumulated score referring to these four items ( $\alpha = .739$ ) yielded no significant difference between the tree diagram ( $M = 3.46$ ,  $SD = 1.023$ ) and the unit square ( $M = 3.46$ ,  $SD = 1.036$ ),  $t(146) = 0.000$ ,  $p = 1.000$ . In the same way none of the items yielded a significant difference between the unit square and the tree diagram when investigated individually. Thus, there was no reason to reject our *hypothesis 2* in our first study. However, we could not replicate these results in the second study. When the items were regarded individually, a t-test yielded significant differences for item (b) ( $p < 0.05$ ) and (c) ( $p < 0.01$ ). Also, the accumulated score referring to all four items ( $\alpha = .634$ ) yielded a significant difference between the tree diagram ( $M = 3.01$ ,  $SD = 1.11$ ) and the unit square ( $M = 3.67$ ,  $SD = 0.52$ ),  $t(54) = 2.762$ ,  $p = 0.008$ ).

In the first study, the mean values of correct answers for the tree diagram were almost equal for all of the four items a, b, c and e addressing subset relations that were in line with the hierarchy of the tree diagram (88%, 85%, 86%, 86%). In contrast, in the second study for every item differences appeared. However, the performance for item (d) was lower for both visualizations. This might indicate that the subset relation (d) is more difficult to perceive than the other subset relations and that the visualization with the unit square is more helpful in this case.

## Discussion of the results

For the situation of the flower girl, our results show a very clear effect in favor of the unit square. This was the case in the first study and, with very similar results, in our replication study. Nevertheless, we suggest for future research to prove this effect also for other contexts. In another study with 143 students of electrical engineering, we replicated the effect for subset relations that are not in line with the hierarchy of the tree diagram for two more different contexts. It is further desirable to investigate the effect of those subset relations used in the items a, b, c and e in more depth. This is especially the case since our results for this kind of items seems to be ambiguous. The replication study yielded significant differences referring to the efficiency of the tree diagram and the unit square in supporting students solutions in tasks where the subset relations are in line with the hierarchy of the tree diagram. Although this result was not expected and we further hypothesize that this result will not be replicated in further studies, it agrees with our overall hypothesis, i.e. the supremacy of the unit square to visualize situations in which the Bayes' rule has to be applied.

There are further aspects that that could be investigated in more detail. For example, there is the question of the order in the sequence in the tree diagram. It might be interesting to study the effect of the transposed order (roses / carnation on a lower level than red / white) and to compare it with a rotated unit square (roses / carnation arranged vertically and red / white arranged horizontally). This setting could be clarified if the hierarchy of the tree actually is the reason for the results in our study.

Moreover for the context of Bayesian reasoning, the results of Binder et al. (2015, p.6) suggest an advantage of the  $2 \times 2$ -table compared to the tree diagram, although no statistical difference between  $2 \times 2$ -tables and tree diagrams was reported. Thus, it is an open question if  $2 \times 2$ -tables are equally efficient than unit squares to make subset relations transparent or if there is an additional effect of the unit square due to the redundant geometrical and numerical representation.

Finally, there are further possibilities for visualizing set relations. One of these possibilities that was used in mathematics teaching is the double tree (Wassner, 2004). Thus, it could be interesting if a specific version of the tree diagram is able to decrease the weakness of the tree diagram to identify appropriately set relations.

## Implications

The main result of our research seems nearly trivial: Visualizations have to visualize the main aspects of a mathematical concept if they aim to support students' understanding of this concept. Accordingly, a subset relation must be transparent when the aim of the visualization is to represent subset relations. However, it is by no means at all trivial to identify the crucial aspects of a mathematical concept. Actually, the tree diagram is very prominent in statistics education research (Veaux, Velleman, & Bock, 2012) and also psychological research (Binder, Krauss, & Bruckmaier, 2015) for visualizing Bayesian situation that necessitates applying Bayes' rule. However, our research gave evidence that – compared to the unit square - the tree diagram is not efficient to visualize the set relation that is crucial to understand the structure of a Bayesian situation since it requires a subset relation that is not in line with the hierarchy of the tree diagram.

Our results have firstly some consequences if statistics education is regarded. Sloman et al. (2003) expressed that bringing out nested set structure has been identified as being important for the improvement in Bayesian reasoning tasks. Thus, restricted to teaching and learning probability, our

results imply to reconsider the role of the tree diagram to support students' learning referring to probability and Bayesian reasoning. This would be a considerable shift in statistics education (c.f. e.g. (Gigerenzer, 2014; Wassner & Martignon, 2002). A little bit more globally, it could be considered if proportions, and in particular proportions of proportions could be appropriately visualized by a unit square to emphasize the connection between proportions of proportions and conditional probabilities. Thus, the unit square could potentially be understood as a visual connection between fractions and probabilities.

More generally, our results imply to focus the discussion of visualizations on the structure of visualization and on its relation to the structure of the represented mathematical concept. While the superiority of visualizations is a consensus in mathematics education as we outlined in the introduction, it is a crucial objective to find out which visualization best fits to a mathematical concept, especially in situations where several competing visualizations exist as it is the case for Bayesian reasoning situations. For example, Binder et al. (2015) show that the tree diagram supports Bayesian reasoning compared to pure symbolic representation, whereas our results imply that the required subset relation is not transparent in the tree diagram. Indeed, in recent research, the unit square outperformed the tree diagram in Bayesian reasoning tasks (Böcherer-Linder & Eichler, 2017; Böcherer-Linder, Eichler & Vogel, in press). Therefore an ongoing task of educational research should be to precisely identify the relation of a visualization and its structure and the mathematical concept and its structure. One main message of our paper is that this relation is not sufficiently investigated, but could considerably impact on students' learning.

# Enactive metaphors in mathematical problem solving

Daniela Diaz-Rojas<sup>1</sup> and Jorge Soto-Andrade<sup>2</sup>

<sup>1</sup>University of Chile, CIAE, Santiago, Chile; [diazr.daniela@gmail.com](mailto:diazr.daniela@gmail.com)

<sup>2</sup> University of Chile, CIAE, Faculty of Science, Mathematics Department, Santiago, Chile;  
[sotoandrade@uchile.cl](mailto:sotoandrade@uchile.cl)

*We are interested in exploring the role of enactive metaphorizing in mathematical thinking, especially in the context of problem posing and solving, not only as a means to foster and enhance the learner's ability to think mathematically but also as a mean to alleviate the cognitive abuse that the teaching of mathematics has turned out to be for most children and adolescents in the world. We present some illustrative examples to this end besides describing our theoretical framework.*

*Keywords: Metaphors, enaction, representation, visualisation, cognitive bullying.*

## Introduction

Our concern in this paper is the role of metaphor, more precisely enactive metaphor, in the teaching and learning of mathematics, particularly in mathematical thinking arising in, or triggered by, problem posing and solving. Fostering mathematical thinking in the classroom is a widespread aim in mathematics education indeed (OECD, 2014), but in our viewpoint we have a much more severe and dramatic issue to address: not only mathematical thinking is not fostered in our classrooms (Chilean and worldwide), but mathematics has turned out to be a tool of torture for millions of children, who cannot escape from it. This has been recently acknowledged as “cognitive bullying” or “cognitive abuse” in the English literature (Watson, 2008; Johnston-Wilder & Lee, 2010). a practice that is “at best marginally productive and at worst emotionally damaging” (Watson, 2008: p. 165). We thus echo Tillich’s famous statement: “the fatal pedagogical error is to throw answers like stones at the heads of those who have not yet asked the questions”. To tackle this complex and systemic problem, a multidisciplinary approach is most wanted, where a first diagnosis emerges: traditional (and abusive) teaching of mathematics tends to thwart cognitive brain mechanisms installed during millions of years of evolution, that we would need on the contrary to recognise, appreciate and tap into in the context of learning, to wit: metaphorising, enacting, collaborating...

Our main hypothesis is that practice of metaphorising, especially enactive metaphorising, in the classroom, might be a fundamental means to contribute to alleviating this situation of cognitive abuse towards students without forsaking their access to mathematical thinking, but on the contrary fostering it. It is our hypothesis that the way a mathematical situation is metaphorised and enacted by the learners strongly determines the ideas and insights that may emerge in them and may help to bridge the gap between the “mathematically gifted” and those apparently not so gifted or mathematically oriented. A big challenge is then trying to figure out under which conditions enaction and metaphorising, more precisely enactive metaphorising, impact on mathematical thinking processes as hypothesised above.

We intend here to pursue our recent research on metaphorising and enacting (Díaz-Rojas & Soto-Andrade, 2015, 2016; Soto-Andrade, 2015). Our earlier work on metaphor in the learning of mathematics was presented already in CERME5 (Soto-Andrade, 2007).

In this paper we focus on some examples and case studies that illustrate the role that metaphorising and enacting may play in the spectrum of mathematical thinking elicited by problem posing and solving. The contextual background of our case studies involves a variety of learners in Chile: prospective secondary math teachers, in service primary and secondary math teachers, first year university students majoring in social sciences and humanities, undergraduate and graduate students in mathematics, primary and secondary students.

## Research questions

Which is the role of metaphorising and enacting in mathematical problem posing and solving at various levels? To which extent do they influence mathematical thinking elicited by the problematic situation, in particular moving amongst various mathematical registers of representation to change the problem? Do they shape our understanding of the processes involved, notably the relation between problem and learner, emotional overtones included?

How does the interplay between affect and metaphoring helps in alleviating cognitive bullying in the teaching of mathematics, and even lead to enjoyment of learning and doing mathematics?

## Theoretical framework and state of the art

### Metaphorising in cognitive science and mathematics education.

Widespread agreement has been reached in cognitive science that our ordinary conceptual system, in terms of which we both think and act, is fundamentally metaphorical in nature (Gibbs, 2008; Johnson & Lakoff, 2003). In mathematics education proper it has been progressively recognized during the last decades (English, 1997; Lakoff & Núñez, 2000; Sfard, 2009; Soto-Andrade, 2007, 2014, and many others) that metaphors are not just rhetorical devices, but powerful cognitive tools, that help us in grasping or even building new concepts, as well as in solving problems in an efficient and friendly way. See Soto-Andrade (2014) for a recent survey. We may visualize (conceptual) metaphors (Lakoff & Núñez, 2000) as mappings from a more down-to-earth “source domain” into a more abstract “target domain”, carrying the inferential structure of the former into that of the latter. For the learning of mathematics we emphasize the “poietic” role of metaphor that brings concepts into existence, through “reification” (Sfard, 2009). In view, here lies the main difference between representation and metaphor: we *re-present* something given beforehand but we *metaphorise* to try to fathom something unknown or a concept not yet constructed. For instance, we construct the concept of probability when, studying a symmetric random walk on the integers (a frog jumping on a row of stones in a pond), we see the walker *splitting* into 2 equal halves instead of going equally likely right or left (Soto-Andrade, 2007, 2015). In what follows we will use metaphorical language as a meta-language to describe cognitive or didactic theories of interest to us, since – we claim – a theory is essentially the unfolding of a metaphor (Soto-Andrade, 2014).

### Enaction in cognitive science and mathematics education

Varela metaphorized enaction as the laying down of a path in walking (Varela, 1987, p. 63), as in Machado’s famous poem, when he introduced the enactive approach in cognitive science (Varela,

Thompson, & Rosch, 1991). In his own words: “The world is not something that is given to us but something we engage in by moving, touching, breathing, and eating. This is what I call cognition as enaction since enaction connotes this bringing forth by concrete handling” (loc. cit). Less radical enaction in mathematics education may be traced back to Bruner (1966), inspired by Dewey’s “learning by doing” (Dewey, 1997), who characterised enactive, iconic and symbolic modes of representation. For recent significant theoretical and practical developments see Proulx (2013). In what follows we are especially interested in enactive metaphors, where the learner is whole bodily engaged, as opposed to “sitting metaphors” in the sense of Gallagher and Lindgren (2015).

### **(A) didactic situations and didactic contract**

The theory of didactical situations (Brousseau & Warfield, 2014) might be described as the unfolding of the *emergence metaphor* in math education: mathematical concepts we intend to teach should emerge in a suitable challenging situation the learner is enmeshed in, as the only means to “save his life”. No real learning is possible if mathematical concepts are airborne from Olympus. Such a situation is called a *didactic* situation, because of the didactical intent of the teacher who set it up. It becomes an *adidactic* situation when the teacher definitely steps back to let the learners interact on their own with the setting, with no hope of fathoming beforehand her didactical design or the mathematical content she is aiming at. Key metaphors are likely to emerge, as sparking voltaic arcs, in and among the learners, when enough “didactical tension” is built up in an adidactic situation for them. The notion of *didactical contract* (Brousseau, Sarrazy, & Novotna, 2014) is also of interest to us, in the context of the teacher-student relation. It is in fact a keen metaphoric description of the mainly implicit and unspoken mutual expectations, beliefs and commitments regarding the actions and reactions of the partners involved in a didactic or adidactic situation.

### **Affect in mathematical problem solving**

The role of affect in mathematical problem solving is often neglected in spite of its significant incidence in learner’s performance (Mason, Burton, & Stacey, 2003; Hannula, 2014). Here we are specially concerned by the role of negative emotions that trigger a learner’s emergent metaphorising that can transform a problem that is a tool of cognitive bullying into a friendlier one. The outcome of this may be, for most learners, a positive feeling of liberation from the Procrustean bed of arithmetic and algebra, for instance (see example 2 below).

### **Methodology and experimental background**

Our research includes an experimental facet, where our methodology mainly relies on qualitative approaches, to wit: Case Studies (Stake, 1995), Participant Observation techniques and Ethnographic methods (Spradley, 1980).

In all, 4 cohorts of learners have been involved in our teaching and learning according to our metaphoric and enactivist approach from 2014 to 2016. They include prospective secondary school physics and mathematics teachers in a one-semester course in number theory at the University of Chile; students in a one semester first year mathematics course in the social sciences and humanities option of the Baccalaureate Programme of the same University; in service primary and secondary school teachers engaged in one week professional development workshop in the South of Chile, in service primary school teachers engaged in a 15 month professional development programme (mathematics option) at the University of Chile at Santiago; graduate students working towards a

Ph. D. in Didactics of Mathematics, at the Catholic University of Valparaíso (UCV), most of them secondary school math teachers holding a Master in Didactics of Mathematics. They were chosen because they constituted a broad spectrum of learners we had access to while performing our usual teaching duties at the University of Chile, besides some invited workshops elsewhere, with whom our overarching approach could be tested. Learners, working most of the time in (random or spontaneous) groups of 2 to 4, were observed by the teacher or facilitator and an assistant, the latter assuming the role of participant observer or ethnographer (Spradley, 1980; Brewer & Firmin, 2006). Among aspects observed were: level of participation, questions and answers, horizontal (peer) interaction, emergence of metaphors, especially idiosyncratic ones, spontaneously or under prompting, gestural language of learners and teacher, expression and explicit acknowledgement of affective reactions from the learners. Snapshots of their written output in problem solving activities were taken and videos of their enacting moments were recorded.

### **Illustrative examples and case studies**

We present and discuss here two paradigmatic examples, in geometry and arithmetics, that we have come across during our teaching at the University of Chile, to illustrating important aspects of our theoretical perspective, often neglected in usual approaches. The case of randomness has been dealt elsewhere (Díaz-Rojas & Soto-Andrade, 2015). Our geometrical example deals with the exterior angles of a polygon and their sum: a typical geometrical notion often abusively and gratuitously introduced, with no context or motivation. In arithmetic, we recall the consecutive sums of positive integers problem, thoroughly discussed in the literature (e.g. Mason et al., 2003)

#### **Example 1. The sum of the exterior angles of a polygon**

We have observed that almost every in service and prospective secondary mathematics school teacher in our country, after introducing exterior angles coming out of the blue *after* inner angles and explaining them in terms of the latter, calculates dutifully their sum from the sum of the inner angles, that depends on the number of sides of the polygon. Doing a bit of algebra they finally wind up discovering that the sum of all exterior angles is  $360^\circ$ , independently of the number of sides! Surprising! This traditional way to “get into” the task (Proulx, 2013), is not very appealing for most students, that experience it as “blind calculation” (a case for cognitive bullying). When trying to fathom out exterior angles of a polygon however a first thing to do – from our perspective – would be to metaphorise it, to get into the task in a more transparent way. Not just reciting its formal definition, of course. Among the metaphors emerging amongst the learners we work with, the most frequent are “a polygon is an enclosure between crossing sticks” (most popular among primary school teachers) and “a polygon is a closed path, made out of straight segments”. Enacting the first metaphor triggers the idea of manipulating the sticks, as to make clearly visible the exterior angles first and then shifting them parallel to themselves to get smaller and smaller homothetic polygons. In this way teachers *see* that the sum of all exterior angles is  $360^\circ$ , instead of blindly calculating. Enaction of the metaphor “polygons are closed paths” by the learners themselves, literally lying down a polygonal path in walking, enables them to immediately “see” that the sum of the polygon’s exterior angles corresponds to a complete revolution (Díaz-Rojas & Soto-Andrade, 2015). In this way they realise that exterior angles, not inner angles, are the convenient data for the walker to inflect or bend his path as wanted. Analogously for the sum of all acute angles of a pointed star... We noticed that metaphorising a polygon is an unusual challenge, almost a violation of the

didactical contract, for both students and teachers. But once they feel they are allowed to, even prompted to, metaphors begin to arise, shyly at first. The enactive metaphoric approach conveys here a completely different experience of mathematics than the traditional one, including the role of gestures, movements and, more broadly embodiment, in the learning of mathematics, particularly in problem solving (Libedinsky & Soto-Andrade, 2015).

### **Example 2. Which numbers are consecutive sums? Just an arithmetic problem?**

The question is: Which numbers are sums of a string of consecutive (positive) integers. An unexpected question to many learners, however familiar with Gauss well known trick to sum  $1 + 2 + \dots + 100$  in a wink. From our perspective it is interesting to observe how easily this question (or any question) emerges in the learners, once their attention is drawn to this sort of sums. Our hypothesis is that learners' reaction here is heavily dependent on their previous schooling and the amount of cognitive abuse they have endured. As a typical example we recall an informal short meeting to chat about "the mathematical experience" with a class of 12th graders from a Waldorf school, to whom we told about consecutive sums (just what they are), period. After a few seconds, a girl said: Which series of numbers do you obtain that way? We claim that in usual problem solving this is an often neglected aspect: enactively letting questions emerge instead of asking them... Another often neglected aspect in problem solving is the affective reaction a problem elicits in the learner. This sort of arithmetic problem quite often triggers a feeling of distaste, especially in adolescents. This negative emotion may have the immediate positive effect of stimulating the learner to metaphorise, to transform the problem into a more attractive or friendly one, i. e. a creative reaction! This is very rarely observed in our prospective teachers and Ph. D. students. Apparently didactical contract weights heavily here: learners are not supposed to transform or metaphorise the problems they receive, nor are they supposed to *like* or *dislike* mathematical objects or procedures, just to understand them or not.

We observed that every learner tackled the problem arithmetically first, doing some experimenting (some calculating small consecutive sums, others following the opposite path: checking whether 2, 3, 4, 5, etc. might be consecutive sums). Some got a closed formula for a consecutive sum but did not see what numbers are so obtained. Those who checked numbers one by one arrived quickly to the (surprising) conjecture that powers of 2 cannot be reached. In fact they re-traced Mason et al. (2003). The proof of the conjecture remained elusive until some noticed that powers of 2 do not have odd divisors and so devised an algebraic proof of the conjecture. The fact that conversely a number which is not a power of two must be a consecutive sum remained in the shadow for 45 minutes or so. At this point, we asked prospective teachers whether they liked the way we were tackling and solving the problem. Two of them said that the conjecture was interesting and that they understood the algebraic procedure but that they were not very happy about it. Fernanda said that she was not fond of this algebraic yoga, although she was able to carry it out. For Enrique this algebraic approach was easy but he was unhappy because he had noticed (giving private lessons to secondary school students) that for most students algebraic calculations are not appealing at all. So both were motivated to look for different, may be geometric, approaches.

For Ph. D. students, didactical contract played in the opposite direction: after working on metaphorising some months before, when asked now whether they were satisfied with their discovery regarding powers of 2, several students thought about metaphorising the problem, looking

at the numbers as quantities of dots arranged in clever ways. Andrea, an insightful female student, drew a trapezoidal house with a slanted roof (of slope 1) and so transformed the problem to a question about the area of this trapezoid. Some tried to remember the area formula, but others, like three clever prospective teachers, saw by rearrangement or compensation that their trapezoid could be turned into a rectangle with the same base. But then they realised that this worked only “half of the time”: for an odd basis! In that case the area has an obvious odd divisor. For the even case, some conjectured that they could get a two-step horizontal roof, each step of equal length and so the idea emerged of slicing vertically the trapezoid into two “halves” of equal base and putting one on top of the other. Some went into distinguishing the cases: half base odd or even. But others had the idea of putting one “half trapezoid” topsy-turvy on top of the other, getting in this way a rectangle of odd height and half base. Then, a prospective teacher had the idea of borrowing from scratch a copy of the original trapezium and coupling both to obtain a rectangle with either odd base or odd height and whose area is twice the original one! The proof of the converse conjecture was left open. Regarding liking or disliking, graduate students at UCV were more enthusiastic about the geometric approach than prospective secondary teachers. Roughly two thirds of the latter said that they did not feel comfortable with geometry so that they preferred calculating algebraically! In fact even when trying to think in geometric terms, they quickly reverted to algebraic calculation. On the other hand happy visualizers realised that the trapezium area may have any value in the continuous case but not in the discrete one, because something pops up that has no continuous analogue: Parity! A surprising fact for them, who knew, from their laptop screens, that the discrete models the continuum well. The question remained open as to whether we can see geometrically that the area of a rectangular trapezium cannot be the volume of a hypercube.

From our perspective this is an emblematic example of the possible “unfolding” of an “arithmetic” problem that that can be solved by some algebraic yoga (that many students do not appreciate at all) but can also be metaphorised as a geometric problem, more appealing to others. This metaphorising “prompts” us to jump naturally into the continuous world and get some inspiration there. We realise also the hard way that there is a tricky property of discrete shapes with no analogue in the continuous world: parity! Discrete lengths, areas or volumes may be odd or even, although asymptotically however parity vanishes... Remarkably, even insightful discussions of this problem found in the literature (e. g. Mason et al., 2003) remain confined in the arithmetic-algebraic realm, not taking advantage of the avenues and possible generalisations that metaphorisation may open up.

## Discussion

We have shown several important aspects of the role of metaphorising and enacting in mathematical thinking elicited by problem posing and solving. First, we have seen that the way we metaphorise and enact determines the ideas and insights we may have when tackling a problem. Then, how metaphorisation triggered by distaste of the problem may allow the learners to move from one realm to another, instead of remaining confined in just one. By so doing, they may take advantage of different intuitions and handlings, eventually much friendlier to them, that enhance their mathematical thinking and also alleviate the cognitive abuse they have been exposed to. Indeed, an acknowledged negative affective reaction to a proposed problem may trigger creative metaphorisation to change it. In this way metaphorisation appears as a means to empower students to transform an unappealing problem given to them, something especially relevant for adolescents

who otherwise have the feeling of being abused by being forced to follow prescribed rules to solve nonsensical tasks (Watson, 2008). Also visualization appears as concatenation of metaphors: In the case of consecutive sums: “numbers are quantities”, “summing is putting together”, “factorizing is rearranging to form a rectangle” etc. Furthermore, it appears that usual problem solving, as found in the literature, tends to neglect, the important role of metaphorisation and enaction, as a learner’s first reaction when tackling a problem that looks opaque to him or her. Not only because this may allow the learner to solve an otherwise unyielding problem but also because it may allow him or her not just to solve the problem but to “see” a solution, turning a hitherto blind calculation into pellucid insight. Finally the enactive and metaphoric perspective reshapes our understanding of the relation between problem and learner in problem posing and solving, that appears as a quite more circular and entangled process than usually acknowledged, where each one codetermines the other.

# Diagrams and mathematical events: Encountering spatio-temporal relationships with graphing technology

Francesca Ferrara and Giulia Ferrari

University of Torino, Italy; [francesca.ferrara@unito.it](mailto:francesca.ferrara@unito.it), [giulia.ferrari@unito.it](mailto:giulia.ferrari@unito.it)

*This paper presents the diagrammatic activity of some secondary school students exploring motion through graphing technology, which captures a pair of space-time graphs on a single Cartesian plane. Focus is on a written task about the connections between two imaginary movements and (between) the corresponding graphs. Drawing on a vision that conceives mathematical thinking as a place of events instead of objects, we discuss three unexpected diagrams for how they bring forth inventive and speculative possibilities for learners to encounter and problematize spatio-temporal relationships, rather than seeing them as ways of being mistaken.*

*Keywords: Graphing technology, movement, diagram, event, problematic.*

## Introduction

In this paper, we deal with the issue of how students might learn about a representational system in which temporospatial relationships are the ground for the mathematical doing. Our interests are also in how visual, proprioceptive and kinaesthetic aspects of experiencing these relationships might move the learning of mathematics in unexpected and unconventional directions. We follow here de Freitas (2013) in rethinking mathematics as the place of events, instead of objects, where creativity and contingency prevail and the problematic—rather than the axiomatic—better capture the vitality of mathematical activity. The idea is that deduction “moves from the problem to the ideal accidents and events that condition the problem and form the cases that resolve it.” (Smith 2006, p. 145). Thus, mathematics is concerned with the occurrence of events more than with the existence of objects, and attention is on the material encounters with the mathematical.

In this perspective, we present an activity that was carried out with grade 9 students working with graphing motion technology to study function. In particular, the technology requires that two remote controllers of the Nintendo Wii game console (Wiimotes) are moved at the same time in front of a sensor bar, and it displays two space-time graphs on the same Cartesian plane. In the graphs, space is given by the distance of each controller from the bar. Thus, the software captures the movement of the Wiimotes over time. Our focus is on a written task that asks the students, divided into groups, to draw a space-time graph related via movement to a given graph. The task is called “Rob and Bob”. In it, Rob and Bob are the names of two little robots that are imagined to be moving the controllers in front of the sensor. The graph associated to Rob’s movement is given on paper, together with the instructions with which Bob is supposed to be moving with respect to Rob. The students are expected to complete the task adding Bob’s graph on the Cartesian plane. We will discuss how three different graphs are presented as solutions to the task from different groups, and we will develop how we think that these are significant in terms of the novel mathematical meanings that the students are articulating. In the meanwhile, we will also draw attention to aspects of the experience with the technology that might support this novelty, raising issues about the role of perception on the one side, and about the features of the technology on the other side.

## Theoretical highlights

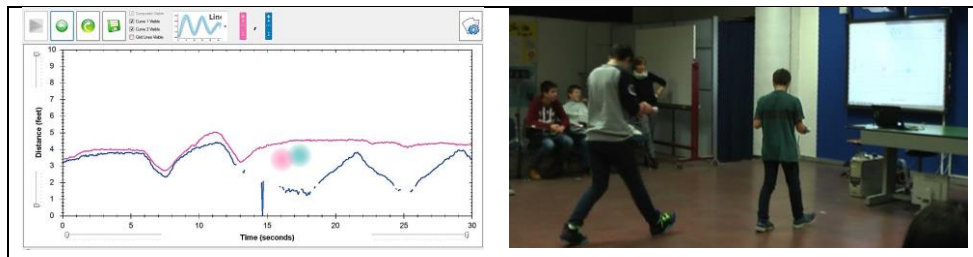

The representational system we refer to in this paper is the (space-time) Cartesian plane, which our students encounter through activity with the technology. However, we want to trouble traditional ideational assumptions that conceive such system as inhabited by mathematical figures or functions that, in their essence, are representations (particular instantiations or attributes, concrete instances) of some form, inert, transcendent, abstract and disembodied. In fact, claims de Freitas (2013), “the process of instantiation fails to capture the creative and material act of individuation that is entailed when we do mathematics.” (p. 586). We instead embrace an animate vision of the mathematical drawing/creation or act of drawing/creation of a figure or a function as event-structured, full of potentiality, temporality and movement, immanent, contingent to material circumstances, and incidentally subject to transformation. This positions us in the broad discussion on the theorising about the embodied nature of mathematics thinking and learning, which attempts to look at knowledge in non-representational ways and to overcome body/mind Cartesianisms (see e.g. Nemirovsky et al., 2013; Sinclair, 2014; Ferrara, 2015; Roth, 2016). According to this view, learning is much more about encountering concepts than about recognizing concepts. Cutler & MacKenzie (2011) might argue that thus the challenge is to treat learning as an ontological rather than an epistemological problem, staying away, we would add, from opposing the mathematical and the physical. The issue of representations is crucial here. As Sinclair (2014) points out, it is not that “symbols, diagrams, programming languages and even gestures” (and any other system, we would add) “do not at times *function* to re-present mathematical concepts and relations”, rather “they are inevitably bound up with bodies and discourses and thus potentially poised to open up new meanings.” (p. 174, *emphasis in the original*). Our own reading of this makes sense as regards our commitment to a mobile view of mathematics and mathematical doing that tries to escape concrete versus abstract and matter versus thought divides (Ferrara & Ferrari, 2016). In Ferrara (2015), these divides are challenged through a vision of perception and creation in/of mathematics for which perceiving is conceiving, thinking is acting and creating is learning. The work of philosopher Gilles Châtelet (1987, 1993/2000) on inventive diagramming was provocative to us in considering the centrality of mobility or virtuality to bridging the physical and the mathematical. The virtual is the necessary link between the two realms. Roth (2016) also draws on Châtelet to underline how one way of thinking about dynamic systems is just in terms of the virtual. We can better understand this if we take the examples that Châtelet (1987) makes about historical contributions of new ideas by Leibniz and Abel. Leibniz theorised differential calculus thinking of points as if they were alive, as powers of explosion (“puissances d’explosion”), while Abel saw the curve not as fixed but in terms of its power of receiving intersections (“comme puissance à recevoir des intersections”). The virtual restores concepts to mobility, granting them inventive force and power. For de Freitas (2014), Châtelet shows us “how we might study a particular practice for how its lines of flight flourish and act generatively in unfolding new *intensive* dimensions.” (p. 290, *emphasis in the original*). The virtual is that which nourishes encounters with mathematics, linking the concrete and the abstract and allowing recoding the indeterminate contours of the sensible and the intelligible. This has to do with the potentiality or virtuality that is always entailed in perception: “We never just register visual information from that which is in front of our eyes: we see potentiality, relationality, mobility, occurrence. Students are not seeing an object; they are seeing an event” (de Freitas, 2014, p. 298).

In this paper, we take this perspective to look at the students' mathematical encounters with spatio-temporal relationships, focussing on the material and virtual dimensions of these encounters.

## Method and activity

The activity, which is the focus of this paper, is part of a classroom-based intervention (Stylianides & Stylianides, 2013) aimed at introducing the concept of function through the use of graphing technology. The wider research had the main purpose of investigating how learners might articulate meanings for functional relationships through modelling motion, and how their embodied activity with the technology might affect these meanings. A class of 30 grade 9 students and their regular mathematics teacher participated in the study, which lasted for a period of about three months with weekly sessions. During this time, the students worked on individual tasks, in groups of three people and in pairs of groups, taking part in class discussions. The authors were both present in the classroom and two cameras were used to film the mathematical activity of the students during all the sessions. Data for the research analyses are based on the films and students' written productions and diagrammatic activity. A microethnographic methodology (e.g. Streeck & Mehus, 2005) is essentially chosen for studying interactions and discourse in the classroom through strands of semiotic and representational activity over short periods of time, drawing attention to the material circumstances of the mathematical events.

The technology the students used in the case we consider here is WiiGraph, an interactive software application, which leverages two Wiimotes to display the space-time graphs of two users moving the remote controllers in front of a sensor bar. WiiGraph provides several challenges and composite operations, including shape tracing, maze traversal and ratio resolution. Choosing the plain visualisation (Line), the software captures the distances of the controllers over time and two graphs appear, in real time and with different colours, on a single Cartesian plane. Figure 1 shows a case of this type of visualisation for a 30-second default time and two students who move the controllers.

**Figure 1: The graphical system in Line and two students moving**

Visual and bodily (especially proprioceptive and kinaesthetic) interactions partake in the students' encounters with the graphical system in relation to experiencing spatial and temporal aspects with the technology. We will not refer to other types of graphical activity, since this is the one of interest in the case of Rob and Bob.

The task was given in a written form to the class during the second session and did not imply direct use of the technological devices. In the first session, the students explored Line and its graphical potential, became acquainted with the devices and started discussing about pairs of functions (for example, horizontal or slanted straight lines), with graphs originating in real time and projected on an interactive whiteboard. The activity of Rob and Bob was designed with the purpose of unfolding the

slope/speed relation (early insights emerged out of class discussion in the first session), and how it may reveal relationships between two space-time graphs (functions).

### Rob and Bob

The task was faced by the students divided into groups of three people, and followed by a class discussion led by one of the authors. It focuses on an imaginary experience with WiiGraph in which two little robots move (the controllers) in front of the sensor bar, but only the graph associated to one robot's movement is given (Figure 2a). The text of the task is the following:

*Rob and Bob are two little robots, which can be taught to move in front of the sensor very precisely. Suppose that, in response to Rob's movement, WiiGraph produces the line below (Figure 2a). Imagine that Bob also moved: it started together with Rob, at the same distance from the sensor, but moved at a double speed and in the opposite direction.*

- Which graph would WiiGraph show for Bob's movement?
- Did Rob and Bob meet again after the start?

*Justify your answers.*

The task has an unconventional nature with respect to the representational system offered by the technology, because it does not ask the students to merely reason on the model to motion, or motion to model, shift. Instead, information about the missing graph is given in terms of the relationships between the two robots' movements ("double speed", "opposite direction"), so that the students are moved to think about the relationships between the two graphs (double slope with opposite sign), through their perceptual and bodily experience with the tool. In addition, the simultaneity of the two movements, which by the way recalls the usual way of using the tool, is embedded in information about the starting instant/point ("it started together with Rob", "at the same distance").

**Figure 2: (a) The given graph, (b) The expected solution to the task given by one group**

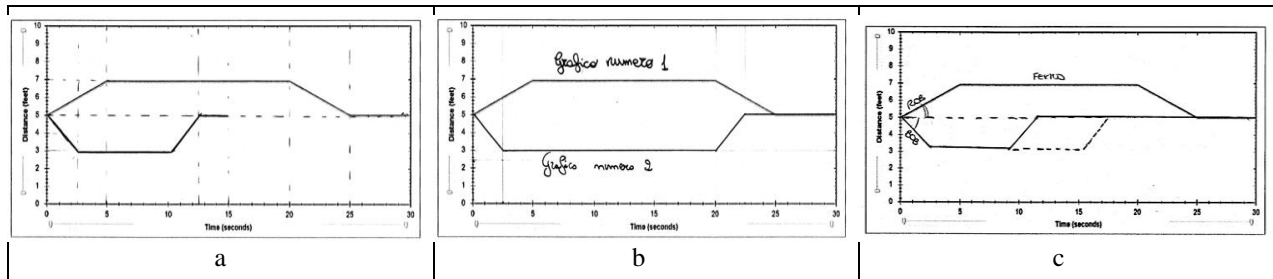

The given graph is that of a piecewise function made up of four pieces, which capture alternate ways of moving by Rob: stepping further from the sensor for the first five seconds, stopping for the next fifteen seconds, returning to the starting position in other five seconds, and stopping for the last five seconds (Rob keeps constant speed in each time interval). We expected the students to complete the Cartesian plane drawing a graph like the one in Figure 2b. It is the graph of a piecewise function again made up of four pieces, defined on the same sequence of time intervals as the given graph. These pieces correspond to four ways of moving by Bob: getting close to the sensor for the first five seconds, stopping for the next fifteen seconds, returning to the starting position in five more seconds, and stopping for the last five seconds (however, Bob is supposed to cover double space with respect to

Rob, according to the constraint of moving at a double speed. Of course, this is true when he moves, and trivially when he does not, since the distance covered is null).

Instead of looking at the expected graph as the correct one and speaking of difference in terms of being mistaken, we dwell on different unexpected solutions emerged from the groups about their potential to bring forth new relational possibilities for the two robots' movements as well as for the pair of graphs. In the next section, we take these solutions as the problematic actualizations of the mathematical events that the groups encounter in solving the task. It is this idea of novelty that speaks directly to inventive mathematics and makes students alive to their engaging with the task.

## Graphs and discussion

The groups worked on the task for half of the time, then they took part in a collective discussion in which their graphical solutions were compared. Only one group drew the expected solution (Figure 2b), while eight out of ten created one of the three unexpected lines shown in Figure 3 (For the sake of ease, we refer these lines to three graphs labelled with numbers 1, 2 and 3).

**Figure 3: Unexpected solutions — (a) graph 1, (b) graph 2 and (c) graph 3**

The three graphs added for Bob's movement have some similarity. They all show that taking into account information about opposite direction and capture it visually in the diagram is not an issue for the students. Each added graph is made up of four pieces, which embed the opposite way of moving with respect to Rob: first getting close, then returning to the start (first a decreasing piece, then an increasing piece). Not even slope is an issue: the double speed of movement is double slope in the three diagrams. However, the duration of Bob's movement is problematic for the students. In fact, while there is correspondence between ways of moving there is no embodiment of duration: there is no correspondence between time intervals in which both robots either move or stand still. The lengths of the horizontal pieces are different from each graph to the other, and the constraint for Bob to move at a double speed with respect to Rob is no longer preserved. Thus, the problematics of duration evolved along various accidental threads for the students, driven by their perceptual and bodily engagement with the task. These broke with causal connections and direct determination, opening up to speculative and inventive investments and to a generative movement, implicating the perturbation of spatio-temporal relationships. For example, in the case of graphs 1 and 3 (Figures 3a and 3c), some encountered the event for which Bob already stands still while Rob is still moving and, later, Bob moves towards the starting position while Rob is still standing still. Some groups introduced the new event in which the second robot stops just after fifteen seconds, in the very middle of the experience with WiiGraph, and ideally disappears from the view of the sensor, so that the second graph might accidentally stop in the middle of the diagram (Figure 3a). Almost all the students engaged with the kinaesthetic question of Rob and Bob always covering the same space, no matter the time spent, as

shown in the three diagrams. These threads are actualized through the groups' written explanations, then during class discussion. Types of explanation are the following:

Graph 1: *"The line we represented is half of Rob's line. The lines are steeper because speed is doubled and Bob moved faster than Rob and in the opposite way. The graph ends at 15 because Bob, moving at a double speed, stopped at half of 30."*

Graph 2: *"The two configurations are different from each other, indeed slopes also change since times change: Rob is slower. So, covering the same space in different time, there will be a higher steepness."*

Graph 3: *"Bob goes at a double speed with respect to Rob, so it finishes 'the lap' before Rob. The rest of the way it stood still and at the end it met Rob. Speed changes between the ways of Bob and Rob, indeed Bob has to cover the same space backwards using half of the time."*

The logical equivalence between double speed as double distance in the same time and as the same distance in half of the time is lost, and the problematic of covering a fixed space in less time drives students' perception and visualisation in the diagramming of the missing graph. Graph 1 (Figure 3a) is the most coherent in respect to the axiomatic way of reasoning about double speed but at once the most incoherent in relation to kinaesthetic actions with the technology. Briefly speaking, it is nothing but a temporal shrinking of the given graph. Instead, graph 3 (Figure 3c) is in line with the usage of WiiGraph, because it embraces all the thirty seconds of the modelling process. The same occurs in the case of graph 2 (Figure 3b), which is particular though, since it struggles to depict the simultaneity of the two robots' movements. In the discussion, different students actualize in different ways the problematics that sustain the mathematical events that occurred in solving the task. Below, Lorenzo, Luigi, Giulio and Oliver bring forth in the discourse the issues of duration and simultaneity of movements, of moving at a double speed and of covering the same space, issues that are entangled in their diagrammatic and written activity. Lorenzo speaks about graph 1 (Figure 3a), Luigi and Giulio refer to graph 2 (Figure 3b), while Oliver argues about graph 3 (Figure 3c).

Lorenzo: 'Cause, moving at a double speed, distance remained constant, even though it was the opposite, but maybe, if Rob performed a movement in 10 seconds, Bob performed it in 5 seconds because speed was double.

Luigi: For me, hem, the graph took up the same time because, moving simultaneously, maybe, at the time they were moving, it took less time for one than for the other one to cover the same space, to move in the same space, but then one stood still until the other one also did move again, so both graphs last for 30 seconds. (...)

Giulio: For me, it [the graph] finished at 30, 'cause it's not that Rob [Bob] could know Bob's [Rob's] movement in advance, so it [the graph] cannot finish at 15, it [Bob] has to wait for it [Rob] to perform the same but opposite movement, 'cause we did see Bob's graph (*miming it in the air*) but if they move simultaneously, it means that one cannot anticipate the movements, so it cannot finish at 15 seconds. (...)

Giulio: We depicted slope at 2,5 seconds but then we stood still until 20 seconds, 'cause anyway it's true that time is halved, but Bob doesn't know what Rob will do later, so it has to wait for it.

- Researcher: Did you say that time is halved?
- Giulio: Yes, 'cause it [Bob] does things in half of the time, it's true, however it's not that he can know what it [Rob] will do later, hem, 'cause we do know it, but if they move simultaneously...
- Oliver: Bob does our graph with the movements with which it's been set up, and then, in the end, it's not that it waits for Rob, it goes on just as it likes and wants, then at a certain point, when movements are finished, it stops and the line keeps straight for the rest of the time.
- Researcher: Are you saying that time is halved?
- Oliver: Yes, because of the double speed. (...)
- Lorenzo: Indeed, for explaining a little the graph, I said that if there's a distance to cover, and that distance is 50 kilometres and you go at a speed of 50 kilometres per hour, it takes you 1 hour to cover that distance. Instead, if you go at 100 kilometres per hour it takes you 30 [minutes].
- Giulio: Yes, for me he's right about the first piece, but then if you stand still, so speed is null, zero times two is always zero and so speed has to be equal in the positions in which it stands still, for me.

Discourse with the researcher unfolds the event-nature of unexpected threads traversed in solving the task. We see how the students inscribe themselves into the temporality of imaginary situations with the robots. The ways of perceiving this temporality are different for different (groups of) students: some imagine that one robot has to “wait for” the other to know what to do (Giulio, Luigi); for others, coordination is not needed (Oliver) or considered (Lorenzo). Time is duration and simultaneity of movements: both aspects become problematic for learners. Both are crucial in making sense with WiiGraph of time as the independent variable in space-time functions.

## Conclusive remarks

In this paper we have discussed some unexpected graphical solutions to a given diagramming task based on modelling motion through the use of Wii graphing technology. We have focused not on how these solutions were incorrect with respect to the expected diagram, but on ways in which they brought forth new possibilities for the students to encounter spatio-temporal relationships. In so doing, we looked at visual, proprioceptive and kinaesthetic aspects of experiencing the technology as that which sustained the occurrence of new mathematical events in the classroom, bringing into being problematic perturbations of the given situation, like shrunk graphs as well as not coordinated movements and fixed paths, which break with the conventional visualization and activity of the representational system in use. The written, the diagrammatic, the discursive and the bodily, as the groups attempted to grapple with the task (to make sense of it), have to be seen as that which animated the task without ever exhausting it or fully determining it. The temporality of the events speaks directly to the material contingency of learning: the students are dynamically affected by the diagrammatic activity while telling stories of motion related to graphing technology.

# Emerging and developing multiplicative structure in students' visuospatial representations: Four key configuration types

Carla Finesilver

King's College London, UK; [carla.finesilver@kcl.ac.uk](mailto:carla.finesilver@kcl.ac.uk)

*Visuospatial representations of quantities and their relations are widely used to support the understanding of basic arithmetic, including multiplicative relationships. These include drawn imagery and concrete manipulatives. This paper defines four particular configurations of nonstandard representation according to the spatial organization of their visual elements. These are: unit containers, unit arrays, array-container blends, and number containers, all of which have been observed to support developing multiplicative thinking, allowing low-attaining students to work with the equal-groups structures of natural number multiplication- and division-based tasks. Student-created examples are discussed, and pedagogical and diagnostic implications considered.*

*Keywords: Visuospatial representation, multiplicative thinking, arithmetic, low attainment.*

In their early encounters with quantitative relationships, children become aware of concepts such as conservation of number, counting, etc., through interactions with collections of objects. For example, addition as the joining of collections and subtraction as removing a subset of objects from a collection – in which the ordering of individual objects is unimportant – can be considered conceptual ‘grounding metaphors’ (Lakoff & Núñez, 2000). Various models of children’s arithmetical problem-solving development indicate a broadly similar progression from early concrete/enactive-based reasoning, to imagic/iconic, to abstract/symbolic reasoning (e.g. Bruner, 1974; Piaget, 1952). Within this broad outline, the actual external representations of learners’ thinking during problem-solving include many possible sub-varieties (e.g., sets of actual objects, pictures of objects, tally marks in different configurations, dot arrays, etc.), and many possible categorizations of these for analytical purposes. The construction of appropriate analytical frameworks is necessary for the discerning of inter-individual differences and intra-individual trajectories (Meira, 1995; Voutsina, 2012). This is particularly the case when studying atypically-developing learners (Fletcher et al., 1998).

This aim of this paper is to share one aspect from the qualitative analytical framework for student- and co-created visuospatial data used in Finesilver (2014), delineating four particular types of visuospatial representation and demonstrating their use with selected examples. The project took an essentially grounded analytical approach, and so whilst this paper does not report results as such, a sample of research data is included with brief description of the process.

## Theoretical background

To understand multiplication and division represents a significant qualitative change in learners' thinking compared to understanding addition and subtraction (Nunes & Bryant, 1996). These authors, amongst others, have recommended a *replications* model of multiplication, which is highly relevant both to counting-based strategies and to unitary drawn or modelled representations of multiplicative relationships. A central concept for considering this particular aspect of representation is *spatial structuring*:

We define spatial structuring as the mental act of constructing an organization or form for an object or set of objects. The process [ . . . ] includes establishing units, establishing relationships between units [ . . . ] and recognizing that a subset of the objects, if repeated properly, can generate the whole set (the repeating subset forming a composite unit). (Battista & Clements, 1996, p.282)

There are two main forms of spatial structuring with which unitary visuospatial representations of multiplicative relationships emphasise their replicatory structure: by creating some kind of boundary to separate groups of units from each other, or by organising them in a pattern based on regular spacings. These two organisational strategies roughly correspond to Lakoff and Núñez's (2000) grounding metaphors *Arithmetic as Object Collection/Construction*, and to two of the common unitary configuration types I introduce below, *Unit containers* and *Unit arrays* (see Figures 1 Figures 2).

Creating *container* configurations – i.e. visible boundaries within which the individual units of each group may be in any configuration – is particularly intuitive. Research that includes container representations (or equivalent) has been mainly focused on young children and their intuitive concrete models, such as sharing items (e.g. Carruthers & Worthington, 2006; Kouba, 1989). Rectangular *array* configurations, in which the groups are structured and defined by a configuration of all units in regular rows and columns – are also widely used in educational contexts. Research including array representations generally focuses on older children, grid arrays, and involves content such as rectangular area measurement; however, dot arrays have been shown as a powerful tool for supporting work in multiplication (Barmby et al., 2009; Harries & Barmby, 2007; Izsák, 2005; Matney & Daugherty, 2013), and, less frequently, division (Jacob & Mulligan, 2014). No prior studies were found that included both container and array representations, focused on the secondary age group and allowed freedom of representational strategy across multiple interviews and tasks.

## Data

The data discussed below, including all examples, derive from a larger research project using microgenetic methodology to elicit and study emerging and developing multiplicative structure in low-attaining students' visuospatial representations within a flexible context (Finesilver, 2014).

There were thirteen participants, aged 11-15, attending mainstream schools in London, and identified by their teachers, educational histories, and initial sifting assessments as particularly numerically weak compared to their peers. Although having complex individual etiologies and patterns of arithmetical issues, they had in common difficulties experienced at the particular stage of moving from additive to multiplicative thinking (as highlighted by Nunes and Bryant, above).

The representations were produced during individual or paired problem-solving interviews carried out by the author (four per participant). Participants worked on tasks based within two multiplicative scenarios chosen for their ease and likelihood of visuospatial representation. These were 'Biscuits' (numbers of biscuits shared between numbers of children) and 'Passengers' (numbers of different-sized vehicles required to transport numbers of passengers). There were also some calculations presented symbolically with no scenario. The representational media available were multilink cubes, coloured pens and paper. Some representations were co-created by student and researcher at 'cognitive snapshot' points (Schoenfeld, Smith, & Arcavi, 1993), i.e. when a participant was unable to proceed further independently, and support was given in the form of a minimal 'nudge' prompt;

(e.g. ringing or counting a group aloud). Due to project methodology, support cannot be easily quantified (especially gestural interaction) and is not attempted in this paper. Documentation was via audio recording, photographs, scans of students' papers, and field notes.

### Four key types of representational configuration

Over 200 visuospatial representations were collected (exact figures cannot be given as participants re-appropriated whole and parts of prior representations for subsequent tasks and expansions). The great majority were found to group into four types; inclusion criteria, as defined below, were allowed to emerge, then refined, as part of a grounded analytical process. The most common types, (*unit*) *containers* and *arrays*, will be familiar. A smaller substantial proportion combined both container and array elements, and a further type emerged which I call *Number Containers*. (There is only space to include a few examples here; more will be included in this paper's accompanying presentation, or see Finesilver (2014) for a complete set.)

#### Unit Containers (UC)

*Criteria: Groups of two or more units enclosed by visible boundaries. Includes representations where units are aligned in rows and/or columns, but these do not represent divisor/quotient or multiplier/multiplicand.*

**Figures 1(a-d): Examples of Unit Containers**

Overall, this was the most common type (106 instances); eleven of the cohort chose to draw unit containers at some point while working on a task, although some much more frequently, and even the least able could sometimes use them independently. For the students with the severest arithmetical difficulties (e.g. dyscalculia), who could not make any start independently, visuospatial prompts were provided, e.g. drawing a set of circles ("plates") for 'Biscuits'. UCs were for the most part drawn, often with various scenario-based decorative elements, but some made use of mixed-mode, mixed-media representations with cubes or other physical units placed in drawn containers (see Figure 1d).

#### Unit Array (UA)

*Criteria: Groups of two or more units aligned in rows and columns, where number of units in the rows/columns represents divisor/quotient or multiplier/multiplicand.*

**Figures 2(a-d): Examples of Unit Arrays**

Plain unit arrays (of dots, tally marks, etc.) were used frequently (47 instances), the majority being produced independently by nine of the cohort, and an almost exclusive choice for three participants. All were drawn, and none constructed with cubes. (This may be surprising, as it is easy and visually effective to produce cube arrays. However, in general it was the arithmetically weakest students who made greatest use of concrete media, and that group also tended to prefer container representations.)

With a shift of perspective between vertical and horizontal structure, a learner may see that both rows and columns are formed of a set of equal groups, which underlies the commutative principle. This was independently noticed by some participants; e.g. on being asked to work out 28 biscuits shared between four people followed by 28 shared between seven, some re-used the same array, while others produced both  $4 \times 7$  and  $7 \times 4$ , only realizing the equivalence after completion.

### Array-Container Blend (ACB)

*Criteria: Unit array representation with additional containing rings, where number of units in each row/column/container represents divisor/quotient or multiplier/multiplicand.*

**Figures 3(a-d): Examples of Array-Container Blends**

While 47 instances of successful ACB use were collected, many of these were co-created and/or drawn during one particular task (see below); however, 27 were otherwise produced independently by participants. These were used mainly in ‘Passengers’ and the bare tasks, usually (although not always) with each row or column being counted out then ringed before proceeding to the next. Taking the additional time and effort to superimpose rings onto an array was thus clearly considered advantageous for certain participants on certain tasks. One student in particular began with a strong preference for plain dot arrays, but once she had seen an ACB, switched almost exclusively to that representation type for subsequent tasks.

In one particular (and uncharacteristic) task on multiplicative relationships, students were directly encouraged to produce an ACB which had both rows and columns ringed. A certain behaviour was observed with this representation type alone: some students independently looked back at it during later tasks and interviews for reference, in some cases ‘bookmarking’ it. As the numbers involved were different to those in their current task, and they only took a brief look, I suggest the images were functioning as an instant visual reminder of the commutative property of multiplicative structures.

### Number Containers (NC)

*Criteria: Container representation with numerals (rather than unit marks) representing the number in each group written inside, or close by, each container.*

**Figures 4(a-d): Examples of Number Containers**

Unlike the previous three configuration types, NCs were not found in the literature or theorized prior to fieldwork, and some students introduced them spontaneously. Having observed their successful use, I included them in some later interactive support occasions, but of the 30 instances collected (from 9 participants), 22 were entirely independent. This change from unitary (iconic) to non-unitary (partially symbolic) representation is very significant cognitive step. Note, however, that some participants still chose to incorporate decorative elements from the task scenario (i.e. the vehicles were still depicted, although individual passengers were not).

## Discussion

### Students' use of the four types of representational configuration

Unit container representations allowed those students with the greatest arithmetical difficulties to create manipulable simulacra of imaginable scenarios, with as much visual resemblance as they preferred, to carry out organized sharing and grouping distributions and record their thinking. Unit array representations (with or without rings) allowed those students with a grasp of equal-groups structures, but who were not yet confident working symbolically, to perceive and make use of replicatory patterns spatially structured along two dimensions. However, the split between participants choosing to include container and/or array structuring elements also indicated personal preferences as a separate factor to arithmetical ability. (This has potential for further investigation, involving testing participants' visual pattern recognition).

**Figure 5:  
Transitional  
representation**

While some individuals displayed firm preferences for container- or array-based forms throughout, others' representational strategy choices changed over the course of interviews, and sometimes intra-task. For example, Figure 5 shows a student's representation for calculating the number of 7-seater vehicles needed for 21 passengers, starting with a container resembling a car, then immediately discarding decorative elements and containers, in transition towards an array format.

Increasing the quantities within tasks (for those students judged likely to cope with the challenge) sometimes resulted in strategic change, in particular the introduction of number symbols. However, the general persistence of container elements surrounding those symbols (i.e. Number Containers) is striking. As seen in Figures 4b and 4d, non-mathematically-functional decorative elements (bus wheels, aeroplane wings) were included inconsistently. From a purely calculation-based viewpoint, students using NCs might as well be using plain columns of numbers – therefore the container elements clearly fulfil some other, non-enumerative, yet important, function. I suggest containers forms are a powerful visuospatial/perceptual phenomenon relating to equal-groups number structures and relationships, which persists later than might be expected. It is reasonable to expect that as

confidence is gained, the containers begin to disappear (but could be retrieved as a reassuring strategy at times of low confidence – for example, when tasks increase in difficulty).

Obviously, all types of representational configuration were used to a great extent for the enumeration of quantities, and for the visuospatial organization of these quantities so that the correct set of objects (units or groups) could be enumerated. However, it is worth noting that the representations created were not immediately rendered useless once a task solution was found. Students completed visuospatial patterns when an incomplete pattern would have been sufficient to obtain an answer; they sometimes added further organizational (or decorative) detail after giving an answer. Occasionally they even created a whole new representation to record their working retrospectively, or to help them explain an exciting discovery they had just made about numerical relationships (e.g. the commutative principle). The fact that these representational activities were important to the students for their own sake (i.e. not just for obtaining the answer in a single task) suggests that they can be an important part of these students' developing arithmetical reasoning, and their real and perceived agency in this development.

### **Representational configurations and developing multiplicative thinking**

Representations of mathematical objects [...] can be seen as concretizations of abstract mathematical concepts and at the same time as representations of real objects. (Wittmann, 2005, p.18)

The four related types of representational configuration defined and discussed above integrate numerical and spatial concepts to form visuospatial mathematical objects that allow such a dual role: concretizing numerical relationships and representing real-life objects referred to in scenario tasks.

Whilst all four types represent equal-groups arithmetical structures, they do not fall along a single line of progression (see Figure 6, below). In the same way that concrete representations (e.g. modelled with cubes) are not necessarily less mature than iconic ones (e.g. drawn images), different types of configuration have different affordances which may be relevant at certain points. Number Containers, being non-unitary, are a clear progression from Unit Containers in terms of calculation, by requiring step-counting or repeated addition rather than unitary counting. However, Unit Arrays better instantiate the two-dimensional, reversible, nature of multiplicative relationships, whilst the ringing of rows or columns in ACBs could link procedural and static conceptions of multiplication/division.

The analysis of a set of relatively open-ended, student-generated, qualitative data based on their use of four key types of representational configuration highlighted a particular aspect of these students' late- and slow-developing multiplicative thinking: the many small adjustments that together can indicate a gradual change of focus of attention from units to groups, all happening within what is often considered to be a single stage of 'counting-based strategies'. Whether a task is multiplication- or division-based, there is a total quantity which is made up of, or can be separated into, equal groups. In terms of enumeration, the most basic strategies involve counting without any awareness of the repeating structure, while the more advanced ones make use of it. In terms of representational strategy, the most basic involve manipulating concrete or drawn units individually, to seeing and using visuospatial repeating patterns of units, to manipulating component groups as though they were units, to – eventually – focusing on these groups as new, composite units.

An individual's progress in this move from units to groups as main focus may be diagnosable via their representational strategic choices, along various possible trajectories (see Figure 6). (The bracketed items are likely or potential subsequent steps which, however, did not feature in the project from which this data derives.)

**Figure 6: Potential developmental trajectories through representation types**

Regarding this change of focus, there is a particular point of interest in ACBs: although they are still unitary representations (i.e. every unit is visibly present and countable), the visual and enactive emphasis on ringed subgroups serves to shift the student's level of visual focus, drawing attention away from the units and towards the groups. Thus, it encourages the possibility of seeing containers (enclosing well-aligned sets) as the new 'units' for manipulation. Meanwhile, with NCs, the replacing of (iconic) units with (symbolic) numbers is not only important for its progression toward standard notation, but as another part of this change of focus from units to groups – the change from using one mark to stand for one thing, to using one mark to stand for a collection of many things.

Even from a small sample of students it is clear that their patterns of capability, difficulty, and the representations which work best for them, are complex, interrelating, and individual. There is no single ideal path through from, for example, dealing out a pile of physical items to a set of actual present people, and carrying out a fully symbolic division calculation. However, from a teaching/learning perspective it appears important that at no stage is the leap too wide or too hasty, and that there are visual links when moving from more intuitive to more abstract representational strategies. From an analytical perspective, I suggest that tracking students' use of these four key representational configuration types in their arithmetical problem-solving (both in their initial choice of type, and in the emerging and developing spatial organization of elements within representations) may be beneficial in further study of the progression from additive to multiplicative thinking.

# Identifying key visual-cognitive processes in students' interpretation of graph representations using eye-tracking data and math/machine learning based data analysis

Enrique Garcia Moreno-Esteva <sup>1</sup>, Sonia White <sup>2</sup>, Joanne Wood <sup>2</sup> and Alexander Black <sup>2</sup>

<sup>1</sup>U. of Helsinki, Faculty of Educational Sciences, Helsinki, Finland; [enrique.garciamoreno-esteva@helsinki.fi](mailto:enrique.garciamoreno-esteva@helsinki.fi)

<sup>2</sup>Queensland University of Technology, Brisbane, Australia; [sl.white@qut.edu.au](mailto:sl.white@qut.edu.au)

*We present a mathematical and computational analysis, partially based on machine learning techniques, of the visual scan-paths obtained during a graph interpretation task which allows us to identify when the problem solver succeeds in solving the problem with a fair degree of accuracy, and helps to understand the visual-cognitive processes at work during the problem solving task.*

*Keywords: Graph interpretation, eye-tracking, machine learning, mathematics education, gaze metrics*

## As a way of introduction: About the task and machine learning

Eye-tracking is quickly becoming an established technique for investigating cognitive processes involved in the learning of mathematics and other subjects (Lai, et al., 2013). Unfortunately, the analysis of eye-tracking data is difficult and laborious, often involving frame by frame analysis (Garcia Moreno-Esteva, Hannula & Toivanen, 2016). We partially overcome this difficulty here, with the use of machine learning and other mathematical techniques. Using a desktop eye tracking system, children completed a mathematics problem that incorporated a bar graph. The visual scan-paths and the accuracy of the response are analyzed in order to understand how a child “reads a graph”. We are trying to gather from our data and its analysis, a story of what happens when several children are confronted with such a task. What do they look at? Do the gaze patterns influence the success or accuracy when responding to the task? With this information we may be able to more reliably infer the cognitive processes completed by children.

## The problem-solving task

In Brisbane, Australia, a group of 113 children (mean age 8.67 years), all in the second half of year 3 in school, completed the graph problem solving task. As part of a larger project, children completed a series of eye tracking tasks (reading, mathematics) in a quiet room near their classroom. The mathematics tasks included odd-even judgement, magnitude comparison, and problem solving tasks: interpreting a bar graph and navigating a coordinate grid. The focus of this presentation is the graph problem solving task. This task was designed based on the Grade 3 Australian Curriculum Mathematics where Grade 3 children are expected to be interpreting and comparing data displays (ACARA, 2016). A similar graph interpretation task features in a Grade 3 Australian standardized achievement test. The children were shown the following: a) a bar-chart, where the height of each bar indicated a the number of hours worked by Sarah during a given week; b) a labeled coordinate system, where the x-axis had the week number labels, and the y-axis had numbers corresponding to hours; c) a sentence indicating Sarah's hourly wage; d) another sentence indicating the task to completed related to Sarah's wages in Week 3. Curcio (2010) describes a sequential framework for children's

data comprehension, this framework includes; *understanding*, *interpretation* and *prediction* with data. The current graph task required each child to *understand* and *interpret*: reading the question and basic details of the graph (*understanding*), and then reading between the different elements of information (*interpretation*) in order to complete the computation and arrive at the correct solution for Sarah's Week 3 earnings. A Tobii eye-tracker operating at 300 Hz recorded the locus of focus of their eyes throughout the activity - including the initial *understanding*, and steps involved in *interpretation*. The threshold for fixations was set at 100 ms (Tobii Technology, 2014). It was hoped that the eye tracking information (fixations and saccades) might shed light on the different cognitive steps involved in the task. Initial qualitative evaluations of the eye movements demonstrated children who did not progress past the first *understanding* stage, as they did not identify the question being asked or relevant information on the graph. Other children were able to *understand* the task and progressed to specific *interpretation* of relevant information - with a variety of behaviors demonstrated. For example, some children had high numbers of fixations and saccades around relevant areas, whereas others had fewer and longer fixations on relevant areas. These initial qualitative observations were systematically investigated using machine learning techniques.

The data included 113 visual scan-paths (for purposes of the forthcoming discussion, the *inputs*), and 113 answers (the *outputs*), considered as correct (1) or incorrect (0). The visual scan-paths consisted of sequences of pairs, each pair including the duration of a fixation in milliseconds (ms), and the location of the fixation. The visual scan-path information can be visualized as a video (or a static picture) in which the fixations appear as a sequence of red dots that have a size proportional to the duration of the fixation, and which are connected by lines to neighboring fixations.

After inspecting the visual scan-path videos, it was evident that it would be difficult to disentangle patterns of visual processing that might reveal cognitive processing of different children. It was decided that further mathematical/computational analysis of the data might provide further insight. Since the nature of the input data is sequential, classifying the visual scan-paths and test results (inputs and outputs) with a Markov model based machine learning technique was selected as an appropriate analytic method.

### **A word about machine learning techniques**

The proprietary algorithm (*Mathematica's* Classify function) was used to do the machine learning analyses, using a Markov model method (Wolfram Language and System Documentation Center, 2016). In this analysis you select a subset of the sample (input – visual scan-path - and output – result - data) to analyze (*classify*) with the machine learning algorithm. From that analysis a *classifier* is then used on all the inputs (visual scan-paths) to predict the outputs (0 or 1, incorrect or correct). The predicted outputs from the classifier are then compared to the real outputs, and the percentage of correctly classified outputs can be calculated (some examples are provided in subsequent sections).

### **Our research question**

Our research question is simply, what can we learn or infer about cognitive processes related to the graph interpretation task described with mathematical/computational/machine learning based analysis techniques of the eye-tracking data, and maybe, could these techniques be of further help in analyzing the data pertaining to other well defined mathematics problem solving tasks?

Our techniques are general, in that they can easily be applied to other eye-tracking data consisting of a sequence of fixations given by the coordinates and the durations of the fixations as inputs, and a set of two or even more categories as outputs. We hope to make the programs available to other researchers wanting to undertake this kind of analyses at a later stage or our research.

## The analyses and corresponding results

In this section we will describe three kinds of analysis for which we obtained encouraging results. Other possible analyses will be discussed in a later section pertaining to directions of future work.

We partitioned the visual stimulus (the graph on the screen; Figure 1) into areas of interest (AOIs), where the most critical areas of interest are labeled as A1 (wage information), A2 (week number), A3 (week 3 bar), and A4 (number region containing the number of hours corresponding to week 3), and other areas of interest which are less critical, or irrelevant, are labeled with letters B and C and a number, respectively. In addition, we labelled the whitespace around the critical areas as ZZ.

**Figure 1: partition of the task sheet into areas of interest (AOI's).**

As a result, data items look like the following:

$\{\{227, A1\}, \{563, B2\}, \{267, C2\}, \dots, \{287, C2\}, \{517, A1\}, \{1443, A3\}\} \rightarrow 1,$

**Figure 2: a typical data item with pairs of elements corresponding to durations in milliseconds (numbers) and AOI's (letter and number juxtaposed) of the fixations, and the result after an arrow.**

In the example above, the first fixation occurred on area of interest A1 and lasted 227 ms, the second one on AOI B2, with a duration of 563 ms, and so on. At the end the arrow with a 1 after it indicates that the child solved the problem correctly.

### Finding a small and highly representative subset of data (developing a training set)

In order to find small and highly representative sets of data items corresponding to correctly and incorrectly solved instances of the task, we tried to find the smallest subsets of data items (henceforth called *training sets*) on which we could generate classifiers that predicted outcomes with a high degree of accuracy. After building classifiers based on randomly selected subsets of data items, we could generate a classifier that correctly predicted up to 75% of the test results, and this was using only four data items in the training set (3.5% of the *sample*). It would have been impossible to test all sets of four data items out of 113 (there are 6,438,740 such combinations) so we made a number of

classifying testing runs for randomly selected subsets of size 4, and chose some of those sets which yielded classifiers with a high prediction rating. We then inspected the videos of some of these sets and tried to observe what might have been visually outstanding in these. Our prediction rate is marginally better than human experts can do after training on very large data sets. In the world of machine learning, a rating of 75% with a training set of size 3.5% is an extremely good result in what is called supervised learning (since the training set we found is so small, this is called semi-supervised learning (for machine learning principles, consult Hastie, Tibshirani & Friedman, 2009)).

From this inspection, we detected parameters to investigate further with machine learning and other techniques, including sequencing, duration and number of fixations and other more elaborate metrics.

### **Analysis type 1: the order of fixations in the sequence – does it matter or not?**

One question we had was whether the order of fixations in the sequence matters, or whether there is something else at work. Some literature in psychology indicates that the order of fixations affects certain cognitive function such as memory (e.g. Bochynska, & Laeng, 2015; Rinaldi, Brugger, Bockisch, Bertolini, Girelli, 2015). First, we tested overall order, building a classifier using the entire sample data. Its predictive rate is over 99% (using this technique we get only one mismatch between predicted and real outputs, due to a faulty item which we were able to locate through the application of the classifier itself). We then permuted the order of the fixation duration and AOI pairs at random in the visual scan-paths, and passed the permuted input data through the classifier we obtained using the entire sample. Even with the permuted data, we obtain a classification rate which is over 97%. From this we cautiously concluded that the order of the fixations in the sequence has little impact on whether the child responds to the question accurately.

As an additional check, we investigated whether the order of fixations within critical AOIs mattered. If this were occurring, it might distinguish *understanding* and *interpretation* of the graphical information (Curcio, 2010). In order to study this, we extracted just the pairs of elements corresponding to critical elements, and eliminated the rest of the data elements. With these modified data items, we built a classifier, using training sets of size 13 (approximately 11% of the sample size), and passed the rest of the modified data items through the classifier. This resulted in a prediction rate of up to 66%, which is good but not nearly as good as we had hoped. This indicates that the order in which students inspect critical areas might be of some importance, and it deserves further study. This also led us to a different form of analysis (type 3), even though much more needs to be done than we did here.

### **Analysis type 2: number of fixations and duration of engagement on task**

The number of fixations and their duration (see figure 3) for the subjects is extremely revealing even though the analysis is less complex. These fixation duration profiles could be interpreted like a simple fingerprint of student engagement and ability. Our analysis of the number of fixations and their duration gives a clear indication that visual scan-paths can be quite revealing about what the students can or actually do. To state the results briefly, children who respond correctly take a short amount of time (under 30 000 ms) to provide an answer and have a smaller number of fixations (mean of 69) than children who respond incorrectly. Most of the children who respond incorrectly take at least 35 000 ms to respond or have more than 69 fixations. The statistically significant duration averages for children who respond correctly and those who do not are 30 000 ms and 35 000 ms respectively, and

69 fixations vs 77 fixations respectively. Interestingly, a few children (34 out of 113) who take a short amount of time and have a small number of fixations, typical of children with a correct response, provided an incorrect response. In most of these cases children had gathered the correct information from the graph but had made a calculation error. There are 17 children for which we have not yet determined an adequate explanation of their performance. Had those children read the graph incorrectly? Had they understood the task? When interpreting the graph and performing the computation, did concepts become confused? We found that these 17 children completed the task very quickly relative to the other participants, with a mean response time of approximately 25 000 ms. This information leads us to speculate that these children may not have been fully engaged in the task or in some respect confused or wandering. In summary, we can pick out, in each case, the children according to their response from a quantitative analysis by looking just at the duration of their engagement and the number of fixations during their involvement in the task. In the future, we plan to do an Artificial Intelligence based cluster analysis of the number and duration of fixation profiles only, hoping that they will separate out into four categories: those of children who respond correctly, those of children who do not read the graph correctly, those of children who read the graph correctly but miscalculate, and those of children who “do something else”. There is interest and possibly a growing body of work around this topic, whether it is possible to classify gaze patterns according to the state of mind of the participant subject. It is definitively one of our goals in this and future research (e.g., Horrey, Lesch, Garabet, Simmons, Maikkala, 2017).

**Figure 3: number of fixations and duration profiles of successful child (blue) and unsuccessful child (orange) – the x-axis is the number of fixations, the y-axis is time, the duration of fixations, in ms**

### Analysis type 3: duration ratios and frequency ratios

From viewing the videos it appeared that children who get the problem right seem to spend a substantial amount of time looking at critical data, and seem to look at such data more frequently. These parameters were assessed quantitatively, making a distinction between the importance of the area of interest (e.g. A, B, C), and not between the areas themselves (e.g. A1, A2, A3 etc.). Thus, we measured the total amount of time a subject spent looking at critical AOI's (with labels Ax), and non critical areas (Bx, Cx, and ZZ), and also measured the frequency with which a subject inspected an AOI labeled with A, B, C, or ZZ. The total duration of fixations on areas A, B, C, ZZ became DA, DB, DC, and DZZ, and we considered the ratio  $DA/(DB+DC+DZZ)$ . We then computed the means of this ratio for the students who successfully solved the problem and for those who did not. The means were used to compute a threshold value and make predictions as to who would

successfully solve the problem or not. The same approach was used for frequencies (call the total frequency on A-critical areas FA, FB for B-critical areas, FC for C-critical areas, and FZZ). We computed an analogous ratio where the quantities FA, FB, FC and FZZ were weighted by coefficients 1, .5, .25, and 0, respectively. The rationale for using weights in the case of frequencies is to account for the fact that looking at less critical AOI's, for example, whitespace (ZZ), can easily occur as a result of distraction while inspecting the graph or while moving from a fixation in an important area to another one, and therefore, they are overrepresented and should carry a smaller weight in the frequency count. We acknowledge there are alternative approaches that could be used.

With the two thresholds used in combination one can predict the results with an accuracy of 77%. The thresholds were combined in such a way that if a child spent both, enough time on critical areas, and looked at them frequently enough, the result would be success, and otherwise, it would result in an incorrect response. So it seems that both these parameters are indicative of a child's ability to successfully solve the graph interpretation task. A post-hoc statistical analysis was done on the means obtained for the duration ratio and the frequency ratio to show that they differ in a statistically significant way. Assuming a normal distribution of the duration ratios, the means of children who were successful and unsuccessful were 1.13 and .76, with a standard deviation of .43 and .42 respectively. These means are statistically significantly different  $p < .001$ . Similarly, having tested for the normal distribution of frequency ratios the means are 1.81 and 1.33, with standard deviations of .53 and .54, and  $p < .001$ , showing again a very significant difference.

### **A note about validity and reliability**

The results discussed here would need to be validated with further experimentation. For example, do the results hold if the experiments are repeated with systematic variations, changing the height of the bars, the number of the week, and the salary for Sarah? Similarly, do the results remain invariant cross-culturally? We have thought of replicating the experiments, with children of the same age and/or background knowledge, in different English speaking countries and in different cultures with different languages. This work remains to be done. The reliability of these results is given in as much as the calculations are straightforward and easy to check, and the data is clean data as provided by a commercially tested device. It is hoped that in the future, a functional version of the paper can be republished in a way that the reader can verify the programs and use the programs with his/her own data.

### **Conclusions and direction of future work**

In this report we have discussed the kind of visual processes that might be at work when a child is solving a graph interpretation task, a discussion derived from a machine learning analysis of eye-tracking data collected during the problem solving sessions. It would seem that there is strong evidence to support the claim that the order of the fixations during the problem solving session plays almost no role in the child's ability to succeed in the problem solving task. It would also seem that the amount of time and the number of times spent looking at areas where there is information which is critical for the solution of the problem relative to the amount of time and frequency of glances at other areas is definitively an important indicator of a child's ability to successfully complete the task.

As to how these results would affect teaching practices, one could conclude that it is important that

the teacher directs the student attention to what the critical information might be, where it might be located, and how to use it when teaching how to interpret graphs of this sort.

There are many other measures that can be studied (or have been studied, but are not reported here). We mention just a few, without further explanation: string edit analysis, lag analysis, cluster analysis, longest common sequence analysis. The limit in how to analyze gaze tracking data is our imagination.

## Acknowledgements

The first author wishes to acknowledge very valuable on-going discussions with Nora McIntyre, at the Department of Psychology, University of Sheffield, with whom very valuable discussions ensued about the possible measures discussed here, and about classifying gaze patterns according to the subjects state of mind.

# Epistemic and semiotic perspectives in the analysis of the use of digital tools for solving optimization problems in the case of distance teacher education

Veronica Hoyos

National Pedagogical University, Mexico; [vhoyosa@gmail.com](mailto:vhoyosa@gmail.com)

*The purpose of this work is to revisit from an epistemic and semiotic point of view the use of technological tools for solving problems of optimization accomplished by in-service secondary teachers participating in an online course intended for their professional development. This approach allowed to analyze teacher limitations on operational resolutions, and drew hypothesis about difficulties for experiencing processes of reflection on their own resolution without the implementation of adequate collaboration tools for working between them or by themselves and at a distance.*

*Keywords: Epistemic and semiotic framework, teaching and learning of mathematics at distance, resolution of optimization problems using technological tools, online teacher professional development in mathematics.*

## Theoretical frame

In the work that it is presented here it is reviewed new data on the resolution of in-service secondary teachers using mathematics technology (*GEOTREBA* in this case) to solve optimization problems. These teachers were participating in an online course for their professional development, mainly in relation with the incorporation of mathematics technology into their practice, but primary they were learning to use technology and learning to do mathematics with technology<sup>(i)</sup>. In this context, it has been important to know teachers' strategies during the resolution of complex mathematical tasks using technology, because these allowed to identify the mathematical resources displayed by teachers, as well as their understanding of the content that were at stake.

Is in relation with the teacher (or student) understanding of the mathematics content at stake that this paper deals with the role of representations in mathematics teaching and learning, because in according with Duval (1994), "there couldn't be understanding of the content represented without coordination of the representation registers, regardless of the representation register used. Because the peculiarity of mathematics in relation to other disciplines is that the objects studied are not accessible independently of the use of language, figures, schemas, symbols<sup>(ii)</sup>..." (Duval, 1994, p.12)

Moreover, school optimization problems in general are designed for the modelling of real situations. However, the mathematical representations that come into play (e.g. formulas, graphs or symbols, and the treatments or operations carried out with them) obey a set of rules and operative principles within a context of mathematical theories previously established. Thus, when a statement is made in mathematical terms, the validity or not of such statement comes into play, and this within a well-defined theoretical context (Habermas 1999, quoted in Balacheff 2010, p. 5/36). Balacheff expresses this complexity of mathematical work as follows: "mathematical ideas are about

mathematical ideas; they exist in a closed ‘world’ difficult to accept but difficult to escape” (Idem, p. 5/36).

Finally, it is from the perspective of determining the domain of epistemological validity<sup>(iii)</sup> of the computing devices for human learning (Balacheff, 1994), that Balacheff & Sutherland (1994) have found a way to characterize a computational learning environment with reference to a given field of knowledge, but also the forms of analysis that make sense of the differences between distinct computational environments, as well as its potential contribution, specific to the enterprise of teaching and learning of mathematics.

Therefore, for the sake of the work that is being presented here it is worth to be mentioned that in order to specifically analyze what the teachers were mathematically doing when solving the optimization problems with the technological tools (see more in Hoyos 2016), it was only possible using Balacheff and colleagues’ theoretical notion of epistemological validity (e.g. Balacheff 1994-2004; Balacheff and Sutherland, 1994), and Duval’s work on the coordination of representation registers of mathematics, specifically of graphs (Duval, 1994). These authors have illustrated the different contributions certain software has in different virtual learning environments (Balacheff et al, 1994-2010), and here it is noteworthy not only that the teacher (or student) learns to recognize those different register of representations (Duval, 1994) that are put in play by distinct computational devices or digital tools, but also the need of the coordination of representation registers than an appropriate use of computational devices involves when the validation of a solution is in question.

## Collection of data and analysis

The data that are going to be showed here were part of performances of the in-service secondary mathematics teachers participating in certain online courses implemented by the MAYTE (an acronym for Mathematics and Technology) team (Hoyos, 2009-2012). These data are presented here for identifying what these teachers accomplished specifically for their mathematics learning during the six-month of online training courses they were participating into. In the MAYTE team’s courses, the mathematical activities were developed around an understanding of concepts, learning procedures or mathematical techniques that relied mainly on asking participants in the program for the resolution of some specific mathematical problems, while only providing a brief list of instructions and explanatory text on the mathematical content. In this context, these courses generally did not include tutorial indications related to the mathematical resolution of the tasks requested.

It is noteworthy to emphasize here that it was possible until now to analyze the means or the strategies that participant teachers displayed using *GEOTRELLA* to solve the problems or learning situations provided by the MAYTE team by applying the constructs of epistemological and didactical validity of computational environments. Briefly, in the online MAYTE program (see Hoyos, 2012), the activities consisted of using digital tools that were freely available on the Internet to solve math problems. The mathematical content was approached synthetically through a capsule of the content, and the digital tools for solving the mathematical problems consisted of a variety of mathematical software, particularly software of dynamic geometry (SDG). Next it is described one of the prototypical math problems to be solved by the teachers participating in the program, the

practical context in which it was proposed and how the teachers finally managed to solve the tasks involved. Two of the selected optimization problems that teachers should solve are as follows:

- 1) A refinery can process 12,000 barrels of oil per day and it can produce Premium [high octane] and Magna [unleaded] gasoline. To meet the demand, the refinery must produce at least 2200 barrels of Premium and 1500 of Magna. The distribution center for the Premium is 30 km from the refinery and the Magna distribution center is from 10 km. The transportation capacity of the refinery is 180,000 barrels/km per day (This means that 180,000 barrels are transported 1 kilometer per day). If the benefit is 20 pesos per barrel of Premium and 10 pesos per barrel of Magna, how many barrels of gasoline should be produced daily to maximize the benefit?
- 2) A certain animal fodder is a mixture of two food products, namely A and B. Each kilogram of A has 100 units of protein, 18 of fat, and 400 of carbohydrates. The kilogram of B has 200 units of protein, 2 of fats, and 300 of carbohydrates. The aim is to make bags with a mixture of A and B products, each of which should contain at least 500 units of proteins, 18 of fats, and 1500 of carbohydrates. If the kilogram of A costs 3 pesos and the one of B costs 4 pesos, determine the number of kilograms for each of these products that must contain each bag of food so that the cost is minimal. (Week 8, Task 1. *Geometry and Algebra* Course. Specialization MAYTE, Hoyos et al., 2009-2012).

Most teachers' solutions to these problems were based on the identification and formulation of several algebraic expressions that modeled the given actual situation, and they were accorded to the data provided; as well as doing a graphical representation using GEOGEBRA, based on the algebraic expressions that firstly were elicited. Such procedures were needed to determine the region of feasibility and the coordinates of the points from which it was possible to obtain the maximum or the minimum cost, depending on the initial conditions of each problem. The solution that is going to be showed here (a data table and a graph in GEOGEBRA) was taken from the documents the teachers uploaded to the platform, and were evidence of a solution strategy composed of these elements: translation from the initial conditions to algebraic expressions, and representing the data through the software GEOGEBRA. Therefore, the teachers obtained a representation of the feasibility region from which the value of maximum benefit should be deducted (in the case of the first problem). In their graph, the feasibility region was shaded, and the problem in all cases was still unsolved after the graphic was made, because a point (with coordinates  $(x,y)$ ) needs to be found by means of exploration and through calculating the values of the function of two variables  $f(x,y)$ , and that in the region of feasibility (for attaining or not the benefit maximum for Problem 1 or the minimal cost for Problem 2).

Next it is shown that the teacher solution starts by constructing a table to organize the information of the data included in the text of the problem, and immediately afterwards it refers to the graph included in his solution.

T1 [One of Participant Teachers]:

If the benefit is 20 pesos per barrel Premium and 10 pesos per barrel Magna. How many barrels of gasoline must be produced each day for maximum benefit?

	Minimum Production	Distance	Benefit
Premium (y)	2200	30	20
Magna (x)	1500	10	10

Solution:

According to the problem data, inequalities are the following

$$x + y \leq 12,000$$

$$10x + 30y \leq 180,000$$

$$x \geq 1500$$

$$y \geq 2,200$$

Where  $x$  is the number of barrels of Premium,  $y$  the number of barrels of Magna, the function that gets the maximum benefit is

$$f(x) = 20x + 10y$$

To obtain the benefit maximum, it should be drawn the graph of the following functions using 'geogebra'

$$x + y = 12,000$$

$$10x + 30y = 180,000$$

$$x = 1,500, y = 2,200$$

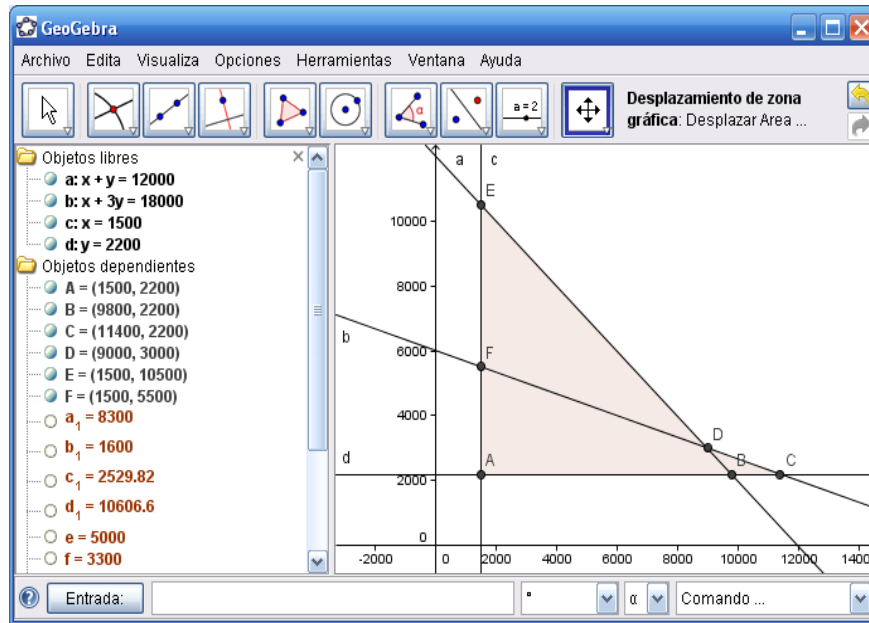

To find the value of  $x$  and  $y$  that maximizes  $f(x)$  function, we take the points that meet the initial conditions of the problem. Using the graph, you can see that the solution set is drawn within the limits of the lines and the shaded region.

In the graph, we can see that the points A, B, C, D, E, and F are some of the points that are possible solutions, but points C and D are not feasible, so substituting each of these points in the function to maximize the number of barrels of Premium gasoline, the solution obtained is  $x = 9,800$ . And the number of barrels of Magna is:  $y = 2,200$ .

Giving a maximum benefit for  $f(x) = 218,000$  bpd

The reader should note that the image of *GEOGEBRA* showing the representation of the feasibility region is part of the teacher's solution and it shall be inserted here.

Also it should be noted that seeing the image, in first place it must be considered that in T1's solution there is a mistake related to the notation that the teacher T1 chose, by which instead of denoting the function of two variables as  $f(x,y)$ , the dependence of the function  $f$  was only indicated on a single variable, insofar as writing " $f(x) = 20x + 10y$ " to refer to the function from which the maximum benefit will be established. Note that T1, after having adequately defined the region of points that satisfied the initial conditions, ended by not carrying out an exploration of the values in the region of feasibility, question that would bring T1 to obtain the requested maximum value.

Moreover, what is perhaps most interesting is to note that for the computer learning environment in question, in this case constructed mainly for exploration and use of *GEOGEBRA* and for the conversion of mathematical representations (Duval, 1994) required to solve the problem, an epistemological change in the conditions of the teacher (or student) is raised (Balacheff, 1994-2010) linked to the use of the software in the situation or problem proposed, and to the mathematical complexity of the task involved. A sign of this could be that a real graph of a function in two variables should be represented in a three-dimensional space. The difficulty then in the problem of optimization posed resides in that for solving the situation in question it is also required reflection, specifically when following the suggestions included in the capsule of content. These suggestions appeared beneath to the text of the problem: (i) to draw lines parallel to the axis and intersecting inside the feasibility region, and (ii) to explore the variability of the values of the benefit function  $f(x, y)$  within the feasibility region and/or on points of the indicated parallel lines, which would allow to calculate the maximum value requested in Problem 1.

Of course, there is another way to solve this problem, for example, by associating any point within the feasibility region to the value of the benefit function, such exploration could thus be carried out directly using *GEOGEBRA*, starting by dragging the point over the feasibility region and verifying the increase or decrease as the chosen point were varying. Moreover, this type of exploration would also help to reduce or eliminate the confusion T1 had concerning the double variability upon which the function  $f$  was dependent. For example, for point E with coordinates (2507.66, 6006.86) the value of the function  $f(x, y)$  equals 110,222 approximately. And it can be proven that the value of maximum benefit is  $f(x, y) = 149,924.05$  when the approximate values for  $x$  and  $y$  are  $x = 2993.81$ , and  $y = 9004.79$ .

Briefly, to finally arrive to solve a problem posed in a classical school context of optimization problem solving, the teacher (or student) shall find that there is a very close relationship between the modeling of a real situation, the use and treatment of mathematical representations that come into play and the coordination of the representation registers in use. Thus, a possible trajectory for the resolution of such problems could consists of: (a) surpassing the initial difficulty of the formulation of a series of mathematical statements that model the real situation by the usage of mathematical

representations to model the actual situation; (b) advancing to get a diagram where the possible solution could be found by putting into play certain digital tools (in this case *GEOGEBRA* inherent digital tools) for the mathematical treatment or the conversion of such representations (Duval, 1994); (c) formulating a new mathematical statement, namely the possible mathematical solution to the posed problem. However, it is noteworthy that from a mathematical point of view the teacher (or student) having passed by (a), (b) and (c) has not yet concluded with the mathematical task in question, mainly because in the mathematics ‘world’ it is always necessary to carry out the validation of any mathematical statement last obtained or formulated (Balacheff, 2010, p. 19/36).

## Conclusions

Because the difficulty to solve resides in to reflect on at least one of the three following possibilities: (i) on  $f$  as a function of two variables and that its graph would then be in  $R^3$  and not in  $R^2$ , while plotting the region of feasibility is being carried out in  $R^2$ ; or, (ii) to reflect on the sense of the instructions and/or suggestions given at the end of the text of the problem, suggestions that concerned with the construction of parallel lines to explore the maximum value of the function  $f$ ; or, (iii) on the possibility of carrying out an exploration using *GEOGEBRA*, starting by dragging a point over the feasibility region and verifying the increase or decrease of the function  $f$  as the chosen point was varying; it is worth to see that all of them are entirely relied on a necessity of feedback or teacher (or student) control of their activity within the software (see Balacheff & Sutherland, 1994, p. 15). But this control usually is relied on the coordination of the representation registers or on the comprehension of the mathematical content in question, which is usually not accessed directly by working alone within the software and at a distance.

Briefly, in a trajectory to finally arrive to solve a problem posed in a classical school context of optimization problem solving, the teacher (or student) shall find that there is a very close relationship between real situation modeling, the use and treatment of mathematical representations that come into play and the coordination of the representation registers in use. Therefore, the principal results in the analysis that has been instrumented here are as follows:

- (1) The learning environment was in part defined using a computational device (in this case *GEOGEBRA*) as a procedural tool for the conversion, use and treatment of the different mathematical representations (Duval, 1994), in this case the equations and graphs that came into play in the given situation of optimization;
- (2) However, to transit from a procedural context where a possible solution was found to a theoretical one to validate it, an epistemological change is required (Balacheff, 2010, p. 6/36). In this case, it consisted in instrumenting reflective tools, which are not automatically available within *GEOGEBRA* by itself.

Therefore, this work has allowed to advance a hypothesis of necessity of digital collaboration according to specific participant’s (teacher or student) activity, a support to accomplish the epistemological change already mentioned. It would be included in the computational device, or otherwise it would be provided by tutorial intervention (e.g. Soury-Lavergne, 1997).

These final remarks mean it is not enough to have access to mathematics technology and/or Internet free resources to achieve expertise or comprehension of certain mathematical content addressed. Yet

perhaps what is most interesting is that the analysis from this epistemic and semiotic perspective sheds light on how to move forward by correcting the design, incorporating elements missing in the programs reviewed, instrumenting teaching guides (or constructing hypothetical learning trajectories) or working with digital materials as collaborative tools that could promote exploration and reflective thinking to be applied in the solution of certain mathematical tasks, as those that were showed now in the situations under study. In other words, in the same way that social interactions do not in principle have an impact on learning but rather depend on the content and forms of interaction chosen, the use of Internet digital tools and computational devices will have an impact on teachers and teaching (or students and learning) when instrumentalization of Internet resources had been exercised to gain knowledge, or to teachers (or students) get control of the activity within the software (Balacheff & Sutherland, 1994, p. 15), specially by themselves.

## Notes

<sup>(i)</sup> Both modes are at the beginning of the incorporation of innovation at the school, according to the PURIA model. Following this model implies that teachers should experiment with the mentioned modes to advance toward successfully incorporating technology into classrooms (Zbiek and Hollebrands, 2008; Hoyos 2009-2012).

Briefly, the PURIA model consists of five stages named the Play, Use, Recommend, Incorporate, and Assess modes: “When [teachers are] first introduced to a CAS... they play around with it and try out its facilities... Then they realize they can use it meaningfully for their own work... In time, they find themselves recommending it to their students, albeit essentially as a checking tool and in a piecemeal fashion at this stage. Only when they have observed students using the software to good effect they feel confident in incorporating it more directly in their lessons... Finally, they feel they should assess their students’ use of the CAS, at which point it becomes firmly established in the teaching and learning process” (Beaudin & Bowers 1997, p.7).

<sup>(ii)</sup> French is the original language of this quote: “il ne peut pas y avoir de compréhension du contenu représenté sans une coordination des registres de représentation, quel que soit le registre de représentation utilisé. Car la particularité des mathématiques par rapport aux autres disciplines est que les objets étudiés ne sont pas accessibles indépendamment du recours à un langage, à des figures, à des schémas, à des symboles...” (Duval, 1994, p.12)

<sup>(iii)</sup> The domain of epistemological validity of a computational environment is characterized by at least four dimensions: (1) the set of problems that the device can propose; (2) the nature of the tools and objects that provide its formal structure; (3) the nature of the phenomenology that is displayed on the interface that is accessed directly by the user; and (4) the kind of control available for users in the computational environment with the feedback that the latter provides (Balacheff & Sutherland, 1994, p. 15).

*Our study is based on a national research project called Arithmetic and Cooperation at Elementary school (ACE). The main objective of this research is the designing of a curriculum for first grade students. This communication focuses on the analysis of an extract from a lesson proposed by this curriculum. During this lesson, the students work on the notion of difference, which is introduced with the help of several systems of representation. These systems are already known by the students. The analysis of the extract shows that the past and future situations can be related to each other. We point out that the students' continuity of experience can produce knowledge growth. This growth specifically occurs when the teacher's uttering activity directs the students' actions while they use the systems of representation. This uttering activity allows a reshaping / remodeling /modification of former knowledge through the systems of representation.*

*Keywords: Elementary school mathematics, continuity of education, semiotic representation .*

This paper focuses on the continuity of epistemic experience in mathematics. We argue that systems of representation constitute a prominent way of achieving such continuity. We sketch the role of a specific system of representation (the number line) to build of the number sense at first grade. This research is based a larger French national research, arithmetic and cooperation at Elementary School (ACE). It offers a complete arithmetic program to 6-7 year-old-students (First grade). The conception of this curriculum relies on available scientific knowledge in different areas (Cognitive Neuroscience, Science of Education, Developmental Psychology and Didactics of Mathematics). A specific part of the conception of the curriculum is built within what we call a cooperative engineering (Sensevy, Forest, Quilio, Morales, 2011; Morales, Sensevy, & Forest, in press). This engineering consists of two spheres. The sphere 1 gathers a multi categorical team (PhD, teachers of study classes, researchers, teacher's trainers, pedagogical advisors) and the sphere 2 is constituted by 120 experimental classes. In the first year of the experiment (2011-2012), the sphere 1 designed the mathematical situations of the curriculum. These situations were implemented in the « study classes », and redesigned on line in the course of the implementation process. The first year of the experiment, the sphere 1 designed eleven modules corresponding to forty-five sessions. The second year of this experiment, this curriculum has been implemented in 60 experimental classes (*versus* 60 control classes) and in 120 experimental classes (*versus* 120 control classes) the third year (2013-2014). The experimental classes' involvement in this curriculum and their feedbacks allowed numerous improvements of the initial design proposed by the research team situations.

This cooperation between researchers and teachers showed a willingness to create a didactic continuity in student's experience through the use of representation of the number systems that are present in the progression throughout the year. We assume that in the joint action between students

and teacher, the systems of representation may authorize the continuity of the student's experience. But, how precisely this can be built in joint action between teacher and students? Here we can rely on Dewey's conception of continuity. "The principle of continuity of experience means that every experience both takes up something from those which have gone before and modifies in some way the quality of those which come after" (Dewey, 1998, p.27).

## The Joint Action Theory in Didactics

Our analyses will build on the Joint Action Theory in Didactics (JATD) originated in comparative approach in didactics (Sensevy, 2011; Sensevy, Gruson, & Forest, 2015; Ligozat, 2009; Tiberghien & Malkoun, 2009; Venturini & Amade-Escot, 2013). Among the theoretical tools provided by the "JATD", we use mainly the contract/milieu dialectics and the reticence/ expression dialectics. When facing a new problem, students are confronted to what we call to a *milieu* (Brousseau, 1997; Sensevy & Tiberghien, 2015), as the epistemic structure. This milieu can be seen as the state of problem, what "has to be known" (Sensevy et al, 2015). Students have to face a rather enigmatic set of elements that they have to relate in order to build a system of meanings, in the knowing of what has to be known » (Sensevy, Gruson, & Forest, 2015). For example, for someone who has to do something with a representational system, the milieu is a specific symbolic organization of the system of representations itself. The milieu offered opportunities of enquiry, in which students have to connect elements of knowledge. They deal with this milieu by relying on the knowledge built in the preceding didactic joint action, *the didactic contract*, what "is already known". This relationship between contract and milieu is a dialectal one, because the understanding of a given milieu depends on the nature of the contract that guides the student's efforts.

In order to enable the student to learn, teacher enacts strategies to engage student's action. Interactions between teacher and students are determined by the didactic contract (Brousseau, 1997). In fact, the teacher knows the knowledge that students will have to learn. But he must not tell directly all what he knows. Thus, he has to make choices, in his teaching, about the equilibrium between saying/showing (expression) and remaining tacit/hiding (reticence). This is the reticence-expression dialectics. The two dialectics (contract-milieu and reticence-expression) are entangled, in that expression or reticence can be oriented to "contract " ("what is already-there"), or "milieu " ("what has to be known").

The research on the using of manipulatives and representations focus on the necessity of enabling the students to rely first on manipulative and concrete "objects", then to study iconic (analogical) representations of numbers (Bass, 2015; Schmittau, 2005, Davydov, 1975) then to write down equations in canonical form. This process seems very close to the tradition in Chinese textbooks (Bartolini Bussi et al., 2011; Sun, 2011; Ding & Li, 2014) and can be thought of as "concreteness fading" (McNeil et al., 2012; Fyfe et al., 2014). In this communication, we will try to show how in the new situation in which the notion of the difference (subtraction) is introduced, the systems of representation of number can guarantee a kind of continuity of experience. In fact, the "translational principle for representations systems" in a representational game (Morales, Sensevy & Forest, 2016) can allow students to understand the concept of the difference between two numbers.

## Methodology

To discuss these questions, we focus on a specific moment of teacher's practice in a study class, with an experimented teacher, who belongs to the research team (sphere1). The data were collected in december 2013, in a first grade classroom of a French primary school. The twenty five students of this classroom were aged 6-7. This study follows a qualitative approach.

In this extract, the students collectively search the difference between two additive writings with two terms. In this communication, we focus on the introduction of a new piece of knowledge, the notion of difference between two numbers. In the preceding sessions, the students orally compared the production of two hands ads (students showed a number on the two hands, the statement) and a launch of two six-sided dice. The statement wins if it was bigger (in some cases smaller) than the two-dice throw. Then, students compared the two additions with two terms in reference to the situation of the "Statements" (fingers and dice). The result of this comparison was written in the form of a quality or an inequality with the mathematical signs « $=$ ,  $\neq$ ,  $>$ ,  $<$ ». These two additions were represented in two number lines to solve or prove the comparison, as we can see below (figure 1).

**Figure 1: An example of comparison between  $2 + 4$  and  $5 + 3$  on the number line**

The choice of this extract is motivated by the following reason: this extract shows how the continuity of student's experience could be developed through the use the systems of representation. This extract can be considered as a mesoscopic level of the description, the pivotal level (Sensevy et al., 2015), which allows relationship between what preceded and what is going to follow. So, we can analyze the didactic transactions *hic et nunc*. We can characterize and describe the motives and the forms that directed teacher and students 'action. This description can show the teacher's strategies to make the didactic time forward.

## Analyze

### Presentation

This part of the curriculum "ACE" is organized around a connected series of situations. The initial situation of this curriculum is the situation of the "Statements game" (fingers and dice). One die (marked with standard dot patterns for 1-6) is about to be thrown. Beforehand, the students use their fingers to make a "statement" (for example, a student shows two fingers on her right hand, and three fingers on her left hand). The die is thrown. The students compare their statement with what is indicated by the die. If the sums are equal, the pupils have won. After this oral comparison, students compare an addition (two terms  $\leq 5$  with a number  $\leq 6$ ). The progressive complexification of the situation guides students to increasingly rich comparisons: the number of hands (students) is increased, so the number and the nature of dice (1 to 10 dice are played with), the rules of the game are changed (for example a pupil no longer wins because he has the same number as in the

statement, but because he has a lower or higher number). These connected situations should allow the students to build a real mathematical experience, particularly in the handling of representation and symbolic writing systems, as we will show in what follows. A number line is also introduced on which students represent the numbers. Indeed, the students manipulated a concrete object (the fingers) and they translate fingers by an iconic (analogical) representation of number (the number line) and wrote down equation in canonical form ( $2 + 4 = 6$ ). For example, a student shows two fingers on his left hand and four fingers on his right hand, then she draws these numbers on a number line:

And she writes down this addition:  $2 + 4 = 6$

To understand various properties of numbers, students had to compare different representations of the same mathematical reality to become progressively able to recognize the differences and the similarities between these representations.

Since the beginning of the year, students acquired knowledge related to compare numbers. This comparison is performed first orally with the production of «two or three hands ads" and a launch of six-sided die. Then, students compared an addition in two or three terms with a throw of dice. They used the mathematical signs « $=$ ,  $\neq$ ,  $<$ ,  $>$ » (for example, to compare  $3 + 1$  et  $5$ , students write  $3 + 1 < 5$ ). This situation become more complex when students have to compare two additions in two terms. Finally, students deal with the question of the subtraction on the basis of the comparison between two additions, in the continuity of the previous situations. The study is accompanied by the use of the number line.

The students have built a semiotic knowledge to represent the comparison between two numbers. The number is seen as a measurement. It refers to "the quantity of fingers" in two hands. The number line shows the number like a length measurement. This ancient knowledge is the *didactic contract*, the habits of action with which teacher and students are going to approach the new knowledge, the difference between two numbers. The extract of the session that we chose introduces the difference between two numbers from the comparison of two additions and the terms "larger than and smaller than". The difference is a gap between two numbers, two length measurements. Four episodes will be analyzed. Here is a synoptic view of this analyzer.

Episodes	Content
Episode 1	Presentation of the instructions by the teacher
Episode 2	a) Comparison, looking for the difference between " $1 + 3$ " and " $1 + 1$ ". b) Proposal of two students: (tdp 15) " $1 + 3$ " is larger than " $1 + 1$ ". c) Proposal of another student: the difference between " $1 + 3$ " and " $1 + 1$ " is 3.
Episode 3	a) The difference (tdp 53). b) Introduction of the two hands by the teacher to confirm the difference 3.
Episode 4	Introduction of the number line by the teacher to search the difference between " $1 + 3$ " and " $1 + 1$ " (tdp 68).

**Table 1: Extract division**

We abstract the four episodes and provide a short analysis.

### Search for the difference between two numbers (episode 1, 2 3)

The teacher asks the students to look for the difference between " $1 + 3$ " and " $1 + 1$ ". He presents the instructions like this:

Teacher: Today, we are going to begin a new game. It is always a game with statements. But today what we are going to make, it is to compare ours statements. We look for which is the larger statement, the smaller statement but that I would know how much more and how much less (...) we are going to find, this calls in fact the difference.

Actually, the students meet difficulties to find the difference between " $1 + 3$ " and " $1 + 1$ ". They compare the two numbers and look for the larger number or the smaller number with the term-by-term strategy or by computing. They do not focus on "difference". Confronted to the difficulties of the students, the teacher suggests to illustrate « the two additions " $1 + 3$ " and " $1 + 1$ " » by a statement with both hands. The following picture (figure two) shows such a statement comparison.

**Figure 2: Translation of " $1 + 3$ " and " $1 + 1$ " by two statements**

Unfortunately, this *translation* between the mathematical symbolic writing and the hands statements in a game of representation does not bring the students to produce an adequate answer. "The semiotic habit" of the contract, which considers fingers as instruments to compare numbers, impedes a new designation of numbers, the difference.

### Using the number line

Therefore, the teacher introduces in a milieu two number lines on which students have to represent both additive writings. A student writes a first bridge above the first interval of the number line (hence representing the number "1") and a second bridge above three intervals (between the second and a fourth graduation, hence representing the number "3"). He writes down above these bridges the numbers 1 and 3. Then, he draws below the number line a bridge of four intervals and writes down the sum number (4).

Teacher: It is good the statement makes four as Neil shows us. On the second line, what are you going to draw?

On the second number line, the same student draws two consecutive bridges and a bridge of two intervals, signifying the sum number (2)

**Figure 3: the representation of “1 + 3” and “1 + 1” on the number lines**

Teacher: What do you see in the two number lines? Do you see if the 1+3 is largest than 1+1?

The students provide answers different answers: “three”, “four” and “two”. The teacher asks one student to show how he knows that his statement is largest.

Student: because here is the two [He slides his finger from the third graduation (number “2”) on the first number line to the third graduation (number “2”) of the second number line] It’s a part of four...

The student draws a bridge between the second and the fourth graduation on the first number line.

**Figure 4: Representation of the difference on the number line**

The teacher's expression encourages a translation between the symbolic writing and the number line. But, in the same time, she's reticent because she doesn't say how to draw these additions on the number lines. The teacher thus refers to the preceding contract. She just says: “What do you see in the two number lines? Do you see if the 1+3 is largest than 1+1?” This question can be seen as a “milieu-oriented situation”. The action of the student is moved toward the effective representation of the difference on the two number lines. But, though this expression, the teacher is reticent because she remains silent when the student searches the difference. She indicates where the student must look but the research stays under the responsibility of the student. The number line affords to show concretely the gap between the two numbers, the difference between the two length bounded by the bridges, the sum of the two additions. The students investigate an instrument, the number line, on which they know already how to play (in the situation of comparison). By using this instrument, they achieve not yet explored potentialities of this semiotic system. In particular, the number line shows a number included in another.

## Results

The students investigate different systems of representation to find the difference between two numbers: symbolic writing, concrete representation with the hands, number line. All these

representations are known by the students. First, the symbolic writing is translated by statements on the two hands. Then these statements are translated into two number lines in what we may call a translation game, which is a particular representational game (Sensevy, 2011; Morales, Sensevy & Forest, in press). The preceding semiotic knowledge is "re-experienced" by the students. In this way, we can say that the systems of representation are instrumental (Dewey, 1938/1998) in that they allow investigating new knowledge. The semiotic habits are accommodated in a new situation, a new knowledge, allowing the continuity of experience. However, the re-experience of a semiotic system for introducing a new knowledge requires a subtle enunciative work for the teacher, given that the different strategic systems in teacher's action can be a contract oriented or a milieu-oriented transactional activity. In this communication, we have shown how the expression-reticence game of this teacher enable her to introduce in the milieu a system of representation (the number line) already known by the students (contract) in order to understand new properties of this system (then considered as a milieu). This teacher's strategy enables the students to investigate the difference between two numbers while leaving them the responsibility of this enquiry (Dewey, 1938/1998).

## Discussion and conclusion

However, these results ask to be worked. It is necessary to explore on a long duration this continuity of the experience of the students in mathematics through the systems of representation (Joffredo-Le Brun, 2016). In particular, it is necessary to note that such continuity can be built only through a real epistemic continuity of the knowledges within the curriculum. The design of such a curriculum has to be performed through the effective experience of the teachers, within an iterative process, as it is the case in the ACE research.

# Visuo-spatial abilities and geometry: A first proposal of a theoretical framework for interpreting processes of visualization

Elisa Miragliotta<sup>1</sup> and Anna Baccaglini-Frank<sup>2</sup>

<sup>1</sup>University of Ferrara, Department of Mathematics and Computer Science, Ferrara, Italy;  
[elisa.miragliotta@student.unife.it](mailto:elisa.miragliotta@student.unife.it)

<sup>2</sup>University of Pisa, Department of Mathematics, Pisa, Italy; [anna.baccaglinifrank@unipi.it](mailto:anna.baccaglinifrank@unipi.it)

*We propose a theoretical interpretation of visuo-spatial abilities, as classified in the field of Cognitive Psychology, in the domain of Euclidean Geometry. In this interpretation we make use of Fischbein's theory of figural concepts and of Duval's cognitive apprehensions. Our interpretation lays the foundations for a new theoretical framework that we propose as a tool for qualitative analysis of students' processes of visualization as they carry out geometrical activities. In particular, we present analyses of excerpts from a set of activities designed and proposed in a didactical intervention aimed at strengthening visuo-spatial abilities of a group of students identified as the weakest from a selected 9<sup>th</sup> grade class of an Italian high school.*

*Keywords: Geometric reasoning, spatial thinking, visualization, visuo-spatial abilities.*

## Introduction

Research in the domain of *visualization* and *spatial thinking* has pursued several purposes: understanding the different imaginative strategies used by students (Owens, 1999); studying the effects of teaching practices, aimed at encouraging processes of visualization (Presmeg, 2006); developing theoretical constructs, useful for the interpretation of students' perception of geometric shapes and how this perception improves in learning geometry (Duval, 1995; Fischbein, 1993, Mariotti, 2005). Some ideas in this field have been developed from the psychological studies on *mental imagery*. Since the advent of Cognitive Psychology and contemporary Neuroscience, researchers have been elaborating models to describe processes related to visualizing and using mental imagery, and they have listed sets of *visuo-spatial abilities* involved (e.g., Cornoldi & Vecchi, 2004). However, a shared definition of these abilities does not exist yet. Nor have the fields of Mathematics Education and Cognitive Psychology been able to elaborate common grounds to study visualization processes, in which they are both interested.

In this paper we propose a theoretical interpretation of visuo-spatial abilities, as classified in the field of Cognitive Psychology, in the domain of reasoning in Euclidean Geometry, that was developed as part of a study that has been recently carried out (Miragliotta, 2016; Miragliotta, Baccaglini-Frank & Tomasi, submitted). The study had two main objectives: on the one hand, we attempted to give a theoretical analysis of some visuo-spatial abilities in the context of learning Euclidean Geometry; on the other hand, we used such theoretical interpretation to study the effects of a set of activities proposed (for the most part) using a Dynamic Geometry Environment (DGE) in terms of strengthening the students' visuo-spatial abilities (as it is widely accepted that DGEs yield great potential in fostering processes such as visualization, as well as in mediating, in general, the learning of geometry: e.g., Mariotti, 2005; Baccaglini-Frank, 2010; Leung, Baccaglini-Frank & Mariotti, 2013). In this paper we will concentrate on the description of theoretical analysis of the

visuo-spatial abilities considered and on its power as a tool for qualitative analysis of students' behavior as they carry out geometrical activities. As an example of how the framework can be used, we will analyze an excerpt taken from a question (not involving the use of any DGE) of the post-intervention interview of a student from the group of students identified as the weakest of the Italian high school class of involved in the study. Since for what we present in this paper the role of the DGE is marginal, and space quite constrained, we will not discuss visualization in a DGE.

## Theoretical background

According to Clements and Battista (1992), *spatial reasoning* “consists of the set of cognitive processes by which mental representation for spatial objects, relationships, and transformations are constructed and manipulated” (ibid., p.420). Referring to Kosslyn (1983), these authors observe that geometrical reasoning requires spatial reasoning, which includes four classes of image processing: generating an image; inspecting an image to answer questions about it; transforming and operating on an image; maintaining an image in the service of some other mental operation. In particular we are interested in processes involving two-dimensional geometric objects.

From the perspective of Cognitive Psychology, generating and processing mental images take place within a complex process of acquisition and use of cognitive abilities, including those denoted *visuo-spatial abilities*. A list of these appears in Cornoldi and Vecchi (2004, p. 16). We elaborated our theoretical interpretation starting from the following set of abilities: *visual organization*, the ability to organize incomplete, not perfectly visible or fragmented patterns; *planned visual scanning*, the ability to scan a visual configuration rapidly and efficiently to reach a particular goal; *spatial orientation*, the ability to perceive and recall a particular spatial orientation or be able to orient oneself generally in space; *visual reconstructive ability*, the ability to reconstruct a pattern (by drawing or using elements provided) on the basis of a given model; *imagery generation ability*, the ability to generate vivid visuo-spatial mental images quickly; *imagery manipulation ability*, the ability to manipulate a visuospatial mental image in order to transform or evaluate it; *spatial sequential short-term memory*, the ability to remember a sequence of different locations; *visuo-spatial simultaneous short-term memory*, the ability to remember different locations presented simultaneously; *visual memory*, the ability to remember visual information; *long-term spatial memory*, the ability to maintain spatial information over long periods of time.

To interpret how these general cognitive abilities might come into play during reasoning in the specific context of Euclidean Geometry, we referred to theoretical constructs elaborated in mathematics education to this purpose.

### Fischbein's theory of figural concepts

The *Theory of figural concepts* (Fischbein, 1993) describes geometrical figures as follows:

A geometrical figure may, then, be described as having intrinsically conceptual properties. Nevertheless, a geometrical figure is not a mere concept. It is an image, a visual image. It possesses a property which usual concepts do not possess, namely, it includes the mental representation of space property. [...] all the geometrical figures represent mental constructs which possess, simultaneously, conceptual and figural properties. (ibid., pp. 141-142).

According to Fischbein *figural concepts* “reflect spatial properties (shape, position, magnitude), and at the same time, possess conceptual qualities - like ideality, abstractness, generality, perfection” (ibid., p. 143); a geometrical figure is made up of two fundamental components: the figural component and the conceptual component. From the developmental point of view, initially the visual aspect is dominant, and gradually the role of formal constraints becomes more important, until the construction of *figural concept* is reached (Mariotti, 2005).

### **Duval’s types of cognitive apprehension**

Today the importance of visualization in mathematics is widely recognized. Since several studies have addressed visualization in different ways, we clarify that our interpretation is in line with the definition given by Arcavi (2003).

*Visualization* is the ability, the process and the product of creation, interpretation, use of and reflection upon pictures, images, diagrams, in our minds, on paper or with technological tools, with the purpose of depicting and communicating information, thinking about and developing previously unknown ideas and advancing understandings. (ibid., p. 217, emphasis added)

Peculiarities of visualization in geometry have been highlighted by Duval (1995) in describing different approaches to dealing with geometric figures: *cognitive apprehension* stresses that “there are several ways of looking at a drawing or a visual stimulus array” (ibid., p. 143). Duval speaks of four cognitive apprehensions. *Perceptual apprehension* responds to the laws of figural organization and identification of form, and helps to “recognize something (shape, representation of a thing,...) in a plane or in depth” (ibid., p. 145) at first glance. In a perceived figure we can also recognize sub-figures that do not depend on its construction. *Sequential apprehension* “is required whenever one must construct a figure or describe its construction” (ibid., p. 146). Here the sub-figures emerge in a specific order, depending on the geometrical construction, on technical constraints of the instrument used and on mathematical properties. Furthermore, Duval (1995, p. 146) claims that “mathematical properties represented in a drawing cannot be determined through perceptual apprehension”, indeed, “a drawing without denomination or hypothesis is an ambiguous representation”. So, indications given through speech help us to identify properties of a perceived geometrical figure, thanks to the *discursive apprehension*. Here we are in the domain of deductive reasoning. The apprehension that has a heuristic function in problem solving is the *operative apprehension*. This apprehension depends on different ways of modifying a figure that happen only within the figural register and that are independent from mathematical knowledge.

Each type of apprehension seems to be related to different cognitive processes that could be accomplished through the coordination of different visuo-spatial abilities as we hypothesise below.

### **Grounding for a new visuo-spatial abilities framework**

While maintaining the classification proposed by Cognitive Psychology, we selected a subset of visuo-spatial abilities and provided an interpretation in the specific context of geometrical reasoning. We used the *Theory of Figural Concepts* to interpret the terms “model” and “image” as follows: *image* is the figural component of a geometric figure; *model* is a synonym of figural concept in which image and concept realize their dialectic. Since our interpretation aims at being a

stronger lens for analyzing students' processes than the visuo-spatial abilities as described in the Cognitive Psychology literature, there is not always a one-to-one correspondence with such abilities.

- *Visual organization* is the ability to recognize figural concepts from incomplete or not perfectly visible representations.

*Visual organization* seems to be an ability that intervenes in tasks that require the recognition of figures within another figure, or in the recognition of a simple figure within a more complex figure. This ability echoes Duval's *perceptual apprehension*.

- *Visual scanning* is the ability to recognize the properties of a figure starting from its representation.

This representation can be static or dynamic. It depends on the task and on the context in which it is proposed. For example, in the case of a dynamic figure in a DGE, *visual scanning* is involved in the recognition of properties that are invariant under dragging (see Leung et al., 2013). This ability echoes Duval's *perceptual apprehension*, but we also recognize in this ability some aspects of his *sequential* and *discursive apprehension*. For example, when observing a quadrilateral obtained through steps of a specific construction starting from two perpendicular lines, we can notice that quadrilateral seems to have a right angle. However, to recognize the property "having a right angle" only observing the figure on the screen, one needs to look at its written geometrical construction and deduce that the point one vertex is at the intersection of two perpendicular lines.

- *Visual reconstructive ability* is the ability to reconstruct, in a given representation, the figural component of a figural concept, starting from written or verbal instructions, or starting from partial representations.

For instance, the reconstruction could be realized following a sequence of construction steps given explicitly, using appropriate tools (ruler and compass, primitives in DGE, ...), otherwise it could be realized planning these construction steps. It involves the ability to correctly visualize the relationships between the elementary figural units involved (such as points on lines, perpendicular lines) following the steps of a geometric construction or creating a new construction. This ability echoes Duval's *sequential apprehension* and his *discursive apprehension*. The *visual reconstructive ability* seems to intervene, for example, when carrying out the construction steps of a known geometric figure; when completing the steps of an incomplete construction; when following the steps of a given geometric construction.

- *Imagery generation ability* is the ability to instantly mentally reproduce the figural component of a figural concept recovering it from memory or generating it anew.

This ability seems to intervene when one is asked to visualize a geometric concept, for example, while imagining a sequence of construction steps. Coupled with *long-term spatial memory*, this ability seems to be involved in the retrieval of the prototypes (that is, in Kosslyn's terms, a "stored model of a shape") of geometric shapes and of their properties. Coupled with *spatial sequential short-term memory*, it seems to intervene in the identification of particular geometric loci.

- *Imagery manipulation ability* is the ability to use the properties of a figural concept or to manipulate figural aspects of a figural concept, taking into account the theoretical relationships between elementary figural units of which it is composed.

This ability is involved in tasks that require mental manipulation of a figure in order to transform it into a new one. This ability echoes Duval's *operative apprehension*, but also differs from it. The mental manipulations on figure are tightly connected to the figure's conceptual component. Indeed, to manipulate a figure maintaining given properties, strong conceptual control over it is required, as highlighted also by Arcavi (2003), who emphasizes, as well, the high cognitive demand involved:

Seeing the unseen may refer to the development and use of an intervening conceptual structure which enables us to see through the same visual display. (ibid, p. 234)

When visualization acts upon conceptually rich images (or in Fischbein's words when there are intervening conceptual structures), the cognitive demand is certainly high. (ibid, p.235).

- *Spatial sequential short-term memory*: this ability seems to be present in various processes of geometric reasoning; here we consider it, in particular, as the ability to remember different configurations assumed by the figural component of a figural concept during an observed or imagined manipulation.
- *Long-term spatial memory* in our interpretation this refers, in particular, to the ability to maintain in long-term memory the figural components of a figural concept.

The last two abilities are involved in solving geometric tasks and are always used in combination with other visuo-spatial abilities. For example, combined with the *imagery generation ability*, *spatial sequential short-term memory* seems to be involved in tasks that require recognizing a particular geometrical locus. Combined with the *imagery manipulation ability*, *spatial sequential short-term memory* seems to be involved in tasks that require remembering the configurations assumed by a figure during an imagined manipulation.

When a solver faces a geometrical problem, s/he interacts with visual or mental images in different ways; a process that seems to occur frequently is imagining the consequence of a (mental) manipulation of the figure. Such process can be carried out through the use of the various abilities listed above that expert solvers combine in an immediate and automatic way. So consider this as an ability in its own right, that we will call *geometric prediction*, intending the identification of certain properties or configurations of a new figure, arising from a process of manipulation. This process appears to be coherent with respect to the notion of *anticipatory image* (Piaget & Inhelder, 1966), which suggests an ability to make predictions, orienting both perception and imagination, in the presence of a specific goal.

## Visuo-spatial abilities framework as a tool of analysis

In this section we use the framework to analyze an excerpt taken from a question of the post-intervention interview of a student; he was part of a group of students in the 9<sup>th</sup> grade (students aged 14-15) class of an Italian scientific high school (Applied Science option), identified through a pre-test as having low performance on geometry tasks heavily involving visualization processes; the teaching intervention lasted five lessons and had been carried out using open problems, mostly proposed in the DGE *GeoGebra*. The post-intervention interview involved tasks both in the context of a DGE and with only pen and paper (if requested by the student). In the excerpt the student is solving a task proposed outside the DGE setting. The analysis has the aim of showing the power of

the framework in identifying the proposed visuo-spatial abilities and showing how they can come into play, shedding light onto visualization processes.

**Activity:** the student is given the following task and allowed to use paper and pencil:

Imagine a quadrilateral. Focus on the midpoint of each side. Trace the segments that join the midpoints of consecutive sides. What can you tell me about the figure that is formed?

Below is an excerpt describing what the student says [and does].

Student: It is a quadrilateral, which... which looks like a rhombus, so to speak. [Initially he closes his eyes. Then he places four finger tips (two thumbs and two indexes) on the desk to form what looks like a square, and then, moving along two parallel lines in opposite directions, a non-square rectangle. He drags his fingers back and forth between these two positions.] If quadrilateral is a square it forms a rhombus with congruent diagonals, but if is a random figure...I mean, it depends on the figure. It changes depending on how the points are placed.

Interviewer: Draw it. What are you drawing?

Student: Four scattered points. [He draws (freehand) a quadrilateral with different sides, as shown in Figure 1]

Interviewer: Can you say more about the figure that is formed?

Student: It is a quadrilateral. Mmm...it is a parallelogram!

Figure 1 The student's drawing

In addition to what the student says, the excerpt is interesting also for what he does, which gives further insight into visuo-spatial abilities he may be using. After the first answer, he keeps his eyes closed and moves his fingers on the desk. This seems to suggest that a purely mental process is taking place, and the gesture on the desk seems to be a window onto this process. In order to answer the question, first of all, we would say the student is using the *imagery generation ability* for imagining the first configuration. To this end he needs to recall a prototype of the quadrilateral that is as general as possible (this involves the *imagery generation ability* and *long-term spatial memory*); then he needs to visualize the required elementary figural units (*imagery generation ability*) and go through the steps of the construction (*imagery reconstructive ability*). Now, the student's use of his fingers on the desk is an extremely insightful window onto processes he could be enacting. Our interpretation is that he is using the *imagery manipulation ability*, helping himself with an external image (the quadrilateral with vertexes at his four finger tips) that he can act upon. What is visible of this manipulation are the positions (and their continuous change) of the vertexes. As he moves his fingers (forming what look like various rectangles) he is using *geometric prediction*, possibly aided by *visual scanning*, to visualize the quadrilateral with vertexes at the midpoints of the sides of the manipulated quadrilateral. This interpretation is supported by the fact that the student moves his fingers on his desk seamlessly, he never lifts them up from the surface, and then he selects a position which is coherent with respect to the configuration that he wants to (mentally) observe, and starts to move fingers again. The student seems to be able to manipulate the figure in a manner that goes beyond the kind of transformation described by *operative*

*apprehension*. Indeed, the manipulation recalls much more dragging of the vertices, as can be accomplished in a DGE. This cognitive effect could have been promoted by the kind of problems proposed within the DGE during the activity sessions. The student seems to be looking for extra external support for his *imagery manipulation* and *geometric prediction* abilities.

Moreover, this excerpt is very interesting because of what the student then decides to draw on the sheet of paper when invited to so do. Although he has only mentioned the case in which the quadrilateral is a square and realized with his fingers various cases of it being a rectangle, he draws a much more general convex quadrilateral. This behavior supports our previous hypothesis that the student seems to need external support for his *imagery manipulation* and *geometric prediction* abilities. On paper it is as if he gains confidence, possibly because the cognitive load from the conceptual control he would need to exercise over the general figure is lowered this way. Once he sees the general quadrilateral and sketches the midpoint quadrilateral he recognizes (*visual scanning* and *conceptual control*) a parallelogram.

## Conclusion

The fields of Mathematics Education and Cognitive Psychology share various research interests; one of these is the identification and classification of strategies and processes involved in visualization. According to Cognitive Psychology, generating and processing mental images take place within a complex process of acquisition and use of abilities, including those denoted *visuo-spatial abilities*. Attempting to interpret visuo-spatial abilities in the context of geometrical reasoning could be beneficial to both fields. In our attempt to give a theoretical interpretation of some visuo-spatial abilities in the context of learning Euclidean Geometry, we used theoretical constructs from the field of Mathematics Education, which led to the introduction of an ability different from the basic visuo-spatial ones, *geometric prediction*, and they also led to highlighting the fundamental contribution, in solving geometric tasks, of *geometric conceptual control* over figures.

This interpretation, which can be seen as groundwork for a new theoretical framework, has allowed us to: (1) design an educational intervention aimed at strengthening visuo-spatial abilities of a group of students identified as the weakest in a selected class; (2) gain insight, through qualitative analysis, into students' geometrical reasoning. We believe that this kind of research can provide new insight into students' difficulties in learning Geometry, and be used to design educational material for strengthening students' visuo-spatial abilities.

# Middle school students' employments of gestural signs: A case study

Samet Okumus<sup>1</sup> and Karen Hollebrands<sup>2</sup>

<sup>1</sup>Recep Tayyip Erdogan University, College of Education, Rize, Turkey;  
[samet.okumus@erdogan.edu.tr](mailto:samet.okumus@erdogan.edu.tr)

<sup>2</sup>North Carolina State University, College of Education, Raleigh, NC, United States;  
[karen\\_hollebrands@ncsu.edu](mailto:karen_hollebrands@ncsu.edu)

*In this research study, we investigated how middle school students created 3-dimensional objects from 2-dimensional figures using an extrusion method. In a summer enrichment program, students used manipulatives and a dynamic geometry program (Cabri 3D). We identified students' strategies for forming 3-dimensional objects with a focus on their gestural signs. The results demonstrated that they most often employed dynamic-pointwise and dynamic-objectwise gestures to demonstrate the lateral faces or edges of 3-dimensional objects. Also, students linked their gestural signs and the Segment tool of Cabri 3D to indicate their reasoning.*

**Keywords:** *Gestural signs, 3-dimensional objects, extrusion, middle school students.*

## Introduction

Gestural signs are important to understand how students make sense of mathematical problems (Arzarello, 2006; Bartolini Bussi & Baccaglini-Frank, 2015; Radford, 2009). Signs (e.g., verbal or oral texts) are characterized as “something which stands to somebody for something in some respect or capacity” (Pierce 1932; 2.228). Also, students produce signs using an artifact such as manipulatives. Bartolini Bussi and Mariotti (2008) refer to signs that are produced using an artifact or any action related to the use of it as *artifact signs*. Students reason about tasks with the use of an artifact and exploit *mathematical signs* (e.g., mathematical definitions, proofs). Research studies address that students link artifact and mathematical signs employing gestures (Bartolini Bussi & Baccaglini-Frank, 2015; Maschietto & Bartolini Bussi, 2009). Gestures that are interwoven with other sets of signs facilitate mathematical communication between students (Arzarello, Paola, Robutti, & Sabena, 2009; Bartolini Bussi & Baccaglini-Frank, 2015; Radford & Sabena, 2015). In the current study, with a focus on students' gestural signs, our research question is: “In what ways do middle school students relate the features of 2-dimensional figures and 3-dimensional solids that are created using an extrusion method?”

## Theoretical framework: Semiotic mediation

*Semiotic mediation* “sees knowledge-construction as a consequence of instrumented activity where signs emerge and evolve within social interaction” (Mariotti, 2009, p.428). In a cultural learning environment, students use an artifact or a set of artifacts during a *semiotic activity*, so a piece of mathematical knowledge is mediated. The teacher is aware of the affordances (and constraints) of the artifact and assists students in *using the artifact as a tool of semiotic mediation*. In other words, students produce artifact and mathematical signs (or hybrid signs), so personal signs transformed into the mathematics culture's signs (Bartolini Bussi & Mariotti, 2008).

A student may exploit personal signs that may be unclear for others. Having the role of *cultural mediator*, such signs become meaningful for others under the teacher's supervision. For example,

Bartolini Bussi and Baccaglini–Frank (2015) addressed that a preschooler used a non-existing Italian word “quadrattizzato” referring to the movement of a programmable robot that made turns in a circular motion. The researchers translated it into English with another non-existing word as “squarized O.” They identified children’s and a student teacher’s turning gesture and spiral arrows with reference to the word “quadrattizzato.” The personal sign linked artifact and mathematical signs, and became a meaningful sign in the mathematics culture. The researchers characterized it as a *pivot sign*.

Pivot signs “may refer both to the activity with the artifact; in particular they may refer to specific instrumented actions, but also to natural language, and to the mathematical domain” (Bartolini Bussi & Mariotti, 2008, p. 757). They link artifact and mathematical signs or an artifact/mathematical sign may become a pivot sign (Bartolini Bussi & Baccaglini–Frank, 2015; Bartolini Bussi & Mariotti, 2008). Suppose a student is given a rectangular card and asked to draw the container he should order to hold the stack of the identical rectangular cards until it reaches a certain height. The student may produce a mathematical sign and draw a rectangular prism denoting its edge lengths. On the other hand, he may illustrate the stack of objects and draw a deck of rectangular cards (pivot signs). The deck of cards links the rectangular cards (artifact signs) and the rectangular prism (mathematical sign).

Research studies demonstrated that students’ gestural signs were intertwined with other sets of signs such as verbal signs (Radford & Sabena, 2015; Sabena, 2008). For example, Sabena (2008) characterized high school students’ production of signs while they were engaged in tasks about derivative of functions. Sabena found that students emphasized the dynamic character of derivatives employing gestural signs with other sets of signs. Also, previous research indicated that students’ gestural signs linked artifact and mathematical signs (Bartolini Bussi & Baccaglini–Frank, 2015; Maschietto & Bartolini Bussi, 2009). Bartolini Bussi, Boni, Ferri, and Garuti (1999) characterized the geneses of students’ gestures as pointwise or global (objectwise) with a focus on artifacts (gears) students used. Maschietto and Soury-Lavergne (2013) addressed that artifacts created for the same mathematical topic resulted in exploiting different signs. Primary school students were given to a hands-on tool (gear train of five wheels) and its digital counterpart for learning the place values of numbers. Students employed different gestural signs with the use of each artifact because they had different semiotic potentials. For example, students employed gestures to start the turning mechanism of the wheels using the hands-on tool and denoted these gestures in their written texts. The decimal values were explored in the counterpart digital artifact by mouse clicks. So, using a set of artifacts gives students an opportunity for mathematical learning.

## Methods

The research design was a case study in which the data were collected from a bounded system – a summer enrichment program that took place in a state in the southeastern United States (Stake, 1995). The unit of analysis was semiotic activities. The participants of this research study were selected from a group of rising seventh and eighth grade students (three boys, five girls) attending a summer enrichment program that aimed at promoting students’ thinking in different STEM (Science, Technology, Engineering and Mathematics) areas. A five-day instructional unit was planned. Eight middle school students (three rising seventh grade students, five rising eighth grade students) participated in the research study. Their ages ranged from twelve to fourteen.

On the first day of the program, students were given a spatial ability test and an open-ended survey that indicated their experience with geometry, computers, games, etc. The participants were characterized by these instruments and students with different spatial abilities were paired up. On the second and third days of the program, students created 3-dimensional objects from 2-dimensional figures using an extrusion method (e.g., stacking identical circular cards on top of each other and forming a cylinder). Students were given worksheets and they answered the questions in pairs. In the semiotic activities, they were asked to identify containers (3-dimensional objects) that would hold the stack of identical objects or objects decreasing in size (e.g., coins with a different radius). They used manipulatives and a dynamic geometry program, Cabri 3D. Students were provided pre-image and image figures in pre-constructed Cabri 3D sketches and manipulatives. They were asked to drag objects in Cabri 3D sketches and make an observation. Afterwards, they identified the resultant 3-dimensional objects for holding the stack of 2-dimensional figures. Students formed right and oblique prisms, cylinders, pyramids and cones.

Prior to the summer enrichment program, a pilot study was conducted. Students were allowed to use the *Trajectory* tool of Cabri 3D that allowed tracing points and objects. However, at times, they traced the objects and Cabri 3D showed the answer. Based on the feedback from the pilot study the *Trajectory* tool was disabled from the menu bar. However, the teacher activated the *Trajectory* tool on his computer that was hooked up the projector during he generated a whole-class discussion.

Data included videorecordings of four dyads during each class session including whole class discussions, and students' written and oral responses to the tasks. Also, a program that recorded the computer screen when students used Cabri 3D was used. The researchers watched the videos of students while they worked on the semiotic activities in groups. Their computer screen recordings were watched synchronously. Some screenshots and students' gestures were inserted into the verbatim transcripts.

We focused on students' written/oral responses to semiotic activities and their use of artifacts (manipulatives and Cabri 3D). Students' artifact, pivot and mathematical signs were identified. In the current research study, we analyzed students' strategies for forming 3-dimensional objects from 2-dimensional figures with a focus on their gestures. Students' gestural signs were categorized as static and dynamic taking into account how they were employed. If students' static or dynamic gesture signified an object, it was identified as objectwise. If the gesture stood for a point or a set of points, then we categorized it as pointwise gesture. Four gestural signs were identified: objectwise –dynamic, objectwise –static, pointwise –dynamic, and pointwise –static.

## Results

We identified students' strategies for forming 3-dimensional objects from 2-dimensional figures with a focus on their gestural signs. Students' gestures that linked artifact and mathematical signs were characterized as pivot signs. Also, students produced other sets of signs that were characterized as pivot signs (e.g., graphical signs, verbal signs). However, we give students' strategies in which gestural signs were characterized.

Some students suggested 3-dimensional objects (containers) that allowed no extra space and focused on the exact fit. Students employed objectwise–dynamic gestures to demonstrate lateral surfaces of

solids. For example, Charlotte emphasized that the container for identical triangular cards would be a triangular prism. She employed an objectwise–dynamic gesture as shown in Figure 1 and said:

Charlotte: ...because the prism is gonna come around the edges of the triangles.

**Figure 1: Charlotte makes an objectwise–dynamic gesture to denote the triangular prism**

Some students focused on geometric objects in the artifact and suggested solids based on how the geometric shapes were stacked on top of each other. They interpreted artifact signs and employed static or dynamic gestures to indicate the resultant 3–dimensional objects and focused on the parts of the given artifact. For example, Vince had difficulty identifying the container (rectangular pyramid) for rectangular cards decreasing in size. He kept the height almost in the middle and positioned the rectangle. Afterwards, he employed an objectwise–static gesture to demonstrate the container as shown in Figure 3. He said:

Vince: For this one, I was trying to figure out so if it is – it is coming– it is going like that (makes an objectwise–static gesture as shown in Figure 2). As it decreases it's going like this, it's going like that. Do you see? It's going inward like that.

**Figure 2: Vince makes an objectwise–static gesture to demonstrate the rectangles decreasing in size**

Students connected the geometric shape on the bottom and top in the given artifact producing a gestural sign. They most often made a pointwise–dynamic gesture and connected the pre–image and image points. For example, Sloane identified the resultant object for holding the stack of identical circles employing a pointwise–dynamic gesture. She posited:

Sloane: Because there is a circle on the top and the bottom and that makes a cylinder. Because there is like a straight line right here kinda (Figure 3).

**Figure 3: Sloane makes a pointwise–dynamic gesture to denote a cylinder**

On the other hand, some students made hybrid or objectwise–dynamic gestures to demonstrate the 3–dimensional objects. Virginia denoted the top and bottom of the cylinder with a static–objectwise gesture. Then, she made an objectwise–dynamic gesture and demonstrated the lateral faces of the cylinder as shown in Figure 4. She said:

Virginia: Because basically the same reason as the triangular one (triangular prism). If you place a figure on the top and the bottom, and you connect them, you would create a cylinder (Figure 4), which is basically just a 3–dimensional flat version.

**Figure 4: Virginia’s objectwise–dynamic gesture for denoting the lateral faces of a cylinder**

Students’ gestural signs resulted in using the *Segment* tool of Cabri 3D. On the one hand, some students connected pre–image and image points using the *Segment* tool to demonstrate their thinking (e.g., Figure 5). On the other hand, with the prompt of the teacher, some students used the *Segment* tool and connected pre–image and image points to demonstrate the 3–dimensional objects.

**Figure 5. Vince connects pre–image and image points**

During the whole-class discussion, the teacher exploited the semiotic potentials of Cabri 3D. For example, he activated the *Trajectory* tool and described the 3–dimensional as a collection of two-dimensional objects (Figure 6). He made a stacking action employing an objectwise–dynamic gesture to demonstrate the extrusion (Figures 6). He said: “continuously, I am adding more and more [triangular cards], right?” and emphasized the continuous motion of stacking the figures on top of each other.

**Figure 6. The teacher activates the Trajectory tool of Cabri 3D and makes a stacking action**

Some students used a metaphor and referred to a real-life object or entity to describe the shape of the 3-dimensional objects for holding the stack of 2-dimensional figures. For example, Vince made a connection between the given artifact and a daily life object with which he was familiar. He used a metaphor and made a pointwise–dynamic gesture to denote a CD container. He posited:

Vince: Like a CD. Do you have like a... It's kind of a thing when you... It's like a plastic you put on CD's and you put a nob to stack all the CD's. It's like that."

We identified objectwise–static gestures during students demonstrated the top and bottom of geometric objects or a cone/rectangular pyramid. On the other hand, students most often employed objectwise/pointwise–dynamic gestures. Their gestures signified the lateral faces or edges of 3-dimensional objects.

The aforementioned strategies were not disjointed from each other. We identified that students (during group work or whole–class discussion) used multiple strategies to support their claims. For example, Sloane and Stan had difficulty naming 3-dimensional objects. The researcher having the role of cultural mediator handed the artifact to them and elicited their thinking about the resultant 3-dimensional object for holding the stack of identical triangular cards. Sloane said:

Sloane: Just imagine there are a bunch of triangles in the middle. And then it'd be like (she makes a gesture as shown in Figure 7). It'd have like a longer length on the outside probably be slanted but I don't know... I don't know. It's kind of like a roof to a house. And, I think it would be like a 3D trapezoid. That's kind of how I see it.

**Figure 7. Sloane makes a pointwise–dynamic gesture to denote a triangular prism**

Sloane thought of the 3-dimensional object as a collection of 2-dimensional figures. Then, she produced a pivot sign making a pointwise–dynamic gesture and connected the vertices of the top and bottom triangles. After her gesture, she used a "roof to a house" metaphor to describe the 3-dimensional object (triangular prism). She had difficulty naming the object and called the resultant object a 3-dimensional trapezoid producing an invented signifier. In her reasoning, Sloane used three strategies: focusing on the collection of figures, connecting pre-image and image figures, and using a metaphor. A pointwise–dynamic gesture was employed during she connected pre-image and image figures.

## Discussion and implications

In the current study, we identified students' strategies for forming 3-dimensional objects from 2-dimensional figures producing gestural signs. Students employed gestures frequently to demonstrate extrusion of objects. Similar to what Bartolini Bussi et al. (1999) found, students made objectwise/pointwise and dynamic/static gestures. Students' gestures linked artifact and mathematical

signs, and were characterized as pivot signs. Similarly, Bartolini Bussi and Baccaglini–Frank (2015) identified gestural signs that linked artifact and mathematical signs. Students' gestural signs were intertwined with other sets of signs such as metaphors. For example, students produced gestural signs and used a metaphor when they had difficulty naming an object. Researchers found that gestures facilitated communication between students and teachers (Bartolini Bussi & Baccaglini–Frank, 2015; Arzarello et al., 2009; Radford, 2009; Radford & Sabena, 2015; Sabena, 2008). Gestures facilitate communication, in particular when students produce an invented signifier (Bartolini Bussi & Baccaglini–Frank, 2015).

Students' strategies for forming 3-dimensional objects were associated with each other. When students reasoned about the extrusion activities, they used multiple strategies and defended their conjectures about the resultant 3-dimensional objects. Students used the *Segment* tool of Cabri 3D and connected pre-image and image points to demonstrate 3-dimensional objects. On the other hand, some students used the *Segment* tool with the prompt of the teacher. Students should be given an opportunity to interact with an artifact in a longer period, so they become more comfortable using it and exploit mathematical knowledge.

In Cabri 3D, when a transformation is made, one can see initial objects/points (pre-image) and transformed points/objects (image). We enabled students to see pre-image and image figures in pre-constructed sketches and hands-on tools. New research may demonstrate how students' approaches may differ if they are not provided pre-image figures to identify 3-dimensional objects using an extrusion method.

We were unable to build hands-on tools in which rectangles/circles decrease in size to demonstrate a rectangular pyramid and cone. Students most often used Cabri 3D and changed the height of objects during semiotic activities. They interpreted artifact signs and produced mathematical signs. However, students most often exploited gestural signs during they used hands-on tools. As Maschietto and Soury-Lavergne (2013) emphasize, counterpart artifacts lead to a co-emerging of signs and using a variety of artifacts that have different semiotic potentials gives students an opportunity for mathematical learning.

# Preservice mathematics teachers' types of mathematical thinking: Use of representations, visual-spatial abilities, and problem solving performances

Beyza Olgun<sup>1</sup> and Engin Ader<sup>2</sup>

<sup>1</sup>Boğaziçi University, Faculty of Education, İstanbul, Turkey; [beyza.olgün@boun.edu.tr](mailto:beyza.olgün@boun.edu.tr)

<sup>2</sup>Boğaziçi University, Faculty of Education, İstanbul, Turkey; [ader@boun.edu.tr](mailto:ader@boun.edu.tr)

*The main purpose of this study was to examine preservice mathematics teachers' types of mathematical thinking and to investigate whether there are any differences between different types of thinkers based on their problem solving performances, use of representations and visual-spatial abilities. The sample of the study consisted of 113 preservice mathematics teachers in a private and four public universities. The results showed that although problem solving performances were similar for each type of mathematical thinking, preservice teachers who adopted harmonic and geometric types of mathematical thinking preferred to use schematic representations more than analytic thinkers in their problem solving processes. The findings provided an insight about preservice teachers' preferences for a visual approach and the implications of these preferences for teacher education programs were discussed.*

*Keywords: Types of mathematical thinking, use of representations, visual-spatial abilities, word problems.*

## Introduction

Problem solving has an important role in mathematics and lies in the focus of almost every math curriculum (Van De Walle, Karp, & Bay-Williams, 2010). According to the American National Council of Teachers of Mathematics “one of the most significant aims of mathematics teaching and learning is to develop students' problem solving ability” (Deliyianni, Monoyiou, Elia, Georgiou, & Zannettou, 2009, p. 96). Understanding of problem solving process includes identifying, exploring, implementing, and using visual images, which is related with visualization (Deliyianni et al., 2009). With the rise of constructivism, the importance of the role of visualization in the learning process was emphasized more. The role of visualization in mathematical problem solving is investigated through three main constructs. These are mathematical thinking in terms of predisposition of visualization in problem solving, the use of visual-spatial representations and visual-spatial abilities.

Studies on visualization in mathematics often linked it with mathematical thinking. In a problem solving context, three types of mathematical thinking were suggested according to disposition of visualization (Krutetskii, 1976): the analytic type, the harmonic type, and the geometric type. Students who embrace the analytic thinking style do not feel the need to benefit from visual supports and also they do not have enough strength for the use of visual components. For geometric thinkers it is the contrary. They make use of visual-pictorial components and verbal-logical components have poor influence on their reasoning. The reasoning of harmonic thinker students includes both verbal-logical components and visual-pictorial components and their preferences can change according to the problems that they face.

Teachers' mathematical beliefs and learning experiences affect their mathematical thinking and visual approaches (Presmeg & Balderas-Cañas, 2001). Their thinking styles and use of visuality have an impact on their teaching (Presmeg, 1986b). Therefore preservice teachers' approaches towards different types of mathematical thinking and visual-spatial representations could be an important component of teacher education programs. This necessitates a careful study of the interrelations among teachers' visualization, mathematical thinking and problem solving performance before focusing on how these can be supported through teacher education programs.

The main purpose of the study was to investigate preservice teachers' preferences of problem solving strategies and how their mathematical thinking (analytic, harmonic or geometric types) might affect the visualization process in mathematical word problem solving. Considering the purpose, this study aimed to explore whether there is a significant difference in preservice teachers' mathematical word problem solving performance, use of visual-spatial representations (pictorial or schematic), and levels of visual-spatial abilities based on their types of mathematical thinking.

## Method

Participants were selected by convenient sampling. The study was conducted with senior preservice teachers from one private and four state universities in İstanbul and Ankara, Turkey. 113 students were involved in the study and they were enrolled in Primary Mathematics Education ( $n = 91$ ) and Secondary School Mathematics Education ( $n = 32$ ) programs.

The data were collected with the implementation of two instruments; the Mathematical Processing Instrument (MPI) and the Spatial Ability Tests (SAT) during the second semester of the 2015-2016 academic year. The MPI, which was developed by Presmeg (1985) and adapted to Turkish by Taşova (2011), was used to measure participants' types of mathematical thinking, use of visual-spatial representations, and mathematical word problem solving performances. In order to measure preservice teachers' levels of visual-spatial abilities, SAT developed by Ekstrom and colleagues (1976) and adapted to Turkish by Delialioğlu (1996) were used.

The MPI was developed for the first time by Krutetskii (1976) to measure students' preferences of the use of visual methods. Then Suwarsano (1982) designed the instrument with the same name for elementary school students. According to Presmeg (1995), the instrument that was designed by Suwarsono (1982) was not convenient for teachers. Thus she arranged the instrument in three sections according to fieldwork in which both students and teachers participated. With the new arrangement, the instrument took its final form that consists of three sections. In this study, since participants were pre-service teachers, Section B and Section C of the MPI that were designed as appropriate for teachers was used.

The MPI has two parts: a test that consists of 18 mathematical word problems and a questionnaire that includes a list of possible solutions for each problem. According to participants' responses on the test section of MPI, four different scores were generated. These were mathematical word problem solving performance, pictorial representation score, schematic representation score and visual-spatial representation score. The first score was the total number of problems solved correctly. The others were the total number of times that students reported using the specified type of representation. We used van Garderen and Montague (2003)'s coding for the classification of the representations. As shown in Figure 1, if preservice teachers "reported or drew an image of objects

or persons referred to in the problem” (van Garderen & Montague, 2003, p. 248), the representation was scored as primarily pictorial and if they “drew a diagram, showed the spatial relations between objects in a problem, or reported a spatial image of the relations expressed in the problem” (van Garderen & Montague, 2003, p. 248), the representation was scored as primarily schematic. Visual-spatial representation score was the summation of pictorial and schematic representations score.

C-2: If the elapsed time since noon (12:00) is accounted for 1 in 3 of the remaining time to midnight, what time is it now?

a pictorial representation

a schematic representation

**Figure 1: Examples for preservice teachers’ pictorial and schematic representations**

According to participants’ responses on the questionnaire of the MPI, visualizing mathematical scores were generated. In this score, without taking into consideration whether the students solved the problem correctly, if the participant chose only a visual problem solving strategy for a problem, 2 points were given. For the responses that did not include a visual problem solving strategy 0 points were given. For the responses including both visual and nonvisual strategies, 1 point was given. Therefore the possible minimum and maximum scores for preservice mathematical teachers’ visualizing mathematical scores were 0 and 36 respectively. In order to group preservice teachers based on their mathematical thinking, participants’ visualizing mathematical scores were used.

The SAT involves spatial orientation and spatial visualization tests. A person’s SAT score was the summation of his or her spatial orientation test score and spatial visualization test score. A person’s spatial orientation test score was obtained from the Card Rotation Test and the Cube Comparison Test. A person’s spatial visualization test score was obtained from the Paper Folding Test and the Surface Development Test.

## Results

In Table 1, descriptive statistics results of participants’ scores for mathematical word problem solving performance, use of representations, and the SAT are presented.

Participants’ Scores	Range	Mean	Std. Deviation
Mathematical Word Problem Solving Performance	7 - 18	14.89	2.28
Schematic Representations Score	2 - 19	8.07	3.23
Pictorial Representations Score	0 - 3	.95	.90
Visual-Spatial Representations Score	2 - 20	9.02	3.29
Visualizing Mathematical Score	5 - 28	13.97	4.73
The SAT Scores	81 - 260	172.80	48.22

**Table 1: Descriptive statistics results for the variables**

In particular, the participants used totally 1047 visual-spatial representations, of which 925 were schematic and 122 were pictorial. Although all participants used schematic representations in their problem solving processes, pictorial representations were rarely used by preservice teachers. The

results also showed that especially for five specific problems, participants did not prefer a visual method for the solutions.

### **Preservice teachers' types of mathematical thinking**

In the literature, there were different methods suggested for the classification of analytic, harmonic and geometric thinking. For example Richardson (1977) determined the groups according to percentages as the first 15% segment of the distribution was analytic type, the last 15% segment of the distribution was geometric type, and others were harmonic type. Galindo-Morales (1994) determined the groups according to prearranged visualizing mathematical scores. Such as who had 22 points and above was a geometric thinker. In Taşova (2011)'s study, the range of visualizing mathematical scores was divided into three equal intervals. However, data from this study necessitated considerations upon the classification method. Results showed that for 5 specific problems preservice teachers did not tend to use any representations and also they did not select a visual solution in the questionnaire section. A participant with a visualizing mathematical score of 18, which is half of the maximum score, preferred a visual method in at least 9 of the remaining 13 problems. Under these circumstances, such a participant who preferred visual methods over nonvisual methods in approximately 70% of the remaining problems needed to be classified as a geometric thinker.

Due to the considerations mentioned in the previous paragraph, a new approach was adopted for the classification of types of mathematical thinking. The mean visualizing mathematical score was used while deciding on the center of the interval for the harmonic type and the intervals for all three types were found by taking the standard deviation of the scores into consideration. The minimum and maximum scores of the type of harmonic thinking were assigned by the half of the standard deviation of the preservice teachers' visualizing mathematical score around its mean. According to this classification, the number of people grouped for each type of mathematical thinking was 34 (30%) for the analytic type, 48 (43%) for the harmonic type and 31 (27%) for the geometric type.

### **Investigation of group differences**

A Kruskal-Wallis H test was run to determine whether there were any differences in mathematical word problem solving performance between three groups of preservice teachers having different types of mathematical thinking. The results revealed that the distributions of mathematical word problem solving performance scores for each group with different types of mathematical thinking were similar. The medians of mathematical word problem solving scores were not significantly different among the analytic type (mean rank = 15.5), the harmonic type (mean rank = 15), and the geometric type (mean rank = 15),  $\chi^2(2) = 14.468$ ,  $p = .24$ .

In order to determine whether there were any differences in the use of schematic, pictorial, and visual-spatial representations between three groups for types of mathematical thinking a Kruskal-Wallis H test was run. The results revealed that mean ranks of schematic representation scores and visual-spatial representation scores were significantly different between the groups. As a result of post hoc analysis, it was discovered there were statistically significant differences in preservice teachers' schematic representation scores and visual-spatial representation scores between the analytic type (mean rank = 6) and the harmonic type (mean rank = 8) ( $p = .01$ ) and the analytic type and the geometric type (mean rank = 9) ( $p = .01$ ). On the other hand, there were no significant

differences in schematic representation scores and visual-spatial representation scores between the geometric type and the harmonic type ( $p > .05$ ). The results revealed that mean ranks of pictorial representation scores between the analytic type (mean rank = .5), the harmonic type (mean rank = 1), and the geometric type (mean rank = 1) were not significantly different, ( $\chi^2(2) = 2.281, p = .32$ ).

One-way ANOVA test was run to investigate any differences between the SAT scores of groups of participants with different types of mathematical thinking. Shapiro-Wilk test was used to determine the normality of the distribution and the results showed participants' SAT scores were normally distributed ( $p > .05$ ). Levene's Test of Homogeneity of Variance was used to investigate the homogeneity of the variances. A homogeneity of variances was discovered ( $p > .05$ ). However, the SAT scores from the three groups, the analytic type ( $M = 161.83, SD = 50.1$ ), geometric type ( $M = 179.02, SD = 43.62$ ) and harmonic type ( $M = 174.57, SD = 45.57$ ) did not differ significantly ( $F(2, 97) = 1.233, p = .30$ ).

## Discussion

In this section, a discussion of the group differences among types of mathematical thinking according to mathematical word problem solving performance, the use of visual-spatial representations, and levels of visual-spatial abilities is presented.

### The structure of mathematical thinking adopted by preservice teachers

The findings showed that 30% of the preservice teachers were analytic type, 43% of preservice teachers were harmonic type, and 27% of preservice teachers were geometric type. The slightly high proportion of the trend for the harmonic type was consistent with the literature. Hacıömeroğlu and Hacıömeroğlu (2013) found that most of preservice teachers adopted the harmonic type of mathematical thinking. Taşova's findings (2011) supported that the harmonic type of thinking was the most commonly adopted by preservice teachers whereas the least percent of the preservice teachers were geometric thinkers. In the current study, these differences were not clearly seen and the classification method could be the reason for it. Hacıömeroğlu and Hacıömeroğlu (2013) found that senior preservice teachers used visual methods more than juniors. Therefore they related this difference with seniors' experiences through teaching mathematics and practicum courses. Since participants of the current study were also seniors and the data collection was done close to end of the second term, their final year experiences may have had an impact on their preferences.

### Mathematical word problem solving performance according to types of mathematical thinking

Results showed that there was no significant difference among groups with analytic, harmonic, and geometric types of mathematical thinking in terms of problem solving performance. While the findings were supported by some studies (Kolloffel, 2012; Suwarsono, 1982) there were some conflicts in the literature. While Lean and Clements (1981) suggested that the preference had a significant effect on performance and students who preferred nonvisual strategies outperformed visualizers, Moses (1977) claimed that visual solution methods guide college students to more effective solutions. These controversial findings in the literature might be caused by sample selection. The studies applied the same instrument with some adjustments to different groups such as elementary school students, college students, and teachers. The participants' individual

differences like how they were taught, grade level, courses they were enrolled also could be factors influencing this relationship. In terms of performance, Presmeg (1986a, 1986b) suggested that there were internal and external factors, which could make a group superior compared to others. She discussed that textbooks and teachers' teaching styles emphasized nonvisual methods. Therefore this situation could favor for analytic thinkers. It could be also that school exams might constrain students' use of visual methods, which could take more time for solutions (Presmeg, 1986a). However with the educational developments the role of visualization and its importance in problem solving was recognized (Deliyanni et al., 2009). Visual approaches were included in both teacher education programs and curriculums. Therefore preservice teachers could be experienced with both visual and nonvisual approaches during their methods courses and school practices. These experiences through university life may reduce the influence of these internal or external factors on performance.

### **Use of visual-spatial representations according to types of mathematical thinking**

The results showed significant differences in the use of schematic representations and visual-spatial representations among groups with different types of mathematical thinking while no difference was found in the use of pictorial representations. Preservice teachers did not tend to use pictorial representations as much as elementary or high school level students did as the previous studies suggested (van Garderen & Montague, 2003). The frequency and the variance of preservice teachers' pictorial representations scores were very low. The rare use of pictorial representations by participants may be one reason for not observing significant differences between the groups.

In the current study harmonic thinkers and geometric thinkers had similar preferences for use of representations in problem solving whereas analytic thinkers were separated from the others by using fewer representations. These findings were different from Sevimli and Delice's study (2011). They found that analytic thinkers and harmonic thinkers had similar preferences for use of representations and their use of representations were significantly less frequent than geometric thinkers. There might be two reasons for the differences in these findings. One of them was the mathematical context of the studies. Sevimli and Delice (2011) carried out their study on a specific topic: definite integrals. They discussed that in calculus courses students were mainly taught nonvisual methods and algebraic expressions. The context of definite integral and how it is taught can lead the students to using algebraic solutions. On the other hand word problems that were used in this study might have promote preservice teachers to use representations in solutions.

The second reason could be that the participants did not express all problem solving procedures in their mind on the paper in the current study. For the context of working on definite integrals, although representations were not preferred by preservice teachers during the problem solving processes, when they used it might be a difficult procedure to operate representations in mind. The context requires specific graphical representations that include complex processes (Sevimli & Delice, 2011) and they could push the preservice teachers for operation on paper. However the representations that were used in solutions of word problems could be formed in mind. They did not have a complex structure as much as graphical representations that used in integral context. Further studies could be conducted for different mathematical contexts. Researchers might prefer interviews in data collection processes to detect representations that people construct in their mind.

## Levels of visual-spatial abilities according to types of mathematical thinking

The findings of the current study did not show statistically significant differences in preservice teachers' visual-spatial abilities in terms of types of mathematical thinking. Taşova (2011) suggested that geometric thinkers were more successful in visual-spatial ability tests than analytic or harmonic thinkers. However he did not run a statistical analysis to compare the groups for types of mathematical thinking in terms of their levels of visual-spatial abilities. There are various other studies that documented no significant relationship between people's visual-spatial abilities and their preferences for visual or nonvisual methods (Hagarty & Kozhevnikov, 1999; Moses, 1977; Lean & Clements, 1981; Suwarsono, 1982). Krutetskii (1976) suggested that there were many other factors, which effects people's preferences like learning experiences. Therefore further studies could investigate such factors beyond focusing only on peoples' visual-spatial abilities.

# Teaching mathematics with multimedia-based representations – what about teachers' competencies?

Julia Ollesch, Fabian Grünig, Tobias Dörfler and Markus Vogel

Heidelberg, University of Education, Germany; [olleschj@ph-heidelberg.de](mailto:olleschj@ph-heidelberg.de);  
[gruenig@ph-heidelberg.de](mailto:gruenig@ph-heidelberg.de); [doerfler@ph-heidelberg.de](mailto:doerfler@ph-heidelberg.de); [vogel@ph-heidelberg.de](mailto:vogel@ph-heidelberg.de);

*Multimedia-based representations play a major role in mathematics and mathematics education. Consequently, they are important with regard to teaching purposes, as they are supposed to be useful to represent mathematical structures and processes in different ways. Within the presented project we developed an instrument by using video-vignettes in order to assess the competencies of mathematics teachers for multimedia use in mathematics lessons. For coping with complexity we reduced the instrument's focus on two facets: cognitive load and mutual supplement of multimedia representations. As the work is still in progress, we here focus on the project's theoretical background as well as on the development of the assessment instrument based on video-vignettes.*

*Keywords: Multimedia-based mathematical representations, technological pedagogical content knowledge, assessing teachers' competencies, video-vignettes, secondary school mathematics.*

## Introduction

Since mathematical objects are conceptual and invisible, the meaning of representations plays a major role in mathematics and mathematics education. The necessity of representations for the fundamental understanding of mathematical concepts has already been postulated by Duval (2006). Therefore, it is of importance that students work with multiple representations of the mathematical content early on. Doing so they can benefit from complementary expressions and viewpoints of the subject matter and are able to improve and deepen their understanding (Ainsworth, 1999). However, as a teacher it is insufficient to simply present multiple representations to the students. It is necessary that the students build and understand the connections between different representations and gain a coherent mental model (Seufert, 2003). Schnotz and Bannert (1999) illustrate the interaction between descriptional and depictional representations in their integrated model of information processing. According to their work, these two different kinds of representations complement each other in a synergetic way to form a mental model of the represented content. With the construction of a mental model through multiple representations, students also gain in cognitive flexibility (Spiro, Coulson, Feltovich, & Anderson, 1988). According to Mayer (1997) students can also achieve better results when learning with multiple representations, however, there is practical as well as empirical evidence that this is not always the case in classroom instruction. A teacher's knowledge about multiple mathematical representations and their kind of use in the classroom can obviously not be neglected.

In this paper we first establish the theoretical background for the use of multiple, dynamically linked representations in mathematics education and the related professional competencies required of teachers in this context. After that we describe the development of a test instrument to assess these competencies from a particular theoretical point of view.

## Theoretical background

Especially multimedia can offer possibilities to develop and implement learning environments containing multiple mathematical representations. When working with multimedia-based representations, mathematics teachers should, among many other things, know the benefits and pitfalls of (dynamically) linking multiple representations while also being aware of the cognitive load generated by them. Therefore a variety of technological knowledge, skills and competencies must be combined with pedagogical knowledge and content knowledge of the subject matter.

### Linking multiple mathematical representations

Computer-applets based on multimedia representations are not only suitable to illustrate both descriptional and depictorial representations (Schnotz & Bannert, 1999) at the same time, but they are also useful to establish a dynamic link between them. That way it is possible to present even more information about the mathematical content than the representations could provide without being linked to each other (Kaput, 1989). The dynamic linking and the mutual supplement of the different representations provide different approaches to the mathematical content, especially because of the automatic translation of effects when changing one representation. Providing different approaches could cause synergetic effects on the construction of coherent knowledge structures (Seufert, 2003). Moreover, the automatic translation between unrelated representations could decrease the cognitive load of the learner and leaves more capacities for the process of understanding (Ainsworth, 1999). Especially in the subject of mathematics, multimedia-based representations are appropriate to demonstrate the character of mathematical processes (Vogel, Girwicz, & Engel, 2007).

However, there are also disadvantages that come along with multimedia-based representations. As much as they can encourage a deeper understanding, they could also lead to misconceptions (Hadjidemetriou & Williams, 2002), if they are misleading with regard to their external arrangement. Likewise too many multiple dynamical representations could cause a heavy extraneous cognitive load, so that the students do not have any capacity for the intended germane load (Chandler & Sweller, 1991). If the extraneous cognitive load gets too heavy, students often tend to split their attention (split-attention-effect) and focus on one form of representation only (Brünken & Leutner, 2001). Hence reducing the extraneous cognitive load is of high importance when using multiple dynamic representations in mathematics teaching.

In his work, Mayer (2009) gives different principles that should be considered in constructing multiple dynamic representations: The coherence principle, for example, states that people learn better when irrelevant material is excluded. Particularly regarding the mutual supplement of multiple representations these principles are a good guideline for constructing effective multimedia-based mathematical learning environments.

### Technological pedagogical content knowledge

Apparently, the profitable use of multimedia-based representations in mathematics lessons is not only a question of mathematics education, but concerns didactics of mathematics and psychology as an interdisciplinary field of multimedia learning. Certainly, teachers first have to decide from a mathematical point of view whether the mathematical content is adequate for the use of multimedia and which aspects of the content should be presented within this use of multimedia. In the second step it is important to implement the mathematical content into a computer-applet with regard to

available pedagogical and psychological insights of multimedia learning. The technological pedagogical content knowledge, that is needed for the profitable use of multimedia-based representations, is an “emerge of knowledge that goes beyond all three ‘core’ components (content knowledge, pedagogical knowledge and technological knowledge)” (Koehler & Mishra, 2009, p. 66) and requires extensive knowledge about all the aspects of multimedia learning. The TPACK-framework (Koehler & Mishra, 2009) extends the taxonomy of Shulman (1986) by adding technology knowledge which results in three new intersections: technological content knowledge, technological pedagogical knowledge and technological pedagogical content knowledge (TPACK).

Accordingly, the complexity of competencies needed to use multimedia-based representations in an effective way in mathematics lessons is high. Beyond their mathematical content knowledge teachers need an extensive knowledge about the media and technology they want to use as well as its chances and difficulties for multimedia learning. Consequently, teachers are confronted with new challenges (Koehler & Mishra, 2009) and need to develop the competencies to identify the chances and difficulties that go hand in hand with the use of multimedia-based representations (Spanhel, 1999). However, according to Koehler and Mishra (2009) many of the teachers do not feel prepared for the use of modern technologies to present these kinds of representations.

### **TPACK in context of multimedia learning in mathematics education**

The internet provides many existing computer-applets which mathematics teachers could use in their lessons (for example see [www.geogebra.org/materials](http://www.geogebra.org/materials)). The question is if a chosen applet supports or prohibits the understanding of mathematical concepts and processes and how to determine its benefit. As far as we know there are no criteria given for evaluating an applet with regard to both mathematical and psychological aspects of multimedia learning. While several studies investigated the effect of multimedia-based representations on learning outcome in general, there is still little known on how to evaluate applets with interdisciplinary criteria of multimedia learning. Also it is little known about the competencies mathematics teachers need for an effective use of multimedia-based representations in their classrooms.

Hence it is the research goal of this study to develop a test instrument to assess competencies regarding the technological pedagogical content knowledge (TPACK, cf. Koehler & Mishra, 2009) and the interdisciplinary aspects of multimedia learning in mathematics education.

### **Assessing mathematics teachers’ competencies in using multimedia-based mathematical representations by video-vignettes**

As functional and geometrical thinking build an essential base for the understanding of mathematics and *elementary functions* as well as *geometry* also play a major role in the German curriculum of secondary schools (Kultusministerkonferenz, 2012) we decided to focus on these two mathematical contents when starting to develop the intended test instrument. These contents deeply involve the understanding of their dynamic aspects (for instance while studying covariance of functions, transformations of geometric figures or whole families of functions or geometric objects), so multimedia-based representations could be an appropriate tool in teaching functional and geometrical thinking. Functional thinking includes mainly three aspects of functions: aspect of assignment, aspect of covariance and view as a whole (cf. Vollrath, 1989). Especially for handling the aspect of covariance dynamic representations are an appropriate tool, because changes in one variable and their

effects can be directly visualized in other representations. Also for acquiring geometrical thinking, multimedia-based representations can be helpful: Geometrical thinking is based on the understanding of geometrical terms and conceptions (Ulfig & Neubrand, 2013). Young children already develop an understanding for geometrical terms, but mostly ignore the similarities (Heinze, 2002). For example they are not able to understand that a square is a special representative of rectangles. With dynamic representations it is possible to illustrate not just one example of a geometrical object, but to construct a whole class of objects by using the dynamic transformation (Kittel, 2009).

On base of our theoretical considerations it is necessary to investigate also psychological aspects beyond the mathematical ones. According to an intensive literature review, we determined eight facets of psychological aspects of multimedia learning as basis for the test instrument: *relation to the content* (e.g. Spanhel, 1999), *efficacy of the use of multimedia* (e.g. Mandl, Gruber, & Renkl, 2002), *limitations of the representations* (e.g. Mandl et al., 2002), *misconceptions* (e.g. Mayer, 2009), *cognitive load* (e.g. Chandler & Sweller, 1991), *individual promotion of the learners* (Wauters, Desmet, & van den Noortgate, 2010), *mutual supplement of multiple representations* (e.g. Mayer, 2009) und *simplifying (mathematical) content* (e.g. Kittel, 2009). Within the development of the test instrument we conducted a multistage expert-rating in order to validate, but also to empirically support a selection of two of these eight facets for purposes of reducing complexity in this first approach. This process will be described more detailed later on.

### **Video-vignettes and their construction**

Since video-vignettes are assumed to be an effective way of measuring teachers' competencies (Blomberg, Stürmer, & Seidel, 2011), we developed, for the time being, a pool of 36 video-vignettes, that show various situations during mathematics lessons using multimedia-based representations. Video-vignettes are short sequences of a classroom situation that show critical problems: to evaluate these situations the observing person needs special competencies (Rehm & Bölsterli, 2014). Figure 1 shows an example of a script for a video-vignette related to the psychological facet *mutual supplement of multiple representations*.

The vignettes are constructed with a closed-ended question type. Multiple statements have to be rated on a scale from one to six according to its appropriateness for the presented situation. An example of statements is shown in Figure 2.

After the development of 36 vignettes, they have been validated in a multistage expert-rating.

### **Validation of the constructed video-vignettes**

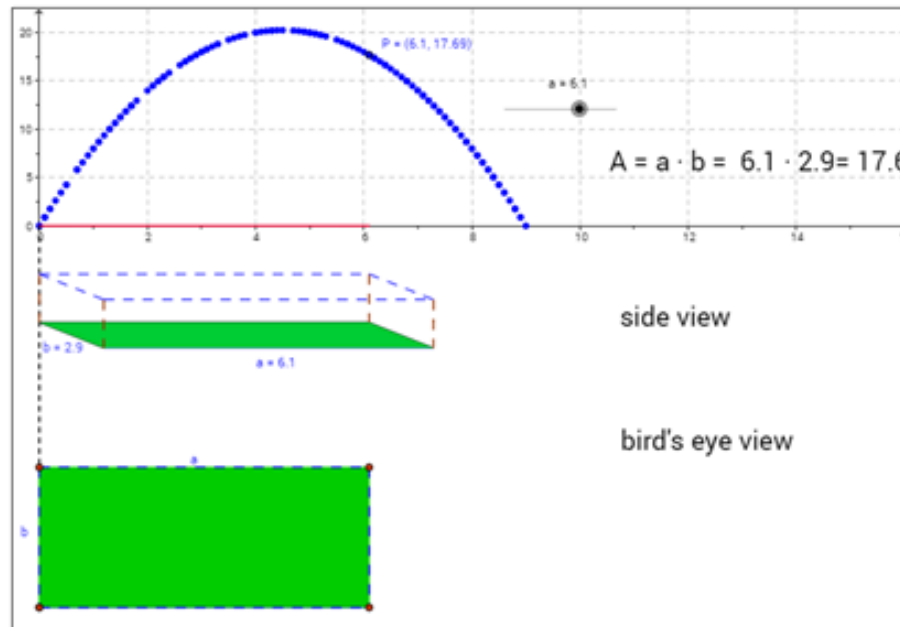

First the constructed vignettes were evaluated by nine experts in a semi-standardized qualitative interview. The aim of these interviews was to assure the relevance and the clarity of the presented situations in the vignettes. Afterwards the vignettes were rated by 104 experts in a quantitative interview. The aim here was to reassure the evaluation of the qualitative interviews as well as to analyze the distribution of the answers on the scale from one to six of each statement. Moreover, the experts could give comments on each of the vignettes. The answers and the comments of the experts from the quantitative rating were analyzed regarding four criteria: *focus regarding the mathematical content of secondary school, distribution of the answers to the statements, relevance for school and clarity of the vignette and comments of the experts*.

In the 10th grade of the Paula-Fürst secondary school Miss Schäfer gives the following computer-applet to her students for working in pairs:

### Area of the enclosure

You got a new rabbit and now you want to build an enclosure for it.  
Your parents give you 18 m of fence for the enclosure.  
How long do the sides have to be so that the rabbit has the most space he could get with this fence?

Pull the slider to see the enclosure and the according function.

[In the background the following conversation can be heard:]

Miss Schäfer: "Is everything alright?"

Can: "No, Timo does not understand that the function displays the area!"

Timo: "Yeah, I do not know why there is a round function while the area is a rectangle!"

**Figure 1: Example of a script for a video-vignette according to the psychological facet mutual supplement of multiple representations**

Based on the multi-stage expert rating and psychometric properties of the instrument we chose the most appropriate vignettes and determined the two psychological facets of multimedia learning *cognitive load* and *mutual supplement of multimedia representations* as the focus for the final test instrument. Cognitive load refers to the trichotomy from Chandler and Sweller (1991): intrinsic cognitive load, extraneous cognitive load and germane cognitive load (cf. section theoretical background). So the aim is to explore if prospective teachers can estimate the cognitive load. The mutual supplement of multimedia representations refers to the interaction between two or more forms of representations of the same issue (cf. section theoretical background; Ainsworth, 1999; Kaput, 1989). Using these interactions between different forms of representations could involve many chances, but also risks. For example, it is important to link the different representations to gain an understanding of coherence (Seufert, 2003). However, as mentioned above different forms of representations could also cause the split-attention-effect (Brünken & Leutner, 2001).

Please evaluate the computer-applet with regard to the (mutual) supplement of the different representations (graph of the function, side view of the enclosure, bird's eye view of the enclosure) from your pedagogical content knowledge point of view.

I do not  
agree at all

**Figure 2: Example of statements for the vignette from Figure 1**

### Assessment

After the reduction of the vignettes as well as the reduction of the psychological facets, we revised and adapted five vignettes for each of the psychological facets as well as six to seven items for each vignette. The formulation of the items was parallelized between the vignettes in order to assure that the important aspects of each of the psychological facets are tested.

These ten vignettes were again validated in a pilot study and as the results were promising, they were used in the final assessment. In this assessment we also included covariates to prove the discriminant validity of the test instrument: pedagogical knowledge and content knowledge. Preliminary results with 261 prospective teachers in Baden-Württemberg already show evidence for the discriminant validity of the test instrument: As expected from the TPACK-framework (Koehler & Mishra, 2009) the test score of the developed vignettes shows a weak correlation with the two constructs *pedagogical knowledge* ( $r = .17, p = .01$ ) and *content knowledge* ( $r = .29, p < .001$ ). Furthermore we could prove expected correlations with the educational progress of the prospective teachers ( $r = .14, p = .03$ ) as well as the number of attended courses addressing the use of computers in mathematics lessons ( $r = .17, p = .03$ ).

### Discussion and outlook

The research goal was to develop a test instrument in order to assess the competencies mathematics secondary teachers need for an effective use of multimedia-based representations in mathematics lessons. Therefore, we considered both mathematical and psychological aspects of multimedia learning and developed a test instrument for the mathematical contents of *functions* and *geometry* as well as for the psychological facets *cognitive load* and *mutual supplement of multiple representations*. With the conducted multistage expert-rating and the preliminary results of the assessment we could confirm the validity of the test instrument.

At the moment, we conduct an assessment with the final test instrument in order to research the development of the previously described competencies during the practical phase of the studies of prospective teachers. Moreover, the test instrument will be complemented with further mathematical content: *algebra* and *stochastics*. At the current stage of the project, new vignettes are developed for these two subjects which will supplement the current test instrument. The new test instrument will

then be able to test a wide range of mathematical content knowledge combined with knowledge about the psychological aspects of multimedia learning.

# Children's drawings for word problems – design of a theory and an analysis tool

Barbara Ott

University of Education, St. Gallen, Switzerland; [barbara.ott@phsg.ch](mailto:barbara.ott@phsg.ch)

*Representations are essential for mathematical understanding. In particular, graphic representations are taught as tools for solving word problems. However, not only do children often have difficulties in using them, but there is also a complete absence of research into whether or not children's own graphic productions actually represent the key mathematical elements of word problems. My project, therefore, focuses on this gap by developing a theoretical model and an analysis tool to categorise and map the drawings. This is based on primary school children's drawings, which have been identified as graphic representations of word problems.*

*Keywords: Graphic representations, visualisation, word problems, analysis tool, elementary school students.*

## Introduction

For doing mathematics, the use of external representations is essential. Without them it is virtually impossible to discuss or gain insight into mathematical problems (Dörfler, 2008; Hoffmann, 2005). In external representations mathematical patterns may be apparent and can be analysed. They are also important in the mathematical learning process. Bruner (1966) explains the power of external representations for learning “as its capacity, in the hands of a learner, to connect matters that, on the surface, seem quite separate” (p. 48). Accordingly, representation is quoted as a process standard in several standards and curricula (e.g. NCTM, 2000).

Within a range of external representations, graphic representations allow certain aspects of space to be mapped onto specific elements of content (Stern, Aprea & Ebner, 2003). They can be defined as a “data structure in which information is indexed by two-dimensional location” (Larkin & Simon, 1987, p. 68). Every element of a graphic representation contains information not only to do with its own location, but also nearby elements. Graphic representations, therefore, constitute a key tool for problem solving (Polya, 1967).

Nevertheless, it is often reported that children have difficulties in using graphic representations as a tool for problem solving (Fagnant & Vlassis, 2013; van Essen & Hamaker, 1990). In some studies, it is shown that the use of graphic representations can be trained (e.g. Fagnant & Vlassis, 2013; Diezmann, 2002). However, there is a lack of research into the actual extent to which children's individual drawings represent key mathematical aspects of a given word problem. This study (Ott, 2016) aims to make a contribution to this gap.

## Research interest

This research focuses on self-generated children's drawings for word problems. It addresses the main question as to what extent these drawings represent the mathematical structure of the word problem. More specifically, two research questions are defined:

- 1) Which features are key in drawings for word problems?
- 2) How do they manifest themselves in children's drawings for word problems?

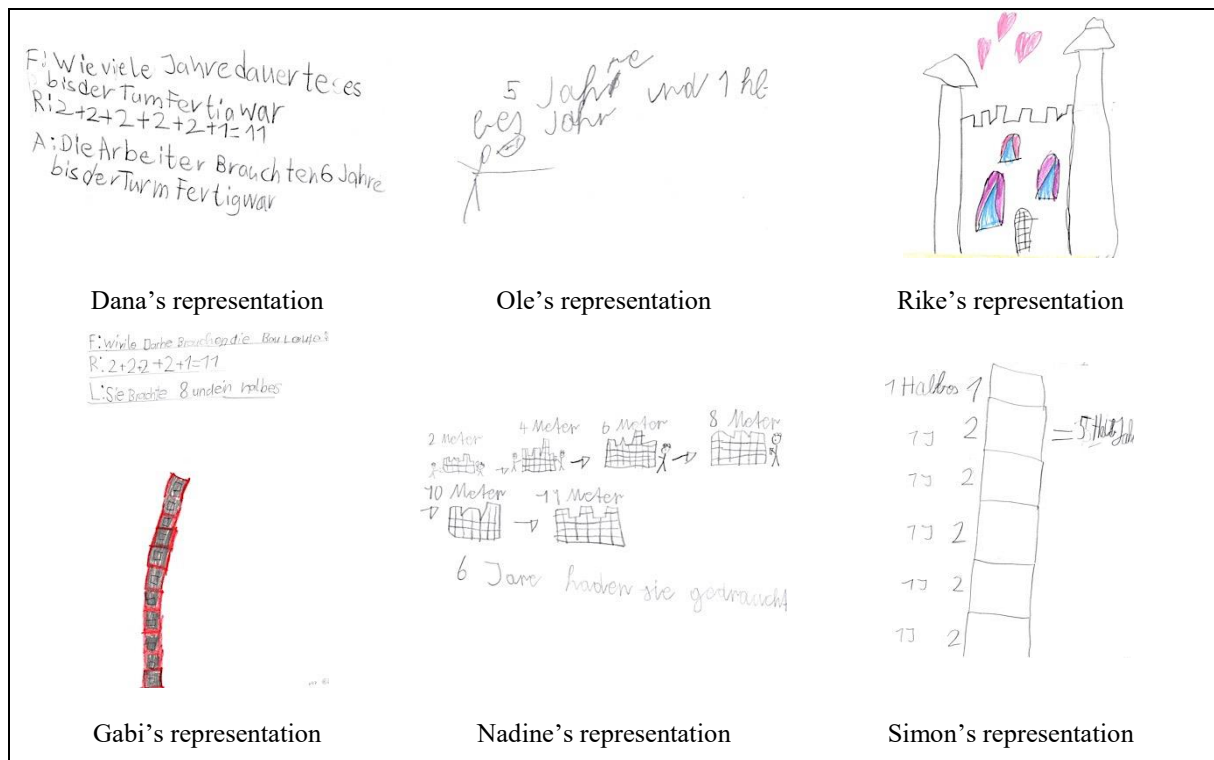

Finally, the study aims to design an analysis tool for children's word problem drawings, based on theory and split into various categories.

## Methods

### Data collection

A paper and pencil test was given to two first grade and two second grade classes in two German primary schools. 42 first graders and 35 second graders participated in the test. The average age of the first graders was 6 years and 4 months, whilst the average age of the second graders was 7 years. By pure chance, there were 35 girls and 42 boys.

The test was conducted at the end of the school year's first half. At that time, the first and second graders could solve addition and subtraction tasks in the number ranges up to 20 and 100 respectively. The first graders had experience in drawings for equations and finding equations to match drawings. Students of one second grade class (N=19) had additional experience in drawing sketches for word problems.

**Figure 1: Children's drawings for the tower-item (Ott, 2016)**

The test consisted of six word problems based on schoolbook tasks. The level of difficulty differed, in accordance with how much the verbal texts implicitly suggested objects and hence ways of drawing (Ott, 2015, 2016). Testing took place on two successive days, three test items a day. The instructor read the items out aloud to the students, who were then requested to draw their thoughts on a plain sheet of paper, so as to be understood afterwards by the instructor. Figure 1 shows six examples of children's drawings for the following word problem: *Once upon a time there was a king who wanted to have a tower of 11 meters in height. The tower was built over the course of several years. Every year, the workers built 2 meters. How long did it take for the tower to be built?*

## Analysis

The children's 438 individual depictions from the test have been used both to develop a theory of drawings for word problems and also an analysis tool, based on various categories. To this end, the drawings have been analysed via a combination of qualitative content analysis (Mayring, 2010) and theoretical coding (Strauss & Corbin, 1996). Developing a theory and the design of an analysis tool took place simultaneously in an iterative process according to representation theories.

## Results

The analysis of the children's drawings revealed as key either for a draft of a theory or an analysis tool the following three features: The *mathematical structure*, the *mathematical matching* and the *degree of abstraction*. In analysing the drawings, it is important to differentiate between these features, details of which are presented below.

### Mathematical structure

#### Theory

A *mathematical structure* may be defined by set theory: An amorphous set is structured by defining relations and operations between its elements (Rinkens, 1973). This definition is used to identify both the mathematical structure of word problems and also of graphic representations.

Word problems are verbal descriptions of situations with a focus on mathematical relations (Veschaffel, Greer & de Corte, 2000). They can be characterised as “descriptive” (Schnotz, 2014, p. 47) representations. Information is presented sequentially with the quantities and nouns being related to each other by verbs and prepositions. Thus, structural information is integrated into the text and the word problem is thus given a mathematical structure. Accordingly, the verbs and prepositions serve as relational symbols (Schnotz, 2014, p. 47), without which the quantities and nouns would be unrelated – this applies equally to the elements of an amorphous set. Because of the verbal construction with verbs and prepositions as relational symbols, a relationship between the quantities will be defined. Consequently, a structure is given to the quantities and nouns. In the word problem presented here, the quantities and nouns “tower”, “11 meters”, “year(s)” and “2 meters” are related by the verbs and prepositions “of”, “built” and the adverbial phrase “every year”.

For a sound graphic representation, it is necessary to identify key objects in the text, e.g. quantities, objects or people mentioned, that are relevant and necessary for the mathematical structure. To achieve this, structurally relevant objects signs (Peirce, 1965) need to be invented, which can be regarded not only as physically analogous to the objects but also symbolic. Graphic representations can be characterised as “depictional” (Schnotz, 2014, p. 47). Compared with word problems, graphic representations do not include relational symbols. Indeed, a structure is given to the signs for structurally relevant objects by mapping them to certain aspects of space. To this end, the signs for structurally relevant objects have to be set out on the sheet in such a way that the arrangement represents the word problem's verbally described relationships. Such graphic representations have the character of diagrams (Dörfler, 2006). For instance, in Simon's graphic representation (Figure 1) the signs for structurally relevant objects “1J”, “1 Halbes”, “2”, “1” and the rectangles are arranged in vertical columns side by side.

#### Analysis tool

Six categories of how the mathematical structure appears in children's drawings for word problems are identified: A representation is

- *non-graphic* if it consists only of calculations or texts;
- *off the text* if it possesses graphic elements, but there is no link to the text with regard to the content;
- *illustrative* if it possesses graphic elements with a link to the text but no structurally relevant objects are represented;
- *object-related* if it possesses graphic elements with a link to the text and structurally relevant objects are represented although relations between them are not identifiable in the arrangement;
- *implicitly diagrammatic* if it possesses graphic elements with a link to the text, structurally relevant objects are represented and relations between them are identifiable in the arrangement; the relations are not explicitly emphasised;
- *explicitly diagrammatic* if it possesses graphic elements with a link to the text, structurally relevant objects are represented and relations between them are identifiable in the arrangement; the relations are explicitly emphasised.

**Figure 2: Analysis tool for the mathematical structure**

In contrast to text analysis, such as the qualitative content analysis (Mayring 2010), it is impossible to analyse units step by step in a drawing. The analysis tool introduced here, therefore, arranges the categories in a decision tree guided by key questions, which lead to category definitions. The categorisation of a child's drawing takes place step by step in a strictly dichotomous procedure. Only if a question has to be answered with 'no', will the drawing be classified into the associated category. As long as questions can be answered with 'yes', the categorisation process is not yet finished. This way, each of the children's drawings can be clearly categorised. In Figure 2 we can see the decision tree.

We will now categorise the children's drawings shown in Figure 1. Dana's solution is an example of a *non-graphic* representation. It consists of text and a calculation but no graphic elements. Ole's

drawing is an example of a representation that is *off the text*. A stick figure with a speech bubble is drawn, which contains the answer. The drawing contains no link to the problem's content. In contrast, Rike's graphic representation with a castle and hearts contains a link to the text, because a tower as part of a castle is drawn. Gabi's representation of a tower also comprises graphic elements with a link to the text. The tower is subdivided into 11 rectangles, which could represent the 11 meters that are structurally relevant objects. Relations are not identifiable in this representation and hence it is an example of an *object-related* representation. Nadine and Simon's representations are both graphic with links to the text and structurally relevant objects, e.g. the tower. Nadine's representation is a sequence of pictures. In each picture, one can see the height of the tower in a given year. Thus, the relations between the meters and the years are identifiable and the representation is, therefore, diagrammatic. The relation is not explicitly emphasised and the representation is, therefore, an example of an *implicitly diagrammatic* representation. In Simon's drawing, the height of every tower section is shown in one tower only. Next to every section of the tower, one can find the years necessary for the work to be completed. Thus, the relation between meters and years is not only apparent but also emphasised and it is, therefore, an example of an *explicitly diagrammatic* representation.

## Mathematical matching

### Theory

In a representational system (Palmer, 1978) the correspondences between the represented and the representing "world" (p. 262) are important. In regard to the mathematical structure, this idea is used to define how a word problem is matched with a graphic representation. If there is a match, they are "informationally equivalent" (Palmer, 1978, p. 270).

We call a relation of text and drawing a *mathematical matching* if the word problem and the graphic representation are informationally equivalent on both object and relational levels. Accordingly, if there is a match between the quantities and nouns on the text side and the signs for the structurally relevant objects on the graphic side (object level), and if there is a match between the verbs and prepositions on the text side and the arrangement of the signs for the structurally relevant objects on the graphic side (relational level), then there exists a complete matching between the word problem and the graphic representation.

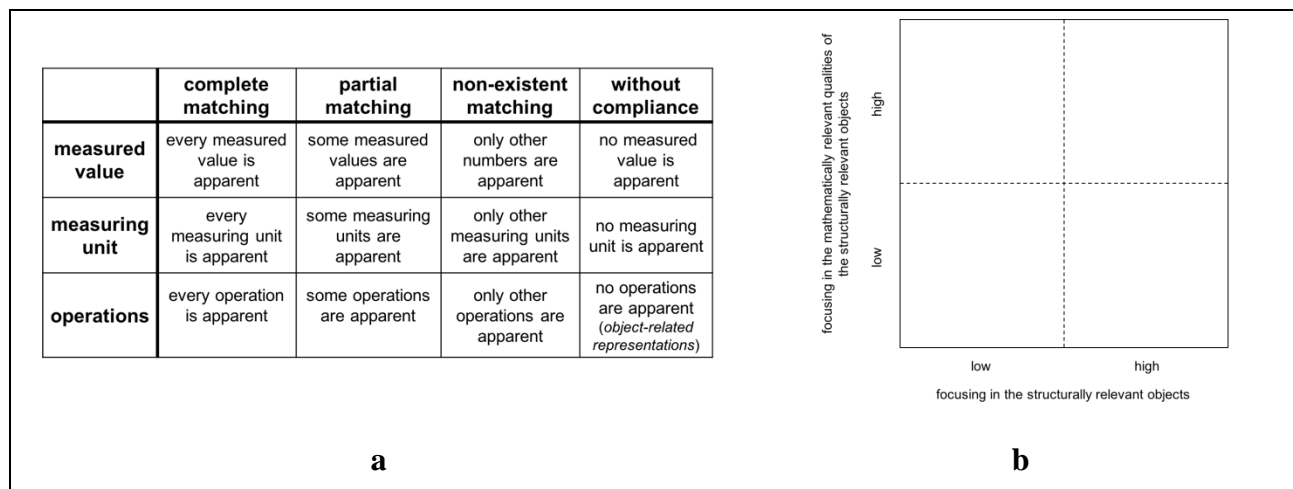

### Analysis tool

The matching between word problems and graphic representations is analysed with regard to the mathematical structure. Only *object-related*, *implicitly* or *explicitly diagrammatic* representations are, therefore, analysed (see above). Representations of the other categories do not contain elements of a mathematical structure and accordingly there is no matching between them and the word problem.

For analysing the match between the quantities and signs for structurally relevant objects, it is useful to distinguish between the measured value and the measuring unit. Numbers can also be considered as discrete quantities (Müller & Wittmann, 1984). For analysing the match between verbs and prepositions and the arrangement of signs for structurally relevant objects, we have to consider the operations of the word problems.

The variation of match between graphic representations and word problems with regard to the *measured value*, the *measuring unit* and the *operations* can be scaled (Mayring, 2010). The match can be *complete*, *partial* or *non-existent*. If it is non-existent, the quantities or operations graphically represented are other than those given in the word problem, e.g. an addition instead of a multiplication. It is also possible, that the quantities and operations are not apparent in the graphic representation. They are *without compliance*. In the analysis tool the possibilities are arranged in a 3x4 matrix, where each matching can be marked with a cross. Arithmetically, 64 combinations are possible (see Figure 3a).

In Simon's representation (see Figure 1), measured values (11 and 2) are apparent as well as measuring units (meters and years) and the operations (addition of meters and years, meters per year). In Nadine's drawing each measured value and operation are also apparent. With regard to the measuring units, only meters are identifiable. In Gabi's representation the operations are without compliance. With regard to the measured values, only the 11 is apparent. So far as measuring units are concerned, only the meters are identifiable in the squares.

**Figure 3: Analysis tool for the a) mathematical matching, b) degree of abstraction**

## Degree of abstraction

### Theory

Children's drawings for word problems are realistic to a greater or lesser extent. For analysing this, the idea of abstraction is used, which can be defined as a focusing of attention on certain aspects (Peschek, 1988). This idea is used to define the *degree of abstraction*.

We characterise the *degree of abstraction* in a graphic representation as being the degree of focusing on representation of the word problem's mathematical aspects (Ott, 2015). The foundations for the mathematical structure of a graphic representation are the structurally relevant objects (see above), that are important in defining the degree of abstraction, for which two indicators are identified:

- 1) Focus on the structurally relevant objects in the graphic representation - no objects other than the structurally relevant objects are drawn.
- 2) Focus on the mathematically relevant qualities of the structurally relevant objects - the signs for structurally relevant objects are not decorated and represent only the mathematically relevant qualities.

### Analysis tool

Given that the degree of abstraction becomes apparent when focusing on the structurally relevant objects and their mathematically relevant qualities, only *object-related*, *implicitly* or *explicitly diagrammatic* representations are analysed (see above). Representations of the other categories do not contain structurally relevant objects and they are in themselves, therefore, not abstract.

Both of the indicators for the degree of abstraction can be pronounced ‘low’ or ‘high’. Consequentially, it is possible to distinguish four categories for the degree of abstraction: *High-high* or *low-low* if each indicator is identified as high or low respectively, and *high-low* or *low-high* if one indicator is identified as low and the other as high. In the analysis tool the possibilities are arranged in a 2x2 matrix (Figure 3b). Both indicators have to be regarded separately in analysing a child’s drawing, which is then classified in the category that fits both results.

In Simon’s representation (Figure 1) the focus on both structurally relevant objects and their mathematically relevant qualities are high, contrary to Nadine’s representation. Here, signs for other objects are drawn such as people and the tower decorated with battlements as a structurally relevant object. In Gabi’s representation, the focus on the structurally relevant objects is high, because only the floors of the tower are drawn, which are decorated with colour and squares.

### Conclusion

This study has focused on the main question of the extent to which children’s drawings for word problems represent the actual mathematical structure. For this purpose, the *mathematical structure*, the *mathematical matching* and the *degree of abstraction* have been identified as substantial features of such graphic representations. Children’s drawings for word problems vary greatly in the way they are depicted. In the analysis tool, the extent of the substantial features’ occurrence in children’s drawings has been modelled, so that each drawing can be clearly categorised. The analysis tool has been tested with an inter-rater reliability of  $K=0.81$ . It could, therefore, be applied in further research. In the second part of the research presented here it has been used in an intervention study looking at graphic representations of word problems (Ott, 2016).

# How the representations take on a key role in an inclusive educational sequence concerning fraction

Elisabetta Robotti

Università degli Studi di Torino, Dipartimento di Filosofia e Scienze dell'Educazione, Italy;  
[elisabetta.robotti@unito.it](mailto:elisabetta.robotti@unito.it)

*The design analysis of an inclusive educational sequence concerning the teaching and learning of fractions (Robotti, et al., 2015) is the focus of this work. Referring to the principles of Universal Design for Learning, developed by the Centre for Applied Special Technology to reduce barriers in learning, we analyse the design of the educational sequence focussing on fractions and devoted to classes where students with certifications of mathematical learning disabilities (MLD) were present. From the point of view of mathematics education, we refer to the theory of semiotic mediation (Bartolini-Bussi, Mariotti, 1998) in order to clarify the cognitive role of artefacts taken into account in class activities. In particular, the use of artefacts to solve tasks produces representations that contribute to develop of mathematical meanings aimed in the teaching activity.*

*Keywords: Mathematical learning disabilities, Universal Design for Learning, fraction, number line, artefact.*

## Introduction and conceptual framework

The focus of this paper is the analysis of an inclusive educational sequence concerning the teaching and learning of fractions already described in detail in CERME9 (Robotti, et al., 2015). In the paper presented in CERME9 we discussed how, in the context of Semiotic Mediation (Bartolini, Mariotti, 2008), the choice of particular artifacts and the design of tasks related to their use, allowed students to grasp different meanings of fraction. Now, I would like to discuss why that educational sequence was "inclusive" for learners with certifications of mathematical learning disabilities (MLD) or difficulties in math or with low achievement in math. To this aim, I will refer to the theoretical framework of Universal Design for Learning (UDL) and I will analyse how the design of the activities follows the guidelines and principles of UDL in order to reduce barriers in learning. Therefore, the rationale for referring both theoretical frameworks is to consider learning difficulties in a context of math education: if the Semiotic Mediation framework allowed us to design a structured educational sequence for teaching and learning different of meanings of fraction (for this, see CERME9 proceedings), the UDL framework, allowed us to design and analyse those tasks in order to be inclusive for MLD students, students with difficulties or with low achievements. Even if there isn't consensus on definition and identification of MLD students (Karagiannakis, et al., 2014) and the inclusivity (Ianes, 2006) is not a construct used consistently across different fields (education, society...) or in different countries, in this research work, we considered as "inclusive educational activities" the educational activities, developed in the context of the class, which face to the special needs of MLD students including dyscalculic students, students with difficulties in math and students with low achievement in math. In other words, according to the UDL framework, we consider "inclusive educational activities" those that meet the needs of all students of the class. UDL is based on a set of principles and guidelines that have been elaborated to increase access to curriculum for all the students, including those with disabilities. These principles and guidelines have a general valence and they are devoted to various application contexts. In this paper we refer to the context of math

education. At the core of UDL is the belief that there are three networks in our brain that support learning: (i) The Knowledge/Recognition Networks, which are involved in identifying and interpreting sound, light, taste, smell, and touch. They are essential to learning because students are expected to comprehend a text, interpret formulas, identify cause/effect relationships, etc. UDL states that it is possible to support the knowledge/recognition networks providing Multiple Means of Representation (1° principle) to give learners various ways of acquiring information and knowledge. This principle has three supporting guidelines: provide options for Perception; provide options for Language, Mathematical expression, and symbols; provide options for Comprehension; (ii) The Strategic Networks, which are involved in planning, executing, and monitoring actions and skills. In learning, they occur, for example, to solve a problem, use an artefact, take notes and listen to a lecture. UDL states that it is possible to support the Strategic networks providing Multiple Means of Action and Expression (2° principle) to give learners alternatives for demonstrating what they know. This principle has three supporting guidelines: provide options for Physical action; provide options for Expressive skills and fluency; provide options for Executive function; (iii) The Affective Networks, which are responsible for establishing priorities and interests. UDL states that it is possible to support the Affective networks providing Multiple Means of Engagements (3° principle) to stimulate interest and motivation for learning. This principle has three supporting guidelines: provide options for Physical action Recruiting interest; provide options for Physical action Sustaining effort and persistence; provide options for Physical action Self-regulation. According to UDL frameworks, representations seem to be “the ways [to] perceive and comprehend information”, produced by visual or auditory means, or contained in a printed text. Therefore, UDL considers representations as signs of different nature (visual, auditory, kinaesthetic...) produced by different means (or artefacts). In the Theory of Semiotic Mediation, Bartolini and Martiotti state that: “[...] any representation comes to life because of a human construction that makes it possible, in other words any representation is supported by an artefact” (Bartolini, Mariotti, 2008, p. 747). Even if the difficulty in articulating an accurate definition for the term “representation” is recognized in math education, we want to stress that, in his theoretical framework Duval states the importance of connections both within and amongst different representational registers as absolutely fundamental to deep understanding of mathematics (Duval, 1999). According to this, Arcavi (2003) stresses the essential role of visual representations in the learning of mathematics and he defines “visualization, as both the product and the process of creation, interpretation and reflection upon pictures and images, ...” (Arcavi, 2003, p. 215). Visualization, visual representations and more general representations were taken into account in our analysis presented in CERME 9 discussion. As described in that analysis, the teaching of the notion of fraction is a quite delicate issue, which requires insightful ways of structuring didactical activities. In that occasion, we stressed how the importance of spatial processes, performed on the base of spatial skills, can be important in mathematical performances where explicit or implicit visualization is required, as in the case of learning of fractions. Therefore, the visual non-verbal, the kinaesthetic-tactile and the auditory channels were considered as preferential for designing inclusive educational activities concerning fractions. Finally, Goldin (1992) outlined a unified model for the psychology of mathematics learning, which incorporated cognitive and affective attributes of visualization as essential components in systems of representation in mathematical problem solving processes. From the above considerations, we can observe that, even in the domain of math education, the aspects related to multiple means of representations and their relations, multiple means of action and

expression and multiple means of engagement are taken into account. For this reason, we use the three principles of UDL to analyse the design of an educational sequence about fractions whose purpose was to be inclusive (in the UDL sense), that is to say, to meet the needs of all learners of the classes, even MLD students. Moreover, we will adopt the framework of Semiotic Mediation to analyse the role of the artefacts in the educational sequence in order to reach the aimed educational goals. More in detail, we will show how the design of the different tasks, requiring actions on artefacts, can be interpreted through the three principles of the UDL to analyse the efficacy both of construction of meanings for the notion of fraction and of inclusion for MLD students.

### **An example of inclusive educational sequence**

I will briefly recall the main activities characterising the educational sequence concerning fractions, described in details in TWG13 of CERME 9 (Robotti & al., 2015), which was carried out in 22 classes (nine 5th grade classes, six 4th grade classes, and seven 3rd grade classes) involving around 400 students, of which 20 were certified MLD students (Robotti & al., 2016): (1) Partitioning of the A4 sheet of paper (named “placemat”). (2) Partitioning of a strip of squared paper: given a certain unit of measure (number of squares) on the strip, position a fraction on that strip ( $1/2$  or  $1/3$  or  $1/4$ , ....); given different units of measure on different strips, on each strip a same fraction is represented ( $1/2$ ); chosen an appropriate unit of measure on the strip, different fractions are represented on that strip (e.g.,  $1/3$  and  $1/5$ ). (3) Placing fractions on the number line. (4) Placing coloured tags, labelled with fractions, on a “string on the wall”.

The learning difficulties concerning fractions seem to be due, among other things, to the lack of connection between different meanings of fraction (Charalambous, Pitta-Pantazi, 2005) and to the fact that only some of them are fostered (e.g. the meaning of “part/whole”), (Pantziara, Philippou, 2011). Moreover, some visual representations are favoured (such that of the pizza) even if they could hinder the learning of the different meanings of fraction (Fandiño Pinilla, 2007). The main learning difficulties identified in Italian national assessment (INVALSI tests) are related to: managing the meaning of the “equal” sign (for instance, What does it means obtaining “equal parts” of the whole?); switching from a fraction to the unit that has generated it; managing equivalent fractions; ordering fractions on a straight-line even without transform them to decimal numbers. In the following, I will discuss how principles and guidelines of UDL can be effectively used to analyse the design of the tasks, which allow overcoming these difficulties. The analysis of actions required by tasks on the artefacts, will show how the educational aims and the aims of inclusion were achieved.

### **The artefact “placemat”**

The “placemat” is a A4 sheet of paper that, at the beginning of the sequence will be in white colour but that, in the following, will be coloured. The mathematical meanings to be mediated by the “placemat” are: 1) construction of fractional units starting from a given unit of measure (the A4 sheet of paper) by folding and cutting out the A4 sheet of paper; 2) equivalence between fractional units, by folding or cutting the fractional units in order to show the equivalence between the surfaces. This allows to overcome the difficulty related to the interpretation of “equal parts of the whole” as “congruent fractional units” instead of “equivalent fractional units” (see above); 3) sum of fractional units in order to obtain the given unit of measure (in this case, the A4 sheet of paper). This can be realized covering the A4 sheet with different fractional units. This allows to come back to the unit of

measure starting from the fractional units. According to Guideline 1 of first Principle of UDL, learning is difficult if information is imperceptible to the learner, or when information is presented in formats that require extra effort for him/her (for example, decoding the text “one half” or decoding arithmetical expressions “ $1/2$ ” for a dyslexic student). To reduce barriers to learning, it is important to ensure that key information are equally perceptible to all learners. For this reason we provided the same information through different modalities (e.g., through the possibility of touching and manipulating the pieces of A4 sheet, through vision of their drawing on the notebook, through hearing or reading an arithmetical expression). In other words, through different forms of representation (Guideline 2, Principle 1). Moreover, the colour, which characterises fractional units later on, plays the role of support to long-term memory for students with learning disabilities or simply students with math impairment. Once the information are made accessible, our educational sequence aims to help students transform them into useable knowledge. As pointed out by the Guideline 3 of the first Principle of UDL, this depends upon “information processing skills” like: selecting useful information, integrating new information with prior knowledge, strategic categorization and active memorization. Individuals differ greatly in their skills in information processing, but effective design of task and presentation of information in accessible ways can provide the scaffolds necessary to ensure that all learners are able to process information. Therefore, we designed educational activities in which students have to act on the artefact, in order to produce representations (for instance, by cutting or folding different pieces of paper referring to the same fractional unit in order to show the equivalence of their surfaces or choosing appropriate fractional units to cover the A4 sheet in order to show that the sum of appropriate fractional units gives the unit of measure 1), and they have to put the obtained representations into relation. Indeed, the actions, performed by students on the artefacts, produce situated signs (representations) through which students, with the help of teacher’s mediation, construct the mathematical meanings aimed for (in that case, equivalent fractions or  $2/8+3/4=1$ ). In order to help students remember the mathematical meanings described, the teacher asks students to: reproduce on the note-book the operations performed with the artefact; write down the content of the class discussions; write texts in which the processes developed in the activity are explicitly linked to knowledge. This allows recalling and using knowledge in the future and it provides options for expression and communication. As a matter of fact, it is well known that there is no medium of expression that is equally suited for all learners and for all kinds of communication. This means that, according to the second Principle of UDL, students with learning disabilities may excel, for example, in interpretation of drawing data (e.g., the drawing of “placemat” covered by different coloured fractional units), but they may falter when asked to read data provided in a table or in arithmetical expression (e.g.  $1 = 2/8+3/4$ ).

### **The artefact “strip of squared paper”**

The strip of squared paper is a strip with squares of 1 cm, 10 cm high and approximately 1 m long. In the strip there are some integer numbers (0, 1, 2, 3, ...) and fractions are constructed. The mathematical meanings mediated by the “strip of squared paper” are: 1) Fraction as operator on a given unit of measure: once a unit of measure is considered, the teacher asks students to place on the strip a given fractional unit and then a given fraction (equal or more than 1); Comparison, by means of a perceptive strategy, of fractional units that should be positioned on different strips of paper; 3) Relationship between a fractional unit and a chosen unit of measure: considering different units of measure on different strips, the teacher asks to place the same fractional unit (for instance,  $1/2$ ) on all

the strips; 4) Ordering fractional units: considering on a strip an appropriate unit of measure (given by the l.m.d. of the denominators), the teacher asks to place different fractional units. This allows students to compare them in a concrete way; 5) Equivalence between fractions: considering on a strip a given unit of measure, the teacher asks to place different fractions. Among them there are some equivalent fractions. We note that some mathematical meanings concerning fraction, such as equivalent fractions or comparison of fractions, are already presented in previous activities with the artefact “placemat”. Once again, the first principle of the UDL is used in this educational sequence providing different means of representation (that is, different artefacts through which representations can be performed). In this activity, the students produce different representations: linguistic signs associated to the name of the fraction expressed in verbal language (“One half”), in verbal visual language (the writing “One half”) and arithmetical language (“ $1/2$ ”). The teacher institutionalizes the relationship between the different signs in terms of rational numbers. Thus, the construction of meaning related to the notion of rational number, is based on both the interplay between different types of semiotic representations, according to the first principle of UDL, and by different actions on artefacts producing those representations, according to the second principle of UDL. Moreover, we note that the colour, perceptive option already provided in the A4 sheet of paper, is used with the same aim also in the activities with strip of squared paper. Thus, the fractional units constructed on the strip are coloured with the same colour of the respective fractional units constructed by A4 sheet of paper. Therefore, the colour assumes the role of a support for memory and also of an artefact, which allows students to link the meaning of fractional unit constructed with the “placemat” (fraction as a *part of a whole*) with the meaning of fractional unit constructed by the strip of paper (fraction as *operator*). Moreover, we have taken into account different strips where different units of measure have been considered and where have been represented a given fractional units. The strips are put one beside the other (proving option for physical actions, as called for by the second principle of UDL) and the relationship between unit of measure and fractional units becomes perceptively evident, reifying Guideline 1 (provide options for perception) of the first principle of the UDL. In order to link the meaning of fraction as part of a whole and as an operator to the meaning of rational number on a number line, we need to switch from the artefact “strip of squared paper” to the artefact “number line”. For this reason, the teacher asks the students to represent, on the *same* strip different fractional units:  $1/8$ ,  $1/6$ ,  $1/4$ ,  $1/3$  and  $1/2$ . Thus, in order to represent all fractional units on the same strip, students need to find a suitable graphic strategy that maintains the colour without superposing different colours on the strip. They adopt coloured notches. Positioning on single strip different fractions makes the ordering of fractions exactly like that of the other perceptively evident numbers. Here the semiotic potential of the artefact “strip of squared paper” associated to the tasks proposed by the teacher becomes evident, playing a key role in fostering identification of fractions as rational number on the number line. I will show this in the following session.

### **The artefact “number line”**

The number line is drawn by students on their note-book. It is a number line of positive numbers starting from the point 0 and it is presented as the natural “crushing” of the paper strip. Therefore, on the number line, students place fractions without transforming them into decimal numbers. The mathematical meanings supported by the “number line” and the tasks proposed are similar to those proposed in activities with the artefact “paper strip”. This allows all students to find continuity both between the artifacts proposed and the construction of the aimed for mathematical meanings.

### The artefact “string” on the wall

The artefact "string on the wall" consists of a string in nylon whose ends are fixed to two adjacent walls of the class (such as a wire for drying clothes). On it, students hang some tags labelled with fractions (in this case, tags are coloured accordingly with the colour used in previous activities) or natural numbers (in this case tags are white). The string simulates the number line starting from zero, which is placed at the left end and the position of the unit is made to vary dynamically sliding the corresponding labelled tag attached with a clothes' peg. In this case, however, the positions of the other tags do not vary dynamically at the same time or automatically as a consequence of the new placement of the unit: their motion requires a specific action in order for the numbers on the line to maintain the desired mathematical relationships. Tags are made so that they can be hung in "clusters" to ensure that tags corresponding to equivalent fractions have the same position on the string. The mathematical meanings supported by the “string” are: 1) Ordering of fractional units or fractions: once the unit of measure has been defined, by positioning the tag labelled with "1", the tags labelled with fractions need to be hung in the correct position; 2) Equivalent fractions: since their tags correspond to the same position on the string, they are hanging as "clusters" and they represent classes of equivalence. Students named them "caterpillars" whose first tag (corresponding to the irreducible fraction) was called "head of the class"; 3) Density of the numerical set  $\mathbb{Q}$ : "enlarging" the unit of measure, that is to say increasing the distance between the tag corresponding to 0 and that corresponding to 1, it is possible to hang on the strip more and more fractions. This operation, repeated many times, allows constructing a mental image connected to the idea of infinity. We note that, when tags on the strip become numerous, one needs to "enlarge" their position to make room for other tags. This action on the string is a situated sign used by the teacher to introduce the idea of density in the set  $\mathbb{Q}$ . Therefore, the representations of fraction on the string (tags labelled with fractions), their position on the string and the action performed on the tags are in line with the first principle of the UDL according to which different forms of representation are needed in order to capture information and transform them into knowledge. The colour of tags, the position of tags on the string, the dynamic position of tag labelled with “1” on the string, recall actions and representations performed in previously activities. Once again, this allows linking different representations and actions to the same mathematical meaning, by supporting long-term memory. According to the principles of the UDL, this contributes to making mathematical meanings accessible to the students.

### Discussion and concluding remarks

The first principle of UDL (Providing Multiple Means of Representation) and the related guidelines provide useful references in order to choose artefacts and define tasks which allow overcoming obstacles and difficulties in understanding some of the different meanings of fractions (*part of a whole*, *measure* and *operator*). In order to provide different means of representation, we considered different artefacts: the “placemat”, the strip of squared paper, the drawing number line and the “string” on the wall for “hanging out” fractions. Each of them allows students to produce different semiotic representations: pieces of paper as fractional units, coloured sections of the strip as fractions or fractional units, points on the number line, coloured tags labelled with fraction hanging on the string. We note that these representations are of different nature: physical, visual or symbolic. Thus, following the Semiotic Mediation Theory, each artefact allows students to produce situated signs (for example, the sign “enlarge” the tags’ position on the string), which will be interpreted as mathematical

signs by the teacher's mediation (in the case above, the sign is used by the teacher to introduce the idea of density in the set  $Q$ ). The aim is to single out mathematical aspects relevant to the activity and make them accessible to all students through representations; this should allow them to use those mathematical aspects in future. To reach this aim, the design of educational activity (presentation of information, choice of the artefact on which students can act, task design in large sense...) is essential to ensure that all learners have access to knowledge. We note that in our educational sequence about fractions, learners construct mathematical meanings (for instance, the meaning of equivalent fractions) acting on different artefacts (A4 sheet, strip of paper, number line and "strip on the wall") and different representations carried out by those artefacts (fractional units of paper, coloured part of the strip, point on the line and coloured tags composing a "caterpillar"). According to the first principle of the UDL, we state that this is not yet sufficient to ensure the construction of the mathematical meaning, that is to say of usable knowledge (for example, the meaning of equivalent fractions). It is necessary that these different representations be put in relation with each other (for example, two equivalent fractions correspond to the same point on the number line or on the "strip" on the wall because they have the same surface extension as a sheet of A4 paper). Moreover, it is necessary that they be always available to learners during the whole teaching sequence. Thus, according to the second principle of the UDL (Providing Multiple Means of Action and Expression), the action performed by students on different artefacts allows to put into relation different representations associated to the same notion (such as, equivalent fraction) or associated to different meaning of fraction (such as "a part of the whole", in the case of placemat, or "fraction as operator", in the case of strip of paper). The third principle of the UDL (Providing multiple means for engagement) supports the engagement of students in the arithmetic activity concerning fractions. It suggests options to challenge all students, appropriately. Designing activity where a "real" situation requiring a solution was the starting point. As a matter of fact, acquiring new information must be received by the student as a necessity to deal with the challenge posed by the activity. Thus, since the narrative aspect is very important in primary school teaching, the work with the "placemat" started with a letter, sent by a pizzaiolo (pizza chef), where he asks students to realize coloured placemats for his restaurant. The need to make placemats according to the pizzaiolo's requests was, for primary school children, a stimulus to take in information and to process them in order to get new knowledge useful for the activity's aim. To create conditions for the students' self regulation and self assessment in the activity we asked students to work in pairs or in small groups and to compare, by the class discussion, the results of work with the other groups.

# Using manipulatives in upper secondary math education – a semiotic analysis

Marit Hvalsøe Schou

Laboratory for Coherent Education and Learning, University of Southern Denmark;  
[maritschou@imada.sdu.dk](mailto:maritschou@imada.sdu.dk)

*The use of manipulatives in upper secondary education is not common, although they hold learning potential in contributing to students' conceptualizing and establishing of relations. In this case study it is investigated how the concept of recursive sequences as a description of growth can be seen in the written reflections from students having engaged in activities with manipulatives like matches and LEGO® and with only minor teacher interference. The analysis of students' answers is carried out by a combination of Radford's Theory of Objectification and Peirce's Theory of Signs. By interpreting the type of signs, the kind of arguing and the nature of the words used by students in various activities involving manipulatives, it is possible to acquire knowledge of the significance of the manipulatives in students' conceptualizing.*

*Keywords: Upper secondary mathematics education, manipulatives, semiotics, conceptualizing, objectification.*

## Introduction

For centuries manipulatives have been used in mathematics education as a pedagogical means for learning at all levels. A visit to the Institute of Mathematics at the University of Göttingen, Germany reveals an entire floor display of manipulatives used in university teaching (Stewart, Mühlhausen, & Miyazaki, 1993). Today the use of manipulatives is still common in primary and lower secondary school as a way of making the teaching concrete and meaningful. On higher levels where deduction and generalisation are important issues, manipulatives are rarely seen and research on their use is scarce (Bartolini & Martignone, 2014). Previous studies show that manipulatives can help students perform algebraic reflections and actions in pattern-generalizing tasks in primary and lower secondary school by joint student-teacher interaction (Radford, 2008). Here it will be investigated how the use of manipulatives can be seen in student reflections on the concept of growth in this upper secondary education.

## Theoretical framework

Generalisation depends on symbolization (Otte, 2006) and many teachers use symbolic representations extensively without connecting them to other representations thereby preventing their students the chance to explore or reflect on these relations (Steinbring, 2005). The use of manipulatives is an alternative way of bringing in abstraction and generalisation in teaching, enhancing the development of mathematical knowledge (Mitchelmore, 2002). In his Theory of Objectification, Radford (2013, p. 26) states: "Learning [...] is the noticing of something that is revealed in the emerging intention projected onto the signs [...] in the course of practical concrete activity [...] and is hence transformed into knowledge."

A semiotic analysis of the representations and the communication about these representations, i.e. the signs the students produce, is used to investigate the mathematical knowledge developed. Each

observation of student work is treated as a *semiotic bundle*, a system of signs produced by a student or a group of students while they solve a problem or discuss a mathematical question. (Arzarello, Paola, Robutti, & Sabena, 2009).

Presmeg et al. (2016) demonstrate the usefulness of Peirce's semiotics in analyzing students' work with representations. Peirce defines:

A sign, or *representamen*, is something, which stands to somebody or something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. That sign which it creates I call the *interpretant* of the first sign. The sign stands for something, its *object*. [Peirce 1965, 2.228, italics in original]

A sign to Peirce thus consists of a triad (representamen – object – sign). Each of these can be interpreted in terms of his categories (of which there are three: “possibility, existence and law”). Here I use in particular two trichotomies: *icon*, *index* and *symbol* referring to how the sign stands for its object, and the *token-type* distinction (omitting *quali-sign*).

An *icon* is a sign that shares a likeness with the object it represents either as an *image*, a *diagram* or a *metaphor*. An *image* has a resemblance or a simple quality in common with the object – a drawing of a real thing; a *diagram* is a sign representing relations, e.g.,  $x^2 + y^2 = r^2$  represents the points of a circle. A *metaphor* represents a parallelism where the character of one sign is expressed in a law-like manner in the other, like when a symptom, fever, of illness is seen as an increased temperature at a thermometer. An *index* is related to the object it represents by either a causal connection or by ‘a purposeful act of connecting the signs’ like using ‘*f*’ as the name of a certain mathematical function. Finally a *symbol* is connected to its object by habit or law, e.g. designating  $\pi$  to refer to the ratio between the circumference and the diameter of a circle.

The *token-type* distinction applies to the sign alone. A *token* refers to the sign itself; consider the letter ‘e’, this letter appears many times – as a *token* – on this page. It is also possible to refer to ‘e’ as a general – as a *type*, stating that ‘e’ appears a particular number of times on this page.

A thorough explanation of Peirce's trichotomies of signs is offered in (Short, 2007) whereas mathematical examples can be found in (Otte, 2006) and (Sáenz-Ludlow & Kadunz, 2015).

The teaching design rests on the Theory of Didactical Situations, TDS (Brousseau, 2006). The epistemological foundation of TDS is that new knowledge is obtained in two steps: first as personal knowledge *connaissance* in working with a given problem and second as formal, scientific knowledge *savoir*, which can be share with and understood by others.

TDS distinguishes between *didactical situations* where the teacher participates, and *a-didactical situations* where students engage in activities on their own. *Devolution*, where the teacher introduces and hands over the problem, *validation* and *institutionalisation*, where the ideas and results are tested and then related to the scientific knowledge of the solution, are all didactical situations. The main focus of this case study is, however, the a-didactical situation where students interact with the *milieu*, which contains the tools that the students have at their disposal (symbolic or material as well as the other students in the group). An important issue in designing the milieu is to ensure that it provides feedback on how the students progress in order to solve the problem.

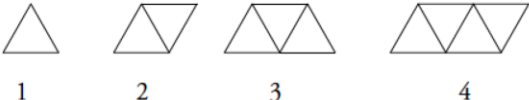

Within this framework the study will try to answer the question: *How does the use of manipulatives in teaching reflect in students' answers about growth, exemplified by recursive sequences?*

## Method

The case study considers one lesson (100 min.) of a ten-week teaching sequence about differential equations in an upper secondary mathematics class with 25 students. The aim of the lesson was to enhance the students' understanding of the concept "growth" using recursive sequences. After a short devolution where the purpose of the lesson, describing the growth of certain patterns, and the milieu containing worksheets and manipulatives like matches and LEGO® were introduced, the students worked in groups of 4 for 60 min. During this period teacher intervention was very sparse. Figure 1 shows an example of an activity/worksheet. As preparation for the validation and institutionalisation the students were asked to share results, ideas and reflections with their fellow group members in a logbook prompted by questions given by the teacher. Part of the logbook writing was done in class and the rest at home using a Google Docs document shared by the group members. The empirical data consists of the logbooks and field notes from classroom observations.

The logbook entries were analysed through a qualitative content analysis (Hsieh & Shannon, 2005) for words indicating the concept of growth, like 'grow' and 'rise' (coded with underscore in the statements). In addition, words referring to the manipulatives (coded in **bold**) were noted.

To describe the patterns and how they evolved, the students introduced a 'sequence of signs'. They explained each sign and how they came on to it, and they used the sign as a starting point for the next sign they introduced. In order to examine the knowledge obtained by the students during the teaching sequence, data was analysed with respect to (1) the type of sign, applying Peirce's categories, (2) how the use of manipulatives show, according to the nature of the marked words, and (3) mathematical reasoning, according to Radford's definition of generalizing patterns (Radford, 2008).

<p>The sequence of figures shown is made of matches. The first is made of 3 matches, the second of 5 matches etc. The sequence can be continued with figure no. 5, 6, 7, 8 ...</p> <div style="text-align: center;">  <div style="display: flex; justify-content: space-around; width: 100%;"> <span>1</span> <span>2</span> <span>3</span> <span>4</span> </div> </div> <p>Build and describe the next figures and tell how many matches you need to build them.</p> <p>Figure no. 2 has been made by adding matches to figure no. 1 <u>in a specific way</u>. Figure no. 2 has been made from no. 3 etc. Explain how you move from one figure to the next in the sequence. Describe the pattern for adding new matches.</p> <p>Explain how this pattern affects the <i>number</i> of matches, you need, to go from one figure to the next in the sequence. That is how can the number of matches in one figure be found from the number of matches in the previous figure?</p> <p>If you want to know how many matches you need to build figure no. 37 it is rather time consuming to build and count the number. Use the pattern you have described above to predict how many matches you need for figure no. 37.</p>
--

**Figure 1: An example of an activity**

## Results

In this section, we will look at two logbook entries and one episode observed in class that show how the use of manipulatives contributes to obtaining knowledge of growth.

Figure 2 shows the first logbook entry on the question: *Choose the pattern from one of the activities and explain how the pattern developed. Use drawings/pictures/symbols describing the growth.*

For a start we observed how the number of **matches** grew. We found that there was a rise on two **matches** in every step. You can almost say that in each step a new triangle is mirrored on to the right side of the **figure**.

Figure no.					
	1	2	3	4	5
No. of <b>matches</b>	3	5	7	9	11
<u>Rise</u> in number	2	2	2	2	2

We decided to make a formula to calculate the numbers of **matches** in figure no. 37. As the number rises with 2 for each figure, 2 is a constant and has to be multiplied by the figure no. But then the number is one too little. Therefore we add another constant in the formula namely +1.

The formula can then be written: The number of **matches** in the figure = the number of **matches** the figure grows with \* figure number + 1.

We also considered other ways of describing the growth after having discussed our results in class. Here we noticed the constant rise with 2. This was the constant change between the earlier and the next figure. Therefore we could write down the relations:

$$T(1) = 3$$

$$T(2) = T(1) + 2$$

$$T(3) = T(2) + 2$$

$$T(4) = T(3) + 2$$

**Figure 2: A logbook entry with marked words**

The semiotic bundle in figure 2 shows how the students, based on the pattern they have built of matches, introduce three signs: a table inclusive a drawing of the pattern, a ‘formula’ written in words and a list of the first four terms of the recursive sequence describing the pattern. On figure 3 one can see how any one sign evolves from a previous sign. The photo on the left shows the pattern build of matches.

**Figure 3: Signs introduced by the first group**

The students begin by describing what they notice in the pattern they have built from matches, and they draw the pattern as the first line in a table. There is no explanation on the rest of the table but

my interpretation is that this is ‘a conditioned reflex’ as the students have made many tables like this with an independent variable (figure no.) and a dependent variable (no. of matches) when working with growth as a continuous function. The table is *iconic*: the previous text indicates that the students partly take it *diagrammatic* as it describes the relation between two subsequent figures. It also works in part as an *image* as the drawn pattern looks like the pattern made of matches.

In the table, the students also state the difference between two subsequent figures and this number is used for producing the next sign, a ‘formula’, from which they can calculate the number of matches in figure no. 37. The students notice that the increase is constant 2, which leads them to the first term of the expression. Using Radford’s definition of pattern generalization (Radford, 2008) we see that they use naïve inductions for producing their formula. Instead of arguing for the y-intercept, they guess and test the value. The formula itself is a partial translation of the previous arguments to a semi-mathematical language. This sign is partly *diagrammatic* stating a relation between the figure number and the number of matches and containing the *symbols* ‘+’ and ‘\*’. It is interesting that the students do not finish the translation to a conventional formula (e.g.  $f(x) = 2 \times x + 1$ ) introducing *indices*  $f$  and  $x$ . Most groups did at this stage. Instead they keep the original *iconical* terms ‘figure no.’ and ‘no. of matches’ closely related to the manipulatives.

Finally, after a validation and institutionalisation where the idea of explaining growth as a recursive sequence was discussed, the students decide to include this view as, not mentioning the important issue, though, that every new term is built on the previous term. They introduce an *index*  $T$  to stand for the number of matches but do not find a general expression using the symbol  $n$  for the figure number like  $T(n) = T(n - 1) + 2$  seen in other logbook entries.

We see that the signs used for representing the object Growth include various kinds of icons as well as indices and symbols. In many of the icons there is a close link to the use of manipulatives i.e. the way the students obtain their ‘data’ and how they explain relations in the pattern. The manipulatives are not clearly visible in their reasoning, though. As a result of the analysis we may conclude that the understanding of growth for this group of students now includes some very concrete conceptions based on activities with manipulatives (matches), and these are pointing towards a more abstract understanding that has not yet been reached. The relations produced indicate that they take the pattern as a *token*. They have not yet reached the stage of considering the pattern as a *type* in order to produce general relations.

In some of the worksheets the use of manipulatives were not explicitly mentioned but replaced by drawings of squares, dots etc. Some groups, though, were using the manipulatives mentally, which in figure 4 is shown as a mixture of the terms ‘squares’/‘LEGO® blocks’ in their explanations.

[...] In other words, the figure consists of a typical **tower** of **LEGO® blocks** where each level is 2 broader than the previous so that one **unit** is sticking out on each side. Therefore the number of extra squares in the figure rises for every figure because the bottom is 2 **squares** bigger every time. You start with  $T(1) = 1$ . That is the first **LEGO® block**. [...]

**Figure 4: Logbook entry showing the use of mentally evoked manipulatives**

The group has not built this pattern physically, but in the context of other activities with manipulatives they use a mental picture made of LEGO®. Figure 5 shows the squares from the worksheet and the mentally evoked manipulatives. Like in the entry in figure 2, the text indicates that the *iconic* sign is partly *diagrammatic* as it describes the relation between two subsequent figures and at the same time works as an *image* as the drawn pattern looks like the pattern made of LEGO® blocks, which the students have evoked in their mind.

**Figure 5: Alternating between two signs**

As in figure 3, this group bring in various words describing growth; several terms refer to the manipulatives thereby showing the importance of the artefacts in the learning process.

The last example does not directly refer to the manipulatives from the activities but shows how a student seizes the idea of applying a concrete artefact in explaining a mathematical concept. The episode happened during the validation of the results from the activities described above. During the discussion it became obvious that many students had great difficulties with this new and different way of looking at the concept of growth. Their prior knowledge, connected to continuous functions, seemed very persistent. During the discussion one of the students reacted:

“No, no. We talk about the growth, the change – not the actual number. Look... [she jumps up from her chair, looks around and grabs a pile of **books** from the neighbouring table] ...If we start with, say 1 **book**, [she puts one book on the table] and then in the first step we put 2 **books** on top of it, and then in the next step 2 more **books** and 2 more **books** and so on. [For every step she places 2 books on top of the stack on the table, see figure 6]. It doesn't matter if there are 1 or 3 or 5 **books** in the **pile**. The important thing is that it grows with two **books** every time. *The difference* is two.”

**Figure 6: The pile of books holds many interpretations of a sign on Growth.**

The student makes use of concrete artefacts in order to explain to her peers how to understand growth. She applies what is easily accessible in a classroom: books! As a representation of growth, the sign contain qualities of all three kinds of *icons*: the growing stable of books is an *image*, the relation of adding two more books in each step is a *diagram*, and by insisting on seeing the difference in each step (two more books every time) instead of the height of the stable, it becomes a *metaphor*. The student clearly states that this is just one way of visualizing how something grows. From the many different words used to indicate growth she demonstrates a wide understanding. It is an example of how manipulatives can be used as visualising a challenging concept rather than a starting point for general, symbolic expressions, which we saw in the logbook entries.

## Discussion and conclusion

The case study demonstrates how the use of manipulatives shows in students' answers and reflections when describing a mathematical activity, e.g. building of patterns. By using concrete artefacts they are able to describe how patterns develop and translate this description to an expression of how the number of parts in each figure of the pattern grows. In the logbook entry (figure 2) the students use an intermediate stage mixing words and symbols, not reaching the final stage expressing the formula in formal mathematical language. Other groups, not considered here, argue for an algebraic expression.

Students use various words referring to different aspects of growth. Some are everyday language e.g. sticking out, broader, bigger, grow, rise and extra; whereas others are mathematical terms like add, multiply, change, growth etc. Often the everyday language is linked with the manipulatives, and the words might not have been evoked in a purely abstract context without the artefacts present. The semiotic analysis reveals that the signs introduced by students are predominantly iconic, many of these images. (Otte, 2006) argues "[...] iconic representations and perceptions are essential to introduce anything new into mathematical discourse", and he notices, "Mathematics teachers very often dislike iconic representations and perceptions, believing them to be confusing and not controllable with respect to their impact" (Otte, 1983). This case study shows how students benefit from the use of artefacts by bringing in numerous iconic representations.

While figure 3 shows that very simple patterns can be visualized as drawings without actual physical materials, classroom observations, not treated here, reveal that patterns in 3D demand the use of actual building blocks. In both cases students use the names of the manipulative i.e. "matches" or "LEGO®". Even when the physical artefact is not needed, students can apply a mental image of the artefact in their mathematical reasoning.

In former research results about the use of manipulatives in lower secondary education, Radford (2008) emphasizes the importance of joined-labour between students and teacher. In this study, the students were expected to be much more self-reliant as they were soon to end their upper secondary education, hence the use of a-didactical situations. The results, though, show that even students in the last year of upper secondary school need guidance in order to make their procedures and ideas converging with the mathematics curriculum as stated in the Theory of Objectification (Radford, 2008).

There are reasons to be somewhat cautious of the results. Using Peirce's categories of the relationship between object and sign is complicated as Presmeg, Radford, Roth, and Kadunz (2016) state: "the distinctions are subtle because they depend on the interpretation of the learner". They continue: "the distinctions may be useful to researchers or teachers for the purpose of identifying the subtlety of a learner's mathematical conceptions if differences in interpretation are taken into account." Thus, there are reasons to be careful in the interpretation. Earlier work of, among others, Radford (2000) shows comparable results indicating that the result of this case study is veridical. The semiotic analysis is based on students' statements, and it cannot always be taken for granted that students are conscious about the precise meaning of the words they use. The fact, though, that the analysis of most logbook entries share the features exemplified here indicates that the approach used in this study is rather robust with respect to the lack of carefulness in student language.

The results points towards several areas worth further investigation. In his study Radford (2008) shows how students can be led to algebraic generalisation, introducing mathematical symbols for unknown quantities. This can be taken further by studying how students make sense in already evolved algebraic expression, and whether manipulatives can be supportive. In upper secondary education students are presented with a large number of such algebraic expressions, which they are expected to manipulate and use but often fail to understand. Another interesting aspect is the significance of *prior knowledge*. In figure 2 we saw how the students were led to look at the relation between a figure number in the pattern and the total amount of matches in that figure resulting in a functional expression. This behaviour was even more apparent in other entries, not shown here, and could very well originate from their knowledge of continuous functions. Although prior knowledge often helps students in new contexts, it can also prevent them from going in the desired direction.

# The use of artifacts and different representations by producing mathematical audio-podcasts

Christof Schreiber and Rebecca Klose

Justus Liebig University, Department of Mathematics Education, Gießen, Germany

[christof.schreiber@math.uni-giessen.de](mailto:christof.schreiber@math.uni-giessen.de)

[rebecca.klose@math.uni-giessen.de](mailto:rebecca.klose@math.uni-giessen.de)

*This paper focuses on the role of artifacts and different forms and modes of representation when learning mathematics at primary school level. This will be exemplified alongside the use of an interactive approach, in which mathematical audio-podcasts are produced. Audio-podcasts are a communication tool that generally focuses on oral means of representation. During the production process of mathematical audio-podcasts however, the students use different forms and modes of representation as well as produce and use different artifacts. With regard to this, field experiences will be shared.*

*Keywords: Mathematical audio-podcasts, artifacts, forms and modes of representation.*

## Artifacts and different representations

The role of artifacts for mathematical learning is of great importance. Artifacts generally encompass objects that are produced by human beings and are materially present and durable. A learning artifact in particular, refers to an object developed by students, which displays their knowledge (Kafai, 2006). Besides artifacts that are material in nature, there are virtual ones that comprise of tools of the information and communication technologies. Different artifacts support different forms of representation and have a great influence on cognitive development (Bartolini Bussi & Mariotti, 2008).

The education standards for teaching mathematics also emphasise the transfer of various modes of representations, since they enable students to communicate their mathematical ideas and understanding as well as support the modeling and interpretation of mathematical phenomena (NCTM, 2000). Kress (2010) defines ‘mode’ as

a socially shaped and culturally given resource for making meaning. *Image, writing, layout, music, gesture, speech, moving image, soundtrack and 3D objects* are examples of modes used in representation and communication. [...] Modes offer different potentials for making meaning. These differing potentials have a fundamental effect on the choice(s) of mode in specific instances of communication. (p. 79)

Therefore, being able to use different modes of representation during a mathematics lesson is a central aspect and supporting competence across all school levels. The mathematical register in the classroom also comprises of the multiple semiotic modes:

Language, mathematical expressions, and visual diagrams, as well as the gestures and actions of participants in the classroom, together construct meaning. (Schleppegrell, 2007, p. 142)

With regards to the role of written representation for mathematical learning, working with the products of students’ writings has been common practice for some time now (Morgan, 1998). In the project ‘Math-Chat’ (Schreiber, 2013b), the use of written representations is the main means in the

problem solving process and focus of the analysis. In primary school, written-based communication is often used in the case of reflections and documentations of the students' learning processes, for example, in journals referred to as 'journal writing' (Borasi & Rose, 1989); and also after having solved math problems. Thus, writing is often considered "an activity that is in itself conducive to learning" (Morgan, 1998, p. 2). In this sense, it is assumed that writing might help students organise their thoughts by externalising them in a written form. This strategy of 'writing to learn' has to be distinguished from 'writing to communicate'. The tool 'writing to learn' enables students to become more active learners by questioning and reflecting on information, whereas 'writing to communicate' aims to demonstrate their learning in different forms of written assignments (Meiers, 2007).

It is oral communication that generally provides the participation in mathematical discussions and conversations, aiding with the understanding of mathematical signs (Meiers, 2010). Apart from speaking and explaining, mathematical learning also requires the acquisition of skills, such as listening, questioning, defining and proving (Ontario Ministry of Education, 2006). Pertaining to mathematical interaction and communication processes, research on mathematical didactics has attributed an increasing importance to the use of gestures (e.g. Goldin-Meadow, 2003; Huth, 2014). Kendon (2004) defines 'gesture' as "a name for visible action when it is used as utterance or as a part of an utterance" (p. 7). Gestures that are used in accompaniment with speech represent the same components of the expressions uttered. As such, gestures and spoken language can be seen as inseparable and interdependent modes of the same language system (Huth & Schreiber, 2017).

To further explain the interwoven use of oral and written communication in a medial and conceptual manner, the linguistic model of orality and writtenness by Koch and Oesterreicher (1985) and well explained by Fetzer as the "two dimensions of orality and writtenness" (2007, p. 79; translated by the authors: „Zwei Dimensionen von Mündlichkeit und Schriftlichkeit“) is used. Koch and Oesterreicher (1985) have developed a model of communication that distinguishes between medial phonic and medial graphic communication and between communicative immediacy and communicative distance. The medial phonic and the medial graphic realisation of communication are dichotomous, whereas the conceptual realisation can be placed on a scale between the communicative immediacy and the communicative distance (Figure 4; Schreiber, 2013a).

Considering the example of a personal talk, it is not only medially phonic, as there is an emotional closeness to the dialogue partner and thus, also conceptually oral. Although writing in a diary is medially graphic, it is conceptually oral, informal and characterised by its 'closeness' to the reader. An administrative directive, in contrast, is medially graphic and also conceptually an example for communicative distance. In this case, the language is strictly formal.

This paper will refer to 'forms' of representation when pertaining to Koch and Oesterreicher's linguistic model of orality and writtenness and 'modes' of representation when used according to Kress and Schleppegrell's definitions as mentioned above.

## Audio-podcasts for mathematics

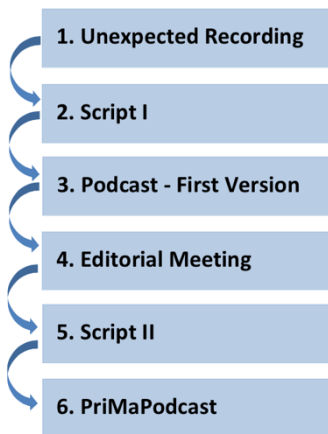

Figure 1: Process of production of PriMaPodcasts

Audio-Podcasts, which we use as learning artifacts in school, primarily focus on the aspect of orality, as the process of creating an audio-podcast produces an oral product. Schreiber (2013a) developed ‘PriMaPodcasts’ to serve as tool, in which oral and written forms of representation are alternated and interwoven permanently. ‘PriMaPodcast’ is the coined term for a mathematical audio-podcast produced by primary school students. The students undergo a process in which they develop specific mathematical content in stages up to a point where a version of the explanation is ready to be published on the internet (Figure 1). The different forms of representation, the medial and conceptual realisations as well as the use of artifacts will be presented by illustrating each production step below. For more information on the aims, the production steps, the audio files and the

scripts, please visit our blog ([www.uni-giessen.de/primapodcast-bili/](http://www.uni-giessen.de/primapodcast-bili/)). Before giving insights into the production process, three aims of the mathematical audio-podcasts will be described:

**Learning:** The exclusive use of oral representations can support learning. This can be brought forth when learners have to deal with one specific topic in depth and are required to refrain from using any written or graphical representations, thus, solely relying on oral means of communication.

**Diagnosis:** A teacher gains insight into a learner’s mathematical concept and understanding by listening to the learner’s recorded utterances. The spontaneous and planned recordings can be analysed during and after the production process.

**Research:** As mathematics is a written and graphically based science, focusing on oral representations is an interesting area for research. Therefore, using the recordings, the aim is to investigate to what extent learners use mathematical language to express their workings.

The focus of this paper will be on the last aim. This will be illustrated in the following. The production process will be depicted through excerpts from an empirical example. These consist of recordings and documentations that were produced at a bilingual school in Offenbach am Main, Germany. The selected study sample is from a dissertation project (Klose, 2015) and it consists of fourth graders that were taught mathematics bilingually (German/English) since first grade. Within the scope of the research project, the students’ task was to produce a podcast in English. The empirical examples were transcribed and analysed by means of the interaction analysis (Krummheuer & Naujok, 1999). Excerpts of the transcribed utterances and scripts will be presented and commented thereafter. All citations of the transcripts are marked in angle brackets <like this>.

### Production steps

In step 1 (‘Unexpected Recording’), a small group of students is unexpectedly confronted with the mathematical question ‘What is symmetry?’. The students record their responses with a voice recorder. Hence, in this step, the focus is on oral communication and representation. The medial realisation of the recording is phonic and conceptually oral as seen in the following.

In this example, the students answer the questions as follows:

- ur speaker: statement:
- 01 Student 1: what is symmetry (4s) o k a y . I think eh symmetry uhm there are symmetry lines/ . . uhm . and < miss brand had talk about it
- 02 Student 2: < and
- 03 Student 2: I think uhm in symmetry/ we have symmetry lines and uhm there are . uhm . . uhm . there are . .
- 04 Student 1: (*whispers*) symmetrical% (4s) I think there are (*the thumb, index and middle finger of the right hand, which is open and facing upwards, are being spread apart and then joined to meet in the middle*) forms % . uhm #
- 05 Student 2: # y yes
- 06 Student 1: < (speaks softly) that are symmetrical and%
- 07 Student 2: < there are forms that what you can do in three d and in two d (...)

In this excerpt, both students express their mathematical ways of thinking by speaking out aloud. The students associate the term ‘symmetry’ with ‘symmetry lines’ as seen in <ur01> and <ur03>. Student 1 remembers in <ur01> that her mathematics teacher had mentioned symmetry in class before. Furthermore, they relate ‘symmetry’ to “forms” <ur04> and “forms that what you can do in three d and in two d” <ur07>. As early as seen in this excerpt as well as later on, gestures are already going into action. This step not only prompts the students to think about the topic, but also supports them to clarify and organise their thoughts and reflect on specific content (Pimm, 1987).

Figure 2: Script I, Student 2's drawing as an approach to explain line symmetry

In step 2 ('Script I'), the students research their topic and create a script. They are free to decide the format, structure and amount of detail they wish to include. In order to gather information, they are given different resources, such as the internet, textbooks and worksheets. They also have the possibility to use concrete material. Thus, different artifacts can serve as basis for oral communication and written-graphical representation.

The students of the empirical example were inspired by the work material and referred to various approaches of line symmetry. In particular, student 2 used the geoboard and drawings (Figure 2) to support her with the activities related to line symmetry. In their script, they explain ‘symmetry’ through the approach of folding (Figure 3).

Figure 3: Script I, folding as an approach to explain line symmetry

The students continue by mentioning ‘drawing’ and ‘reflecting’. The writing activity itself may be considered a tool for ‘writing to learn’. Dealing with different artifacts and resources, this writing underlies the principle of connecting what has been read, viewed, heard and experienced with what

the students have understood so far (Meiers, 2007). The medial realisation of the script is graphic and its linguistic conception is - depending on the kind of script - a rather informal written type.

In step 3 ('Podcast - First Version'), oral representation is essential, as the students are required to read the assigned parts of the script aloud for the recording of the first podcast version. Up to this stage, the team works independently: The students make their own decisions concerning the mathematical matter and their performances without any intervention from the instructor. The medial realisation of the recording is phonic and its linguistic conception is a more formal spoken type.

fv	speaker:	statement:
01	Student 2:	what is symmetry there are axis symmetry reflection symmetry and partition symmetry there are symmetrical shapes
02	Student 1:	symmetrical shapes are shapes that you can fold in the middle and then both sides are the same
03	Student 2:	you can draw symmetrical shapes with faces . vertices and edges
04	Student 1:	edges are the lines and vertices are the places where they come together faces are the places in between the edges and in German we call them flächen
06	Student 2:	you can make symmetrical shapes in two d and three d
07	Student 1:	examples for symmetrical shapes are a square a circle a triangle a hexagon a pentagon and a trapezoid
08	Student 2:	s some some shapes have got more than one m mirror line

In step 4 ('Editorial Meeting'), the small group of students receives feedback from their peers and the instructor. They use this to reflect on their work in terms of content, style and language use. At this point, the instructor poses specific script-related questions and asks for more precise explanations. Again, different artifacts, such as the script, the audio files and objects and especially the students' written products, support the discussion and serve as basis for better clarifications in oral communication.

In the presented empirical example, the different types of symmetry were correctly named and distinguished. For this purpose, various kinds of materials were used. By means of their drawing (Figure 2) the phrase 'line of symmetry' was introduced. Several locations to draw the line of symmetry were discussed. Thereby, the instructor's focus shifted from 3D towards the symmetry of 2D shapes. Together with the other group, they reviewed and checked how many lines of symmetry a circle, quadrilaterals and different types of triangles could have.

In step 5 ('Script II'), the students start to improve their first script in small groups. The students have the opportunity to use the same material and artifacts again. They may discuss and share their knowledge before writing down a second script. Thus, oral communication serves as basis for written representation. The writing activity of creating a second script may be linked to the strategy of 'writing to communicate' (Meiers, 2007). Since the second script serves as basis for the final podcast version, the learners decide on the content they wish to present to the audience. The script is medially graphic and conceptually rather an elaborated written type since the students clearly want to present their knowledge accurately and in a structured manner.

In the empirical example, the students took up most of the suggestions given during the editorial meeting as they tried to differentiate more distinctively between the different types of symmetry.

This, however, appeared to be challenging, as they focused on 3D shapes again and listed some of their properties instead of looking at 2D shapes.

In step 6 ('PriMaPodcast'), they record a final podcast version based on the second script. This will be published on the internet. Again, written representation serves as basis for the oral form of representation. Hence, the recording is medially phonic and conceptually more of an elaborated type.

pr	speaker:	statement:
01	Student 2:	what is symmetry. there are line symmetry reflection symmetry and rotation symmetry . there are symmetrical shapes
02	Student 1:	symmetrical shapes are shapes that you can fold in the middle and then both sides are the same . that's line symmetry
03	Student 2:	rotation symmetry is when you have a symmetrical shape and you rotate it a little bit and then the shape the shape looks the same as it was before
04	Student 1:	reflection symmetry is almost the same like line symmetry but you have to put a <b>mirror</b> in the middle of the shape\
05	Student 1:	you can draw symmetrical shapes with faces vertices and edges
06	Student 2:	examples for symmetrical shapes are a square a circle a triangle and in three d a sphere a pieramid and a cube
07	Student 1:	you can make symmetrical shapes in two d and three d
08	Student 2:	almost all shapes have got more than <b>one</b> line of symmetry

As described in the production process, the students' products can be classified into Koch and Oesterreicher's model as follows (Figure 4):

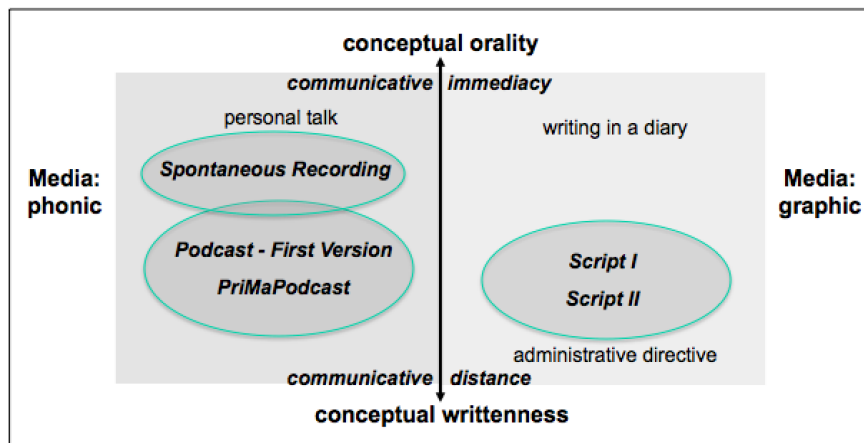

Figure 4: Model of writtenness and orality; (Fetzer, 2007, p. 79/ Schreiber, 2013a)

## Conclusion

The use of artifacts and various representations in the mathematics classroom is of high relevance. The interactive approach of producing PriMaPodcasts follows this assumption by comprising various modes and forms of representation. The aim is to produce a learning artifact; a final product of oral nature. Publishing the final version on an online blog serves as an exceptional motivation for the students. In the process, they undergo various stages, in which they can expand their knowledge through discussions and learn different approaches to present them. Mathematical concepts and language competences can be strengthened as shown by the empirical example.

## Field experience

So far, mathematical audio-podcasts have been used in different areas of teacher education. Firstly, we produced audio-podcasts for mathematics with students at primary school level. Besides German podcasts, some students also produced mathematical audio-podcasts in various other mother tongues (e.g. Russian and Turkish) as well as different languages of instruction (e.g. English and Spanish) in bilingual schools.

Secondly, students who are studying to become primary or secondary school teachers, created mathematical audio-podcasts. Moreover, they supervised the production of the mathematical podcasts of school students. It is important for the university students to have gone through the steps themselves prior, so as to understand the production procedure clearly. Hence, they gain a better understanding of how demanding it can be for younger learners to explain a concept without any preparation and solely using orality. The deepening of mathematical content and its reflection are another focus of the audio-podcasts. The university students become aware of the increase in knowledge and are able to internalise and reflect on already learnt content. Content knowledge ranges from secondary school mathematics to areas covered during university lectures.

Thirdly, the idea of mathematical audio-podcasts serves as research method. As part of a PhD project, the use of mathematical language in bilingual learning settings will be investigated further. The overall interest lies in the question of how bilingually taught learners use the language of mathematics in both their target languages (English and German) when asked to present mathematical content (Klose, 2015).

# The role of representations in promoting the quantitative reasoning

Lurdes Serrazina<sup>1</sup> and Margarida Rodrigues<sup>1</sup>

<sup>1</sup>Escola Superior de Educação de Lisboa, UIDEF, Instituto de Educação, Universidade de Lisboa, Portugal; [lurdess@eselx.ipl.pt](mailto:lurdess@eselx.ipl.pt), [margaridar@eselx.ipl.pt](mailto:margaridar@eselx.ipl.pt)

*In this communication, we discuss the role of representations in the development of conceptual knowledge of 2nd grade students involved in additive quantitative reasoning through the analysis of the resolutions of two tasks that present transformation problems. Starting to discuss what is meant by additive quantitative reasoning and mathematical representation, we present after some empirical results in the context of a teaching experiment developed in a public school. The results show the difficulties with the inverse reasoning present in both situations proposed to students. Most students preferably use the symbolic representation, using also the written language as a way to express the meaning attributed to its resolution. The iconic representation was used only by a pair of students. Representations have assumed a dual role, that of being the means of understanding the students' thinking, and also supporting the development of their mathematical thinking.*

*Keywords: Mathematical representations, transformation problems, additive quantitative reasoning, inversion.*

## Introduction

This paper is part of the Project “Adaptive thinking and flexible computation: Critical issues” being developed by the Schools of Education of Lisboa, Setúbal and Portalegre. Its main goal is to discuss the role of representations in the development of 2nd grade students’ conceptual knowledge that is present in different levels of understanding of numerical operations/relations when they solved two tasks. These were conceived with the aim to develop quantitative additive reasoning, as a means of understanding this same reasoning. The tasks present transformation problems included in the classes of search of initial state (Vergnaud, 2009). They are the last ones of a sequence of six tasks that was applied in the context of a teaching experiment developed in a public school in Lisbon. The empirical data analysis focused on representations aims to discuss the inferences we make in the reasoning of the students but also their role in the development of students' reasoning.

## Mathematical representations and quantitative reasoning

Quantitative reasoning, within the additive structure, focuses mainly on relations between quantities (Thompson, 1993), being that the problems of transformation aimed at finding the initial state have increased cognitive complexity for 2nd grade students by requiring an inverse reasoning (Vergnaud, 2009). The representations are interconnected with the reasoning given the relevance of their role in the understanding of students’ reasoning (NCTM, 2000). But, the representations also assume an important role in students’ learning, constituting cognitive means with which they develop their mathematical thinking (NCTM, 2000; Ponte & Serrazina, 2000). In a broad sense, a representation is a setting that can represent something somehow (Goldin, 2008). The term “representation” refers both to the process of representing and the result of this process. In mathematics education, representations are privileged tools for students express their mathematical ideas, still working as helpers in the construction of new knowledge (NCTM, 2000). However, a mathematical representation cannot be

understood or interpreted in isolation, since only makes sense when part of a more comprehensive and structured system in which different representations are related (Goldin & Shteingold, 2001).

According to Stylianou (2010), the way as representations are used in classroom has impact in students learning and this largely depends on the role of the teacher, using “student-generated work as a launching point for discussions” (p. 339). This idea is reinforced by Ponte and Serrazina (2000) when they say that how mathematical ideas are represented influences profoundly the way they are understood and used. For example, according to Vergnaud (2009), the inverse transformation can be represented by two symbolic representations -- the algebraic one and the arrow diagram -- considering, however, that while the algebraic representation is not suitable for children in elementary school, using the diagram representation the teacher can help students connect, immediately, the different components of the relationship, namely the direct and inverse transformations, giving meaning to the temporal motion go forward and backward.

**Figure 1: Arrow diagram (Vergnaud, 2009, p. 87)**

Figure 1 presents a representative diagram of subtracting 7 to the final state in the situation "John has just won 7 marbles in playing with Meredith; now he has 11 marbles; how many marbles did he have before playing?" (Vergnaud, 2009, pp. 86-87). However, while recognizing the importance of this representation, the author states that children need several examples of the inverse transformation in order to be able to effectively understand it. "Several kinds of awareness are needed: you lose what you have just won; or you win what you have just lost; you go backwards as many steps as you have gone forwards and reciprocally" (p. 87).

For Ponte and Serrazina (2000), the main forms of representation used in the primary education are: (i) *the oral and written language*; (ii) *symbolic representations*, like numbers or the signs of the four operations and the equal sign; (iii) *iconic representations*, like figures or graphics; and (iv) *active representations*, like manipulative materials or other objects. It is through the analysis of the representations used by students that the teacher can become aware of their thinking and help them in the construction of own representations in mathematical language.

NCTM (2000) also emphasizes the role of idiosyncratic representations constructed by students when they are solving problems and investigating mathematical ideas, in that it can help them in understanding and solving problems and provide "meaningful ways to record a solution method and to describe the method to others" (p. 68). Observing these representations, teachers and researchers can understand the ways of interpreting and reasoning of students.

## Methodology

This study follows a qualitative approach within an interpretive paradigm. Its methodology of *design research* is part of a perspective of learning design, in order to produce local theories of teaching and learning sequences that are resources and references available to inform the practices of teachers and researchers (Gravemeijer, 2015).

The data were collected in a second grade classroom (7-8 years old), with 26 students, of a public primary school in Lisboa. The Project team defined a sequence of tasks with the aim to develop the

calculation flexibility in addition and subtraction problems. The process of tasks elaboration included previous testing of some (namely the ones focused in this paper), through clinical interviews (Hunting, 1997) with students of the same grade. It is a technique that is directed by the researcher and seeks a description of the ways of thinking of respondents. The task sequence was previously discussed and analyzed with the classroom teacher having been made minor adjustments. Classroom teacher explored the task sequence with her students (a task every week). During their schooling the empty number line had been used regularly both by the teacher and students.

The data collection was made through participant observation of the authors of this paper, which drew up field notes and supported by video recording, subsequently transcribed. The written records of the students were also collected. All these data were analyzed and triangulated. By ethical reasons, the students' names were changed to ensure confidentiality.

In this communication we analyze two tasks (Figure 2), proposed to the students in the same class (given the similarity between them) and presented on the same sheet of paper, with space for the respective resolution.

<p style="text-align: center;"><b>Game of marbles I</b></p> <p>Ana and Luís played a game of marbles together. At the beginning both had the same number of marbles.</p> <p>Ana won 3 marbles from Luís and had 7 at the end of the game.</p> <p>How many did Luís have at the end of the game, knowing that he did not win marbles?</p> <p style="text-align: center;"><b>Game of marbles II</b></p> <p>Ana and Luís made a game of marbles.</p> <p>Ana won 6 marbles from Luís and had 10 marbles at the end of the game.</p> <p>Luís won nothing and had 3 marbles at the end of the game.</p> <p>Compare the number of marbles of Ana and Luis before the game and at the end of the game.</p>
--

**Figure 2: Performed tasks**

These were the last ones of the sequence solved by students. With the previous exploration of the other tasks, students had already worked the relationship between wins and losses over a marbles game, realizing that what a player wins, the other loses. All the tasks were first solved in pairs. In this class, after all pairs had solved the two tasks, the teacher promoted a collective discussion with whole class, from six pairs resolutions (three on each task) who presented their work on the blackboard.

## Exploring the tasks

In this section we present and discuss some examples of tasks' resolutions. Their choice was made taking into account the diversity of representations presented by the different pairs and being representative of what happened in class.

### Game of marbles I

The resolution of Alexandre and Rosa shows the inversion of reasoning as a critical aspect. Thus, they took first 10 marbles for both players from the sum of 3 ("Ana won 3 marbles") with 7, not mobilizing an inverse reasoning to determine the initial number of marbles.

**Figure 3: Alexandre's diagram for Game of marbles I**

Alexandre's diagram (Figure 3) represents the wins and losses of marbles as they are thought by the pair of students. But, when asked by the teacher they erased all they did and made it again on their worksheets (this diagram was seen in the video records). The new representation (Figure 4) reveals the necessary inversion to find the initial number of marbles. They got it for Ana, but they seem to forget that both players had at the beginning the same number, as in Luís' allusive representation, they retired 3 marbles from 7.

**Figure 4: New Alexandre's diagram for Game of marbles I**

Vítor and Joana can reverse the reasoning to the case of Ana but they show a lack of understanding of the situation alluding to Luís (Figure 5).

**Figure 5: Vítor's diagram for Game of marbles I**

This diagram helped the children's thinking in the sense that it respects the temporal order of the game: the initial marbles on the left and the final ones on the right side. However, they did not look again for the initial situation, that is, if Ana won, Luís has to have less at the end of the game.

Rui and António used symbolic representations presenting a number line with two curve lines that represent the inversion of addition and subtraction (Figure 6). Like the anterior pair, they reversed their reasoning to Ana but they assumed the same situation to the player Luís, stating that he won 7 marbles at the end of the game. Here the term "won" means the absolute number of marbles at the end of the game and not a quantitative difference. The distinction between the quantitative difference and the result of an arithmetical operation is a critical aspect that emerges from this resolution.

because

At the end, Luis won 7

**Figure 6: Rui's diagram for Game of marbles I**

The word "because" explains the inversion used to determine the number of initial marbles, justifying it with the inverse relationship between addition and subtraction. The order in which they placed the operations shows the inverse reasoning process: first, they determined the initial number of marbles (the initial state), and after they confirmed the resultant final state with the inverse relationship.

Tiago and João used a table disposition (Figure 7), with columns for each of the two players and the lines for the different moments of the game, the top line to the beginning of the game and the bottom to the end.

both

the same

Luís ended up with one

difference

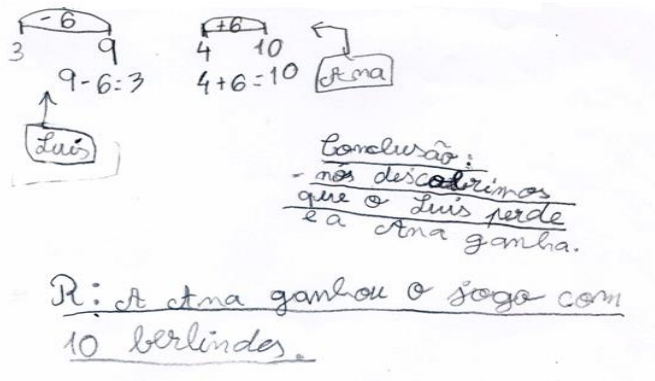

**Figure 7: Tiago's diagram for Game of marbles I**

It was the only pair in the class, which established the difference between the final numbers of marbles, although not required, focusing on the difference as an additive comparison of quantities. It seems that the representation used allowed them to manage two data at the same time, the quantity of marbles and the transformation after game.

## Game of marbles II

Alexandre and Rosa read the problem. Immediately, Alexandre said: "Luís started with 9 and Ana started with 4." Once Alexandre had understood the previous problem when the teacher questioned their resolution, as mentioned before, here he already coped well with the unknown initial state, solving mentally the problem, through an inverse reasoning.

On the diagram's lines (Figure 8), the numbers are placed in ascending order, getting the initial number of marbles on the right for Luís and on the left for Ana. Their answer is focused on the absolute amount of marbles of Ana at the end of the game and not on the comparison.

Conclusion: we discover that Luís loses and Ana wins.

R: Ana won the game with 10 marbles.

**Figure 8: Alexandre's diagram for Game of marbles II**

Vítor and Joana used the line representation (Figure 9), adopting the temporal criterion as they did in the previous task, putting the initial marbles on the left and the final ones on the right side and at this time they got the right solution.

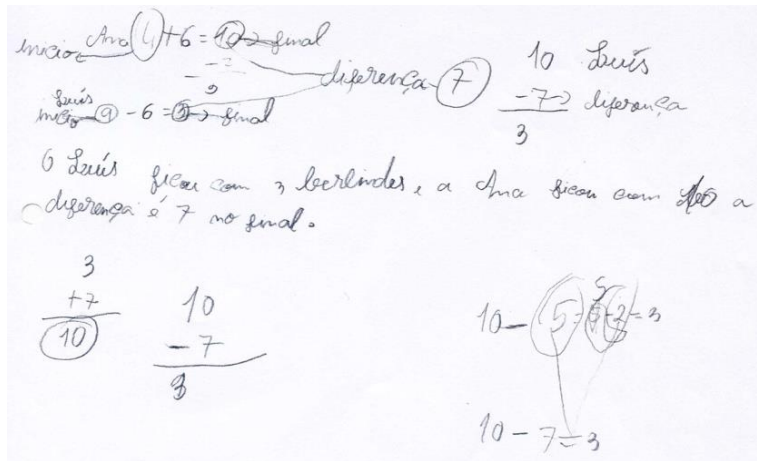

**Figure 9: Vítor's diagram for Game of marbles II**

Rui used an iconic representation of Ana's marbles: first, the six marbles won from Luís; then the initial 4 marbles (probably counting them until the total 10); and finally the three final marbles of Luís. He was not able to reverse his thinking in order to determine the initial marbles of Luís.

**Figure 10: Rui's diagram for Game of marbles II**

Tiago surrounded the numbers to assign their meaning, recording the player and the time of the game to which they relate (Figure 11) and respecting also the temporal order of the game.

Luis got 3 marbles  
and Ana got 10,  
the difference is 7  
at the end.

**Figure 11: Tiago's diagram for Game of marbles II**

Tiago focused the additive comparison of the resultant final states, recording that "the difference is 7 at the end".

### Final remarks

The inverse transformation is a critical aspect in solving the tasks (Vergnaud, 2009). Thus, the first representations used by Alexandre in *Game of marbles I* show a reasoning associated with prototypical situations of addition asking for final states and not initial ones. Students seem to cope more easily with this kind of transformation in the second task after having understood the inversion involved in *Game of marbles I*. For this understanding the teacher's questions seem to have been fundamental.

An example is the case of Alexandre and, although he did not fully solve the first problem, managed to overcome the obstacle of inversion in the second task solving it mentally very fast. Despite the inherent difficulty of the inverse transformation, the productions of the students in the class reveal a widespread understanding of an aspect of inverse thinking: what a player wins, the other loses.

Students seem to have essentially privileged two forms of representation (Ponte & Serrazina, 2000): the written language and symbolic representations. Just a pair of students used the iconic representation in support of symbolic representation (Rui and António). Among the symbolic representations used, there was a predominance of horizontal dispositions of the calculations, although the use of the empty number line also had had a significant expression, helping to think about the transformations involved in problems. We should stress that empty number line had been used by these students and her teacher since the first grade. Thus, the curved lines, which represented the transformation, supported the thought around the wins and losses, as well the temporal motion. The table disposition also seems to have helped the students (Tiago and João) to structure and relate the various elements of the problem: the two players and the two time points of the game.

Analyzing student productions, we can infer different levels of quantitative additive reasoning. While most learners focused on the absolute amounts of marbles, Tiago focused on quantitative difference as a quantitative result of comparing two quantities additively to find the relative change (Thompson, 1993). So, for the majority of students, the notion of difference as an additive comparison of quantities is a problematic aspect.

The representations used by the students had a dual role. On the one hand, they were windows to interpret their reasoning. On the other hand, they were scaffolds that helped to think mathematically demanding situations, taking into account their ages. It should be stressed that the teacher's role, making questions, not giving answers, while students were doing their work was also essential. As stated by Vergnaud (2009), the development of a conceptual field involves not only situations and schemes but also symbolic tools of representation.

# Maths Welcome Pack: A multi-sensory introduction to mathematics for high school students

Giulia Bini

*Keywords: Secondary school mathematics, experiential learning, multisensory learning, mathematics activities, learning motivation.*

## Introduction and theoretical framework: Before the box

This poster is about the experience of an “on field” project started in 2014 with a group of 28 14-y.o. students attending to the first year (9<sup>th</sup> grade) of Liceo Scientifico and a 10cm cube cardboard box containing a collection of items that led to a two weeks journey through the focal points in the act of doing mathematics, which are the new entries of the high school approach to the subject, such as proofs, their necessity in mathematics and the related use of a proper symbolic language.

It has been conceived as a starter for the study of high school mathematics, but it also proved an effective strategy to boost students’ learning motivation and long-term knowledge retention about the subject as a whole.

As Raymond Duval points out, “the goal of teaching mathematics, at primary and secondary level, is neither to train future mathematicians nor to give students tools, which can only possibly be useful to them many years later, but rather to contribute to the general development of their capacities of reasoning, analysis and visualization” (Duval, 2006, p. 105). Taking this perspective, I wanted to investigate the effectiveness of a multi-sensory approach, which is quite frequent for lower grades but isn’t a common practice for secondary mathematics teaching and learning, through the means of Arzarello’s *semiotic bundle* theory, widening the semiotic system horizon “to contain gestures, instruments, institutional and personal practices and, in general, extra-linguistic means of expression” (Arzarello, 2006).

The project had a double goal: from a research point of view, I aimed at focusing on the “cognitive functioning underlying the various mathematical processes” (Duval, 2006, p. 104) and exploring the efficacy of “a rich semiotic bundle with a variety of semiotic sets” (Arzarello, 2006) to foster students’ understanding of some pivotal mathematical concepts. From a didactic point of view I wanted to verify that this approach, which took its strength from “a gradually growing and multimodal cognitive environment” (Arzarello, 2006) could help students in building up long lasting memories connected to the practice of mathematics through the act of giving “personal meanings to mathematical objects” (D’Amore, 2003, p. 19).

## Methodology: Inside and Outside the box

The study explores how students answered to questions and problems prompted by the 12 items in the box, during the first two weeks of the school year (approximately 10 hours of teaching). Data has been collected by the teacher through classroom observation and assessment of the assigned homework.

The content of the box, described in detail in a [multimedia presentation](#), varied from tactile objects like the piece of string which triggered the ice-breaker kinaesthetic activity **The Magic Knot** (Can you tie a knot in a string without letting go of the two ends?) to a paper cut with an extract from a 1742 letter from Christian Goldbach to Leonhard Euler which lead to the unveiling of **The Goldbach mystery** (What is the Goldbach conjecture? And why is it a conjecture and not a theorem?).

A good example to illustrate how the notion of semiotic bundle can be used to decode the activities of students solving a mathematical problem is **The mystery of the four triangles** (Can you build exactly 4 equilateral triangles using six toothpicks of equal length?). Searching for the answer to this problem students came up with the wrong construction seen in fig.1.

**Figure 1**

Discussing this solution, they brought into play an articulate semiotic bundle made up of:

- gesture: manipulating the toothpicks to build the solution
- speech: discussing why the construction in the figure is wrong
- written signs: drawing other possible solutions
- arithmetic representation: figuring out that the slanted toothpicks in Figure 1 weren't long enough to play as diagonals of the square
- geometric representation: figuring out that the triangles in Figure 1 couldn't be equilateral

Expanding the semiotic bundle from gesture to arithmetic representation, they became gradually aware that the construction couldn't be solved in two dimensional space and it eventually helped them to elaborate the correct solution.

### **Conclusions: Beyond the box**

The described case shows how the use of a full range of different types of representation (verbal, gesture and iconic exemplification) has been a key point in the procedure of developing the meaning of the mathematical objects involved. In the following school years (14-15 and 15-16), this class group attested in two synergic ways how successful this opening experience has been: on one hand, they proved to remember vividly the content delivered through the box and on the other they become more metacognitively aware of the importance of creating a range of different representations in order to have access to a mathematical concept or problem.

# Representations of fractions in mathematics education: What do students learn?

Cecilia Sveider

Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden  
[cecilia.sveider@liu.se](mailto:cecilia.sveider@liu.se)

*Keywords: Representation, fraction, primary school.*

## Introduction

During the past years the mathematics education community as well as the educational research of teaching and learning have seen representations as a useful tool for communicating information and understanding (e.g. Lesh, Cramer, Doerr, Post, & Zawojewski, 2003; NCTM, 2000). NCTM (2000) advocates students to “create and use representations to organize, record, and communicate mathematical ideas; select, apply, and translate among mathematical representations to solve problems...” (NCTM 2000, p. 64). In the present study, ‘representations’ refers to Goldins (2002) definition that a representation can represent something else, for example, symbolic expressions, drawings, written words or diagrams. Different representations can be used to shed light onto different aspects of a complex mathematical concept or relationship (e.g. Cai, 2005; Cathcart, Pothier, Vance, & Bezuk, 2006). For example, when learning about parts of a whole, teachers and students can use a manipulative representation, as sectors of a circle or as pieces of a rectangle.

## Purpose

The aim of the present study is twofold. Firstly, investigate how teachers and students use representations of fractions focusing on finding a fraction regarding either part- whole or part of set aspect. This would for instance entail examination of which type of representation, how they are used and in which order they are used. Secondly to examine what students learn in mathematics lessons, regarding representations of fractions.

## Hypothesis

The hypothesis is that a more frequent use of different representations, by either teachers and or students, will enhance the students’ knowledge of fraction as part of a set or part of a whole. This is in line with what have been suggested by Cai (2005); Cathcart, Pothier, Vance, and Bezuk, (2006) concerning different representations.

## Method

The collection of data consists of two parts, (a) video recordings of lessons and (b) pre- and post-tests (“RB2 or RB3 Diamant” which is part of the Swedish National Agency for Education’s test materials). Video recordings enable data to be analyzed repeatedly and seen by other researchers in order to contribute to the study. Data will be analyzed with respect to variation theory (see for instance Marton, 2015). The pre- and post-test are a measurement to document effects of using representations of fractions during the mathematics lessons. To examine group differences between pre- and posttest repeated measure ANOVA is used.

## Participants

Ten primary school teachers and approximate 250 students in Sweden, New Zealand, and Singapore, respectively, will be part of the present study.
