I believe that this research will contribute to the ongoing discourse on issues and challenges of the integration of digital resources in classrooms and offer 'working hypotheses' for future research.

*The use of technology and other resources for mathematical learning is a current issue in the field of mathematics education and lags behind the rapid advances in Information and Communication Technology. Technological developments offer opportunities, which are not straightforward to exploit in regular teaching. In CERME10 TWG16, the recent research findings, issues and future questions have been explored and discussed in detail. In this introductory chapter, we will outline the scope and focus of the work, describe the results with respect to existing questions, and identify upcoming topics as well as missing topics that might set the agenda for future work in this domain.*

*Keywords: Digital resources, mathematical learning, educational technologies.*

### Scope and focus of the Working Group

In recent years, discussions within the CERME-technology-group have confirmed the relevance of Information and Communication Technology (ICT) for the learning of mathematics. ICT provides a range of resources, such as software, handheld devices and online classroom activities. This range of resources has been compared to non-digital resources, such as textbooks, worksheets and other types of tools and manipulatives. The impact of both digital and non-digital resources on mathematical learning has been of great interest to our working group. The scope of this working group was to explore and discuss opportunities and possibilities, as well as challenges and limitations, of technological resources for student learning. We wanted to establish an overview of the current state of the art in the use of technology in mathematics education, including both practice-oriented experiences and research-based evidence, as seen from an international perspective and with a focus on student learning, as well as to suggest important trends for technology-rich mathematics education in the future, including a research agenda. TWG 15 is closely related to this theme, but focuses on the teachers' roles and practices.

In the pre-conference call for papers and poster proposals, theoretical, methodological, empirical or developmental contributions were particularly welcomed on the following topics:

- Analyses of the impact of using digital and non-digital technology on students' learning;
- New forms of digital resources, including mobile devices and dynamic e-textbooks;
- Digital assessment of and for learning;
- E-learning, blended mathematics education and (Massive Open) Online Courses for mathematics;
- Influence and use of social media in students' perception of learning mathematics;
- Promoting communication and collaborative work between students through ICT;
- Using ICT for out-of-school informal mathematics learning;
- Examples of the use of technologies devoted to the support of students with disabilities.

This introduction provides an overview of the 24 presented papers and 6 posters and the discussions in TWG16 building up on theories and past research on digital technologies and other resources for mathematical learning. We especially refer to the CERME history of this technology group and consider the results of the 2017 conference as a continuation of the background, aims and scope of the conferences since 1999 (Trgalova, Clark-Wilson & Weigand, to appear). To do so, we will first address “old” questions, then describe upcoming topics, and close off with topics we missed.

## **Taking up “old” questions**

Some contributions to TWG16 continued the discussion on topics that had been addressed in the past, such as the potential of digital tools to evoke the dynamical aspect of manipulating objects within a digital tool, functional thinking, and the use of e-books.

## **Interactivity, dynamics and multiple representations**

Since the early years of using digital technologies in mathematics education in the 1970s and 1980s, interactivity, dynamic and multiple representations played an important role in developing new strategies for understanding mathematical concepts. Dynamic manipulations were prominently present in dragging opportunities in Dynamic Geometry Systems (e.g. Leung, 2008). Digital technologies created easy access to multiple representations and interactions between the user and the software (e.g. Noss & Hoyles, 1996; Moreno-Armella, Hegedus & Kaput, 2008). On a more elaborated level, the interactions between the *knowledge*, the *tool* and the *learner* built three main aspects of digital technologies and were also strongly represented in TWG16 of CERME 10.

Dynamic digital tools can promote conceptual understanding (e.g. Drijvers, 2015) and potentially support low-achieving students. An example is the interactive environment presented by Swidan, Daher and Darawsha, to support the learning of the concept of equivalent equations. An applet gives the possibility to work with numerical, algebraic and/or graphical representations. Moreover, a pan balance represents enactive experiments with “weights” and a slider allows to dynamically change the x-values. The idea is to represent enactive actions and to allow students to work with a visual mediator while changing mathematical objects. The difficulties, limits and obstacles of working with multiple representations are also highlighted. Low-achieving students, for example, can become overwhelmed when faced with a large number of representations, which may prevent their progress. The consequence is *not* to avoid working with multiple representations, but to create didactical reflected learning environments with a successive introduction of multiple representations and reciprocal interpretation of the transition between these representations.

## **Functional thinking**

Another “old” question concerns the prototypical dynamic view of functions while filling bowls with water and asking for the height of water in a bowl as a function of the volume of water in the bowl (Carlson et al., 2002). Lisarelli’s contribution to TWG16 involved the outcomes of investigating different dragging modalities in the frame of the above-mentioned problem, as shown in Figure 1. Users had to be familiar with different kinds of dragging possibilities: (quasi) continuous dragging, discrete dragging (e.g. if only natural numbers are allowed), or impossible dragging, (i.e. where the user tries to drag a dependent point). She argued for the importance of recognizing the aim for a specific type of dragging and considering whether it is a random movement, a movement for testing

possibilities or a guided dragging to reach a special configuration. Such a classification of dragging modalities gives the possibility to observe, describe and analyze students' processes involved in the exploration and solution of dynamic problem solving activities. This example shows clearly a digital tool as a medium, which is – or mediates – between the user and the mathematical concepts.

Figure 1. The Bottle Problem task and its dynamic representation

The interactive worksheets presented by Lindenbauer and Lavicza focus on functional thinking through a situational model (the area of a triangle) and a related graphical representation. The explanation and interpretation of the graphical representation is – especially for lower achieving students – challenging and as the author stated, the help of the teacher may be crucial. These graphical representations allow students to reflect on what the impact of moving the point on the x-axis is by showing the small or big changes to the area of a triangle. Such an approach provides students with an intuitive access to the concept of rate of change.

### E-books

A great variety of digital books or e-books for classroom use exists. Such books may be more or less extended versions of the traditional schoolbooks, including dynamic activities and in-built assessments (Gueudet et al., 2017). The “Creative Electronic Book on Reflection” presented by Geraniou and Mavrikis allows students to explore mathematics situations individually and interactively, and it also encourages them to reflect on their actions while they are exploring and solving mathematical tasks. A key role in the students’ reflection is played by the so-called “bridging activities” which emphasize the mathematics integrated into the book. As claimed by the authors, the design and evaluation of such interactive learning environments, learning paths or trajectories and the promotion of their wider use in classrooms is a new challenge.

### Theories

The discussion on theoretical approaches regarding digital technologies for mathematical learning is also an on-going one within CERME (Trgalova, Clark-Wilson & Weigand 2017). There are some well-developed and experimentally confirmed theories like semiotic mediation (Bartolini Bussi & Mariotti, 2008), instrumental genesis (Trouche, 2004) or the documentational approach (Gueudet & Trouche, 2009), which are also used in many papers and discussions in TWG16. Murphy and Calder, for example, applied a framework including social semiotics and multimodality to interpret screen

casts of students working in a problem-solving application on an iPad, to understand the learning that took place.

In spite of theoretical developments in the field (e.g., see Monaghan, Trouche & Borwein, 2017), Schacht's was the only contribution to TWG16 that paid attention to a new theoretical field. Taking an inferential perspective, he investigated the relationships between mathematical and tool language while working with digital technologies and the transition – or non-transition – from one to the other. He showed how the way in which this transition can be accomplished can have implications on the individual concept formation processes. He especially emphasized the meaning – but also the obstacles – of the transition in the language use (by students) from a tool-oriented language to a mathematical-oriented language. The philosophical discourse about the concept of “digital” (see Galloway, 2014) - “Any discourse that produces or maintains differences between two or more elements can be labelled digital” (Schacht) - might give orientation also in the evaluation of the language transfer in mathematics education.

## **Upcoming topics**

The continuous development of technological tools, which are used both in and out of school, requires us to address old questions under a new perspective. On one hand, this new perspective has to consider new developments in hardware (tablets, smartphones) but also in software (social media, cloud computing). On the other hand, we have to consider new developments in society, science and (mathematics) education, for example with respect of online communication without any limitations in time and space. Goals in education have to be continually rethought and evaluated.

### **3D-geometry**

Regarding the future development and progress of our working group, there are different topics for which we see the potential for further investigations. Kynigos and Zantzos presented a study, during which students were asked to construct the shortest path between two points on a cylindrical surface. To solve the problem, they had to see the relationship between 3D- and 2D-geometry and activated the “old idea” of a turtle geometry which allowed access to difficult concepts like the curvature of a special surface.

### **MOOCs and new kinds of e-learning**

A second aspect is the meaning and the impact on mathematical learning of free available massive open online courses (MOOCs). Khan Academy<sup>1</sup> offers a free tool that allows teachers to monitor students' activity and provide them with feedback and guidance. Vančura used this tool at a Czech high school to provide feedback for students' homework. The investigation showed that weak knowledge of the English language might not be a barrier for students. Vančura also sees the danger of using such courses just for the training of algorithms without developing knowledge of underlying mathematical concepts.

Gray, Lindstrøm and Vestli also used the Khan Academy (KA) tool for pre-service teachers in mathematics who were allowed to substitute their compulsory mathematics assignment with exercises

---

<sup>1</sup> [www.khanacademy.org/](http://www.khanacademy.org/) (06.04.2017)

in KA. They compared their results with those of a control group, learning in the traditional way. At the end, there was no statistically significant difference in the performance of the two groups.

It is an open question whether MOOCs or SPOCs<sup>2</sup> will have an influence on the teaching and learning at schools and universities. Nevertheless, identifying good ways of e-learning will remain important, whether open resources on the internet or special courses integrated in learning management systems are used.

### **Tablets**

Since the very first CERME conference, an important question has always been what kind of interactions take place between the tool and the learner. The goal has always been to bring the individual into the centre of learning. Digital technologies can mediate between mathematics and understanding. Nowadays, the relatively straightforward and intuitive use of digital technologies in the form of laptops and smartphones gives users the chance to not put too much emphasis on the technical aspects of the tool, but to concentrate on the learning. Palha and Koopman created the tablet-driven project Interactive Virtual Math: a tool to support self-construction of graphs through dynamical relations. The aim of the project is to develop a visualization tool that supports students' learning and relational understanding of graphical situations. The medium – here a tablet – allows the students to “draw” graphs using a finger, a digital pen or a mouse, to ask for help and to compare their own solution to the expected solution. According to the authors, this tool has the potential to help students understand functional relationships, but more importantly, allows the students to work on their own, experiment, create self-productions and reflect on them. Until now the authors only evaluated their tool in a small qualitative study.

Tablets will be important tools in the years to come. With multi-touch technologies, gestures have become an essential feature of user interface. The relation between touching and meaning-making might become more important. De Freitas and Sinclair used multi-touch technology and tangible gestures with young children to promote counting on and with fingers. These children used their fingers – one after another – while counting sequentially, they used their fingers simultaneously to represent numbers and they left a trace on the screen with one or more fingers. With the touchscreen interface, and particularly the multi-touch actions, they see the hand involved in a process of communicating and a process of inventing and interacting. “We interpret these speculative comments as an indication that the future of the gesturing hand in relation to new media may involve all sorts of surprises, and that perhaps even pre-school children may count ‘on their hands’ to 100 as they engage with these media” (De Freitas and Sinclair).

### **Smartphones**

Nur Cahyono and Ludwig used smartphones to help students engage in meaningful mathematical activities. A math trail is a walk in which mathematics is explored in the environment by following a planned route and solving outdoor mathematical tasks related to what is encountered along the path. In the MathCityMap-Project students are confronted with special situations and questions along the path, supported by a GPS-enabled mobile phone app. Students were intrinsically and extrinsically

---

<sup>2</sup> Small Private Online Courses

motivated and engaged in this project. Moreover, they got to know more about their environment and model problems related to it.

### **Digital games**

Computer game characteristics could also be exploited for the purpose of mathematical learning. As an example, Gjovik and Kohanova developed a mobile app on the topic of linear functions. The mobile phone is a tool we can expect to see more in mathematics education as learning becomes further individualized and online. In the “Lucky Hockey” game students have to strike a hockey puck along a straight line by entering a linear expression. Prior knowledge concerning the properties of linear functions is required when playing this game and in order to identify the path of the puck so that it hits the coins. The results of this project especially concerning the long term effect have not been satisfactory. The authors conclude that it might be difficult to make applications that facilitate exploration and discovery while doing mobile learning. It might be more effective if quite narrow mathematical topics are used. The concept of linear function might already be a too elaborate topic.

There are many questions around the use of games in mathematics classrooms which still need to be examined. How do we integrate games into the curriculum? When do students play these games? Is the motivation to play these games just an initial effect? What is the impact on students’ learning and understanding? How sustainable is that knowledge over time?

### **Computational thinking**

Robots are starting to play a more important role in our daily life. Robot competitions are quite popular in schools, but these activities usually take place outside regular lessons. The control of the robots, e.g. while walking through a labyrinth, needs algorithmic thinking similar to the turtle geometry of the 1980s. Seymour Papert (1980) originally created the label “computational thinking”, but nowadays this concept has a much wider scope: it includes collecting, analysing and visualizing data, programming, creating computational models, and understanding relationships in systems. Broley, Buteau and Muller presented a model of computational thinking practices based on Weintrop et al.’s (2016) taxonomy for computational thinking in mathematics and science practices. The authors ask for further clarification of this concept and ways to integrate it into mathematics lessons.

### **Missing topics**

If we compare the TWG16 call for proposals with the actual contributions made by the participants, we see some interesting gaps. Firstly, no attention was paid to digital assessment of and for the learning of mathematics. There are on one hand questions concerning written (final) examinations: Which technologies are allowed? Which tools are needed (Drijvers et al., 2016)? Which tasks are appropriate? How do students report their thinking? On the other hand, the question of how formative assessment might be a means to develop student competences is also of interest (Beck, 2017; Black & Wiliam, 2009). These topics have been addressed in some aspects in TWG 15 and in more detail in TWG21 on assessment.

Moreover, the topics of e-learning, blended mathematics education and (Massive Open) Online Courses for mathematics may set the agenda for CERME11. This includes issues such as personalized and adaptive learning, and the design of online feedback for students. The opportunities and constraints of using social media in students’ perception of mathematics and their learning have

also been absent, as was the case for the intriguing topic of virtual and augmented reality. Examples of the use of technologies devoted to the support of students with disabilities have not been addressed either.

With respect to the methodologies in the reported studies, the focus was on small-scale qualitative studies, whereas large-scale experimental studies were not presented. Even if the latter may have pitfalls, the field might benefit from an integration of both qualitative and quantitative approaches, so as to gain sustainability and applicable knowledge on how mathematical learning can benefit from the interaction with digital resources.

## Concluding remarks

Digital technologies are now an element across all CERME groups (e.g., see Ferrara & Ferrari, TWG24; Hogstad, Norbert Isabwe & Vos, TWG14; Montone, Faggiano & Mariotti, TWG4). This indicates how digital tools permeate the mathematics education research landscape and have gained legitimacy across the field. In today's mathematics classrooms, different types of digital technologies are integrated in daily practice: interactive whiteboards, tablets, notebooks, graphing calculators with and without CAS. We have noticed a significant gap between research findings and mathematics teaching and learning practices in the regular classroom. The overall impression is that we cannot yet speak of a sustainable change through the use of digital technology, scaled up beyond the incidental level. We should acknowledge that integrating digital tools in a way that is beneficial to student learning is not as straightforward as we might have thought some decades ago. Thus, a specific working group on digital tools in mathematics education is appropriate within the frame of CERME, even if the impact of technological developments is hard to isolate from its context and from the topics central to other CERME working groups. A TWG dedicated to this issue could make a distinct contribution to important questions on the future of mathematics education.

# A computer-based collaboration script to mediate verbal argumentation in mathematics

Giovannina Albano<sup>1</sup>, Umberto Dello Iacono<sup>1</sup> and Maria Alessandra Mariotti<sup>2</sup>

<sup>1</sup>University of Salerno, Italy, {galbano,udelloiacono}@unisa.it

<sup>2</sup>University of Siena, Italy, mariotti21@unisi.it

*This paper reports on a pilot study concerning a first implementation of a collaboration script, aiming at developing students' argumentative competences in mathematics, as part of an interactive digital storytelling. We discuss the outcomes of the transcripts' analysis, which seem to show that the collaboration script fosters the introduction of the student to the construction of arguments as cohesive texts, independently on the student's skill in mathematics, and that the success of the script depends on the learners' engagement in the story and on the team mood.*

*Keywords: Collaboration script, linguistic, argumentation, mathematics education, e-learning.*

## Introduction

This paper focuses on a part a wider research (Dello Iacono, 2015; Albano, Dello Iacono, Mariotti, 2016; Albano, Dello Iacono, Fiorentino, 2016), aimed to investigate the effectiveness of the design and implementation of a Digital Interactive Storytelling in Mathematics (DIST-M), that is a platform model organizing mathematical learning activities based on social virtual interactions. The DIST-M consists in collaboration scripts implementing a work methodology for the students that, according to Vygotskian perspective, is expected to mediate specific mathematical competences. A collaboration script is a scheme that regulates and structures roles and interaction in a collaborative setting (King, 2007). The choice of the use of storytelling is related not only to motivational aspects and cognitive effectiveness, but also to the possibility of integrating narrative and logical-scientific thought (Zan, 2011). In our DIST-M the student does not create the story, but she interacts with it. In “Programma Discovery” the student assumes the role of a scientist at NASA, member of a team led by Professor Garcia (head of story and voice platform). The goal of the team is to analyse the data coming from a probe launched on a new planet, trying to figure out if this can accommodate life. During the fruition of the story, the student will face problems, whose solution is needed to continue the work of the team. This paper reports on a pilot study concerning an implementation of the DIST-M focusing on the development of students' communication competences in expressing argumentative mathematical sentences, as they can be considered as critical to the advance of mathematical thinking (Ferrari, 2004). The goal is to introduce the student to the construction of arguments written according to a register shared in the mathematical scientific community. We analyse, from a qualitative point of view, the arguments produced by the students under a linguistic perspective, focusing on the organization of the verbal texts, as cohesive texts, which means words and sentences perceived as a whole entity. We also look at the functioning of the collaboration script in terms of the team work and its impact on the success of the activity. We expect that the collaboration script in organizing the roles and actions within the team fosters the production of arguments and counter-arguments, allowing each member to interiorize the so-born practice.

## **Theoretical framework**

### **Collaboration script**

In cognitive psychology, the internal memory structure corresponding to a sequence of actions that define a well-known situation is named script (Schank and Abelson, 1977). Here each actor has specified roles and actions to take. The script is activated every time the individual is in the same situation. In educational context such constructs differ mainly because of its external definition and they aim to regulate roles and actions of students in collaborative/cooperative learning in order to succeed in learning (King, 2007). The use of external scripts has been incremented in computer-supported environment, where the need of pre-structuring and regulating the social and cognitive processes is much more evident. Concerning argumentation, it is well known that the simple request of collaborating does not guarantee the development of argumentative competences. This can be fostered by means of computer-based scripted collaboration (Weinberger et al., 2007), taking advantages on the use of text-based interfaces that allow the students to have more time to read their written argumentations and their peers' ones and to come back to their writings every time they want. According to Vygotsky (1930), "Every function in the child's cultural development appears twice: first, on the social level, and later, on the individual level; first, between people (inter-psychological) and then inside the child (intra-psychological)". Although the scripts are externally designed and imposed to the learners, the goal is that they are internalised along the time through the social practice. Only when the external script is interiorised, then it is successful; otherwise we have once again a repetition of actions externally imposed and learned by heart.

### **Language and cohesion**

As the defined script aims to the construction of arguments, we are interested in how the student can propose verbal arguments to support the solution to a given question, apart from the correctness of the solution. Although some theoretical models regard arguments with no reference to language, as a matter of fact, a written argument is, first of all, a written text, and for the student, the tasks of producing a correct text and an acceptable explanation are closely intertwined. This is why we will use a linguistic perspective with related specific tools such as cohesion. This latter allows creating the texture, which is the quality of being a text instead of a disorganised set of words and sentences (Halliday and Hasan, 1976). Though related, cohesion is different from coherence. The first one refers to the linguistic devices needed to realize the second one, which is instead a mental process, proper of the individuals involved in the discourse. The production of an acceptable argument can be hindered by the lack of either mathematical or linguistic competence. Often students produce written explanations that are plain descriptions of the procedures they have carried out, by means of a set of more or less disconnected clauses where cohesion is marked just by the fact that the text they produce is semantically congruent to the actions they have performed. In other words, their cohesion markers are extra-linguistic, and we cannot tell whether or not the writer is aware of the semantical links among the clauses. We believe that the construction of cohesive texts is the first step towards the development of logically acceptable arguments. The script has been designed with the aim of fostering the student to construct cohesive arguments, which can be interpreted by their pairs, independently on their mathematical abilities.

## DIST-M script

The DIST-M script presented here aims to allow the student to grasp a method of construction of mathematical arguments expressed verbally. The student is involved in tasks alternately individual and social. Social tasks are realized by means of chat and group forum (Figure 1).

**Figure 1: Design of the script**

The chat supports the explicit comparison and it mediates (Bartolini Bussi & Mariotti, 2008) a modality of communal acting (to get an answer, an argument that supports its correctness, a reply adapting to the possible contradictory) that from social activity becomes an own way of working of the student. The forum, through its rules of use, supports the sharing and discussion, and in this way, it mediates the interaction inducing everyone to give their own contribution and to listen the one of others. In the forum, each student writes a description of his/her solution, reads / interprets the writings of others and can / must compare his/her texts with those of others. All this requires significant semiotic processes that besides being expected to foster the development of mathematical meanings, are expected to promote social argumentation experiences that might be internalized and become own internal process of each student. Thus, according to Vygotsky (1930), there is a development of “higher mental functions”. In our case we refer to experiences of argued debate on manner of thinking / solving / answering the question, thus with higher mental functions we refer to argumentative skills, concerning the need to support the correctness of their answers with relevant topics, socially and mathematically acceptable. The functioning of the DIST-M requires different types of interactions: interaction with the script and interaction between the members of the team. The goal is to give a shared solution for the task, but the main achievement for the single student is to formulate his/her own argument (as a text) supporting the correctness of such a solution. In the script specific constraints have been designed to induce the production of personal arguments, their comparison and eventually the elaboration of a final answer, mediating the moving from an informal to a formal expression of the final individual answer.

In the following, we give a brief description of the various tasks constituting the script (Figure 1). At first the group chooses its own Captain talking to group friends in the group chat (Task 1). He is in charge of engaging all the team members in following the tasks of the script. The next task is the interaction with a GeoGebra interactive construction (Task 2). The aim is to investigate and solve a problem posed by the story. After a more purely experiential phase and subsequent guided reflection, the student answers on the forum to an open question aimed to generalize the experience and the results to which the student has come (Task 3). When all students have submitted the response to the Forum, the discussion continues chatting with the aim of achieving a common response that the captain reports on the chat (Task 4). In the next task, the student responds individually to a semi-open interactive question (Task 5). The interaction consists in manipulating the words-blocks available to build the response and motivation to the previous individual and group question, and in receiving a feedback on the correctness. The words-blocks have been constructed using some answers collected in a pilot. In order to highlight the causal structure of an

argument, the causal conjunctions, which are responsible of the cohesion, constitute separate words-blocks from the other ones. Then the student is required to report on the forum the phrase built by words-blocks with the received feedback and he can see the ones by his peers (Task 6). It follows a chat group discussion to reflect on the words-blocks sentences proposed by all the members with the aim of clarifying the correct answer and argument (Task 7). Finally, the student writes in the personal Log Book all information considered useful for the mission, the impressions on the activity, the difficulties encountered and how they were overcome (Task 8).

## Experimentation

The prototype used for the experimentation has been realized by means of open-source or free tools, that have allowed to create new interactive graphical applications and semi-open interactive applications (Dello Iacono, 2015). The pilot study has involved 23 10th grade students of Liceo Scientifico in Pompei (NA, Italy). The students have been split into 6 teams, each of them constituted of 4 students, except one constituted of 3. The teams have been randomly assembled, so that each student at the beginning did not know his/her team mates. Students belonging to the same team could communicate only through the forum and the chat. In the following, we analyse and discuss the experiment with respect to the following key points: (i) the production of verbal arguments for supporting of the solution to a question; (ii) evidence of the different functioning of the script (that is the implementation of the designed learning activity) according to the student's engagement with respect to the story and the team work.

Concerning the first point, we analyse, from a qualitative point of view, the arguments produced during the individual open question and the answer in forum (Task 3 and 6 in Figure 1), that is before and after the semi-open interactive question, in order to investigate the effectiveness of the script. The students are required to answer if and why, fixed a sector in an aerogram, the angle varies according to the radius variation. As we will see in the following, the comparison between the nature of the individual arguments produced during the two tasks shows evidence of an improvement in the cohesion of the explanations constructed. In order to verify the cohesion, we look for the following cohesion markers in the texts produced by the students: lexical repetition (consisting in repetition of words), grammatical repetition (reference, that indicates something already appeared in the text, and ellipsis, that consists in the deliberate omission of words that are required to make up the sense), conjunction which allows to link two parts of a discourse (external, when it refers to a fact, internal, when it refers exclusively to the organization of the text).

Let us consider the team 2. At Task 3 only 1 student provides an argument explaining his/her answer, and he/she is the one who draws team's attention on this request, actually, replying to a mate enquiring of the platform's feedback on his/her answer, he/she says in chat:

1            S7                    me too, but we are required to justify our answer

So next his/her answer in the forum is the following:

2	The quantity to be represented is equivalent to 20%.	A first reformulation of the data of the problem
3 4	$360^\circ:100\%=x:20\%$ $x=(360 \times 20):100=72^\circ$	S7 carries out a calculation

5	Although the radius changes, the size of the angle does not change	A conclusion is drawn on the previous calculation.
---	--	--

What is posted in the forum is mostly like a report of his reasoning (thinking aloud) without any cohesion marker. It can be seen as a report the mental process in the mind of the writer S7 and in his view it is coherent. This may not be the case for a reader, as it was for another student who asked for clarification. So S7, in order to explain to him, transformed such a personal reasoning in a new text.

6	The angle of the coloured part does not change varying the radius	The conclusion becomes the first statement expressing the answer to give.
7	Because in a circle the angle is always $360^\circ$ and then 20% is always $72^\circ$	The previous calculation has been interpreted to become an explanation of answer.

The new text is cohesive. As a matter of fact we note lexical repetition (angle), external conjunctions (because, then), ellipsis (20% refers to  $360^\circ$ ). The difference between the two texts consists in the fact that the cohesion of the text can help the reader to grasp its coherence, which may remain inaccessible for the first text. An effective use of cohesion promoted the shift from a personal report of reasoning to an argument: the sequence statement – calculations – conclusion became a statement plus an explaining argument. Such a cohesive text was generated for communication goals: the request of sharing his/her personal answer seems to have induced the student to better articulate the solution process transforming the calculations into a verbal text providing the reason of such calculation. So the collaborative script has promoted the construction of cohesive argumentations, because of the need of improving communication within the group.

In Task 6, we note a clear improvement: 4 students (that is all members of the team) produce an answer that includes an argumentation. In particular, 2 students (S5 and S8) who did not justify in Task 3, when reporting the answer made of words-blocks, not only produce a justification, but both of them go further the request and rephrase with their own words the arguments.

At Task 3, S8 writes the non-cohesive sentence (there is only an internal conjunction “anyway”):

8        S8        Varying the radius anyway the angle does not change

Then, at Task 6, he writes:

9	The angle does not vary because it is always equal to 20% of the circle angle.	External conjunction (“because”), reference (“it”).
10	The other scientists completely agree with me as varying the radius there is only an extension of it and the angle remains unchanged.	External conjunction (“as”), reference (“it”), lexical repetition (“angle”).

The first sentence is the one constructed by the words-blocks, as required in the Task. Then the student get back in touch with the story and he/she seems engaged and making reference to the scientists, he/she explains in his/her words why all the scientists agree and produces his/her own arguments for supporting the given answer. The second sentence is cohesive. Also in this case the script, requiring reporting the answer constructed by words-blocks and the scientists’ feedback, seems to promote the construction of arguments in terms of cohesive texts.

A similar evolution is shown by student S5. At Task 3, she produces a non cohesive text with no markers of cohesion:

11 S5 The angle does not change, only the radii vary

In following tasks, he/she writes:

12	The angle does not change because it is always equal to 20% of the circle angle.	External conjunction (“because”), reference (“it”).
13	All the members of my team has the same idea. I have the angle is always the same because in a circumference the angle is always 360°, then 20% of 360° is always the same	Two lexical repetitions (“angle”, “360°”), two external conjunctions (“because” and “then”)

Also the student S5 at beginning reports the answer made by the words-blocks, but later he/she refers to the story and he/she seems so engaged to say “my team”, the team of the scientists to which he/she belongs in the story, and when he/she refers to the story, he/she rephrases with his/her own words the answer and its motivation. The sentence constructed by S5 is cohesive. Thus, it seems that the functioning of the script, based on sharing the answers and impelling to find an agreement might lead to appropriate the meaning of argument as explaining and supporting the correctness of the solution by means of cohesive texts.

Let us consider a case where, even if the answer given by the student is not correct, we can anyway observe a shift towards the production of an argument. The student S22 at Task 3 writes:

14	Greater is the radius as much as the angle decreases.	This text is not cohesive (there is no markers).
----	---	--

At Task 6 he/she writes:

15	The angle decreases because it is inversely proportional to the radius but the other scientists do not agree	Two external conjunction (“because” and “but”), ellipsis (“the angle” is omitted in the secondary sentence)
----	--	---

Here we have a cohesive text constructed by means of the words-blocks. Even if the answer is not correct, there has been the production of arguments. So, the script seems to work according our goal (to foster verbal argumentation) independently on the correctness of the mathematical content.

Similar behaviour can be observed in the other teams: we have only 8 students among all teams that produced argumentation at beginning, whilst at the end all of the 23 students do it. In particular, the request of sharing on the chat seems to have a mediating function leading to transform a personal reasoning into a public argument. As shown above, the students do not limit themselves to report the sentences constructed with the words-blocks, but they also reproduce arguments with their own words assembled in a structure similar to the ones suggested by the script.

Concerning the second point, the transcripts show evidence that the effectiveness of the activity is strongly influenced by the students’ engagement with respect to the story and to working in group. The effective work of Team 2 seems to occur because all the members were engaged in the story and shared a good mood allowing collaboration. However, in some other cases, we can see that the

activity fails if this does not occur. Let us consider for instance, team 5. The Task 3 seems to work well, the students are engaged in the activity and produce quite different argumentations:

- |    |     |  |
|----|-----|--|
| 16 | S17 | 360:100  |
| 17 |     | $3.6 \times 20 = 72$   |
| 18 |     | varying the radius the angle does not change   |
| 19 |     | because the percentage is always the same  |
| 20 | S20 | varying the radius the angle indicating the percentage of the considered               |
| 21 |     | stone does not change because 20% of $360^\circ$ is always $72^\circ$ , $360.1/5 = 72$ |

Arriving at the Task 6, we find that they seem to have lost interest in the activity. Looking at the chat transcripts, there is evidence of a change of the team's mood. Actually, students start to become nervous around the end of Task 4:

- |    |     |  |
|----|-----|--|
| 22 | S20 | but we have not yet given the first agreed answer beep |
| 23 | S18 | WE ARE DISCUSSING NOW TO HAVE AN AGREED ANSWER         |
| 24 |     | 20, you are a genius of evil, connect you brain        |

Team mood in chat get worse until the beginning of Task 6:

- |    |     |   |
|----|-----|---|
| 25 | S18 | HAVE YOU UNDERSTOOD?!   |
| 26 |     | DO IT ALL OF YOU 4 IF YOU DID NOT DO IT YET!                                    |
| 27 |     | I said to you in the session share not in the notes, I was sure that you did it |
| 28 |     | Hurry up to write in the sharing session  |
| 29 |     | THERE ARE TWO SESSION OF beep. S20 who are you?                                 |

At the Task 6 the students have lost their initial engagement and do not satisfy completely the requests. It seems evident that the mode of operation has been strongly affected by the negative engagement, in particular of the Captain, and by the impossibility of collaborate.

## Conclusions and future directions

In this paper we have reported on a pilot study concerning a computer-supported collaboration script, aiming at developing students' verbal argumentative competence. The analysis of the students' transcripts seems to show that the collaboration script fosters the introduction of the student to the construction of arguments as cohesive texts, independently on the student's skill in mathematics. Some students shift from producing computations to constructing cohesive argumentations that make use of the previous calculations; some other students, although they do not get the correct answer from the mathematics point of view, also produce cohesive texts as expression of their reasoning. We are now working on a quantitative data analysis, by means of statistical test, coding cohesion of the written students' productions to compare Task 3 and Task 6, in order to confirm the effectiveness of the script as shown by the transcripts in the previous section. Moreover, in order to check that students really interiorized the script and not only repeat what they did before, as well as the use of the cohesion, we are implementing a new script, as continuation of the story, without the word-blocks. There is also evidence that a negative mood in the work team can compromise the success of the learning activity. To this aim, we are implementing a new version foreseeing the introduction of a role for each member of the team, behind the Captain, avoiding that somebody in the group gives away the responsibility. We are going to prove that the

designed script, suitably modified in order to create a positive mood in the work team, promotes effectively the construction of cohesive texts and the fact that there is a strict interconnection between them and logically acceptable arguments.

*“Computational thinking” is a hot topic in math education, among teachers whose curricula now include the term, and researchers who wish to pinpoint what it means and how it could be promoted in classrooms. A recent study resulted in a theoretical model of the computational practices of professional mathematicians and scientists, with the aim of offering teachers a set of competencies around which to build activities for their students. Nonetheless, concrete examples that validate the model and exemplify its use in math classrooms have yet to be discussed. We wish to open up this discussion, which we see as crucial to understanding how to empower students to participate in the computational thinking that has become integral to the mathematics community and beyond.*

*Keywords: Computational thinking, mathematicians’ practices, legitimate peripheral participation.*

## Introduction

Parallel to the invention of the personal computer, Papert (1980) envisioned a world where children fluently use the tool as young mathematicians. Some thirty years later, we’ve witnessed a widespread resurgence of interest in that vision, taking shape in educational reforms (e.g., in Europe; Bocconi, Chiocciariello, Dettori, Ferrari, & Engelhardt, 2016) and research regimes (cf., [www.ctmath.ca](http://www.ctmath.ca)) in the name of *computational thinking*, deemed a 21<sup>st</sup> century skill. Yet, there is little consensus on what this “new” term encompasses or how/if it should be conceptualized within subject areas beyond computer science (Grover & Pea, 2013). In response to these issues, Weintrop et al. (2016) developed a taxonomy of computational thinking practices geared towards science and mathematics. They based their work on a literature review, an analysis of learning activities, and interviews with “biochemists, physicists, material engineers, astrophysicists, computer scientists, and biomedical engineers” (p. 134). They also show, through concrete examples, how the practices might be promoted in physics, biology, and chemistry classrooms. To build on this work, we could ask: What might the computational thinking practices look like in *mathematics* classrooms? Moreover, are they representative of professional *mathematicians’* practices?

In this contribution, we attempt to provide some answers to these questions by drawing on two resources: 1) fifteen years of experience in a sequence of three undergraduate Mathematics Integrated with Computers and Applications (MICA) courses at Brock University, where students create and use computer environments to explore mathematics concepts or real-world situations; and 2) reflections of mathematicians whose research falls within an area recognized by the European Mathematical Society in 2011: “Together with theory and experimentation, a third pillar of scientific inquiry of complex systems has emerged in the form of [...] modeling, simulation, optimization, and visualization” (p. 2). The next section outlines the perspective underlining our work and our approach in preparing this paper. We then present our results, i.e., we exemplify (empowering legitimate peripheral) computational thinking practices in mathematics.

## Theory and methods

The way we interpret “Learning mathematics with technology” in the context of this paper is well explained by Lave and Wenger’s (1991) concept of “legitimate peripheral participation”, whereby students are invited to become mathematicians through engaging in their shared practices. “Mathematics”, then, is not seen as a body of knowledge to be acquired by the student, but rather as a social community to which the student gradually gains membership. Hence, we do not discuss computer “technology” from a cognitive point of view, for example, as a helpful tool in illustrating concepts. We focus, instead, on how mathematicians, the old-timers of their discipline, and students, the new-comers, create and use computer tools to engage in practices considered to be integral to the mathematical community.

Data Practices	Modeling & Simulation Practices	Computational Problem Solving Practices	Systems Thinking Practices

		Creating Computational Abstractions	
		Troubleshooting and Debugging	

**Figure 1: Computational Thinking Practices, taken from Weintrop et al., 2016, p. 135**

In recent work, Weintrop et al. (2016) outline what they believe to be these integral practices (Figure 1). Their framework provides a detailed description, specific to STEM (i.e., science, technology, engineering, and mathematics), of one of three dimensions introduced by Brennan and Resnick (2012) to characterize “computational thinking”: namely, computational concepts, practices, and perspectives. Such frameworks seek to elaborate on the general definitions on which they are grounded; for instance, that of Cuny, Snyder, and Wing, who describe computational thinking as “[t]he thought processes involved in formulating problems and their solutions so that the solutions are represented in a form that can be effectively carried out by an information-processing agent” (2010). Computer programming plays a particularly important role, as it “is not only a fundamental skill of [computer science] and a key tool for supporting the cognitive tasks involved in [computational thinking] but a demonstration of computational competencies as well” (Grover & Pea, 2013, p. 40). Such ideas invoked in us vivid images of our own experiences with/as mathematicians and students creating and using computer tools to do mathematics. And this inspired us to address an apparent void: that is, a comparative picture that highlights the powerful computational thinking employed by professional mathematicians, on the one hand, and, on the other, the potential of students to participate in the same kind of thinking.

To prepare this picture, we re-examined Broley’s (2015) research, which explored the use of programming by 14 mathematicians in their research and teaching. In an interview, each participant described research where they developed and used computer tools. Unbeknownst to us at the time, this provided examples of how some full-membership mathematicians engage in computational

thinking. Amongst them, we chose four that align with the groupings in Weintrop et al.'s (2016) taxonomy. We then reconsidered the data from another study (Buteau, Muller, Marshall, Sacristán, & Mgombelo, 2016) – the 14 MICA projects completed by one student, Ramona – as a source of four examples of peripheral computational thinking. MICA's goal of responding to society's need for professionals proficient in programmable technology made it a natural database for comparison.

## Results

This section provides examples of computational thinking as it might be experienced by full and peripheral participants in the mathematics community. For each category identified by Weintrop et al. (2016), we describe a mathematician's project that we feel effectively exemplifies it. This is contrasted to a MICA project that we see as providing access to the same kind of practices.

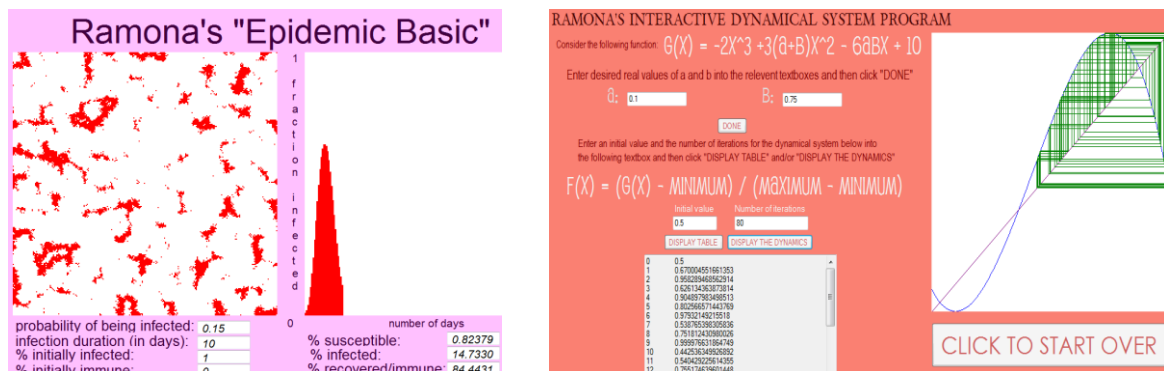

### Data practices

Adèle uses her expertise in mathematics and computing to solve problems in financial engineering. In one project, she developed a model that enables investors to judge the investment potential of various market entities. In particular, the model calculates the risk that an investor will lose money because the investee is unable to pay back what they owe. The tricky part is that most investees have never had such financial problems (e.g., with bankruptcy). To assess a given company or individual, Adèle considers their portfolio: She *collects* their history of actions (e.g., investments, bonds, shares) on the financial market. The basic idea is that as others agreed to invest a certain amount of money in the company or individual, they implicitly demanded to be compensated for the risks they were taking, thereby predicting the probability that the investment would be a good one. Mathematically-speaking, the problem is of an extremely high dimension: Adèle's model contains over 20 parameters that must be estimated for each portfolio by *manipulating* the corresponding data with optimization techniques. Intensive numerical methods are then applied to the specified model to *generate* the data necessary for evaluating the risk of the investee(s) being considered. The result is not a simple measure of the average risk. Adèle must perform a nuanced *analysis* to meet her clients' needs, calculating and *visualizing* probability distributions in order to portray the best and worst case scenarios. About the place of computation in her work, Adèle was blunt: She said there would be no project without it. In fact, when tasked with assessing the risk associated to hundreds of companies at once, she must use computer clusters to get the job done.

In their second of three MICA courses, students in Ramona's cohort were assigned a project similar to Adèle's. During lectures, they were introduced to mathematical ideas related to the stock market. In regards to programming, they also learned how to read data from files. Up to this point, they had worked with data they *created* through simulation; but during this project, they had to use data from Stock Market sources. During two (two-hour) lab sessions, the students initiated their individual work by *collecting* the S&P index, a measure of market conditions, from 1950 to 2002, and writing a program to *manipulate, visualize, and analyze the data* using standard statistical techniques. Students were also required to select ten stocks and, like Adèle, make recommendations to a fictive client based on their own *analysis*. In her report, Ramona grounded her recommendation on the mean and average yearly percentage of her stock selection. Then, as requested, she conducted a regression analysis of a stock over a decade and described how *visualizing the data* as a cloud of points confirmed her interpretation of the coefficient as representing a weak correlation.

## Modelling and simulation practices

Alice's projects are often inspired by a collaborator in need of her modelling and simulation skills. She spoke, for example, of a kinesiologist who initiated a multi-year project about muscles. Alice began by learning about the application, which she knew little about. She could then *design* a system of equations that would allow her to study the features of interest, i.e., tensions, bulges, and fibers; but only once the model was implemented on a computer. During her interview, Alice joked that computation was essential because, unfortunately, the solution to a real-world mathematical model never simplifies to the quadratic formula. While some researchers use existing simulators to gain access to their models' solutions, Alice prefers to have the control of *constructing* her own. This comes at a price: Even if her team starts with an existing code, they still have to think very hard about how they implement their equations, import data, generate meshes, and so on. But all this hard work apparently paid off in this project: Alice described the resulting computational model as "the most complex simulator of its kind", and was hesitant to share its massive code during her interview. This tool was used systematically to investigate issues the researchers initially sought out to *understand*. But by varying parameters in an exploratory mode, they also *found and tested solutions* to an unreported problem: the forming of well-defined fiber structures. During her interview, it was clear that Alice was excited by this discovery, for her collaborator had observed the formation of the exact same fiber structures, but in a real human! In the end, the data collected during this ultrasound experiment of a person on a bicycle *assessed* Alice's model, confirming that it represented "the real thing" in more ways than expected.

**Figure 2: Ramona's epidemic simulator (left) and discrete dynamical system program (right)**

Modelling and simulation practices that resemble Alice's are central to the MICA courses. At the end of the third course, students in Ramona's cohort were asked to use the theory of cellular automata to model and simulate the spread of an epidemic. Students worked individually to *construct* the computational model (i.e., to implement it in VB.Net), complete with a dynamic visualization of the cellular automaton and a complementary graph (Figure 2, left). Using this model, students were invited to observe real-time simulations of certain scenarios with the goal of coming to *understand* the effects of vaccination on the proliferation and diminution of epidemics. They were then told how to extend their models to include the cost of immunization and medical treatment, so to *find* (estimate) *the solution* of a minimal medical cost problem. In her report, Ramona went beyond finding the solution; as required, she also *assessed* the ability of her extended computational model to provide an accurate estimate, finishing with suggestions for improvement.

## Computational problem solving practices

To understand Norman's pure mathematics research, some *preparation* is in order. In his work, a permutation of length  $n$  is just a string,  $\sigma = \sigma_1\sigma_2\dots\sigma_n$ , where each  $\sigma_i$  is a unique element from the set  $\{1, 2, \dots, n\}$ ; for example,  $\alpha = 624531$  is a permutation of length 6. Given another permutation, e.g.  $\beta = 231$ , we say that  $\alpha$  contains the pattern  $\beta$  if we can find in  $\alpha$  a subsequence (not necessarily consecutive) whose numbers have the same relative order as 231. The fact that  $\alpha$  contains the subsequence 451 – 1 is the smallest number, 5 is the highest, and 4 is in between – means that it contains  $\beta$  (we could have equally used subsequences 241, 251, 231, or 453). If a permutation does not contain a pattern, it is said to avoid it; for instance,  $\alpha$  avoids 1234. An interesting problem for mathematicians is to determine the number of permutations  $p_n$  of length  $n$  that avoid a given pattern. It is known that  $p_n$  grows almost exponentially with  $n$ . The growth rate, however, is still unknown for many patterns. In search of one such rate, Norman's team had to build a complex computer tool. The *programming* was delegated to a student, whose life was simplified by the *development of a modular solution* based on an existing subroutine for another pattern. The creation of the entire algorithm, nonetheless, was a team effort, for it involved the careful *assessment of different approaches and solutions*. One option was to calculate the exact value of  $p_n$  for as many  $n$  as possible and then extrapolate the growth rate. But according to Norman, this approach was inefficient: At the time of his project, they could calculate the exact values only for  $n \leq 25$ , which was not enough to provide an acceptable solution. The mathematicians hence chose a probabilistic approach that uses estimates for  $p_n$  rather than exact values. This enabled them to calculate more data points; but their program was still slow. Seeking to *troubleshoot and debug* the problem, Norman suggested that his team try to visualize the permutations. Their decision to represent a permutation  $\sigma = \sigma_1\sigma_2\dots\sigma_n$  as a function that sends  $i$  to  $\sigma_i$  led to the discovery of an unexpectedly striking structure (Figure 3, left). Norman insisted on the importance of *creating this particular computational abstraction*: The pattern would not have been observable, for example, had they produced only a list of matrix entries. And then Norman might have missed out on a novel research direction that occupied him for many years.

Since all MICA projects involve *programming*, computational problem solving practices like Norman's always form a major part of their completion. Starting in the first MICA course, students discuss what makes a math problem amenable to exploration through programming. Since this is new to most of them, they are also led to develop their computational skills through a carefully selected progression of projects, which increase in complexity in terms of both the mathematical content and the programming requirements. For example, Ramona and her peers learned about discrete dynamical systems alongside techniques of displaying graphics in VB.Net, which they applied by creating a program to numerically and graphically explore the logistic map. In a later project, the students were asked to build on this work (i.e., borrow *modular computational solutions* from it) and *program* a tool to explore the system of a two-parameter cubic (Figure 2, right). This new problem required more serious *preparation for a computational solution*, as the domain of the cubic called for the consideration of different cases. Inherent to the programming process was also *troubleshooting and debugging*, *creating computational abstractions*, and *assessing different kinds of solutions*, which may have contributed to Ramona's conclusion in her written report that "creating and working with this program has assisted me to fully grasp the way a dynamical system works by observing the table, the graphs, and the cobweb with countless test values."

**Figure 3: Norman’s discovery of structure in pattern-avoiding permutations (left) and Albert’s computation of trajectories resulting from a perturbation off an orbit close to the moon (right)**

### Systems thinking practices

Albert has studied many complex systems, including those *defined* in celestial mechanics. The three-body problem, for example, seeks to describe the motion of a spaceship in the presence of two bodies, like the Earth and its moon. The complexity of the system is *managed* by ignoring the presence of other bodies, taking the spaceship to have negligible mass, and assuming that the massive bodies move in circular orbits. These explicit boundaries do not render the system useless. In fact, the model has provided initial approximations for real space missions. Moreover, it serves as a rich source of problems that allow Albert to show off the mathematically and numerically sophisticated software he has developed, software that according to him can compute “amazing things” that are simply “not computable” by traditional methods. Albert’s team has computed the uncomputable at different *levels*. Macroscopically-speaking, they have *investigated the three-body system as a whole* by finding and classifying an infinity of its periodic solutions (i.e., closed trajectories where a spaceship could remain in orbit). On a microscopic level, they have explored these orbits in family groups and individually. This latter consideration also helps them *understand some relationships between elements within the system*: For a given orbit, the researchers can determine the set of trajectories that a spaceship could follow after experiencing a slight perturbation. The resulting tube-like structures are like highways that enable space travel to far-away places with minimal effort (and money). One image (Figure 3, right) is enough to convey the importance of visualization in *communicating* Albert’s results.

In each MICA course, the last two weeks are dedicated to challenging original projects wherein students select topics of interest to them. Ramona’s terminal (14<sup>th</sup>) project is an example of how students might engage in practices similar to Albert’s and, as the MICA course creators aimed, “develop their own strategies for handling complex real world problems” (Buteau et al., 2016, p. 144). With two of her colleagues, Ramona *investigated, as a whole, the complex system* associated to the water level changes in Lake Erie (Canada). In particular, they were interested in explaining how and why the level changes over time (i.e., in *understanding the relationships within the system*). They described their initial research in existing literature as “a crucial starting point in [their] project, allowing [them] to obtain an understanding for the changes in the water supply of Lake Erie.” Based on the information gathered, they designed and programmed stochastic and deterministic models of the phenomenon. They then performed an analysis, through simulation, of six case studies, representing the system in various ways on a *different, more microscopic, level*. They used their initial research to justify the assumptions they made, the parameters they chose, and

the case studies they considered in order to *manage the complexity* of the system. This explanation was part of the 26-page report where Ramona's group *communicated their results*.

## Discussion and conclusions

The four pairs of examples provided above aim to render Weintrop et al.'s (2016) framework more concrete, validate its correspondence with a diverse set of authentic professional practices, and provide some insight as to how students might be invited to gain access to them, all within the context of mathematics. Ramona's work differed from the mathematicians' in its magnitude: Her projects were more restricted in scope and length, her computer programs were more naïve, and her findings had less immediate value for the community at large. This is not surprising since Ramona was in a peripheral phase of participating in the mathematics community, where she was simultaneously negotiating entrance into a community of students at a particular university, with its own norms limiting engagement in full-membership mathematical activity. Nonetheless, in exposing Ramona to the computational practices of mathematicians, programs like MICA support a nuanced discussion of what it means to integrate digital tools in students' learning of mathematics.

Many scholars have reported on the ways in which building and/or interacting with digital tools might assist students in meaningfully acquiring mathematical ideas or ways of thinking that are embedded in current curricula. The collection of papers presented in the working group on learning mathematics with technology at this year's CERME conference provides numerous examples. In fact, the main framework used in this paper was built on the premise that learning activities involving computational thinking practices can enrich students' understanding of mathematics and science (Weintrop et al., 2016). This said, the framework was equally inspired by the ever-increasing computational nature of STEM-related disciplines. As evidenced by our examples, and much work that precedes us, the power of the computer has had a major impact on the way that STEM professionals (can) do their work. And so, the *computational thinking* trend presents an opportunity (or perhaps a necessity) for mathematics educators at all levels to reconsider not just the "how" of mathematics teaching, but also the "what", i.e., the knowledge and skills to be taught. After all, students' participation in the computational thinking practices of mathematicians might not just prepare them for a computational future in general; it may also widen their perspectives of the nature of mathematics and who is capable of learning (and doing) it.

Both research and experience tell us that reflecting on the above issues, developing curricula to address them, and enacting that curricula in classrooms are quite different feats. Detailed and extensive frameworks like the one developed by Weintrop et al. (2016) can certainly help support researchers, curricula developers, and teachers. But there is still a need to examine more closely and completely the experiences of students who are peripheral participants in computational communities of practice: What skilled knowledge (i.e., practices) do they *actually* develop? Moreover, how do they identify with communities they are both entering and (eventually) influencing? Given our analysis in this paper, the MICA program provides a rich context within which to study such questions. The answers could lead to an enlightening discussion about challenges and opportunities in bringing about a nuanced technology-rich mathematics education.

# Examining motivation in mobile app-supported math trail environments

Adi Nur Cahyono<sup>1,2</sup> and Matthias Ludwig<sup>1</sup>

<sup>1</sup>Institute of Mathematics and Computer Science Education, Goethe-University Frankfurt, Germany; [ludwig@math.uni-frankfurt.de](mailto:ludwig@math.uni-frankfurt.de)

<sup>2</sup>Mathematics Department, Semarang State University, Indonesia; [cahyono@math.uni-frankfurt.de](mailto:cahyono@math.uni-frankfurt.de)

*The MathCityMap-Project was developed by combining the concept of a math trail program with advanced mobile technology. It aims at providing a new approach to promote student motivation to engage in meaningful mathematical activity. An explorative study was conducted as a pilot using nine secondary schools in the city of Semarang, in Indonesia, and 272 students and nine teachers were included. Using self-determination theory as a framework, we explored the motivation of students to engage in mobile app-supported math trail activity. Data collection procedures comprised observation, interviews, questionnaires, and student work analyses. Findings indicate that intrinsic motivation and identified regulation established an essential part of students' motivation to engage in this activity. The design of the learning environment, the use of mobile app, and the value of the mathematical task have contributed to this result.*

*Keywords: MathCityMap, mobile app, math trail, student motivation.*

## Introduction

A math trail, a path for discovering mathematics, was created as a medium for experiencing mathematics in all its characteristics, namely, communication, connections, reasoning, and problem solving (Shoaf, Pollak, & Schneider, 2004). In such a trail, students can simultaneously solve mathematical problems encountered along the path, make connections, communicate ideas and discuss them with their teammates, and use their reasoning and problem-solving skills. Although the math trail project is not new, supporting this outdoor education with mobile technology is an innovative approach to the program. This idea appears together with the fact that, in recent years, mobile technology has significantly improved and mobile phone use has significantly increased (Lankshear & Knobel, 2006). These advancements have been followed by the creation of many mobile phone applications (apps), including those intended for use in outdoor activities. In learning activities, Wijers, Jonker, and Drijvers (2010) suggested that mobile devices could be employed to facilitate learning outside the classroom. They also suggested that mobile technology could be exploited to support the outdoor educational program. Integrating advanced technology with the math trail program is the basis for the development of our project, called the MathCityMap-Project, in which math trails are facilitated by the use of GPS-enabled mobile phone technology. This project has been developed and implemented in Indonesia since 2013 and has been tailored to this country's situation. The main focus of this paper is to explore the motivation of students to engage in a math trail program supported by the use of a mobile app.

## Theoretical background

The MathCityMap-Project is a project of the math trail program, which is supported by the use of a GPS-enabled mobile phone app and uses specialized mathematical outdoor tasks (Jesberg & Ludwig, 2012). This project was not conceived merely to design and/or use the math trails. Instead, it includes the entire process: preparation (how to design it), implementation (how it runs), and evaluation (how

it impacts student motivation). The mobile phone app, as a supporting tool, was also created and used during this project. Therefore, the theoretical framework for the MathCityMap-Project study is underpinned by the concept of the math trail program, the use of mobile technology in mathematics education, and student motivation in mathematics.

A math trail is a walk in which mathematics is explored in the environment by following a planned route and solving mathematical outdoor tasks related to what is encountered along the path (English, Humble, & Barnes, 2010). In math trail activities, "children use mathematics concepts they learned in the classroom and discover the varied uses of mathematics in everyday life" (Richardson, 2004, p. 8). They discover real problems related to mathematics in the environment and also gain experience connecting mathematics with other subjects. Among the many benefits of a math trail (Richardson, 2004) is the creation of an atmosphere of adventure and exploration resulting from the fact that it is located outside the classroom. A math trail guide, such as math trail map or human guide, must be prepared to inform walkers about the math trail task stops and to show the problems that exist at each location. It also tells about the tools needed to solve the problems, so that the walkers are prepared before starting to walk on a trail. With the rapid development of technology nowadays, it is possible to collect the tasks and design a math trail guide based on a digital map and database.

In recent years, rapid developments in technology have occurred in the scope, uses, and convergence of mobile devices (Lankshear & Knobel, 2006). These devices are used for computing, communications, and information. Mobile devices are portable and, usually, easily connected to the Internet from almost anywhere. This makes them ideal for storing reference materials and learning experiences, and they can be general-use tools for fieldwork (Tuomi & Multisilta, 2010). Their portability and wireless nature allow them to extend the learning environment beyond the classroom into authentic and appropriate contexts (Naismith, Lonsdale, Vavoula, & Sharples, 2004). Wireless technology provides the opportunity for expansion beyond the classroom and extends the duration of the school day so that teachers can gain flexibility in how they use precious classroom activities. The use of mobile devices can also promote positive emotions for students toward learning mathematics (Daher, 2011). These advantages have been exploited through the MathCityMap-Project. Math trail blazers can create and upload math trails into a database through a web portal, then the math trail walkers can access them and complete the math trail with the help of a GPS-enabled mobile app (Cahyono & Ludwig, 2014; Jesberg & Ludwig, 2012).

In this paper, we focus on the exploration of the factors that motivate students to engage in mobile app-supported math trail activity. The academic literature distinguishes between two motivational concepts namely: extrinsic motivation and intrinsic motivation. An influential theory that explicates intrinsic–extrinsic motivation in depth is self-determination theory (SDT, Deci & Ryan, 1985). The SDT model conceptualizes a range of regulation from intrinsic motivation to amotivation. Between these, there exist identified regulation and external regulation. Intrinsic motivation exists when a student is engaged in an activity for his/her own sake/pleasure/satisfaction. Identified regulation refers to engagement that is valued as being chosen by oneself. External regulation is the type of motivation when engagement is regulated by rewards or as a way to avoid negative consequences. Lastly, amotivation is associated with engagement that is neither intrinsically nor extrinsically motivated (Guay, Vallerand, & Blanchard, 2000).

Having outlined the theoretical background for this study, we can clarify the research question: *what is the nature of student motivation to engage in a math trail program supported by the use of a mobile app?*

## Methods

An explorative study was conducted in the city of Semarang in Indonesia involving nine secondary schools. The participating schools represent three levels (high, medium, and low) and two location types (downtown and suburban). This study is a part of development research on the MathCityMap-Project for Indonesia. There were two main phases in this research, namely the design phase and the field experimentation phase. Here, we focused on studying student motivation to engage in the activity that was conducted in the second phase. This phase consisted of an introduction session, a treatment (math trails guided by the app), and a debriefing session. Student motivation was measured using the self-reported Situational Motivation Scale (SIMS) developed and validated by Guay, Vallerand, and Blanchard (2000) based on self-determination theory (SDT). The results of their study exposed that the SIMS represents a brief and adaptable self-report measure of situational intrinsic motivation, identified regulation, external regulation, and amotivation. ‘Situational motivation’ refers to the motivation individuals experience when they are currently engaging in an activity (Guay, Vallerand, and Blanchard, 2000). Therefore, this questionnaire is appropriate to be employed in this project to explore motivation of student to engage in the activity.

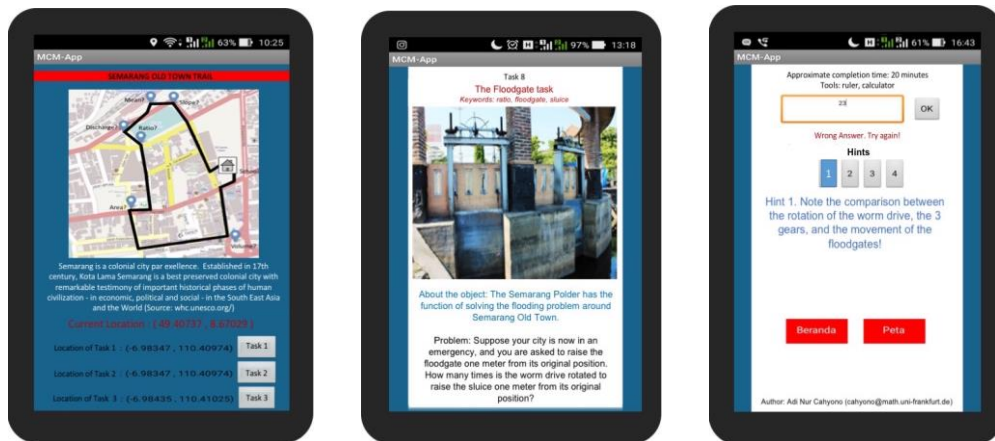

The SIMS is a 16-item questionnaire consisting of 4 subscales, intrinsic motivation (IM), identified regulation (IR), external regulation (ER), and amotivation (AM). In the first part of the instrument, the questionnaire asks, ‘Why are you currently engaged in this activity?’. Respondents are to rate a number of answers using a 7-point Likert scale from 1 (*not at all in agreement*) to 7 (*completely in agreement*) for each item. The items are ‘because I think that this activity is interesting’ (IM), ‘I am doing it for my own good’ (IR), ‘because I am supposed to do it’ (ER), ‘there may be good reasons to do this activity, but personally, I don’t see any’ (AM), ‘because I think this activity is pleasant’ (IM), ‘because I think this activity is good for me’ (IR), ‘because it is something that I have to do’ (ER), ‘I do this activity, but I am not sure if it is worth it’ (AM), ‘because this activity is fun’ (IM), ‘it was my personal decision’ (IR), ‘because I don’t have any choice’ (ER), ‘I don’t know; I don’t see what this activity brings me’ (AM), ‘because I feel good when doing this activity’ (IM), ‘because I believe that this activity is important for me’ (IR), ‘because I feel I have to do it’ (ER), and ‘I do this activity, but I am not sure it is a good thing to pursue it’ (AM).

The four subscale scores are then used to calculate a single motivation score called the Self-Determination Index (SDI) for each student using the following formula:  $SDI = (2 \times IM) + IR - ER - (2 \times AM)$  (Sinelnikov, Hastie, & Prusak, 2007). The SDI score ranges between  $(2 \times 1) + 1 - 7 - (2 \times 7) = -18$  and  $(2 \times 7) + 7 - 1 - (2 \times 1) = 18$ . A higher SDI score indicates the student is more self-determined and more intrinsically motivated to engage in the activity. A positive SDI score indicates that, overall, more self-determined forms of motivational type (IM & IR) are predominant (Vallerand & Ratelle, 2002). Then, open-ended follow-up questions were given to students to deepen the information about deciding factors affecting student engagement in this mathematical activity. Data were analyzed using qualitative methods to discover whether and what kind of motivations influenced these students. Quantitative data were also collected and analyzed. Non-parametric statistical

calculations were performed because the data consisted of ordinal scores, and normality could not be assumed.

## Results and discussion

In the first phase of the MathCityMap-Project study in Indonesia, technical implementation of the project was formulated, and a mobile app was also created to support the program (Cahyono & Ludwig, 2014). Thirteen math trails containing 87 mathematical outdoor tasks were also designed around the city of Semarang (Cahyono, Ludwig, & Marée, 2015). Task authors found mathematical problems that involved objects or situations at particular places around the city. They then created tasks related to the problems and uploaded them to a portal ([www.mathcitymap.eu](http://www.mathcitymap.eu)). In this portal, the tasks were also pinned on a digital map and were saved in the database. Each task contained a question, brief information about the object, the tools needed to solve the problem, hint(s) if needed, and feedback on answers given. Math trail routes can be designed by connecting a few tasks (6-8) in consideration of the topic, level, or location. In designing the trails, it is also necessary to consider several factors such as: safety, comfort, duration, distance, and accessibility for teachers who would observe and supervise all student activity.

**Figure 1: App interfaces (Map: ©OpenStreetMap contributors)**

Figure 1 shows examples of the app's interfaces including an example route, task, feedback, and hint. Math trail routes can be accessed by students via the mobile app, a native app that was created by the research team as part of this project. Installation of a file in \*.apk format was uploaded to the portal as well as the Google PlayStore™. From there, students could download and install the app, which works offline and runs on the Android mobile phone platform. Students can then carry out math trail activities with the help of the app. They follow a planned route, discover task locations, and answer task questions related to their encounters at site, then move on to subsequent tasks. The app informs them of the tools needed to solve the problems, the approximate length of the trail, and the estimated duration of the journey. On the trail, the app, supported by GPS coordinates, aids the users in finding the locations. Once on site, users can access the task, enter the answer, get the feedback, and ask for hints if needed.

In the second phase, field experiments were conducted with 272 students and nine mathematics teachers. Each school was represented by a class consisting of an average of 30 students. They were divided into groups of five to six members. Four schools carried out activities outside the school while five schools conducted activities in the school area. These choices were made because of

conditions and situations (such as: safety and availability of teaching and learning time) unique to each school. The activities were conducted during normal school hours over two 45-minute periods beginning with the teachers giving a brief explanation of the learning activities and goals. Groups then began their journeys, each from a task location that was different from the others (Group I started at task I, Group II from task II, and so on). As the groups trekked the trail, teachers observed and supervised student activities but were not expected to provide assistance because all the necessary information was to be provided by the app. Once the activity was completed or maximum time allowed for the activity had passed, the students moved to the next task. After completing the trail, each group returned to class, then had a discussion with the teacher about the task solutions and what they learned along the trail. At this time the questionnaire was also completed by the students. All 272 students' SIMS responses and SDI scores are summarized in Table 1.

	IM	IR	ER	AM	SDI
N	272	272	272	272	272
MIN	3.50	2.25	1.00	1.00	2.00
MAX	7.00	7.00	6.25	5.50	16.25
AVERAGE	5.9770	4.7215	3.4651	2.9779	7.3180
SD	0.82939	1.23314	0.93080	0.91471	2.92629

**Table 1: Students' SIMS and SDI scores**

Averages SIMS scores for the four subscales varied considerably, ranging from 1.00 to 7.00. The standard deviations indicated adequate variability in all subscales. It is apparent that the nature of these students' motivations to engage in the activity is diverse. However, all had positive SDI scores (ranging from MIN = 2.00 to MAX = 16.25 and average  $\pm$  SD =  $7.3180 \pm 2.92629$ ). This result indicates that overall, their motivation was more self-determined. Positive scores in this case indicate that internalized forms of motivation, namely intrinsic motivation and identified regulation, were predominant. Students perceived the activity to be interesting or enjoyable (an indicator of IM) and meaningful or valuable (an indicator of IR). They were engaged in the activities for their own sakes/pleasure/satisfaction, and their engagement was considered to be a self-choice. This finding is supported by the Independent-Samples Kruskal-Wallis Test (Table 2), which shows that there was a statistically significant difference in score between the SIMS subscales,  $\chi^2(2) = 623.583$ ,  $p = 0.000$ , with a mean rank score of 886.37 for IM, 637.52 for IR, 379.97 for ER and 274.15 for AM.

Compared with others subscales scores (Table 1), the amotivation subscale had low average SIMS scores ( $AM_{\text{average}} = 2.9779 \pm 0.91471$ ), which were contributing factors to the positive SDI scores. These low scores indicate that students enjoyed the activity and found value in it, which was reflected in the intrinsic motivation scores ( $IM_{\text{average}} = 5.9770 \pm 0.82939$ ) and identified regulation scores ( $IR_{\text{average}} = 4.7215 \pm 1.23314$ ). Students also reported being motivated by and were reacting to external demand, an indicator of extrinsic regulation. However, the ER scores ( $ER_{\text{average}} = 3.4651 \pm 0.93080$ ) show they tended to be neutral on this subscale.

	Subscale	N	Mean Rank		Score
Score	IM	272	886.37	Chi-Square	623.583
	IR	272	637.52	df	3
	ER	272	379.97	Asymp. Sig.	.000
	AM	272	274.15		

**Table 2: Kruskal-Wallis Test using subscale (IM, IR, ER, AM) as the grouping variable.**

The open-ended questions asked in the next step focused on two types of motivation, namely intrinsic motivation and identified regulation. The first question was, ‘*Why did you enjoy the activity?*’ We found that 30% of the students enjoyed learning outside the classroom, 23% were excited to use the advanced technology, 18% were satisfied with applying mathematics, 16% liked collaborating, 11% reported different reasons, 2% mentioned negative feelings, and 0% did not give a reason. The second question was ‘*What experiences influenced your consideration that this activity was valuable?*’ (each student could mention more than one experience). Students mentioned application of mathematics in real life 158 times, outdoor mathematical activities 96 times, advanced technology for math 87 times, use of non-standard measuring tools 79 times, team work 72 times, activities in public places 65 times, and other 19 times. These answers showed that most students were delighted to engage in this activity because it was conducted outside the classroom, an unusual setting that offered comfortable conditions and it was a free and fun activity. The use of mobile devices for outdoor mathematics learning activities has become an attraction, encouraging students to engage in this activity. However, as a serious mathematical learning activity, it was not only enjoyable, but the students considered it a valuable activity. They reported that through this activity they learned how to apply mathematics in the real world, even where they had never thought about it in the past. The use of the latest technology in the learning process has also been reported as a valuable experience and new knowledge for them.

The self-reported data and answers to the follow-up questions were cross-checked with information obtained through field observations and the student works analyses. For example, here is one of the results of observations and analysis of student work on the Flood Gate Task, a task located on the Old Town Route. In this task, the problem statement is, ‘*Suppose your city is now in an emergency, and you are asked to raise the floodgate one meter from its original position. How many times must the worm drive be rotated to raise the sluice one meter from its original position?*’. This task is situated at one of the tourist attractions, an icon of the city, namely the Old Town area of Semarang City. All students agreed this was a pleasant place for learning math, and it was near the school where there were lots of trees, a pond, a garden, nice old buildings, and traffic was not too congested. These conditions made them feel joyful and comfortable in performing the activity there. Not only the location was exciting for them, the task was also considered by students to be a meaningful mathematical task because it was an important issue for them as citizens to know how this floodgate works. In this way, they could save their town if there were an impending disaster. Figure 2 shows an example of students working on this task.

**Figure 2: Students work on the flood gate task**

It appears that the students had the opportunity to learn and practice ways of solving real problems by following the stages of mathematizing, namely, understanding a problem situated in reality (I), organizing the real-world problem according to mathematical concepts and identifying relevant mathematics (II), transforming the real-world problem into a mathematical problem that represents the problem situation (III), solving the mathematical problem (IV), and interpreting the mathematical solution in terms of the real situation (V). In addition, working in the environment to find the hidden task location was interesting and challenging for the students. They reported that the more hidden the task location, the more curious they were to find it. It was breathtaking for them when they had to match the coordinates of their current position and the coordinates of the task location. Here, students recognized the importance and attractiveness of utilizing a GPS-based mobile app as a navigation tool in the math trail activity. This is just one example task, and in general, the students' activities in this field experiment were similar. This explanation proves that the results of the student self-report instrument to determine their motivation to engage in activities coincided with actual conditions in the field.

Based on these findings, we conclude that the design and arrangement of the math trail and the mobile app as well as a combination of both have been successful in creating a pleasant situation and attractive environment offering valuable knowledge and experience in mathematics. They embody the aspects of enjoying or being interested in the activity and the use of advanced mobile technology for learning mathematics (an indicator of intrinsic motivation) and of value and meaningfulness of the mathematical tasks and the activity (an indicator of identified regulation), which were generated through the implementation of this project.

## Conclusions

In conclusion, our findings indicate that student motivation to engage in the math trails program supported by the use of a mobile app was complex. Both intrinsic and extrinsic types of motivation, as well as amotivation, were found in the reasons for completing the activity. However, we also found that students reported and demonstrated more intrinsically motivating rather than extrinsically motivating and amotivating factors for engaging in the activity. While intrinsic motivation was an essential part, identified regulation was also important. The design of the project and its technical implementation contributed to these results, as reported by the student through the self-report instrument, and it was demonstrated through their activities and work. Therefore, in the implementation of the MathCityMap-Project, we must be aware of the important role of influencing student motivation when designing a mobile app-supported math trail activity. The relevance and value of the task must be clearly identified and linked to the objective of the project. Most importantly, students must enjoy and be attracted to the activity, both in completing the math trail task and in using the mobile app. These are the main factors that need to be considered when implementing the MathCityMap-Project.

# Mathematical gestures: Multitouch technology and the indexical trace

Elizabeth de Freitas<sup>1</sup> and Nathalie Sinclair<sup>2</sup>

<sup>1</sup> Manchester Metropolitan University, Manchester, UK; [L.de-freitas@mmu.ac.uk](mailto:L.de-freitas@mmu.ac.uk)

<sup>2</sup> Simon Fraser University, Canada; [nathsinc@sfu.ca](mailto:nathsinc@sfu.ca)

*This paper is about the threshold between gesture and touch in mathematical activity, focusing on the role of multitouch technology. Drawing on the work of gesture theorist Jürgen Streeck, we propose and discuss the notion of the tangible gesture, in the context of mathematical explorations of young children with a novel, multitouch iPad environment called TouchCounts designed to promote counting on and with the fingers.*

*Keywords: Technology, multitouch, number and operations, gesture.*

## Introduction

With the advent of multitouch technologies, gestures have become an essential feature of user interface. Touch technologies break with previous computer-based norms, where the hand's actions were *indirectly* related to changes on the screen through mouse and keyboard manipulation. Touch technology invokes earlier drawing technologies in which the hand's actions had a more *direct* relation with a given surface. The digital nature of contemporary surfaces, however, significantly alters the relation between touching and meaning-making.

In this paper, we draw attention to the distinctive gestures new media elicit and produce and the way these new manual activities are changing the way we perform mathematics. We also interrogate the taken-for-granted distinction between the touchscreen gestures common in the technology world and the in-the-air gestures that have been the focus of study in mathematics education research. At first blush, they may seem quite distinct—albeit having the same word—but we follow Streeck (2009) in seeing them as being on a continuum, a perspective that enables us to better appreciate the role that touchscreen gestures might have in mathematics learning.

In the context of mathematics education research, many studies have focused on student and teacher use of gesture in classrooms, but this work tends to code and sort gestures insofar as they are *representations* of thinking. These studies tend to divorce the motoric hand from the feeling swipes and swishes of fingers on screens. Material semiotic approaches to the study of interaction, on the other hand, consider gesture less as representations and more in terms of the material effects they achieve (Roth, 2001; Radford, 2002; Nemirovsky, Kelton & Rhodhamel, 2012). Our goal in this paper is to unpack the implications for understanding mathematics learning in relation to new media. In order to illustrate how these new media gestures operate as expressions of numeracy, we draw on research involving a novel multitouch App in which fingers and gestures are used to count (Jackiw & Sinclair, 2014).

## Gesture as movement

The predominant line of research in gesture studies focuses on movements of the body (especially the hand) and their interactions (i.e. correlations) with speech in communication (Kendon, 2000, 2004; Kita, 2003; McNeill, 1992; 2005). Researchers have identified different categories of gestures

(icon, metaphoric, deictic and beat) so as to distinguish different relations between gesture and speech. McNeill has drawn on Peirce's (1932) semiotics in which signs (icons, symbols, and indices) differ in terms of the nature of the relationships between the signifying sign and the signified. These categories have been used extensively in mathematics education research.

Research that codes gesture only in terms of linguistic potential tends to overlook the physicality of the hand movement, except insofar as such movement contributes to or obscures linguistic meaning (Rossini, 2012). As Streeck (2009) indicates, "it is common to treat gesture as a medium of expression, which meets both informational and pragmatic or social-interactional needs, but whose "manuality" is accidental and irrelevant" (p. 39). Streeck (2009) defines gesture:

... not as a code or symbolic system or (part of) language, but as a constantly evolving set of largely improvised, heterogeneous, partly conventional, partly idiosyncratic, and partly culture-specific, partly universal practices of using the hands to produce situated understandings. (p.5)

Thus he studies gesture for how it is "communicative action of the hands" with emphasis on the term *action* (p.4). This focus on action allows Streeck to study gesture for how it couples with and intervenes in the material world in non-representational ways. Researchers often distinguish between hand movements *in the air* and hand movements *that make graphic marks*, where the former is deemed a gesture and the latter an act of inscription. However, such distinctions become fuzzy when we study the movement of the hand across and through media, where 'media' can be more or less receptive of trace or mark. In other words, all hand movements traverse and incorporate media. We see a trace in certain media, and not in others, but since the logic of new media is to break with current conventions of perception, this distinction is provisional. New media allow for new kinds of traces. This insight allows for new ways of studying numeracy and multitouch technologies. In the next section, we discuss a case study of children working with such technologies, showing how this material encounter entails a very different concept of number *precisely because of the indexical aspect of gesture*.

The question of trace and inscription returns us to how the indexical is different from the iconic. The contiguity aspect of indexicality (the smoke is materially caused and coupled with the fire) is aligned with touch and the way our body connects with another through touch. This approach to gesture supports the systems approach to bodies by which bodies become coupled with the environment they inhabit (Maturana & Varela, 1987). Streeck studies gestures as part of a nested scaling approach to this system, beginning in the world that the "hand knows best", and then examining how gestures operate at greater distance or remove from that world (p. 58). The touch or haptic factor of hand movement is precisely how the fragile interface of inscription or trace is currently produced. Again, we emphasize that this production of a trace is contingent on current configurations of sensory perception and material media.

Most of the hand's features (digits, degrees of freedom of movement, fatty palms, flexure lines, papillary ridges) evolved to facilitate grasping (prehension), and thus the hand "became a 'compromise organ'" in serving multiple purposes (Streeck, 2009). Prehensile "postures" are formed as the hand reaches its target (in our case this will be a screen), during which a pre-conscious calibration of speed and collective force determines the particular movement of the digits, hands and arm. As the hand moves towards the target, there is a strong reliance on peripheral vision

rather than vision directed at the target (Streeck, 2009, p.47). The speed of the gesture reduces as the hand reaches its target. But the moment of contact entails the forming of a new assemblage, when the entire body of the gesturer links up with that which it touches. Thus, we are focusing on how gesture is a hand action that does more than identify or code particular aspects of an object.

The video data discussed below is part of a larger project exploring the power of touchscreen technologies in teaching and learning mathematics in early childhood. Several research studies have already been carried out concerning the way that children learn various concepts using *TouchCounts*, including ordinality (Sinclair & Coles, 2015), place value (Coles & Sinclair, 2017) and finger gnosis (Sinclair & Pimm, 2015). The focus of this paper is less on the learning process using *TouchCounts* than on the various and distinctive forms of hand actions that are involved in creating and manipulating number in this environment.

What is distinctive about the index is that it is a sign that is materially linked or coupled to “its object”. According to Peirce (1932), an index “refers to its object not so much because of any similarity or analogy with it, (...) as because it is in dynamical (including spatial) connection both with the individual object, on the one hand, and with the senses or memory of the person for whom it serves as a sign, on the other” (2.305). For instance, the chalk drawing of a parallelogram on a blackboard is often considered to be an iconic reference to a Platonic conception of parallelogram, but it is (also) an indexical sign that refers to the prior movement of the chalk. This latter indexical dimension is usually not emphasized in the semiotic study of mathematical meaning making, since we tend to focus on the completed trace and dislocate it from the labour that produced it. This focus on the completed sign neglects how the activity of the body and various other material encounters factor in mathematical activity.

## **TouchCounts: A multitouch early number App**

In this paper, we discuss an application that author Sinclair has been involved in creating in which the digital gesture plays an even more central role in the mathematical activity. *TouchCounts* (Jackiw & Sinclair, 2014) is an application that permits young learners to coordinate simultaneously various forms of number: number names like ‘three’, number of taps on the screen, number of discs on the screen and number symbols like 3. It enacts a multimodal correspondence between finger touching, numeral seeing and number-word hearing (a one-to-one-to-one correspondence of touch, sight and sound). The App has two worlds: the Enumerating and the Operating worlds. In this paper, we focus on the Enumerating world, which is the one that children usually first experience.

In the Enumerating World, the screen starts almost blank, except for a horizontal bar called a shelf. In this world, a learner taps her fingers on the screen to summon numbered discs. The first tap produces a new yellow disc on which the numeral “1” appears. Subsequent taps produce sequentially higher numbered discs. As each tap summons a new numbered disc, *TouchCounts* audibly speaks the name of its numeral (“one,” “two”). As long as the user’s finger remains on the glass, it holds the numbered disc, but as soon as she “lets go” (by lifting her finger) virtual gravity makes the number object fall to and “off” the bottom of the screen. If the user releases her numbered disc above the shelf, or “flicks” it above the shelf on release, it falls only to the shelf, and comes to rest there, visibly and permanently on screen, rather than vanishing out of sight “below” (see <https://www.youtube.com/watch?v=7xD-pqnsce0>). Since each time a finger is placed on the

screen, a new numbered object is created, one cannot “catch” or reposition an existing numbered disc by retapping it. We note that, at least initially, the eye plays a prominent role in directing the finger above or below the shelf, but that if one does not care where the disc alights, the tapping of the finger needs little visual direction.

If we take the finger tap as a gesture involving the placement of a finger on the screen, and the subsequent production of an event featuring visual, mobile and aural aspects, then we might say that the gesture is iconic in its relation to the production of unitary quantities, or perhaps even metaphorical for the children for whom such unitary quantities are still “abstract”. But what seems much more pertinent for the children as they engage with this application is the indexical nature of the gesture. The tap both points to the screen, designating one place of contact with it, but also creates a new numbered disc under the soft skin of the finger-pad, a disc which often falls with gravity-like weight. In addition, each tap produces a simultaneous sound. The children can also tap the Reset button, which makes all the numbered discs disappear and resets the count to 1.

While *TouchCounts* was designed to support the development of one-to-one correspondence between number and hand movement, by drawing on the tangible dimension of counting, its use by young children has prompted us to examine both the particular ways in which they use their hands and the implications of their hand actions on the meanings they make around counting, in particular the concepts of ordinality and cardinality (see Sinclair & Pimm, 2015).

## A case study

This case study is drawn from a broader research project that was conducted in daycare and primary school settings over the course of three years. In the excerpt we present, co-author Sinclair was engaged in a clinical interview with a five-year-old kindergarten child named Katy, who is interacting with *TouchCounts* for the first time. (Indeed, it was the first time she was using a touchscreen tablet.) The interview occurs in June and therefore close to the end of the school year. We have chosen the excerpt because it illustrates a range of gestures that have been observed over the course of the research study, while also showing hand motions that have not been explicitly taught. In this case study, the hand actually operates very close to the surface of a screen: pointing to objects on the screen by tapping them; sliding objects along on the screen so as to leave visual and aural traces of the finger’s path; pinching objects together in order to make new ones.

The room is quiet. Without prompting, Katy’s hand approaches the screen, and her finger touches the top of it and slides down to the bottom. A yellow disc appears under her finger with the numeral ‘1’ on it and the sound ‘one’ is made. The index finger moves back to the top of the screen, slowly swimming downwards. A chorus of ‘two’ comes both from her mouth and the iPad. This happens repeatedly, although sometimes only the iPad can be heard announcing the new numbered disc while Katy’s lips move in synchrony ([Figure 1a](#)). The appearance of ‘10’ on the tenth yellow disc attracts attention, perhaps because of its double digits, and Katy bends over to look closely.

Katy looks up again and her finger resumes touching the screen, but now only the iPad counts the numbers ([Figure 1b](#)): she no longer says them aloud herself. After ‘seventeen’, several fingers fall on the screen at once, and then ‘twenty-one’ is heard (since she has tapped the screen with several fingers, only the sound of the final number is said aloud, but the four discs all appear under where she has touched). This produces a pause in the action, and Katy’s lips spread into a smile. All but

the index finger are tucked away, as the rhythmic tapping continues along with the chorus of named numbers. At ‘twenty-seven’ Katy looks up, no longer watching the screen (see [Figure 1c](#)), and she continues swiping and saying numbers. This continues until a finger accidentally land on Reset.

**Figure 1(a). Katy swiping; (b) Following the yellow disc; (c) Tapping while looking up.**

Katy’s finger – as the main organ of touch in this encounter – takes on new capacities through the reset button. It is no longer the organ that can only move or drag the yellow circle. The power of the reset button to recalibrate the tempo and rhythm of this encounter, becomes part of the finger’s potentiality, thereby redefining what is currently entailed in the sense of touch.

## Discussion

Fingers can serve as both a physical extension of what Rotman (1987) calls the ‘one-who-counts’ (p. 27) (usually with an extended pointed finger reaching out to the world) as well as the thing-to-be-counted (in which the gaze is directed towards one’s own fingers): fingers are thus simultaneously subject and object, both of the person and of the world (Alibali & diRosso, 1999). And this is what makes the finger actions of Katy so interesting; the mathematical act of counting with *TouchCounts* fuses this duality and in so doing changes the relationship between the hand and eye, as well as the ears.

Katy’s hand actions change over the course of the episode, not only in the particular muscular form they take, first sliding down the screen as if lingering on the yellow discs to produce or partake in their falling off the screen, and then tapping impetuously so that each new touching of the screen follows the end of the sounds of the voiced numerical. The swiping gesture seems more exploratory while the tapping gesture seems to concatenate into a unit the touch-see-hear bundle of sensations involved in making a new disc-numeral-name. As Streeck writes, tapping is also “characteristic of ritualized behavior” (p. 76), which suggests that Katy has moved from exploration to practice. In both the swiping and the tapping, the finger can be seen as making an indexical gesture, with the trace being both visible and audible, not to mention tangible for Katy.

Although the initial movement and touch of her finger is what produces the disc, it is the disc that drives the swiping movement of her finger. Indeed, both her finger and her eyes *follow* the yellow disc as it heads down the screen. In shepherding the numbered disc off the screen, Katy sees when it’s time to lift her finger and start making a new disc. But with the tapping, the eyes attend to the numerical sign on the disc—indeed, when 10 appears, Katy notices the change from the previous one-digit numerals. In this sense, the eye and the finger do very similar things in the swiping, the

visible trace is followed closely by Katy's eyes as the swiping takes place, so that the hand is subordinated to the watchful eye. With the tapping, the hand seems less subordinated, with the eye only interested when there's a novel situation. When Katy looks up, the hand is no longer subordinate. When Katy's eyes close, her fingers do the seeing and touching as they repetitively tap.

But of course, there is more than the eye and hand involved in this situation. The ear and voice feature importantly as well. Indeed, while the voice is subordinate to the touch (it only speaks while Katy taps), Katy's hand is also subordinate to the ear in that the ear judges the moment of the next tap. And the ear is disrupted by the hand, when several fingers touch the screen at once, causing the voice to jump from "seventeen" to "twenty-one." The eye, which was about to drift off, must return to survey the situation. And the hand returns to its single digit tapping. The importance of the aural and the vocal in this context is interesting in terms of the counting activity at play. Indeed, the ritual origins of counting are oral in nature, and counting with young children is often undertaken as the learning of a song that one memorises and chants. The involvement of the hand in this otherwise oral event provides a visual and tangible trace of the count, while also associating each counted number with a single swipe or a single tap.

One might question whether Katy's actions on the screen, which we might think of as touch-pointing, can really be thought of as gestures. Streeck argues that such touch-pointing gestures (and indeed all gestures) emerge from the touching and handling of things—the tracing (or other "data-gathering devices" such as caressing, probing, cupping) of objects that allows one to discover its texture and temperature (and, for young children, for instance, the difference between a cylinder and a pyramid). When the hand has done its exploring of the object, which fulfills an epistemic function in gathering information, it may then be lifted off the object and inclined to repeat the same movements 'in the air': "the hands' data-gathering methods are used as the basis for gestural communication" (p. 69). Streeck identifies such gestures as being communicative, which for him is the characteristic feature of a gesture. So perhaps Katy's touch-pointing becomes a gesture once she lifts her hand from the screen to do her tapping.

Distinguishing hand movements that explore from ones that communicate is problematic though. As Streeck writes, exploratory actions can become communicative when they are made visible to others, who may join in the action or infer tactile properties. If we look at Katy's swiping and tapping gestures, we might say that they are both exploratory, with the swiping gestures involving prolonged tactile contact that enables her to discover what would happen when her finger touches the glass—that a yellow disc would appear, with a numeral on it; that the disc would move down the screen; that the iPad would speak the numeral's name aloud, and that this could all be repeated as often as she wished. But Katy's swiping and, later, her tapping, are also communicative inasmuch as they tell *TouchCounts* what to do and say. The same might be said for clicks of the mouse or key presses of the keyboard, with the difference that the touchscreen is acted upon by direct hand motions. Instead of disentangling the tracing from the pointing (the exploration from the communication), we suggest that re-assembling them into an indexical enables us to see how Katy's hand movements can tap into the potentiality of the body by reconfiguring the relationships between sensations of touch, sight and sound that are at play. This potentiality mobilizes new mathematical meanings as Katy uses her fingers to count on, to count with and to count out one by one and indefinitely. Streeck recognises that hand-gestures "enable translations between the senses" (p. 70)

as tactile discoveries provide visual information for interlocutors. With Katy though, the tactile discoveries provide visual and auditory information to herself. She is her own interlocutor.

## Conclusion

Streeck argues that hand-gestures cannot be taken only as components of a language system cast apart from the material world and used only to communicate *about* the world. Rather, they are *of* the world, and part of how we *feel* the world around us. This perspective requires us to see the moving hand as “environmentally coupled” (Goodwin, 2007), that is, as inextricable from the things it touches and engages with. But while Streeck implies a vector from the exploratory hand action to the communicative hand-gesture, our case studies reveal how the exploratory hand frees itself from the optic regime and invents meaning as much as it communicates it. This new kind of gesture is possible in large part because of the feedback mechanism of digital technologies, which can talk, push and show back. With the touchscreen interface, and particularly the multitouch actions, the hand is involved in a process of communicating that is also a process of inventing and interacting.

In the example we presented, we have shown that the gestures made by Katy in *TouchCounts* had an indexical nature both because they involved some kind of pointing (with one finger or more) and they left a trace that is both visible and audible. The trace is important in drawing attention to the material engagement of the gestures. The gestures arise out of movements of the hand, but they also result in material reconfigurations that can *give rise to* new movements of the hand. In discussing the effect of new digital technologies in mathematics, Rotman has written about the future cultural neoteny in which speech would “become reconfigured (as it was once before when transformed by alphabetic writing), re-mediated and transfigured into a more mobile, expressive, and affective apparatus by nascent gesturo-haptic recourses” (p. 49). We interpret these speculative comments as an indication that the future of the gesturing hand in relation to new media may involve all sorts of surprises, and that perhaps even pre-school children may count ‘on their hands’ to 100 as they engage with these media.

[jana.trgalova@univ-lyon1.fr](mailto:jana.trgalova@univ-lyon1.fr)

*This theoretical paper reports about our perception of the contributions that the working group TWG 16 about the learning of mathematics with digital media have made during the last CERME 9, taking into consideration the previous and the upcoming ERME conferences. Our analysis highlights the evolution of research questions, methodologies and theories through the lenses of the “didactical tetrahedron” metaphor and the networking strategies and methods. Finally, we point out themes that are, to our opinion, insufficiently addressed and need further discussions within the technology group.*

*Keywords: Mathematics, learning, technology, didactic tetrahedron, networking strategies.*

## Introduction and rationale

‘State of the art’ is a common expression used in surveys, review papers and up to date books reporting on the newest achievements in the research. This is also the ambition of the tenth Congress of the European Society for Research in Mathematics Education (CERME 10) TWG 16 leaders as they have announced:

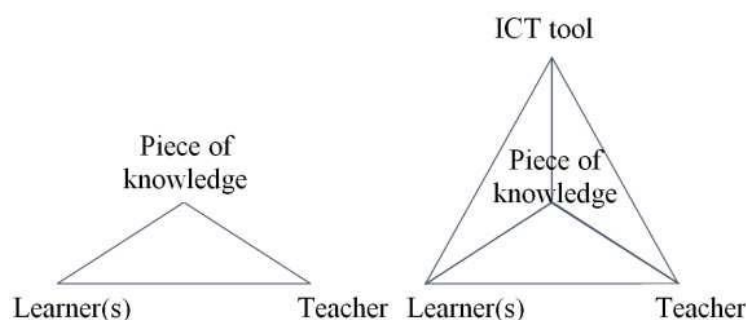

We want to establish an overview of the current state of the art in technology use in mathematics education, including both practice-oriented experiences and research-based evidence, as seen from an international perspective and with a focus on student learning [...] (Call for papers, CERME 10 TWG 16).

There are studies trying to establish such overviews (e.g., Drijvers et al., 2016), but also some claiming to report on the ‘state of the art’ research without sufficient argumentation and full justification of their statements throughout the text. The phrasal adjective ‘state of the art’ fits to advertise a ‘product’ but has our community become mature enough to respond to a challenge of offering ‘state of the art’ descriptions of complex phenomena like the use of technology in mathematics education which has a characteristic of enormous dynamism?

In this article, we do not claim that we have undertaken a meta-research beyond the scope of the CERME although we are aware of the variety of working groups on similar themes at other conferences as ICME, ICTMT, CADGME or ATCM and special issues of journals. Aiming to investigate how the CERME TWG 16 could capitalize knowledge of discussions regarding the learning with technologies, we have rather devoted ourselves to focus on two main issues: 1) *how have the research questions and methodologies about the learning of mathematics with technologies evolved* and 2) *is there a substantial progress regarding the use of the theories*. We begin discussing these two issues through the relations in a “didactic tetrahedron”.

## The “didactic tetrahedron” metaphor

The “didactic tetrahedron” metaphor (Fig. 1 right) was introduced by Tall (1986, p. 6) as an enlargement or adaptation of the “didactic triangle” (Fig. 1 left) commonly used before the advent of technology to analyze the teaching and learning of mathematical knowledge.

**Figure 1: From a “didactic triangle” (left) to a “didactic tetrahedron” (right)**

The integration of an artefact, e.g. an ICT tool, introduces a new component into the teaching/ learning system and creates new relationships between the components of the didactic triangle. Thus, for example the face ALK (A for Artefact or ICT, L for learner and K for Knowledge) represents phenomena related to learning mathematics with technology, such as students’ conceptualizations of given mathematical concepts mediated by technology, or the edge AK highlights phenomena related to new approaches to given mathematical concepts offered by the affordances of a given digital artefact. The didactic tetrahedron has by now been used for analyzing mutual participation of artifacts and their users in a socio-cultural context (e.g. Rezat & Sträßer, 2012) or as a heuristic for studying the implementation of digital media in the teaching and learning praxis (Ruthven, 2012). In this paper, we use it to position the scopes of technology groups at the ERME conferences.

Until CERME 8, issues related to any vertex, edge or face fell within the range of a unique technology group, initially called “Tools and Technologies”. The subsequent changes of the name into “Tools and technologies in mathematical didactics” from CERME 2 to 5 and “Technologies and resources in mathematics education” from CERME 6 to 8 indicate the appearance of enhanced specifications. The growing interest in the theme and the amount of research have led to splitting the technology group into two groups at CERME 9 which have progressed discussing topics focusing on edges and faces having “teacher” and “learner(s)” as a vertex, respectively.

## Research method

In this paper we propose an analysis of the two issues 1) and 2) stated above based on the “didactic tetrahedron” through the: a) Calls for papers of the CERME 8-TWG 15, CERME 9-TWG 16 and CERME 10-TWG 16, b) Introductions to papers and posters of the groups published in the proceedings of the CERME 8 and 9, and c) Papers of these groups published in the proceedings of the CERME8 and 9. In this analysis we also refer to “networking strategies and methods” (Prediger et al., 2008, p. 170).

## Findings and discussion

### a) Evolutions tracked through the Calls for papers since the CERME8

The Call of the CERME 8-TWG 15 guided the discussions by posing three themes referring to design and uses of technologies, students' learning, and teacher professional development in presence of technologies. These three themes clearly refer to the three vertices of the triangular face “ALT (T for Teacher)” in the didactic tetrahedron (Figure 1). Although such structured shape for questioning the themes of interest may not appear straightforward by reading the text in the CERME 9 and 10 Calls, they are indeed meant to contribute to research related to the face “AKT” (TWG 15) and to the face “AKL” (TWG 16). Besides the split of the technology group in two groups, the relation between learning, teaching and digital tools is still present in the issues of the CERME 9-TWG 16 Call, as stated for example in the items “designs of teaching experiments with software and technologies concerning student learning” or “results of empirical studies and investigations especially concerning long-term learning with ICT, massive courses, national programmes of teachers' professional development”. Thus, the face “ATL” remains relevant to both groups.

### b) Evolutions tracked through the Introductions to the papers and posters of the CERME 8-TWG 15 and CERME 9-TWG 16

The Introduction of the CERME 8-TWG 15 corresponds to the Call and is structured according to the three themes (stated in a), i.e. the face “ATL”. Moreover, it goes beyond the affirmed issues by raising a general one for “capitalization of research results” (Trgalová et al., 2013, p. 2500). This general issue has been addressed in an overview for mathematics, technology interventions and pedagogy based on systematic literature review by *Bray* (CERME 8, 2013) and in a survey reporting about undergraduate, master and doctoral studies for promoting the use of technologies in mathematics education by *Scheffer* (CERME 8, 2013). Further on, in this Introduction, it is claimed that a development of “specific methodologies enabling to assess the effectiveness of ICT in learning processes” (Trgalová et al., 2013, p. 2501) is required. The call for a “proper usage of research methods, which are informed by contemporary theories” (Lokar et al., 2015, p. 2438) is present in the Introduction of the CERME 9-TWG 16.

This paper builds on this claim and attempts to further investigate the usage of theories referring to the learning of mathematics in technology-rich environments in the next subsection.

### c) Evolutions tracked through the Papers published in the proceedings for CERME 8-TWG 15 and CERME 9-TWG 16

#### *Evolution of research questions (RQs) and methodologies*

Unlike the frequent use of several methodologies and theories for exploring teaching (e.g. TPACK or instrumental approach), a large assortment of RQs and methodologies comes out from the papers regarding learning phenomena with technologies. We organize them in the following two categories:

- Category 1: RQs referring to at least two of the edges of the face “ALK”

While the most of the papers from this category discussed at CERME 8 focus on the impact of using technology on students' behavior, learning or performance, there is a greater variety of research issues addressed in papers at CERME 9. For example, the qualitative-empirical study by *Kaya, Akçakın, & Bulut* (CERME 8, 2013) related to the RQ: “does the use of Geogebra via interactive whiteboards as

an instructional tool affect students' academic achievement on transformational geometry?" (p. 2596) seems to meet all edges in this triangle. Likewise, a quasi-experimental study by *Kilic* (CERME 8, 2013) considers concepts in geometry (K), a development of geometric thinking and ability of proving in geometry (L) by using a Dynamic Geometry Software (A). Based on teaching experiments with high school students and prospective teachers, *Bairral and Arzarello* (CERME 9, 2015) have raised the RQ: "which domain (constructive or rational) of manipulation touch screen could be fruitful to improve student's strategies for justifying and proving?" (p. 2460). In this contribution, there is evidence not only of the three edges of the face "ALK" but also of the teaching component of the "didactic tetrahedron" by pointing out a lack of research about the teaching of mathematics with the use of touch screen devices besides task design concerns and cognitive implications (p. 2464-2465).

- Category 2: RQs referring to one of the edges of the face "ALK"

Exemplary studies addressing the edge "AL" are: a design based study by *Misfeldt* (CERME 8, 2013) about the students' instrumental genesis with GeoGebra board game, a study by *Persson* (CERME 8, 2013) grounded on students' interviews and teachers' questionnaires about instrumental and documentation genesis, or empirically based case study by *Storfossen* (CERME 8, 2013) about instrumented action of primary school students. It seems that the emphasis on RQs and methodologies studying instrumental genesis regarding the relation "AL" has slightly decreased from CERME 8 to CERME 9.

A paradigm which is noticeable in the CERME 9-TWG 16 papers and was not present before, except for one paper, is the online learning. Although the significant amount of RQs referring to learning through the Web (e.g., peer learning, collaborative learning, networking, flipped classroom) is visible (e.g., *Biton et al.*, CERME 9, 2015; *Triantafyllou & Timcenko*, CERME 9, 2015), many specific questions related to the face "ALK" remain unanswered. For instance, what is the most relevant mathematical content available on the internet and how to locate it or what is a good quality of online teaching/ learning materials for mathematics and how to measure it. Another such question referring to the edge "AL", is about "students' perceptions if and how online resources contribute to mathematics learning and motivation" (*Triantafyllou & Timcenko*, *ibid.*, p. 1573). The diverse nature and the complexity of these questions about online learning, in addition to the methodological approaches applied, mainly small scale studies or online surveys, do not allow generalizing conclusions about its truthful effects for the mathematics education.

Looking at the face "ALK" of the "didactic tetrahedron", an interesting question that could be worth exploring is whether a possession of a "(piece of) mathematical knowledge" leads to gaining an "other (piece of) knowledge" embedded in an ICT tool, e.g., knowledge in computer engineering. Except for one contribution by *Misfeldt & Ejsing-Duun* (CERME 9, 2015) about learning mathematics through programming and algorithms, we have not found others which would report on any kind of connections between learning mathematics and computer science or informatics. Neither have RQs about the learning of mathematics in relation to robotics, augmented reality and artificial intelligence been proposed in any of the calls, the introductions to papers or the papers in the technology group for the learning of mathematics at the CERME 8 and 9. This issue is neither mentioned in the CERME10-TWG16 Call, although we could expect that it may become an emerging one due to curricular changes in some European countries (e.g., France) highlighting algorithms in mathematics education.

### Evolution of theoretical frameworks

Several observations can be drawn about theories and their networking in the papers.

First, the *instrumental approach* (Rabardel, 1995) appears as a widespread theoretical framework at CERME 8, while it is seldom mobilized at CERME 9. The hypothesis that may explain this fact is related to the shift in research questions reported above. However, in the terminology of “landscape of networking strategies and methods” (Prediger et al., 2008), it appears that the instrumental approach has been used for local organization and coordination, rarely combined with other theories. The heterogeneity of research questions at CERME 9 may be related to a greater diversity of ICT tools usage. Besides the commonly used technologies as dynamic geometry systems (DGS), computer algebra systems (CAS) or spreadsheets, innovative artefacts, such as multi-touch screen, Arbol software for developing combinatorics thinking or non-digital Fraction board, raise elderly and new concerns akin to those of tool affordances and multiple representations (“AK” edge of the didactic tetrahedron). Two main frameworks are called for exploring such questions: the *theory of semiotic mediation* (Bartolini-Bussi & Mariotti, 2008) and the *approach of registers of semiotic representation* (Duval, 1993). These two theories seem to go along one with another and have a relatively high degree of integration founded on the strategies for understanding and making understandable, comparing and synthesizing (Prediger et al., 2008). Original digital devices, and possible novel teaching methods enabled by them (e.g., flipped classroom, learning on the Web) may lead to modifications of learners’ perceptions of their efficiency or performance. These are explored through the Vygotskian perspective of object/meaning ratio.

Further observation leads to an assumption that there is a greater variety of theoretical frameworks used in CERME 9 compared to CERME 8 papers (Fig. 2). This seems to correspond to the previous argumentation. Besides the recognizable continuity of the usage of three theoretical frameworks, *instrumental approach*, *constructionism* and *learning by scientific abstraction*, there is a vivid occurrence of numerous others. Yet, “the multiplicity and isolated character of most theoretical frames used in technology enhanced learning in mathematics”, brought to the fore by Artigue (2007) and considered by the author as “an obstacle to the exchange and mutualisation of knowledge” (p. 75), is still not overcome. The heterogeneity of the networking space may further be analyzed by using the flexible triple of principles, methodologies and paradigmatic questions (Radford, 2008).

**Figure 2: Theories used in paper at the CERME8-TWG15 (left) and CERME9-TWG16 (right)**

It is worth noticing that most of the theoretical frameworks considered in the papers are not technology specific. In fact, the *instrumental approach*, *human-with-media concept* (Borba and Villareal, 2005) and the *theory of semiotic mediation* are rare frameworks addressing the interactions between learners and artifact(s), digital or not, besides those between learners and teachers. A widely used technology non-specific theoretical framework is the *theory of didactical situations* (Brousseau, 1997), which is occasionally combined or integrated locally with other theories.

Finally, we wish to draw attention to theoretical concepts that are not mentioned in the papers, although they are particularly relevant for addressing the relation “AK”. Some of them, such as *computational transposition* (Balacheff, 1993) and *epistemological domain of validity* (Balacheff & Sutherland, 1994) are powerful means for ICT tool analysis in reference to a given field of knowledge and in terms of their possible contribution to the teaching and learning.

## Conclusion

Looking through the lenses of the “didactic tetrahedron”, the split of the CERME 8 technology group in two groups since the CERME 9 is not only a practical, organizational necessity due to the rapid growth of the number of scholars interested in the theme. It rather seems as a temporary solution to tackle and deeply investigate challenging questions about each of the faces of the tetrahedron before fabricating ‘state of the art’ reports.

Thinking about the capitalization of knowledge disseminated by the CERME 8-TWG 15 and the CERME 9-TWG 16 relating each of the two main issues in this survey paper, we may conclude the following.

1) *Evolution of RQs and methodologies*. Miscellaneous RQs are emerging rapidly, before the previous are being sufficiently explored. On the one hand, it seems that the trend of publishing findings about the influence of the World Wide Web including social networks and online educational platforms will continue in a relatively large amount despite an apparent lack of specific methodological and theoretical frameworks that could be commonly used to approach topical issues in the field of technology in mathematics education. Applied methodologies for approaching these questions belong within the frame of small scale qualitative empirical studies. On the other hand, research questions, appropriate methodologies and theories about attitudes, accomplishments and inclusion of specific groups of learners as low achieving, gifted and/or disabled students in technology supported learning environments remain urgent in the research agenda.

2) *Evolution of theories*. Is the use of current general theories like those referring to the “didactic triangle” sufficient or is there a need for a development of new ones, which would allow addressing issues specific to technology enhanced teaching and learning of mathematics? The latter seems to be more likely, as shown by a new item in the call for papers in the theory working group welcoming contributions on “theories for research in technology use in mathematics education” (CERME 10-TWG 17 Call for papers), which has not been part of the previous call of the group. Our analysis also shows that exploitation of the networking strategies and methods for understanding, comparing, contrasting, coordinating, combining, synthesizing and integrating theoretical frameworks (Prediger et al., 2008) may be beneficial for further truthful studies of the learning mathematics with technologies.

*With frequent predictions of upcoming technological and economic difficulties triggered by an impending shortage of information and communications technologies (ICT) professionals, the calls are growing stronger to include coding as a core element of school curriculum. These calls are bolstered by the suggestion that coding supports the development of thinking skills – which echoes a longstanding argument for teaching mathematics. Motivated by the parallel, we attempted to investigate some of the common ground between learning to code and the development of core mathematical concepts. We photographed and video recorded children, aged 9–10, as they learned to build and program Lego Mindstorms™ EV3 robots over four days. Our findings suggest that programming supports children’s understandings of decimal numbers and their transitions from additive to multiplicative thinking.*

*Keywords: Coding, robotics, arithmetic, number concepts, elementary education.*

## Introduction

In recent years there has been a growing recognition that information and communications technologies (ICT) are a major contributor to innovation and economic growth. For instance, the Organization for Economic Cooperation and Development (OECD, 2016) considers computer programming a necessity for a highly skilled labour force. Shortages are already felt across the world and demand for highly skilled ICT professionals is expected to rise. In our home country of Canada, for instance, there are predicted shortages of more than 150,000 skilled ICT workers in the next few years. This shortage is impacting IT innovations and revenues (see Arellano, 2015; Clendenin, 2014).

Canada is hardly unique on this count, as evidenced by major pushes around the world to include coding as a core part of school curriculum. In response, some educators and educational systems are shifting from teaching “how to use” software programs toward “how to code.” Estonia and England, for example, have implemented a national curriculum that makes computer programming mandatory for all school-aged students across all grades, and other nations appear to be moving in this direction. For instance, it is currently a topic of political debate in Australia, where the opposition party is calling to have computer programming taught in every primary and secondary school in the country (Roumeliotis, 2015; Sterling, 2015).

In North America, national-level discussions and calls have yet to gather the same sort of momentum, but more and more initiatives are emerging at the local level. For example, the Chicago school district is adopting computer science as a core subject in all public high schools – prompted in large part by support from Google and Microsoft and through initiatives such as *Code.org* and *Hour of Code*, which are dedicated to expanding access to computer science for all U.S. students. Despite the absence of a national strategy in the U.S., messages on the importance of learning to code are frequent, with some emanating even from the President’s office. In fact, coding skills have

been associated not only with empowering individuals and meeting employment needs, but with many aspects of the country's future and security (Pearce, 2013).

Trends toward including coding in school curriculum were preceded by a broadly effective worldwide push to get computers in schools. In 2011, most students (71%) in OECD countries reported having access to computers and the Internet at school. However, most students reported using the computers at school for email, browsing the Internet, word processing or doing individual homework. For the most part, such activities require low-level cognitive thinking and do not challenge students to develop more than basic user skills. Learning how to program a computer, it is typically argued, involves higher-level cognitive processes and provides opportunities for developing higher-level ICT skills.

These sorts of arguments for teaching computer coding parallel long-standing rationales for teaching mathematics. Similarly, many of the structures and strategies within coding bear strong resemblances to elements of mathematical concepts (Papert, 1980). We discuss a few of these resemblances in this paper, focusing on arithmetic.

Conceptual metaphors are one of the ways we understand mathematics (Núñez, 2000). With regard to the concept of number, Lakoff and Núñez (2000) describe “four fundamental metaphors of arithmetic”: *arithmetic as object collection*, *arithmetic as object construction*, the *measuring stick metaphor*, and *arithmetic as object along a path*. The metaphor of *arithmetic as an object collection* is based on a one-one correspondence of numbers to physical objects. With this metaphor a greater size corresponds to a bigger number. For instance, 5 is *greater* than 2 because it forms a *bigger* collection. The metaphor of *arithmetic as object construction* is based on fitting objects/parts and arithmetic operations. For instance, 5 is greater than 2 because an object comprising 5 units is larger than one comprising two. The *measuring stick* metaphor maps numbers onto distances, whereby 5 is greater than 2 because it is *longer*. The metaphor of *arithmetic as an object along the path* is based on arithmetic as motion, by which 5 is greater than 2 because it entails moving further from a common starting point (i.e., zero). Programing robots provides opportunities for illustrating and experiencing these arithmetic metaphors.

## Context

In this interpretive study we asked what mathematics children learn by building and programming Lego Mindstorms™ EV3. Interpretive research is about what meaning individuals construct in their lived experiences (Bhattacharya, 2008). We co-designed learning tasks with a graduate engineering student and co-taught the tasks with the classroom teachers over a course of four sequential days in three-hour daily sessions. The study's participants were 22 children, Grades 4-5 (aged 9–10), at Pakan School at Whitefish Lake 128 First Nation in rural Northern Alberta. Once the children knew the basic coding blocks for moving the robot, they were given Papert's (1980) task of programming a robot to follow a trace out of a triangle, square, pentagon or hexagon. On the third day, they were given the final challenge of building a robot that could find and douse a fire in any of four rooms in a building. Data included video-recordings, GoPro digital images, field notes, and artifacts including saved computer programs.

We video-recorded the four sessions to obtain rich contextual detail of children's mathematical interactions when programming the robots. Using interpretive video analysis (Knoblauch, 2013) we

selected videos and GoPro digital images that exemplified instances of children's mathematical thinking. Video data enables repeated viewing, slow motion, fast motion and frame-by-frame analysis. The selected videos formed the basis for emergent understandings of the children's experiences. The analysis developed through an iterative process of rereading the literature, reviewing the video and GoPro data, and rewriting. As is evident in our analysis, below, video data was vital. In particular, it permitted us to slow down the process and identify the integrated/nested processes of learning that occurred. The three instances that we use to focus our discussion were: (1) a trio of girls learning to program their robot for the final challenge to move a certain distance into the hallway to illustrate a developing understanding of number, (2) a boy tapping the vertices and sides of a triangle to count the number of programming steps necessary for the robot to move around the triangle as an example of additive thinking, and (3) a boy learning how the number of sides and angles of a polygon connects to the number of repeats in a loop, which illustrates a developing shift from additive to multiplicative thinking.

## Findings

In the *numberline* video (see <https://vimeo.com/144996708video>), Krista was helping the pink team program their robot to move into the building. This action required manipulating one block of EV3 code to move the wheels a specified number of rotations. The team members started out with a guess of 0.4 rotations to move the robot into the first corridor of the building. After testing how far the robot moved and observing that the robot needed to move a considerably greater distance, Krista prompted the girls by asking what they should try next. Celina suggested they try 0.5. The small incremental change was still not enough, so Krista suggested they try 2. Two rotations moved the robot too far.

Krista: What is between 0.5 and 2?

Celina: 5.

Suspecting that Celina's response indicated that she and her teammates were unable to summon an appropriate interpretation of decimal numbers, Krista drew a simple number line on the whiteboard.

Krista: What is between 0.5 and 2?

Celina: Oh! 1.8.

The number Celina chose was close to the number of rotations actually required, which indicated she understood the meaning of 1.8. In the exchange above, we take Celina's immediate and satisfactory response to the repeated question as evidence that Krista was justified in her suspicion that the learners were lacking an appropriate interpretation for understanding decimal numbers – or, at least, were unable to extend whatever interpretations that had available to a situation in which distance was measured in wheel rotations. Coding the robot to move compelled the learners to elaborate their understandings. Invoking the number line appeared to provide an appropriate metaphor for helping Celina understand.

In the following sequence of images and descriptions, we summarize how the task of coding the robot to move into a room calls for all four of Lakoff and Núñez' (2000) representations of arithmetic. To begin, the metaphor of *arithmetic as an object collection* is used in most counting situations, whenever the forms being counting are perceived as discrete objects. It is by far the most

common interpretation of number through the task of assembling a robot, by simple virtue of the fact that the robots begin as large collections of separate items. Less obviously, it is also called for in coding moments as programmers translate complicated actions into discrete steps or instructions. And more obscurely too, such conceptual moves as the discretizing of wheel turns, so that they can be counted and thus used as a tool in programming, might be argued to rely on this metaphor. Figure 1 (left) presents an instance of this metaphor, showing that 2 turns is less (i.e., forms a smaller set than) 5 turns.

**Figure 1: Arithmetic as object collection. Number of wheel rotations | Arithmetic as Object construction – combining portions of wheel rotations into single objects**

Figure 1 (right) shows how the metaphor of *arithmetic as an object construction* might be encountered when programming a robot to move. Celina wanted a larger wheel rotation than 0.4, so she added an incremental amount of 0.1 wheel rotations to make 0.5 wheel rotations. Contrasted to the previous metaphor, in this instance, wheel turns are not perceived as discrete objects, but as parseable continuities. Those parsed elements can then be assembled into an appropriate object to move the robot a precise distance.

The *measuring stick* metaphor also featured prominently in the children's programming, and was particularly prominent in the frequent need to interpret wheel turns in terms of actual distances (e.g., when the phrase "1 wheel turn" was deployed not as a description of movement but was a reference to a distance of roughly 12 cm). Figure 2 (left) in reference to the instance in which the room of the hall was shorter than approximately 1.8 wheel turns. In this instance, programming the code block requires understanding measurement.

**Figure 2: Measuring Stick: The length of hall | Arithmetic as an object along the path. The robot travels further with 2 than 0.5**

Figure 2 (right) shows how programming the robot to move draws upon the metaphor of *arithmetic as an object along the path*. In this case, starting place becomes a critical element is that, for example, occurs when the robot enters the room and recurs in the opposite direction when the robot leaves.

To re-emphasize, we observed each of Lakoff and Núñez' four metaphors of arithmetic to be present in programming the robot to move a required distance in the room. The ability to identify to the particular metaphor(s) that a situation is calling for is a critically important teaching competence, as Krista demonstrated in the interaction with Celina. Re-interpreting that brief episode, Krista recognized that Celina was not interpreting number as a distance (i.e., she was not using a *measuring stick* metaphor), and thus reminded her of that metaphor by offering the image of a number line. No explanation other than an image of number that fitted the application at hand was required.

### **Arithmetic Topic 2 – Moving from “additive” thinking to “multiplicative” thinking.**

The need for appropriate metaphors and images of number isn't sufficient for making sense of that entire episode, however, closer analysis reveals a further issue with the children's arithmetic, namely the tendency to default to additive actions rather than multiplicative actions would have been more suitable. That episode began with the group's realization that an entry of “0.4” moved the robot only a small portion of a desired distance. Asked what else they might try, they increased the distance only incrementally by 0.1 (to 0.5) rather than the necessary factor of (roughly) three.

This same tendency to default to additive actions when multiplicative action would have been more productive was witnessed many times across many groups over the four-day project. The *additive thinking* video (see <https://vimeo.com/144820583>) provides a window into any instance of the same phenomenon. In this case, Gene, who was on the floor in orange, is figuring out how many blocks of code were needed for the program. As he counted “one, two, three, four, five, six,” he tapped each vertex and side of the yellow triangle, finally announcing that six steps are needed. Gene's step-by-step of the same two steps (straight, turn, straight, turn, straight, turn sequence) is an example of additive thinking – that is, of construing the situation in terms of a sequence of increments rather than a repetition.

Phrased in terms of coding, Gene opted to repeat the same line of instructions six times rather than employing a loop that ran six times. This happened in spite the fact that he and his group mates had learned how to use loops the day before when they programmed their robot to dance.

In fact, only one of the 8 groups in the class used a loop for the polygon task – suggesting that the move from additive/increment-based thinking to multiplicative/loop-based thinking is more conceptually demanding than is often assumed. The *additive to multiplicative thinking* video (see <https://vimeo.com/144826969>) further illustrates this point, as the classroom teacher along with Krista attempted to help Liam program with loops. Liam, on the left, identified that a pentagon has three sides. When asked to count the sides, he walked around the pentagon counting aloud and announced “5 times.” Krista explains that 5 times is the number of times to repeat the two block codes (go straight and turn) in the loop. In response, Liam exclaimed excitedly, “Yes!”

In the same clip there are two boys who were fine-tuning their robot's program to follow a triangle. Their robot never stopped, which indicates that they are using an infinite loop – suggesting that they are making use of a concept of “repeating,” but likely not a concept of multiplication. After three attempts at tracing out a triangle, they still hadn't crafted a program that would stop their robots.

Davis and Renert (2014) have identified a number of common instantiations for multiplication that are encountered in elementary school classrooms, including grouping, hopping, repeated sums,

stretching and compressing, array- and area-making, and making combinations. Looping, it seems, is another, distinct instantiation of multiplication that is particularly powerful in the activity of programming – in a manner, we suspect, that might be used reflexively to support mathematics learning. Figure 3 below, illustrates two programs for following a triangle. Additive thinking is found with the sequential accumulation of six programming blocks: move forward, turn, move forward, turn, move forward turn. Multiplicative thinking requires recognizing that the triangle can be traced by repeating the move forward and turn blocks three times in a loop. In the exchanges above, Liam appeared to be developing fluency with multiplicative thinking.

**Figure 3: An additive and a multiplicative program for moving a robot in a triangle**

Across the participants there was a pervasive tendency to program robots to trace out polygons as a sequence of same-steps rather than as a repetition of a set of steps (i.e., as enabled with a loop). This tendency was not easily interrupted through instruction, which provides evidence of the complexity of thinking multiplicatively. Even at the end of the four days, during the final challenge, only two of the teams had managed to appreciate the power of loops sufficiently to incorporate them into their programs. Not surprisingly, theirs were also the robots that performed the best. In one of these cases, the code for the winning robot (see <https://vimeo.com/145404678>) involved a loop determining if a fire is present, announcing “Yes” or “No” as appropriate, and activating an arm motion to dump retardant if “Yes.”

Part of the reason that we dwell on this point is that the operation of multiplication is, arguably, the most important concept in grade-school mathematics. Multiplicative thinking is the cornerstone of proportional thinking, which is foundational to advanced mathematics for reasons that include the access it affords to an extended range of numbers (for example, larger whole numbers, decimals, common fractions, ratio and percent), its role in recognizing and solving a range of problems involving direct and indirect proportions, and the power it offers with its prominent place in school-based concepts and processes (Education and Training, 2013). In brief, multiplicative thinking is a key in the transition from early ideas to later ideas (see, e.g., ACME, 2011, p. 20).

## Closing remarks

Our preliminary findings suggest programming robots can support learning mathematics. In the episodes reported, the tasks of programming robots required more than parsing complicated actions into singular direction; they entailed flexible engagement, Lakoff and Núñez’ (2000) conceptual metaphors and mathematical models.

Computer programming aligns closely with concepts and structures in mathematics and we suspect that it might provide other powerful instantiations for mathematical concepts that have not yet been noticed. That suggestion is perhaps not surprising, given the mathematical roots of computer programming. However, to our reading, it is not an aspect of programming that has garnered much consideration in either mathematics education or the technology education literature. Considering

that mathematics literacy and competency with coding are of growing relevance, engagement with emergent technologies can complement and co-amplify mathematics learning, and contribute to evolving understandings of what “basic” mathematics might be for our era.

With regard to important complementarities between learning mathematics and learning to code, the Lego Mindstorms™ EV3 robots and the associated programming language provide a powerful instance of multiple solutions. They afford tremendous flexibility for accomplishing a range of tasks, from the trivial to the complex. None of the coding tasks set for the children in our study had pre-given or optimal “solutions.” Despite that – or perhaps because of that – the children were able to engage in manners that they could recognize as successful, even when “complete” solutions were not reached. With incremental tasks and iterative refinements, children were able to learn more sophisticated and efficient methods for programming the robot. It is not difficult to imagine a mathematics class with similar standards of success.

That said, it is not a coincidence that the winning robot had the most efficient and sophisticated program of the group. Some answers are better than others, and those answers appear to reflect powerful mathematical thinking. Our future longitudinal research will investigate how children’s understandings of mathematical concepts and programming robotics develop over several years.

We believe that the results of this study underscore the importance of developing and implementing a computer programming curriculum in schools. Coding is an emergent literacy that can amplify other critical literacies, while affording access to a diverse range of cultural capitals. The reasons to teach coding go beyond the technical and economic; for us, they are fundamentally ethical.

# Investigating the integration of a digital resource in the mathematics classroom: The case of a creative electronic book on reflection

Eirini Geraniou and Manolis Mavrikis

<sup>1</sup>UCL Institute of Education, University College London, UK; [{e.geraniou, m.mavrikis}@ucl.ac.uk](mailto:{e.geraniou, m.mavrikis}@ucl.ac.uk)

*This paper explores the potential impact of a full teacher-driven design and implementation cycle of an electronic book (c-book). We analyse data gathered from a school case study and identify the potential of the affordances of the c-book technology that allow the integration of various mathematical widgets and reflective activities. Our conjecture is that encouraging flexibility on playful tasks and reflection on ‘bridging’ activities early in the structure of the book prepared the students to more complex constructionist tasks around the concept of Reflection. Looking into the full cycle from design to evaluation this study demonstrates a successful integration of a digital resource in the mathematics classroom and highlights some of the successful components of the resource namely: playful activities for students, matched with carefully designed bridging activities, followed by constructionist activities that allow deeper exploration of the subject matter.*

*Keywords: Mathematical creativity, e-books, transformations, reflection, bridging activities.*

## Introduction

There is a lot of research and many projects that focus on developing digital resources for the teaching and learning of mathematics. Issues though regarding their successful use and integration in the mathematics classroom still remain (Clark-Wilson, Robutti & Sinclair, 2014; Geraniou & Mavrikis, 2015). One of the issues is whether and how students who may become experts in using a digital tool reflect and consolidate their mathematical knowledge (Geraniou & Mavrikis, 2015). Teachers then may not be convinced of the potential value of using digital tools in their mathematics lessons. In our view, a successful integration of such tools also involves the successful transition from interacting with a digital tool to a metacognitive understanding on behalf of the students that the interaction can support their knowledge ‘outside’ the tool.

Our work continues to focus on building ‘bridges’ to the maths involved (and may be ‘hidden’) in digital resources. We are looking into how we can encourage the consolidation of knowledge within digital tools and the ‘transfer’ of knowledge aiming at finding strategies to integrate them successfully into the classroom and the learning process. We define bridging activities as short tasks or questions that are used to intervene and encourage students to reflect upon mathematical concepts and problem-solving strategies they use throughout a sequence of activities (or simple interactions) with a digital tool. Such activities could take various arrangements from questions or prompts within the digital tool to paper-based worksheets or verbal teacher’s interventions. In this paper, we focus on an electronic book resource and, particularly what the Mathematical Creativity (MC) Squared project (<http://mc2-project.eu/>) calls ‘c-books’, which are extended electronic ‘creative’ books that include widgets i.e. objects, other than text ranging from simple hyperlinks or videos to a broad range of interactive digital environments for mathematics such as GeoGebra and other microworlds (c.f. Kynigos, 2015). The project also includes an authorable intelligent support and data analytics engine that allows designers (e.g. teachers) to author the feedback that the system could provide to a student and the data they would like to see from their interaction (Karkalas & Mavrikis, 2016). The idea

behind the MC Squared project is to focus on social creativity in the design of digital media intended to enhance creativity in mathematical thinking (CMT). Researchers collaborating with math educators and teachers join Communities of Interest (COI) that work together to creatively think and design c-book resources reflecting 21st-century pedagogy for CMT.

The focus of the small study presented in this paper has been on designing a c-book including appropriate resources, such as bridging activities (Geraniou & Mavrikis, 2015) with the aim of enabling students to make connections to the mathematical concept the c-book is designed to teach them, in this case, Reflection<sup>1</sup>. We conjecture that designing resources that encourage flexibility on playful tasks and reflection early in the structure of the book prepared the students to more complex constructionist tasks. Looking into the full cycle from design to evaluation we demonstrate a successful integration of the c-book in a mathematics classroom and highlight some of its key components namely: playful activities for students, matched with carefully designed bridging activities, followed by constructionist activities that allow deeper exploration of the subject matter.

## Theoretical framework

CMT has been given many definitions by various authors (e.g. El-Demerdash & Kortenkamp, 2009; Mann, 2005). In the MC Squared project, CMT has been drawn on Guilford's (1950) model of fluency (the ability to generate a number of solutions to a problem), flexibility (the ability to create different solutions), originality (the ability to generate new and unique solutions), and elaboration (the ability to redefine a problem). CMT has also been approached as a thinking 'process' that takes place in the context of a mathematical activity in order to produce a 'product' (e.g. a solution to a mathematical problem). As such the product and process are intertwined. For example, the construction of a geometric artefact is seen as a product that was started as a response to a task (problem), continued with the identification of a set of points, lines etc. that are underpinned by some properties that provide an answer to the task (product). Taking the above CMT's aspects as a starting point, we align our views to Papadopoulos et al.'s (2015; 2016) who consider CMT as the (i) 'construction' of math ideas or objects, in accordance to constructionism that sees CMT being expressed through exploration, modification and creation of digital artefacts (Daskolia & Kynigos, 2012), (ii) Fluency (as many answers as possible) and Flexibility (different solutions/strategies for the same problem) and (iii) novelty/originality (new/unusual/unexpected ways of applying mathematical knowledge in posing and solving problems). Even though CMT seems to be at the core of mathematical thinking, its development through the use of exploratory and expressive digital media hasn't been thoroughly investigated (e.g. Healy & Kynigos, 2010) and the question about the best possible strategies for developing appropriate resources for integrating such digital media and promoting CMT inside and outside of the classroom remains.

---

<sup>1</sup> To distinguish between 'reflection' as a thought process and the mathematical concept 'Reflection', we will use capital letter 'R' for the mathematical concept.

## Authoring c-books

As mentioned above, c-books are special electronic books that are designed within the Digital Mathematics Environment (DME)<sup>2</sup> which has been designed to allow teachers to create sequences of activities involving a number of widgets. It allows teachers to change the feedback messages students receive during their interactions with the c-book and stores all user interactions and scores. As part of a teacher training course, and based on our previous work, we encourage teachers to use DME's affordance to design bridging activities that promote students' reflective thinking on their interactions aligned with the various widgets. We expect these activities to 'bridge' the students' transition to the mathematical concepts, which the digital resource is designed to support (Geraniou & Mavrikis, 2015). These are questions presented and directly linked to the widget's tasks and can be viewed as interventions that encourage students' reflections on their interactions throughout a sequence of tasks, but also introduce and encourage the use of mathematical notation, not necessarily presented within the widgets. Authoring bridging activities within the digital medium of a c-book and recognising the potential value to students' learning progress and outcomes may encourage teachers to use such digital media more often.

### The case of a c-book on reflection

The c-book on Reflection consists of a number of pages involving different tasks mostly in GeoGebra. This c-book (as opposed to others created in COI meetings, during which COI members brainstormed about ideas and activities that could be part of a c-book on a specific mathematical topic), was initially created by the class teacher in this study, who already had a number of prepared resources, which they put together using the affordances of the DME platform to form the c-book. These were resources like book chapters and GeoGebra worksheets. The c-book was also shared with the COI in an effort to gain constructive feedback and improve it.

The learning objective for the c-book was to remind students of the definition of Reflection, which had already been introduced about seven months before, define the Reflection ('mirror') line, consolidate students' prior knowledge and develop their understanding of the concept of Reflection. Even though the c-book technology allows a non-linear browsing of the c-book and students can work on any activity they want, this c-book was designed (and used) as a linear progression for constructing students' knowledge on Reflection by: (i) revising prior knowledge on Reflection through a series of multiple choice questions on certain reflected images where students had to decide which of the four images was the correct reflected image, (ii) revising and practicing on the GeoGebra widget (Figures 1A and 1B), (iii) challenging their understanding of Reflection through a competition task (Figures 1C and 1D) that promoted 'flexibility' in their solving approaches, (iv) challenging further their understanding of Reflection through a problem that challenged further their understanding and took them away from the standard style of questions such as 'Reflect this shape across the given Reflection line' (by not giving them the Reflection line, adding a constraint of the squared frame and giving them a story context to think about) (Figures 1E and 1F), and finally (v) a final assessment task mostly for those who finish faster aimed at recapping what students should know at the end of this c-book unit. We need to emphasize that all GeoGebra tasks were presented as bridging activities through the

---

<sup>2</sup> See [http://ws.fisme.science.uu.nl/dwo/site/index\\_en.html](http://ws.fisme.science.uu.nl/dwo/site/index_en.html) and <http://mc2-project.eu/>

use of added text and reflective questions (see Figures 1A, 1C and 1E) on the side. These were designed as such to challenge students' thinking and understanding of Reflection and help them consider carefully their interactions rather than simply undertake the tasks. The feedback provided to students was of different types: (i) as a tick or cross for correct and incorrect responses, (ii) as a score for the GeoGebra competition task, which identified the number of correct Reflections students reached within the 5 minutes timeframe set by their teacher (Figure 1D) and (iii) as a written text to provoke their problem solving.

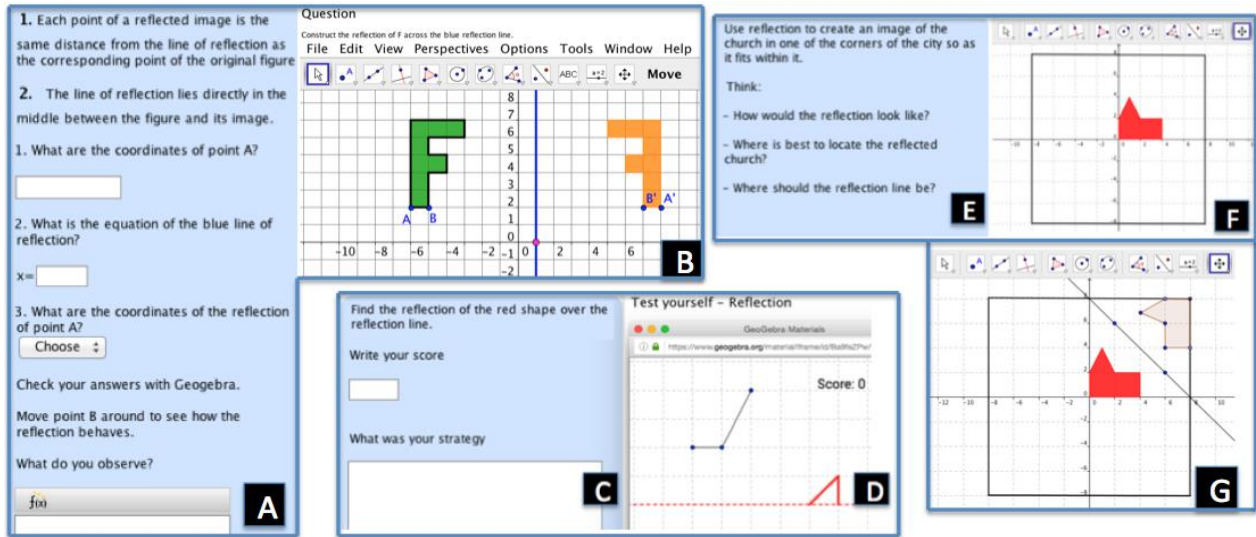

Figure 1: (A – F) Excerpts from the Reflection c-book and (G) a sample solution of (F)

## Data collection

The aim of this case study was to explore the potential of both the Reflection digital book in the light of the affordances of the overall c-book technology i.e. beyond the ability to sequence activities, the potential for automated feedback and reflection that could be used to support bridging activities. The methodological tool used was that of a “design experiment” (Collins et al., 2004), that could act both as a way to ‘engineer’ and support the didactical situation and to systematically study it (Cobb et al., 2003). In this case, we, as a research team, collaborated with a teacher but left the decisions and responsibility of the classroom to the teacher.

Twenty-one 11-12 year old (Grade-7) students together with their class teacher and two researchers participated in the study, which was completed in two lessons in the school’s computer lab. The students had been introduced to the concept of Reflection earlier in the year by working on some simple activities involving reflecting 2D shapes across the Reflection line. According to the teacher, the aim of these two sessions was to revise and consolidate their knowledge, but also to challenge their mathematical thinking against the concept of Reflection. The plan for the first lesson was (i) to remind them of what Reflection is and introduce the mathematical term of ‘Reflection line’ as opposed to ‘mirror line’ when they were first introduced to Reflection, (ii) introduce the c-book technology and (iii) allow students to familiarize themselves with GeoGebra through a challenging task, which acted as a bridging activity to recap prior knowledge. It involved working on some bridging activities, which included mathematical questions (such as ‘find the coordinates’) and reflective questions (such as ‘what was your strategy?’) within the platform. At the end of the first lesson, most students had reached the ‘Church Challenge’ task (see Figure 1E and 1F). During the

second lesson, students continued to work on the ‘Church Challenge’ and then answered a questionnaire to evaluate the c-book.

In addition, at the end of the second lesson, they were given a questionnaire to share their feedback on their learning experience with the Reflection c-book. The questionnaire was a Likert multiple-choice questionnaire consisting of questions such as: (1) How satisfied were you after completing the c-book activities?, (2) How easy to use do you think the c-book is?, (3) How free did you feel to experiment with the c-book and try out your ideas?, (4) I feel I understand Reflection now. Another two questions (5 and 6) gave them options to pick on their thoughts on the c-book and their preferred features. The questionnaire finished with three more questions to request suggestions from students (out of the scope of this paper).

Researchers took the role of ‘participant observers’ focusing on students’ interactions with the digital medium and taking field notes. Besides working with the researchers and other COI members to design the Reflections c-book, the teachers’ role was to offer assistance in technical issues when required during the two lessons and ensure that all students were on task and answered the bridging activities. Our data consists of the logged answers in DME and voice recordings as students elaborated on their interaction and answers. The data analysis was carried out by retrieving students’ interactions with the c-book from the system and interpreting their responses against the CMT criteria presented earlier and by going through their answers on the questionnaire.

## Results

The main outcome based on the data from the bridging activities, in particular, was that students were encouraged to reflect on the GeoGebra task from the start of their interactions. The teacher reminded students of the reflective questions (Figure 1A) and encouraged them to record their answers. The designed automated feedback supported all students to identify correctly the missing coordinates for the ‘F’ shape, its Reflected image and the equation of the Reflection line. In this first bridging activity, students were reminded of what Reflection is and the definition of the ‘line of Reflection’. Both these terms were also introduced to the whole class and discussed with the class teacher at the start of the first lesson. But, we envisaged the repetition would give students a sense of familiarity and they would eventually start using mathematical terms in later tasks and would adopt mathematical ways of thinking. Fourteen (14) of the students provided sensible answers to the bridging question in relation to their strategy. Looking at students’ responses to the bridging activity questions for the first couple of GeoGebra tasks, students were mostly using informal terminology:

Student: we have to flip the shape.

Student: count how many down from the mirror line.

But, in later bridging activities questions, students started to use mathematical terms, such as “the reflected church” or the “reflection line”. For the question on what they notice when they move the ‘F’ shape, their responses were rather superficial:

Student: if you move the green shape, the orange shape moves with it.

They seemed to have noticed that the two shapes (green and orange ‘F’) are linked, but only 2 were able to articulate that they maintain the same distance from the Reflection line. Retrospectively, observing the students talking about their strategies, it might have been better to include some explicit

scaffolding questions here such as “What is the distance from the ‘F’ shape to the reflection line?”, “What do you notice?” etc. These could be followed up by the teacher to clarify what reflection is and how the reflected images are defined.

The bridging activities questions revealed students’ solving strategies and consequently their CMT. For the Competition task, students claimed to use three different strategies: (i) counting boxes across and down, (ii) tilt their head so that the reflection line becomes vertical and (iii) imagine using tracing paper on the screen. In this way, students demonstrated not only that they can come up with some original (for them) solutions but that they can also provide elaborate reflections on their strategies, which is linked to the originality/novelty CMT criteria described earlier. In retrospect, the c-book could have been designed to ask students for different strategies after they come up with one to challenge further their CMT in terms of the fluency and flexibility criteria.

Asking students about their strategy seems to promote reflection on their actions that helped them reach a solution. In particular, the Church Challenge (Figures 1E and 1F) posed a problem that ignited students’ thinking ‘process’ and resulted in a ‘product’, i.e. the reflected church image. In all the previous activities, students were given the Reflection line and their aim was to reflect a given shape. On the contrary with the Church challenge, students had to find the Reflection line and reflect the church image within the square town (see Figure 1G). By writing down their strategy, they recognised the solution ‘steps’ they took, questioned their actions and corrected them when needed. This open-ended problem allowed for exploration, construction of mathematical ideas and flexibility, which are all aspects we used to define CMT earlier (e.g. Papadopoulos et al., 2016).

Sixteen students (16/21 or 76%) managed to complete the task, whereas the rest ran out of time in the lesson. 10 of those got a correct answer. To reach the solution or the ‘product’, students produced creative solving strategies, which they were asked to justify. These strategies involved imagining a tracing paper used on the screen to reflect the church (14% or 3/21), which could be considered original in this context; trial and error technique by reflecting the church in all 4 quadrants and then thinking about reflecting each image within a quadrant to the corner of that quadrant to see which one fits within the square town (33% or 7/21); or another trial and error technique by constructing different Reflection lines and reflecting the church in one or more quadrants (52% or 11/21, see Figure 1G). These two latter strategies demonstrate students’ flexibility through the CMT criteria lens.

As far as the questionnaire is concerned, we are mostly interested in this paper on question #4 where most of the students (85% or 18/21) responded with an answer above 4 in the Likert scale. In relation to their thoughts on the c-books about 60% (13/21) answered that it helped them see the idea of reflection in different ways. This is really encouraging as one of our objectives was indeed to help students expand their understanding. About 43% (9/21) said that it included problems that they would not have tried to solve. This is also interesting as we want to encourage students to appreciate their mathematical abilities. In the open-ended questions, most students complimented the affordances of the c-book by commenting on enjoying the free explorations, testing of their ideas, experimenting, working on new questions and being challenged. While some students had comments for aesthetic improvements (fonts, games, colours etc.) three (3) students made comments that showed that they appreciate the advantages of digital technologies:

Student: the digital book help[s] because you could have actually test[ed] out your ideas and improve if it's wrong or not.

They recognised the dynamicity of such resources and how seeing the immediate feedback on their actions helps them validate their solution. At the end of the two lessons, the teacher also shared his reflections with the researchers and later with the COI. The teacher was impressed with how students were so engaged with the c-book, compared to past lessons without any digital resource and commented on the value of bridging activities and shared ideas on how to improve them.

## Conclusion

This paper provides a good indication of the value of having a digital medium that combines free exploration, but encourages students to reflect upon their actions and make a link between their interaction in a digital environment and their mathematics through bridging activities. Such activities focus on mathematical terms, the definition of concepts, but also the justification for their solutions, throughout their work and 'bridge' the actions to solving a problem in the digital tool to the underlying mathematics (which could otherwise be 'lost').

Authoring activities using various widgets, designing Bridging Activities and in general, participating in the creation of the Reflection c-book re-enforced the teacher's keenness to continue to use digital technologies in their classroom. As a result of this study, the teacher and the COI revisited the c-book that led to further improvements in the book. The most notable of those was breaking down the bridging questions to smaller questions with guidance, and using the feedback affordances to encourage flexibility in terms of the strategies, as an aspect of CMT.

To conclude, this case study demonstrates how the c-book technology can be integrated into the mathematics classroom and promote a positive learning experience through the use of playful activities for students, matched with carefully designed bridging activities, followed by constructionist activities that allow deeper exploration of the subject matter.

## Introduction

Mobile devices, such as smartphones, tablets and laptops, have become an integral part of our lives. Teachers and pupils use them daily for communication, searching for information or for entertainment. Pupils today, born from 1990 to 2010 and recognized as generation Z, are the most technologically advanced generation, often known as digital natives. They were born into the era of the Internet and Facebook; they always want to stay connected with their friends and to use high-speed digital devices (Baker & Evans, 2016). Hence, the wide spread of mobile devices causes a natural social pressure and challenge for educators to include these devices into education, to support learning. Computers, laptops, and netbooks have all been added to classroom settings with the hopes of revolutionizing education, promising vast improvements to pupil outcomes. These technologies, largely, have left education unchanged and in a continual state of need for improvement (McQuiggan, Kosturko, McQuiggan & Sabourin, 2015). Mobile learning offers a novel approach to reach current pupils. By the term *mobile learning* we follow McQuiggan, Kosturko, McQuiggan and Sabourin (2015, p. 31).

It is anywhere, anytime learning enabled by instant, on-demand access to a personalized world filled with the tools and resources we prefer for creating our own knowledge, satisfying our curiosities, collaborating with others, and cultivating experiences otherwise unattainable. Mobile learning implies adapting and building upon the latest advances in mobile technology, redefining the responsibilities of teachers and students, and blurring the lines between formal and informal learning.

Mobile learning offers flexibility in when learning takes place, personalization of content, and gives pupils experience with contemporary technology and relevant skills for the future. So unsurprisingly, mobile learning has been considered as the future of learning or as an integral part of any other form of educational process in the future (Trifonova, 2003).

In June 2016, gaming apps were the most popular apps based on availability, as about 23 % of all apps available in the Apple App Store fit in this category. The second most popular category was

Business (10.22 %), closely followed by the Education category (9.21 %) ('Most popular', 2016). Shuler (2012) has analyzed the Education category from Apple App store. In 2011, more than three quarters (77 %) of the top selling apps targeted preschool or elementary aged children. Early learning was by far the most popular subject/skill-set (47 %), followed by mathematics (13 %). Drigas and Pappas (2015) have analyzed the most representative studies of recent years (2002 - 2013), involving online and mobile applications and tools for mathematics as well as their effect in the educational process. The results of the studies revealed that online and mobile learning applications motivated pupils, making mathematics instruction more enjoyable and interactive than ordinary teaching practices. The analyzed applications were targeted towards one specific area of mathematics, like graphs and functions, arithmetic, algebra, geometry, problem solving or mathematical programming and they were available only in English or Spanish. In light of this, we see it as an important contribution to ongoing research into mathematics education to engage in projects that examine the process of developing applications for mobile technologies as well as studying the effects they could have on learning. Also, providing tools readily available for school teachers was an important factor for running the Apps in Math project, as detailed in the next section.

### **Design and implementation of the Apps in Math applications**

The main goal of the Apps in Math project (AiM) was to develop 25 applications in 15 months for supporting teaching and learning mathematics in lower and upper secondary schools in Slovakia and Norway. In Norway, pupils have relatively good access to technology, compared with European countries. Almost 90 % of pupils use Internet in schools but the most common use is probably the computer and not mobile platforms. After school hours, as much as 94 % of all children aged 9-16 have access to a mobile phone, and 83 % have a smartphone. (Medietilsynet & Trygg bruk, 2014) Several schools have a policy of buying one laptop for each child in school. Most publishing houses have their own apps and games connecting to their textbooks, and there are usually many choices teachers can do regarding software for their pupils. Much is not translated into Norwegian, but this is generally not seen as a big difficulty.

In Slovakia not all pupils have their own smartphone or tablet; the further east one goes, the less pupils have their own mobile device (Micháľková, 2016). In the primary and secondary schools – the typicality is to have three computer rooms per school, in which Informatics is mainly taught, so there is rarely room for mathematics lessons in these specialized classrooms. Pupils usually do not have their own PC. During 2013-2015, thanks to national project supported by EU funding, 22 000 tablets were given to Slovak schools, which usually meant set of 30 tablets per school. Pupils in one school are sharing those tablets; teachers bring them for lesson, at the end of the lesson pupils have to return them, because they will be used in other classrooms. In Google Play or App Store there are very few mathematical apps in Slovak language that are intended to be used in mathematics classes at lower or upper secondary schools. So there is a need for applications, which teachers could use in math classes and for different levels of schooling.

The applications (modules) developed within Apps in Math project focus on various mathematical topics that are part of Slovak or Norwegian curriculum for pupils aged 9-19. The development of modules went in coherence with Design based research (Wang & Hannafin, 2005) and its iterative cycles. The mathematics teacher educators from Trondheim and Bratislava have cooperated with academics and bachelor students of applied informatics at the Comenius University in Bratislava.

Slovak bachelor students in Applied Informatics have programmed the modules based on the specifications from mathematics teacher educators and master and PhD students, as part of their bachelor thesis in informatics. The modules were tested extensively within the local participating groups in Slovakia and in Norway, as well as with pupils in Slovak and Norwegian schools. Reflective analysis of problems and obstacles was done and changes were implemented after each testing. All modules are part of one framework application called Apps in Math and they are divided into five main categories: Numbers, Functions, Geometry, Chance and Logic. Apps in Math is available for Android and iOS<sup>1</sup> platform and in Slovak, Norwegian and English language. Ebner (2015) has divided applications into four categories: stand-alone learning apps, game-based learning apps, collaborative apps and learning analytics apps. Apps in Math has the characteristics of being game-based learning application. Diah, Ehsan and Ismail (2010) have introduced the framework for mobile educational games consisting of four important segments: Learning Theories, Mobile Learning Approach, Games Development Approach and Learning and Education Medium. Most of the modules in Apps in Math apply the constructivism as the learning theory and for the mobile learning approach the games use activity-based themes for informal and lifelong learning.

## Case studies

This section describes two case studies (Study 1 and Study 2) that were conducted to evaluate the effectiveness of mobile learning with Apps in Math application in real-world settings, with lower and upper secondary school pupils. We have chosen the SAMR-model for a quick categorization of the modules, where digital technologies can be placed on a scale from just replacing already existing practicing to facilitate types of tasks that could not have been done without the digital tools (Hudson, 2014). Limited resources and limited time made it necessary to choose for evaluation those modules that were closest to being finished. The module *Lucky Hockey* is based on the classic learning game *Green Globes* (Dugdale, 1982), and several versions of this game has been implemented over the years. The pupils who play the game are going to shoot a hockey puck across an ice hockey arena in order to collect as many coins as possible. The coins are shattered around the play field, sometimes in a random manner, sometimes to provoke a particular shot. The pupil shoots by entering a function expression, using the touch screen controls to alter the parameters of the function (Figure 2). By playing this game pupils should understand what impact the parameters of the function have on a graph. Using the SAMR-model we can say that Lucky Hockey acts as a direct tool substitute, but that the functional improvement allows for a more dynamic and dual view of the representations of a linear graph and the corresponding expression. Hence we can say this app is an augmentation of traditional instruction.

---

Figure 1: Learn mode of Lucky Hockey

Figure 2: First level of Lucky Hockey

The module *House of cards* focus on arithmetic and geometric sequences in two separated submodules called *Arithmetricks* and *Geometricks*. By playing this game pupils should discover relations between the terms of the sequence and be able to write down basic formulae related to these relations. The number sequences are displayed on playing cards. Both submodules have a *Learn mode*, in which basic principles of the sequence are explained. The pupil has to determine the number, which is added/multiplied to/with each of the following sequence terms (Figure 3). The pupil has to answer five tasks correct within the time limit. After 3 incorrect attempts the correct answer is shown. In the next three levels the pupil should select the card, which belongs to the empty red spot in the given sequence within time limit (Figure 4). In the first level first 3 terms are given and the pupil should select the missing card for 4<sup>th</sup> and 5<sup>th</sup> term. Again, using the SAMR-model on Arithmetricks and Geometricks, we note that the effectiveness and readiness of the app makes work with sequences easier than in traditional teaching, or teaching done with real cards. Hence this app too provides an augmentation over traditional instruction.

Figure 3: Learn mode of Arithmetricks

Figure 4: Third level of Arithmetricks

The target group for the *Lucky Hockey* game study was Slovak pupils between the age 14 and 15 (grade 9), who had had no experience in linear functions yet. The goal of Study 1 was to determine which aspects of the linear function concept students seem to approach more effectively through the use of the Lucky Hockey game. Time limited gaming (25 minutes) was meant as an adidactical situation (Brousseau, 1997). The adidacticity was promoted by giving the students full responsibility for the technology-supported exploration of mathematical tasks by retroacting only with the milieu and not the teacher (Sollervall, de la Iglesia, 2015). All together 54 pupils from 2 different schools in Slovakia participated in Study 1 in November and December 2015.

The target group for the *House of Cards* game study was Slovak pupils between the age 16 and 17 (grade 11), who had not learned about sequences yet and had no previous knowledge about arithmetic

and geometric sequences. The goal of Study 2 was to determine which aspects of the arithmetic/geometric sequence concept students seem to approach more effectively through the use of the House of Cards game. All together 49 pupils from schools in Bratislava participated in Study 2 in March 2016. They first played the Arithmetricks game (starting with Learn mode and consequently going through all three levels) for 25 minutes. The next lesson (in the same day) they played the Geometricks game with the same conditions. During both Studies 1 and 2 all pupils used an iPad. No pre-test was conducted since pupils did not have any knowledge on these topics. The post-tests were used to determine the level of acquired knowledge. All pupils of Study 1 and 2 completed the post-tests as part of the evaluation, right after playing the game. The phase of institutionalization took place a few months after Studies 1 and 2, due to prescribed curriculum.

A preliminary study was conducted in September 2015 with 77 pupils of different age (7 - 16), in order to introduce them the early versions of five different games, including the Lucky Hockey game. At this stage, the game was more or less fully working, apart from minor graphical issues. Part of the group (about 20 pupils) tested the Lucky Hockey game. During the testing pupils thought (while playing the Learn mode – Figure 1), that the expression is always  $y = 0x + b$ , because they were able to hit the goalie only by changing parameter  $b$ . This was an obstacle in Level 1, so we had to refine Learn mode and control the possible movements of a shooting player. Most of the pupils liked the game and did grasp the notion of linear function. In the preliminary study we also asked all the pupils about their interest in using smartphones or tablets to learn mathematics in school. Figure 5 shows their answers. 92.3 % of pupils, who answered positively on this question, also said that they would like to play tested games at home. Out of them 46.7 % in the situation when they are bored, 28.3 % for practicing mathematics and 25 % when doing homework.

**Figure 5: Interest of pupils to learn mathematics with mobile devices**

## Results

Figure 6 shows that pupils performed quite well in the post-test of Study 1. The average score was 5.11 and median score of 5. Pupils could obtain a maximum of 7 points, which were obtained by 13 pupils (24 %). Half of the pupils (50 %) scored 4-6.5 points, but there was also one pupil whose score was 0. The results indicate that most pupils learned the slope and intersection-aspects of the function concept on an acceptable level. The lowest score performance they had occurred in the last task, in which they were asked to explain what impact the parameters  $a$  and  $b$  in the expression  $y = ax + b$  had on the corresponding linear graph. Only 46 % of pupils explained it correctly. Nevertheless, they performed better in tasks in which they were supposed to draw a line in correspondence with a given equation (76 %) or select the correct line/equation out of four possibilities that is corresponding to a given equation/line (86 %).

**Figure 6: Box and Whisker Chart of Lucky Hockey Post-test Results**

Figure 7 shows the results of pupils in the post-test of Study 2. It is clear that these pupils performed better in the Geometricks post-test. Here, 50 % of the pupils obtained 8-10 points, while 10 was the maximum. 18 pupils (36.7 %) obtained maximum score, and one pupil obtained the minimum score of 2. The second lowest score was 5, also obtained only by one pupil. The lowest performance was in the last task in which they had to write down the formula for how to find the 10<sup>th</sup> term, if they knew the quotient ( $q = \frac{1}{3}$ ) and the 1<sup>st</sup> term was given as  $a_1$ . Only 51 % of the pupils wrote the correct formula and explained their answer correctly. The most frequent error was made by 7 pupils (8.2 %), claiming that  $a_{10} = a_1 \cdot \frac{1}{3^{10}}$ . In all the other tasks pupils were able to determine the unknown term, if they knew specified values of the 1<sup>st</sup> term and the quotient, or specified values of two consecutive or two nonconsecutive terms, with successfulness of 89 % - 100 %. The scores in the Arithmetricks post-test were slightly lower, with an average 6.82 and 6 as a median score. 8 pupils (16.3 %) obtained the maximum score and two pupils obtained the minimum score of 3. Distribution of scores within the box chart shows that approximately one quarter of the pupils obtained the same score, 6 points.

**Figure 7: Box and Whisker Charts of Arithmetricks and Geometricks Post-tests Results**

## Discussion and conclusive remarks

We note from the results that most of the pupils did learn the important principles of linear functions or sequences at an acceptable level. However, only about 50 % of the pupils were able to answer the last questions correctly. This might have improved if the pupils were to play the games additional times. This hypothesis also arises from differences between how the pupils scored in Arithmetricks and Geometricks post-tests. The pupils did play the Geometricks game after playing the Arithmetricks game and since the principle is not very different, it could cause that they performed better in the

Geometricks post-test. As mentioned above, the phase of institutionalization took place 6 months after the Studies 1-2. While pupils who participated in Study 1 did not remember much about the linear function, it was different with pupils of Study 2. Pupils recalled the main principles of arithmetic/geometric sequence and told the teacher that it was not needed to explain it again: “It’s like in that game we have played.” From observation of the teacher we also note that traditional teaching of sequences went this time easier, probably also due to the mobile learning. The low performance on the last task of the Lucky Hockey post-test could be caused by the nature of the task. In all the previous questions we used numerals instead of parameters  $a$  and  $b$ , whereas on the last question some generalization and explanation were expected. While some pupils may have misunderstood the meaning of the parameters, some didn't give any reply at all or they only explained the role of one parameter. If the phase of institutionalization in form of, say, a discussion among pupils and a teacher took place right after the gaming activity, pupils’ understanding of the parameters’ role might have been better. The interest of pupils to learn mathematics with a mobile device was visible during testing both in Slovakia and in Norway. According to the results of the questionnaire it seems that most of the Slovak pupils would like to include mobile learning in their schooling. Testing of the other various applications from the project, not mentioned in this paper, also confirms that Slovak pupils and teachers consider mobile learning as a motivational way of learning and teaching mathematics (Micháľková, 2016; Kapitulčinová, 2016). Mobile phone games in classroom is a novel idea and it might still cause the engagement of being a contemporary, “fresh” way of learning mathematics, which could be the reason of pupils’ and teachers’ enthusiasm.

The results of Study 1 and 2 suggest that mobile learning can be both motivational for pupils when learning mathematics, and helpful when acquiring new knowledge effectively. Gamification of education has also reached mathematics instruction but resources and research are just beginning to surface. Ideas from the project are being further developed at both participating institutions. Current issues can include utilizing the small touch screen sensibly and also collecting data from how and when pupils use the applications. The mobile phone is a tool we can expect to see more in mathematics education as learning becomes further individualized and online. One lesson learned from this project is the difficulty of communicating mathematical ideas from the idea stage to the actual implementation. This became quite apparent when collaborating with different countries, different levels of study and different study branches. Another lesson from the project is that it turned out to be much easier to develop ideas with a narrow mathematical theme, than to make applications that facilitates exploration and discovery.

# Khan Academy as a resource for pre-service teachers: A controlled study

James Gray<sup>1</sup>, Christine Lindstrøm<sup>1</sup> and Kristian Vestli<sup>1</sup>

<sup>1</sup>Oslo and Akershus University College of Applied Sciences, Norway; [James.Gray@hioa.no](mailto:James.Gray@hioa.no);  
[Christine.Lindstrom@hioa.no](mailto:Christine.Lindstrom@hioa.no); [Kristian.Vestli@osloskolen.no](mailto:Kristian.Vestli@osloskolen.no)

*Khan Academy<sup>1</sup> (KA) is an online learning system of videos and exercises that is freely available and widely used. In this study, 131 students in a mathematics education class were split into two groups. Both groups followed normal instruction, but the treatment group was introduced to KA and given the opportunity to substitute their compulsory mathematics assignment with exercises in KA. This paper presents the results of students' performance on a mathematics pre- and post-test. The results show a statistically significant learning gain for both groups, but there were no statistically significant differences between the two groups on either test. This suggests that using the free and automated KA for self-study and assigned work was as effective for students' learning as other standard resources. Student usage of KA beyond the compulsory exercises, however, did not correlate with results on the mathematics test, possibly due to the limited focus of the test.*

*Keywords: Mathematics education, electronic learning, teacher education.*

## Introduction

Pre-service teachers in many countries struggle with mathematics. In Norway the TEDS-M study concluded that “a big problem in Norwegian teacher education is the poor academic skills of students in mathematics” (Grønmo & Onstad, 2012, p. 55, our translation). To address this challenge, the mathematics entry requirements for all Bachelor of Education students were increased from 2 to 3 (where 2 is the passing grade and 6 the highest grade) in 2005 (UFD, 2005), and increased again to 4 in 2016 (KD, 2014).

Fluency in school mathematics is essential for studying mathematics education. A consequence of pre-service teachers' weaknesses in mathematics is that class time has to be devoted to learning mathematics rather than mathematics education material. *Khan Academy (KA)* is one of many recent online resources offering structured sequences of videos and exercises. This paper reports on a first attempt to integrate KA as part of the mathematics instruction in a mathematics education class. More specifically, the research questions were: How do the learning gains of KA users compare to those in a control group? How much did the students use KA, and what were the associated learning gains?

## Khan Academy

*Khan Academy* began as a collection of YouTube videos made by the founder Salman Khan to help his cousins with their schoolwork. These videos were later integrated into an online learning tool, which had 10 million unique users a month in 2014 (Murphy, Gallagher, Krumm, Mislevy, & Hafter, 2014). Beginning in 2010, the Bill and Melinda Gates Foundation and Google made a significant

---

<sup>1</sup> <https://www.khanacademy.org/>

investment in KA to develop new content and to translate it into other languages (Murphy et al., 2014).

One of the features of the tool is “missions”, which are suggested sequences of videos, exercises and other materials. Learners can reach a level of “practiced” on an exercise by correctly answering 3–5 (depending on the exercise) questions correct in a row without using any hints. The level “mastered” is achieved by answering a mixed selection of questions a set time after the student has achieved the level “practiced”. Gaming features, such as “badges” and “energy points”, are designed to further incentivise completion of exercises and missions.

A KA user can also be a “coach” for other users, such as a class of students. A coach can see the time used by each learner, exercises practiced and mastered, and suggest other exercises, which then appear on the learners’ KA home page.

## **Related research**

There is a small but growing amount of research literature on use of videos for learning mathematics. These report that students see them as useful learning resources (Kay & Kletschin, 2012; Loch, Gill, & Croft, 2012; Loch, Jordan, Lowe, & Mestel, 2014; Wilson, 2013) and there is some indication that such videos can improve exam performance (Jordan, Loch, Lowe, Mestel, & Wilkins, 2012).

Wilson (2013) reports on the use of a flipped classroom approach with a university level statistics class, which resulted in increased student examination performance. KA was one of the resources used by Wilson to supply content to the students. A similar flipped classroom approach was employed by the second author in a physics course for pre-service science teachers (Lindstrøm, 2015). KA was found to have added value to the course based on the following: student compliance with using KA; positive student attitudes to KA; a learning gain measured using a pre-test–post-test design; and useful data in KA for the instructor to tailor teaching to the students’ needs.

In California, (Murphy et al., 2014) conducted an implementation study using KA in nine schools. Schools were of varying type (public, charter and independent) and level (elementary, middle and high schools), and were located in areas with a spread of social-economic profiles. The amount of class time spent on KA varied, and KA was not used outside of school hours. The teachers who used KA reported positive outcomes for student engagement, and an increased capacity to meet the mathematical needs of all students. There was a positive relationship between KA use and test scores as well as students’ attitudes towards mathematics.

In all of the studies mentioned above, the learning gains cannot be uniquely attributed to the online resources, because a control group was not used and there may have been other unreported factors that influenced the learning. This project is a first attempt at a controlled study of mathematics learning with KA.

## **Context**

The requirements to qualify as a primary teacher in Norway are a four-year Bachelor of Primary Education or a relevant bachelor degree and a one-year Diploma of Education. The majority of primary teachers take the Bachelor of Primary Education. In this programme, students must take

courses in mathematics education equivalent to half a year of full time study, and have the option of taking additional courses in mathematics education to become a mathematics specialist teacher.

The students in this study were in their second year of the Bachelor of Primary Education. By the end this year, the students had completed the compulsory mathematics education requirement, which was spread evenly over the first two years. Teaching comprised of 22 sessions of 2 hours and 45 minutes over the course of the academic year with occasional breaks for study trips, thematic weeks and two placement periods (of two and four weeks duration). There were also four 2 hour and 45 minute plenary lectures for the whole year group.

## Methodology

Four of the five parallel classes were included in the study, and two instructors each taught two classes. The first author held two of the four plenary lectures and taught the fifth class that was not included in the study, but was otherwise not involved with the instruction of the students. The other authors were not involved in the instruction of the students in any way.

One class from each of the two instructors was selected at random to be the KA group (the treatment group). There were 59 students in the KA group and 72 in the control group. In the third week of the first semester, the first author gave these two classes a short introduction to KA (10–15 minutes), which included showing how to set up an account, and an example of the videos and the exercises. The students were encouraged to get an account with the first author as coach. Only four students created an account in the first half of the semester, however, so the first author visited these classes a second time in the tenth week of the first semester to remind the students of how to set up an account. Throughout the first semester, the first author sent suggestions to the students for exercises related to the content in their mathematics education course both in KA and through the students' online learning management system, which was the main portal for communicating with the students. At the end of the semester there was still only four students with an account.

During the second semester, the students in the KA classes were given the option of completing their obligatory mathematics assignment in KA or as a written assignment. The KA assignment consisted of reaching the level “practiced” in the following KA exercises<sup>2</sup>: Recognizing fractions 2; Finding 1 on the number line; Equivalent fraction models; Naming the whole; Understanding multiplying fractions by fractions; Percentage word problems 1; Ordering fractions; Multiplying fractions by fractions word problems; and Converting multi-digit repeating decimals to fractions. The written assignment consisted of eight multi-part questions covering the same topics. For example two of the questions were:

Write a number story for the following calculations and illustrate the last two:

a)  $13 \times 0.8$       b)  $10,5 \div 0.3$       c)  $\frac{1}{2} + \frac{1}{3}$       d)  $\frac{1}{2} \times \frac{1}{3}$

Convert to a fraction or a mixed number. Show your working.

a) 0.375      b) 0.545454 ...      c) 1.88888 ...      d) 2.16666 ...      e)  $0.461538\overline{461538}$

---

<sup>2</sup> KA is under constant development. These were the names of the exercises in the spring semester of 2015.

The assignment included instructions on how to set up an account (identical to that given in the first semester), and included the names of the KA exercises. The first author also sent the exercises as suggestions (three per week for three weeks corresponding to when the topics were covered in class). For the final submission, 42 students chose the KA assignment and 17 the written assignment. The control classes submitted the written assignment.

Progress was measured in all classes by a pre-test–post-test design using a 24-item mathematics test developed by the authors. The items were on mathematical topics associated with the second year mathematics education course, and all were within the scope of the grade 10 Norwegian mathematics curriculum (KD, 2013). The test contained: 11 items on fractions, decimals and percentages; 3 items on multiplication and measurement; 4 items on functions; and 6 items on algebra. There was an emphasis on fractions, decimals and percentages because that was the focus of the assignment. The authors wrote eight of the items and used published sources for the other items (Brekke, 1995; Brekke, Grønmo, & Rosén, 2000; Gjone, 1997; McIntosh, 2007; Utdanningsdirektoratet, 2011). Here are two examples of the questions on fractions:

Which of these fractions is half of the value of  $\frac{3}{8}$ ? A:  $\frac{3}{4}$  B:  $\frac{6}{4}$  C:  $\frac{3}{16}$  D:  $\frac{6}{16}$

Place in ascending order:  $\frac{5}{8}$   $\frac{7}{6}$   $\frac{1}{2}$   $\frac{2}{3}$   $\frac{4}{9}$

The pre-test was administered during the first teaching session of the first semester for each class. The same test was used for the post-test and was administered in the second semester during a session for the whole year group approximately one month before the final exam and after the compulsory mathematics assignment was submitted. The students had 30 minutes to complete the test on both occasions. On the cover page of the post-test, there were four brief questions about the students' use of KA, including an estimate of how many hours the student had used KA during the academic year. This information served as a check on the data collected from KA, and to see if anyone in the control group had used KA. The students filled out this information before the 30-minute testing period began. The first author marked the pre-test and post-test according to a marking key written by all the authors. Every item was allotted 2 points, so there was a maximum possible score of 48.

Matched pre- and post-test data were available for 51 students in the KA group and 58 students in the control group. Of the 51 students in the KA group, six students did not register any activity in KA or report using KA on the post-test cover sheet and were thus omitted from the analysis. Of the 58 students in the control group, two students reported on the post-test cover sheet that they *had* used KA during the trial period, and were also omitted.

The student data from KA on time usage was inconsistent (e.g. some students had completed many exercises but had a time usage of 0 minutes) and was thus discounted. On the post-test cover-sheet, not all of the students gave an estimate of their KA usage. In the KA group, those who did, reported an average of 4.4 hours total usage ( $SD = 3.6$ ;  $N = 45$ ). Historical self-reporting of work time is very unreliable (see e.g. Chambers (1992), so this estimate is only a very rough indication.

## Results

The average score on the pre-test for the KA group was 24.1 ( $SD = 8.3$ ;  $N = 45$ ) and for the control group 25.9 ( $SD = 7.2$ ;  $N = 56$ ). This difference was not statistically significant ( $t(99) = 1.17$ ;  $p = 0.246$ ). The average score on the post-test for the KA group was 28.8 ( $SD = 8.1$ ;  $N = 45$ ) and for the

control group 31.4 ( $SD = 7.8$ ;  $N = 56$ ). Again, the difference was not statistically significant ( $t(99) = 1.63$ ;  $p = 0.107$ ). However, the gain for both groups *was* statistically significant: the gain for the KA group was 4.7 ( $t(44) = 5.86$ ;  $p = 0.000$ ) and for the control group was 5.5 ( $t(55) = 7.74$ ;  $p = 0.000$ ). Corresponding results were obtained when just the items on fractions, decimals and percentages were analyzed: there was a statistically significant improvement for both groups, but the difference between the groups was not statistically significant on either the pre-test or the post-test.

**Figure 1: Post-test vs. pre-test results for KA and control groups**

Analyzing the post-test versus pre-test scores, the linear regression lines for the two groups show similar trends (Figure 1). Again, corresponding results were obtained when performing the analysis using only the items on fractions, decimals and percentages.

“Improvement” refers to be the pointwise improvement on the mathematics test from pre to post. When compared with the pre-test results (Figure 2), there is no discernable difference between the two groups.

**Figure 2: Improvement vs. pre-test results for KA and control groups. The diagonal line shows the ceiling for the scores, i.e. the total number of available marks minus the pre-test score.**

Of the 59 students in the KA group, 49 set up a KA account with the first author as a coach by the end of the trial period, of which 44 registered activity by watching videos or doing exercises. Since the data on time usage was unreliable, “KA usage” refers to number of exercises in which the students achieved the level “practiced”. The average KA usage was 44 exercises ( $SD = 21$ ;  $N = 44$ ).

**Figure 3: Improvement in raw marks on the mathematics test vs. KA usage, as measured by number of exercises completed.**

Of the students who registered KA activity, there were 39 who submitted both the pre-test and the post-test. In Figure 3, KA usage is plotted against improvement for these students. The "vertical line" corresponding to 36 exercises represents completing the compulsory assignment. There were 21 students whose KA usage was greater than 36 exercises. It is clear from Figure 3 that there is no correlation between KA usage and improvement on the mathematics test. A similar analysis for the subset of items on fractions, decimals and percentages also showed no correlation.

## Discussion

There were no statistically significant differences between the groups on either the pre-test or the post-test. Both groups had statistically significant gains over the trial period and they showed similar patterns in the scatter plots in Figures 1 and 2. Thus, in this study, KA was *equally beneficial* to the students as the other learning resources available to them. This non-significant result is of interest because KA has practical advantages over other learning materials (e.g., it is free and easily accessible) and the marking time saved by the instructor can be invested in other learning activities. In addition, Lindstrøm (2015) found KA to be beneficial for the instructor as a tool for formative assessment. KA may have yet other advantages for the learners, which could be investigated using qualitative methods. We are aware that the similar gains of the two groups may be due to the testing instrument being too coarse. However, addressing this is outside the scope of this study, and would require a qualitative analysis of students' learning processes with KA to develop a new testing instrument.

In the first semester, despite encouragement from the first author and messages with links to relevant topics, only four students set up an account. In the second semester, without any additional interventions, 45 students set up an account when the compulsory mathematics assignment could be completed using KA. This is consistent with the findings of Lindstrøm (2015) and Murphy et al. (2014) that high KA use is associated with a well planned integration into the course, including using it as part of the compulsory assigned work with consequences for non-compliance.

There were 21 students whose KA usage was greater than 36 exercises (which corresponded to the compulsory assignment), and some of these made extensive use of the tool (Figure 3). It may be surprising that there is no correlation between KA usage and improvement, with no indications of additional gains for the students who completed additional exercises. This may indicate a failure of the test to detect the learning gains; however, it may also be that the students worked on topics not covered by the test. Further qualitative research may be conducted to investigate what motivated these students and what possible learning gains resulted from the additional exercises completed.

## Conclusions

A group of students who used KA showed similar learning gains to a control group that had no restriction on their learning resources but were not encouraged to use KA (and indeed did not, with two exceptions, use KA). As has been seen in earlier studies with KA, high use of KA was associated with a well-planned integration in the course. Some students made extensive use of KA, but there were no correlations between KA usage and measured learning gain. This raises the questions of what motivated the students to complete more exercises than required and whether there were other benefits not detected by our test.

## Acknowledgements

This research project was partially funded by a grant from the Centre of Excellence for Mathematics Education (MatRIC) at the University of Agder<sup>3</sup>. The authors would like to thank MatRIC for their support.

*Digital media warrant a reappraisal of established conceptual fields and a search for new ones densely providing access to powerful mathematical ideas. This study reports secondary students' meaning making around the notion of intrinsically defined curvature in space by means of a tool integrating programming, dynamic manipulation of variable values and a simulation of 3D space. The study involved 15 ninth grade school students' attempt to design the shortest path between two points on a cylindrical surface are presented in this paper. Camera perusal and zoom allow for a change of viewpoints of the constructed figure. The findings yield meanings around concepts notoriously difficult even in undergraduate mathematics, such as differential stereometry, limits and curvature as systematic trihedron state change.*

**Keywords:** Curvature, helix, stereometry, meaning-making, programmable media.

## Introduction

Although curves appear in abundance in primary and secondary curricula, they are given the status of an auxiliary mathematical object to diverse structures either from geometry, e.g. circles-arcs, stereometry, e.g. cylinders-conic sections, or from algebra where the focus is of course on functions. Curvature is hardly discussed as a central notion, particularly in 3D space. Yet, in real physical space curves are truly abundant, in navigation they are key. Representations and notations from the pre-digital era are certainly one of the obstacles for students to access conceptual fields with curvature at their centre (we are intentionally using Vergnaud's construct, 1988). Here we use a digital medium integrating programmability with dynamic manipulation in simulated 3D space to get a sense of the meanings high school students may generate around differential curvature in space.

Curvature can be uniquely defined (apart from its position in space) by three elements of its arc, length, curvature and torsion (Lipschutz, 1969). The notion of curvature, the study of the properties of a curve and of the ways it can be approached consist one of the most important issues in tertiary education, as, for example, in differential geometry. The pre-digital formalism as well as the complicated formulas required consist a significant obstacle so that these notions and differential geometry in general can become approachable to many a student even at the tertiary level (Henderson, 1995; Kowski, 2003).

The encoding of the knowledge about curves, has historically gone through different stages. Euclid defines the curve as 'length without width' or 'end of a surface', without giving its definition in a general form restricted by general findings. But with the emergence of analytic geometry by Descartes, curves were defined as a mathematical sequence of points uniquely identified by two values. Later, the prevalence of the concept of function as a central concept in the curricula of secondary education, established functions as an umbrella under which large parts of mathematics

can be interpreted. As a consequence the only curves introduced in secondary education are graphical representations, namely curves which are represented only as secondary data representations or equations. The appearance of Turtle Geometry (Papert, 1980) constituted a first but most significant suggestion to consider restructuring knowledge (Wilensky, 2010) about curvature.

Papert proposed an intrinsic approach to geometry as a way to use digital media to provide kids with access to powerful ideas in environments rich in opportunity for meaning making (Kynigos, 1993). The intrinsic definition of curve on the plane was thus by means of the 'turtle', the cybernetic programmable unit vector (heading, position, zero length), making alternative state changes with a value approaching zero. So, this geometry addresses the problem of the local description of a curve using the kinematic picture of the curve as the line resulting from position changes (Loethe, 1992). But what about curvature in space? The first digital tool to simulate programmable turtle geometry in space appeared relatively early by Reggini in 1985, so it may be surprising that there was no further epistemological or pedagogical analysis regarding curvature represented with this medium. In space, the intrinsic description of a curve can be achieved by using a mobile system of perpendicular vectors describing the tangent vector and the osculating plane of a curve. The turtle moves only in the direction of the nose and 'sits' on the osculating plane (Loethe, 1992, p.72). Rotation of the trihedron as it moves is given by the curvature and torsion. Precisely, as the rate of change of the tangent is characterized by the curvature, thus the rate of change of the osculating plane is characterized by the torsion of the curve (Aleksandrov et al., 1969, p.75). Our research group has been interested in identifying meanings generated by students around the field of intrinsically defined curvature on the plane, using a tool we developed (we called it 'Turtleworlds') to integrate programmable turtle geometry with dynamic manipulation of variable procedure values (Kynigos & Psycharis, 2003). In this paper we address meanings of intrinsic curvature in space with a new version of the tool which we now call 'MaLT-Turtlesphere' (Kynigos & Latsi, 2007) and start from giving students the problem of the shortest path between two points on a cylinder.

## The theoretical frame

Vergnaud (1988), introduced the notion of conceptual field as a set of situations the mastering of which requires mastery of several concepts of different nature. He claims that "a single concept does not refer to only one type of situation, and a single situation cannot be analyzed with only one concept" (p. 141), and he argues that teachers and researchers should study conceptual fields rather than isolated concepts. In our study we wanted to study meaning making on curvature by giving students the problem of finding the shortest path between two points on a cylinder. We thus perceived the problem as belonging to the conceptual field of 'curvature in space' as the notions, for example, of rate of change and arc length which are involved in the procedure of designing a curve based on the polygonal approximation, are directly related to the notions of curvature and torsion in space. With our basic aim being to examine the meanings the students develop (Noss and Hoyles, 1996) in relation with the notions of differential geometry we designed activities based on constructionism (Kafai and Resnick, 1996). Students would engage in meaning making through bricolage with digital artefacts. In recent years, we have developed a pedagogical design construct and method where we start students off by providing them with a 'half-baked microworld' (Kynigos, 2007). It is a specially designed digital artefact with one or more built in bugs resulting in some

faulty appearance and/or behavior when it is manipulated dynamically. It is designed to challenge students to decompose, change and debug the artefact and then construct something by using the correct version as a building block. Half-baked microworlds serve as starting points for the user to be acquainted with the ideas hidden behind the procedure of their construction.

## The computational environment

The computational environment we used in our present research is MaLT-Turtlesphere (<http://etl.uoa.gr/malt2>) integrating Logo-based turtle geometry with dynamic manipulation of variable values resulting in DGS-like continuous change of the turtle figures at hand. This version of turtlesphere also afforded the insertion of stereometrical objects one of which was a cylinder, dynamically manipulable with respect to some key properties. The turtle movements are determined by following commands: `fd(:n)` and `bk(:n)` which command the turtle to take steps forwards or backwards, `lt(:n)` and `rt(:n)` move the turtle *n* degrees to the left or the right in its plane (osculating plane), and borrowed from Reggini's definition, `dp(:n)` and `up(:n)` turn the turtle upwards or downwards and `rr(:n)`, `rl(:n)` move the turtle around its axis. The basic tools of MaLT-Turtlesphere are the uni-dimensional variation tool (1DVT) which enables the user to dynamically manipulate the values of variables in a represented object and the 2d variation tool which is a two dimensional orthonormal system and is used to determine the co-variation of the values of two variables. An additional characteristic is its 3d Camera Controller which gives students the ability to dynamically manipulate the camera by means of the active vector and observes the object in the simulated 3d space from any side and direction he/she wishes. We should also point out the ability the user has got to insert ready-made 3d objects, such as a sphere or a cylinder, in a 3d virtual space and dynamically manipulate them.

## The problem

The students were given the following problem: 'Calculate and design the shortest path between two points on a cylindrical surface'. Our students were informed that this program would enable them to work out the way they could design such a path and that, at the end, they themselves could use it in order to construct their own models. The students were told that they were allowed to use any method and materials they liked (for example, paper and scissors) and the following half-baked microworld under the name the 'shortest path':

```
to shortestpath :n :s :dx :c
```

```
repeat :n [rl(:s) lt(:c) fd(:dx)] end ('end' is on a separate line, placed here to save space).
```

This microworld comprises a program with four variables each of which express the following: *n* expresses a number of repetitions, *s* expresses the turning of the turtle around the directions of its path, *dx* defining the length of the turtle step and *c* defining the turning of the turtle in its plane. The execution of the above code produces a polygonal line (either in space or in plane) or a straight line. But in the case when *dx* is very small, three kinds of curves can result from the aforementioned microworld, with the characteristic of stability of proportions 'turning and twisting relative to traveled space'. If *s*=0, then we have a curve on a plane. For *s*=0 and *c*=0 line segments. For *s*=0 and *c* ≠ 0 circle arcs. Solving the problem requires finding the shortest path between two points on a cylindrical surface, which means that the target is achieved when *dx* tends to zero. This leads to

limit procedures:  $\lim_{dx \rightarrow 0} \frac{c}{dx} = k$ , which gives the curvature of the circle. If  $s$  is different from zero,

helical lines are generated in space and similar conclusions are drawn (in case  $c = 0$ , a straight line arises). So, this code for creating a helix around the surface of a specific cylinder is half-baked in that it does not contain the property of each of the two turns being a function of the value of displacement ( $fd$ ) and that the value of  $dx$  needs to tend to approach zero. If in the preceding code, we replace arguments with suitable functions and introduce a tail recursion, any line in space can occur. For example, if we replace the arguments of turning and twisting with trigonometric functions, a closed curve in space can occur.

## The method

We adopted a design research method (Cobb et al., 2003). In this paper we discuss part of a broader research, which was developed in three phases: the first phase involving two students 3<sup>rd</sup> grade secondary school, in the second phase with the participation 15 students (a class 3<sup>rd</sup> grade secondary school) and which lasted 24 hours, and finally, in the third phase involving five higher education's students. These particular students of the second phase had already been familiarized with constructions in the logo programming language in the Turtleworlds environment. A sound and picture software (HyperCam 2) was used to record data and enabled the researcher to record the students' actions and the conversations amongst the participants. In order to analyze the students' mathematical thinking we were interested in the ways the students interacted with the available components of the software and in the ways they constructed mathematical meanings. We centrally used the notions of meaning making and situated abstractions, which enabled us to describe how the students construct mathematical meanings based on the functions of the particular software they were using and on the conversations between them (Noss & Hoyles, 1996). We also found the construct of 'instrumentalization' taken from the theory of instrumental genesis (Guin and Trouche, 1999, Kynigos & Psycharis, 2013) helpful in showing us was how the students were trying to change the functionalities of the 'faulty' microworld they were given aiming to produce a different artefact which automatically gives a circle and a helix with the shortest length.

## Findings

### The circle approach through limiting curvature

Even if the majority of students at first turned to the software they had been given in their effort to give an answer, they soon realized something else should be done first to make sense of the problem. They decided to use tangible objects first, paper, pen and the scissors, they had also been given. By selecting two points on the cylindrical surface and then rolling a piece of paper to form a cylinder and un-rolling it, they came to the conclusion that the shortest path could be a circle, a helical or a straight line. Upon un-rolling the cylinder they noticed that the line which was formed would be a straight line on the plane (geodesic in plane) but when they re-rolled up the cylinder, a helix or a circle was formed. Nevertheless, this conclusion, although it seemed to be the solution, did not seem to satisfy the students at all. Here is a typical answer from two students:

Student 1: If we could suppose that the cylinder opens, then okay it is a straight line

Student 2: But if the cylinder could not open? (Meaning: then how could we design the helix?)

They then started exploring the half-baked code firstly by dragging the variable values. All students decided to focus first on getting the code to create a circle around a fixed cylinder. Some kept the value of the `rl` command to zero, some decided to chuck it out of the procedure, starting to work on the formalism. The students at hand took the latter option and tried out dragging to understand the behavior of the turtle path (Brunström & Fahlgren, 2015). For this circle, a common technique was the winding of the polygonal line at a constant circle or at the bottom of an inserted cylinder from the software library. The completion of the first winding lead students to put values  $dx = 1$ ,  $c = 29$ . But when the researcher asked the question about the kind of path that was formed, students concluded by zooming that it was a polygonal line, and a further reduction of  $dx$  was needed. Students, with the help of changes decreased the value of  $dx$  from  $dx = 1$  to  $dx = 0.1$ , and then did the same for  $dx = 0.01$ , while modifying the value of  $c$  as well, as the polygonal line continued to wind in a solid circle. Their attempts brought them to conclude that the turn value should be dependent on the displacement value if the turtle trace was to be a good fit to the base of the given cylinder. They then decided that the code should contain a proportional relation of the variables  $c$  and  $dx$ , and modified the half-baked microworld engaging in an instrumentalization activity. The result for these students and, as it turned out, for the majority of the participants, was a code like the following, with a differentiation in the arguments of the turtle turn:

```
to shortestpath :n :dx
```

```
repeat :n [lt(29*:dx) fd(:dx)] end
```

The dialogue continued yielding that the students considered the circle as a polygon with sides that are constantly decreasing in length:

Researcher: so, for which rates do you get the requested circle?

Student 1: for small  $dx$ , for example 0.1

Researcher: ie for  $dx = 0.1$  will we have a circle?

Student 2: we will have a polygon

Researcher: and which may be the required rates?

Student 2: we can't be exact because as we put smaller numbers, it will be approaching the solid circle (at the same time the student zoom and manipulate the slider of  $dx$  to continuously lower numbers to prove their claim)

The students' efforts show a change in the way they thought about curvature, starting from a static approach (with  $dx$  equaling a constant value of 1) to a dynamic (the more  $dx$  diminishes, the better approach to curvature). This was evident in their correction of the code initially achieved with  $dx$  to be small (usually teams chose for  $dx$  a tenth or hundredth approach). Thus, initially the circle formed by the mean curvature ( $c / dx = \text{constant}$ ) determined the forward movement of the turtle in relation to the  $dx$ . This instrumentalization action resulted in a modification of the shortest path code and provided us researchers with a lens to students' development of a situated abstraction on the concept of curvature. The problem that was given to find the shortest path, thus led them at first to think of curvature as a limit and the circle as resulting from a limiting process and not simply by  $dx$  small. Although a strictly symbolic form of a limit was unknown to the students, the role of the limit process seemed to be played by the slider of  $dx$ .

### **From a static to a dynamic aspect of the helix**

For the construction of the helix with Turtlesphere, students at first could not implement a technical approach as in the circle, since there was not a preplanned helix on the cylindrical surface. So they

resorted to properties discovered during the deformation process of the flat surface and the situated abstraction for the notion of helix which was delivered by them as follows: *'helix is a curve that is wrapped in a cylindrical surface and if it unfolds, a straight line emerges'*. The designing of such a curve though without the use of tangible materials, and the ability to generalize such a procedure demand the use of differential geometry notions which reflect the Frenet-Serret frame movement in space. The students appeared to realize the limitations of tangible materials, and the inability to generalize the procedure in situations when their use is impossible.

The students' speculation stimulated the researcher to turn their attention to the half-baked code they had already had at their disposal. The students chose again to insert a model cylinder with specific dimensions, and by dragging the variation tools they tried to achieve the construction of a helical line which twisted round the cylinder with its two ends being the ends of the generator of the cylinder with the above characteristics. Their initial suppositions referred to values which, although at first sight seemed to have achieved their goal (that is the helical line to twist round the cylinder), the use of the perusal camera proved wrong. Thus, from that time on each and every attempt of theirs initially comprised finding the values for  $n$ ,  $c$ ,  $s$  and  $dx$  with the simultaneous use of the camera and change of the values of the variables. A group of students, at their first correct attempt (with  $dx=1$ ), came to the following values:  $n=14$ ,  $c=25$ ,  $s=5$  and  $dx=1$ . Although they seemed to be satisfied with the result of their experimentations, they continued to experiment after the following questions on the researcher's part:

Researcher: Is this a helix? (They play with the camera, zooming in at the same time)

Student 1: They look like lots of straight lines (they are referring to the line segments which the helical line is composed of and with the execution of the half-baked microworld provides them with)

Researcher: What can you do so that you can turn it into a helix?

Student 1: Eliminate the angles

Researcher: How can you eliminate the angles?

Student 1: If we decrease  $dx$ , let's say to 0.1

Students' instrumentalization initially started by dragging the slider of  $dx$  and with the help of graphical feedback. Since dragging  $dx$  to  $dx = 1$  gave a polygonal line and not the curve as the paper-folding approach, the students started to drag the slider of  $s$ . Their attention now concerned the discovery of the relationship between the three variables ( $c$ ,  $dx$ ,  $s$ ) and the consequent changes to the half-baked code. The situated abstractions that this particular group of students seemed to have built arise from the need to prevent the distortion of the figure and satisfy the 'definition' that had created for the concept of helix based on the paper-folding approach. As  $dx$  took smaller and smaller values a line was given which looks like a helix with a length constantly decreasing and that the ratios  $c/dx$  and  $s/dx$  remain invariant and equal to 25 and 5 respectively. In fact, the rate of change of directions of the segments the turtle is moving on and its plane remain invariant. The replacement of the ratios they discovered in their initial code provided them with what they claimed was the 'correct' code and the solution in demand:

```
to shortestpath :n :dx
```

```
repeat :n [rl(5*:dx) lt(25*:dx) fd(:dx)] end
```

Researcher: Which values provide us with the helix we are looking for?

Student 1: The smaller  $dx$  is the better.

The students seemed to realize that the solution they were looking for did not only consist of the specific values of the variables but it should also combine a limited procedure for  $dx$ .

## Conclusions

The purpose of the present research was dual: Firstly, to study the degree to which this particular digital tool and microworld could form the basis for secondary level students to study notions in the conceptual field of curvature in space and secondly, to study the meanings developed by these particular students in their attempt to design the shortest path between two points on a cylindrical surface. The students expressed mathematical meanings for a number of notions of differential calculus (rate of change, limit) as well as of differential geometry (curvature, torsion and geodesic) which has been shown to be notions difficult to be approached by even math students. One of the major advantages of the method applied is the fact that, not only were students able to visualize the way a normal curve is constructed by the motion of a movable trihedron in space (the role of which was replaced by the 'turtle') but the students were also given the ability to study, explore and symbolically represent these movements via programming and dynamic manipulation. For example, the circle is constructed by the turtle avatar with the characteristic of working stability, and not just through the stability of the ratio  $c / dx$ , i.e. the curvature formula in Logo. The dynamic manipulation resulting in figural change helped the students focus on the limiting process of this ratio which reflects the notion of curvature. The students changed their conception of helix from a static approach to a dynamic aspect, i.e. as a line made from an avatar with the characteristic of stability in both its turning and rotating around the line of motion. Although the way they used to design the helix did not tally with the strict formalism of differential geometry, the answers and the meanings they generated are indicative of the fact that a restructuration of the notion of curve relying on concepts of curvature and torsion, and with the turtle replacing the role of the moving trihedron to create a curve in space, is feasible in secondary education.

*This paper reports on a current case study about the use of dynamic worksheets in a middle school in Austria. These worksheets were designed based on typical problems and misconceptions outlined in the literature concerning functional thinking, and they focus on the representational transfer between situational model and graphical representation. Grade 7 students were video recorded while working on these worksheets, pre- and post diagnostic tests and diagnostic interviews were conducted to examine their conceptions in relation to functions. This case study particularly pays attention to the intuitive conceptions of students, the influence of the dynamic worksheets on these conceptions, and whether or not dynamic worksheets are able to support students in developing appropriate mathematical conceptions. In this paper, some preliminary results are to be discussed.*

*Keywords: Functional thinking, technology, representational transfer, lower secondary school.*

## Introduction

Functional thinking is an important concept in mathematics education. For students, a variety of problems arise while working with functions and thus functional thinking has been widely investigated by numerous researchers. Considering the development of dynamic mathematics software, additional aspects of functional thinking appear. It needs to be examined whether or not dynamic mathematics tasks are able to support students in an early stage of learning functions in developing appropriate conceptions. Based on these issues, we developed dynamic worksheets visualizing the transfer between situational and graphical representations and integrated them into a qualitative case study to examine their influence on students' conceptions.

## Theoretical background

Working with functions is a usual activity in mathematics lessons in school. Vollrath (1989) describes functional thinking as a typical way of thinking when dealing with function and he mentions different aspects of functional thinking. Malle (2000) refers to it and specifies the following aspects in a slightly altered version, which is better suited than Vollrath's (1989) description for the purposes of this research project: Relational aspect (each argument  $x$  is associated with exactly one function value  $f(x)$ ) and co-variational aspect (if the argument  $x$  is changed, the function value  $f(x)$  will change in a specific way and vice versa). The relational aspect represents a static perspective of functional thinking whereas the co-variational aspect describes dynamic processes; particularly in this project, functional thinking comprises of both aspects.

In the context of functional thinking, various difficulties have been found and examined in the research literature. The graph-as-picture error occurs in various forms and means that students see function graphs as photographic images of a real situation (Clement, 1989; Schlöglhofer, 2000). Illusion of linearity means the preferable use of linear or direct proportional models for the description of relations, even if they are not appropriate (De Bock, Van Dooren, Janssens, & Verschaffel, 2002).

Difficulties arise also in the interpretation of slope and growth, for example, if the point of maximum growth is confused with the largest function value. This slope-height-confusion leads also to difficulties in the interpretation of path-time graphs (Clement, 1989). These problems can cause students' misinterpretations of functions and especially of graphs of functions. Vosniadou and Vamvakoussi (2006) suggest – to avoid that intuitive conceptions develop to misconceptions – considering the introduction of mathematical concepts at an earlier stage in mathematics education.

Vogel (2007) stresses that multiple representations of functions, such as graphs, situational representations, terms, and tables are able to represent aspects of functional thinking (relational as well as co-variational aspect) externally, and they have the potential to support students' ability to interpret functions. According to Duval (2006), only the flexible alternation between different representations allows a differentiated approach to mathematical content and forms the basis for sustainable acquisition of skills. But representations have to be considered critically as they influence ways of thinking, they may constrain students' thinking about the concepts involved and are interpreted by students according to their prior knowledge (Vosniadou & Vamvakoussi, 2006).

Dynamic mathematics software such as GeoGebra may support students' development of functional thinking, because it is suitable to emphasize different functional aspects through interactive representations (Barzel & Greefrath, 2015). Research findings in relation to the use of technology in teaching often only show small positive effects on students' learning achievements (Drijvers et al., 2016). Results concerning dynamic representations are more encouraging, because these representations can help students in understanding mathematical concepts (Hoyles, Noss, Vahey, & Roschelle, 2013). Thus, we need to examine in more detail the influence of technology on students' individual conceptions.

### **Conceptions in a dynamic mathematics environment**

Based on problems and examples concerning misconceptions mentioned in literature several dynamic GeoGebra worksheets were designed reflecting multimedia design criteria (Clark & Mayer, 2011). We chose GeoGebra for this study, because it is the most widely employed mathematics software in Austrian schools. Due to the prior knowledge of selected students (experiences mainly with path-time diagrams, direct and inverse proportionality including their graphical representations, but none with the explicit function concept), these worksheets primarily address the representational transfer between situational model and graphical representation. Figure 1 displays a typical worksheet based on a task of Schlöglhofer (2000) addressing a graph-as-picture error.

This GeoGebra worksheet consists of a situational model, in particular an iconic representation of the situation, as well as a Cartesian coordinate system displaying the corresponding graph. In the situational representation on the left side a triangle is displayed. The shaded area left of the dotted line inside the triangle is treated as a function of  $x$ , which is the horizontal distance between the vertex A and the dotted line. Students can move the line and change the size of the coloured area. Afterwards they should formulate a hypothesis about the shape of the graph. In the diagram the coloured area is a function of the distance  $x$ . After clicking the checkbox, the size of the area is displayed. At the end, students should display the graph in order to examine their assumptions about the shape of the graph. In this research project, accompanying tasks assist the students in working with the representational transfer, which is considered particularly difficult conceptually.

## Triangle

**Figure 1: “Triangle”, <http://ggbm.at/GYeY4ayO>**

As the situational model shows an iconic representation, the corresponding task is likely to trigger a graph-as-picture error (Schlöghofer, 2000). It is especially interesting if the dynamic worksheet has the potential to support students’ ability to comprehend the graph.

Such problems concerning functional thinking and theoretical considerations have led to the research questions below. The first two offer a basis for research question three, as we believe this third question contributes the most to the field of inquiry about technology use related to misconceptions. Due to space restriction this paper focuses only on the first and third research question. Future papers will offer further details on research question two as well as more in-depth analyses.

- 1: What conceptions, with particular attention to pre- or intuitive conceptions, emerge concerning functional thinking of students in an early phase of learning functions (grade 7/8)?
- 2: How should dynamic materials addressing to this topic be designed to support students in developing appropriate mathematical conceptions?
- 3: What kinds of influence of these dynamic materials exist on conceptions and internal representations of students of lower secondary school concerning functional thinking?

## Research design

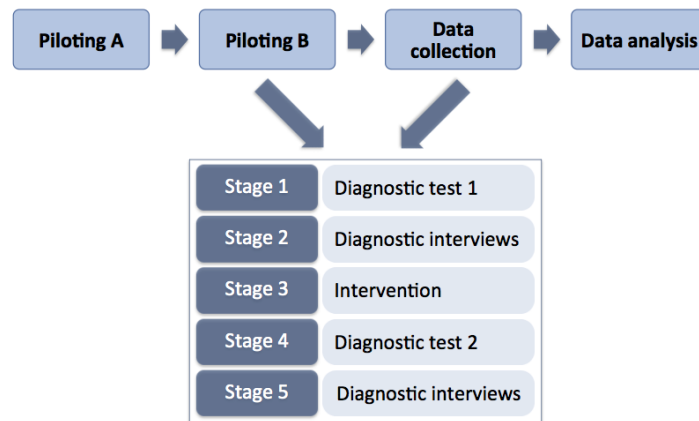

To offer answers to the research questions, we selected a qualitative research approach. The overarching methodology for this research project is an exploratory and collective case study research, but integrating elements of Grounded Theory (Eisenhardt, 1989). The study was conducted in a 7<sup>th</sup> grade classroom of a rural middle school<sup>1</sup> in Austria with 28 students aged 12 to 13, who had some experience in working with graphs (mainly distance-time-graphs) but none with the function concept itself.

Figure 2 shows an overview of the research design. Piloting A was the first phase of the study aimed to evaluate the technical details of the recording procedure, to choose the tasks for the diagnostic tests and the worksheets for the intervention. The second phase – piloting B – consisted of one complete

<sup>1</sup> Rural middle schools in Austria usually have the most diverse student population concerning achievement levels. This is especially true for the selected school in this study, thus this choice offers us the possibility to examine as many different students and their conceptions as possible.

data collection process. After the data collection, the data was transcribed and analysed with qualitative methods described later in detail.

The data collection included five stages. First, all students participated in a diagnostic test based on ten different tasks from literature concerning conceptions (Schlöghofer, 2000; De Bock et al., 2002) as well as a test instrument called CODI (Nitsch, 2015). Afterwards, eight students were chosen for diagnostic interviews (Hunting, 1997) depending on their test responses so that their – incorrect – results represent a wide range of different conceptions related to the various test tasks to obtain an in-depth view of their individual conceptions.

**Figure 2: Research design overview**

During the three-lesson-intervention, students worked in pairs with GeoGebra worksheets addressing different topics guided by accompanying tasks. While working, ten students were audio- and videotaped and the screens of their laptops were recorded. Also, students' paper worksheets were collected. After completing the intervention, another diagnostic test with slightly altered tasks was conducted. Based on the observational data and an analysis of the test results, eight students were selected for diagnostic interviews to investigate the influence of the worksheets on the students' conceptions.

### **Data analysis and preliminary results**

The collected data is divided by the data source to address different research questions (the first test results and the corresponding interview data to approach the first research question, the recordings from the intervention and students' paper worksheets, the second test results and the corresponding interview data to focus on the second and the third research question).

Based on the research methodology, we conducted, for each student or pair of students, a within-case analysis using initial (or open) coding, then compared cases and searched for cross-case patterns using focused coding (Eisenhardt, 1989; Saldaña, 2013).

Further qualitative analysis of the observational data and the interview recordings will give an insight into the conceptions of the students concerning functional thinking as well as the influence of dynamic worksheets on these conceptions. In this section, preliminary results concerning the task "Area" from both diagnostic tests are to be presented, because both task and results exemplify the process of the research.

## Diagnostic test 1

Figure 3 displays a task from the diagnostic test 1 that is similar to the GeoGebra worksheet in Figure 1 and was based on a standard test example concerning the graph-as-picture error from Nitsch (2015). The picture shows a trapezoid, and in the exercise students had to choose one diagram out of four that showed the grey marked area left of the dotted line as a function of the distance  $x$ , and to explain their decisions.

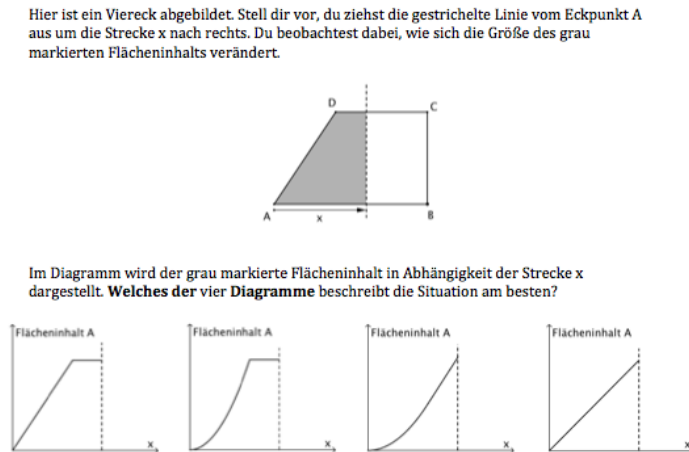

Figure 3: Screenshot task “Area” from diagnostic test 1

Students’ explanations reveal different levels of conceptual understanding. A categorization of students’ solutions and argumentations is visualized in Figure 4. The arrows represent the direction of the representational transfer from the situational model to the function graph, and the categories are arranged according to the correctness and elaborateness of students’ understanding.

The first two categories represent the choice of the first graph addressing the graph-as-picture error. Either the students marked the similarity between both representations, or they already recognized an increase of area but ‘remained’ at the shape of a trapezoid. These answers reveal reasoning from a situational perspective of students, who did not manage to transfer the situational model into a function graph.

Students with explanations of the next three categories achieved transfer to a graphical representation by recognizing an increasing function value, and these explanations were essentially correct. The third category of students, who selected the linear function, did not recognize the irregular change of the function value. Students who chose a correct graph form the last two categories. They either reasoned their choice with an increasing area or – the most elaborated explanation – with an irregular growth of area.

In the next section, we present three student answers to the corresponding task from the second diagnostic test. Students were chosen from the first category (Graph as Picture, Similarity) to

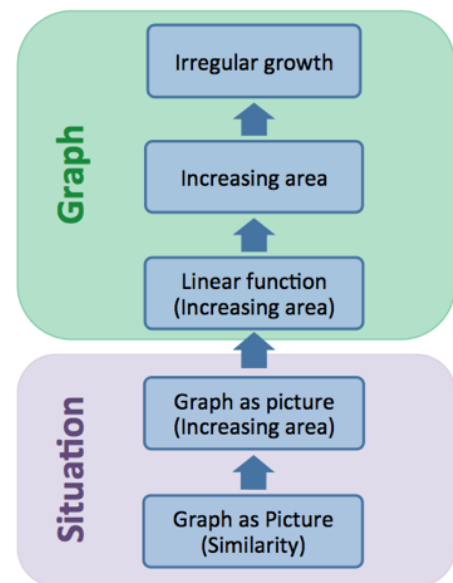

Figure 4: Categorized solutions task “Area”

demonstrate the range of possible developments of their conceptions. The answers represent different extent of influence, also based on the achievement level of these students.

### Diagnostic test 2

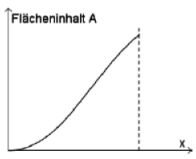

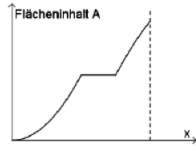

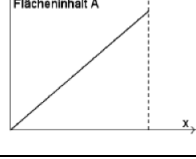

In the second diagnostic test after the intervention, the corresponding task was slightly altered – a trapezoid of another shape is displayed (see Figure 5).

**Figure 5: Trapezoid of task “Area” of diagnostic test 2**

Corresponding to the four function graphs in diagnostic test 1, there are four possible choices for the solution. These function graphs represent the graph-as-picture error, the correct solution, a combination of graph-as-picture and correct graph, and a linear function.

Table 1 presents three students’ solutions and explanations from the diagnostic test 1 category “Graph as Picture (Similarity)” exemplifying a possible diverse influence of the applets. These students were chosen because all three students changed their answers after working with the dynamic worksheets, and due to their different achievement levels they gave a wide range of changes in their results.

Achievement level	Solution	Explanation (translated from German)
High (student 1)		“In the beginning it [the area] increases strongly, then a bit more slowly, ...”
Average (student 2)		“The area is always increasing, except in ... the middle of the trapezoid, it [the area] remains the same.”
Low (student 3)		“You have to consider the x-axis, and because the x-axis is straight, the last ... ought to be correct.”

**Table 1: Students’ answers concerning task “Area” of diagnostic test 2**

Student 1 (high achiever) chose the correct solution, and the explanation reveals a correct understanding of irregular changes of the function value. Also student 2 (average achiever) described the change of area correctly, but he decided for the graph representing a combination of correct graph and graph-as-picture error.

Unlike in the diagnostic test, the GeoGebra worksheet displayed only a triangle and not a trapezoid. Student 2 managed to translate corresponding parts of the situation correctly to the graphical

representation, but was not able to transfer his knowledge to the part of the situational model where the dotted line is moved over the ‘horizontal line’ of the trapezoid.

The explanation of student 3 (low achiever) reveals a lack of understanding concerning the representational transfer and the meaning of Cartesian coordinates. It refers to the students’ look for visual similarities, a solution strategy sometimes used by students during the intervention when confronted with a problem. Further results about students’ test answers, their discussion during the work with the dynamic worksheet (Figure 1) as well as a detailed description of this worksheet and included instructions will be presented in upcoming research papers.

## Discussion

For each task in the diagnostic test, several intuitive and incorrect conceptions appeared. For example, different levels of students’ conceptual understanding have emerged during analysis of the diagnostic test answers. These levels are representing the translation process from situational to graphical representation. Concerning the graph-as-picture error, explanations also made visible that standardized multiple-choice test items were not always able to detect a corresponding incorrect conception. Other results reveal different tendencies of students to use relational or co-variational aspects of functions for explanations. Also the influence of everyday experience is visible in the data, and the influence of formal and informal language (e.g., when students interpret ‘highest speed’ as ‘leading’ or ‘winning’ in distance-time-diagrams) is especially interesting.

The dynamic worksheets have different purposes, for example, visualization, experimentation, and testing hypotheses. The visualization function is supporting students in translating the text into a situational model or into a correct identification of the interesting variable (e.g., the meaning of ‘area’ in the corresponding task in Figure 3). Also, the worksheets have an adaptational influence on students’ conception (e.g., from linear to non-linear increase of function value). In other words they did not alter the conceptions but changed them partly to the direction of a correct conception.

Preliminary results seem to reveal that the extent of influence of these worksheets on students’ conceptions depends on the intuitive conceptions of students and their achievement level. The interpretation as well as the perception of the GeoGebra worksheets is based on the prior knowledge of the students. The observational data repeatedly demonstrated that students tried to connect new content to their experience and knowledge. Considering that students worked without teacher instructions, for high achieving students the dynamic worksheets seem to be more appropriate, whereas lower achieving students would probably profit of teachers’ assistance to reflect their perceptions and interpretations or to draw the attention to the important features of the worksheets.

# Students' use of movement in the exploration of dynamic functions

Giulia Lisarelli

University of Florence, Department of Mathematics, Italy; [giulia.lisarelli@unifi.it](mailto:giulia.lisarelli@unifi.it)

*The concept of function has a central role both at school and in everyday situations. A dynamic algebra and geometry software program allows students to experience the dependence relation and to explore functions as covariation. In this paper we propose a description of different dragging modalities and the analysis of a protocol in which two students work together on a problem that involves coordinating two covarying quantities. The analysis has been carried out through this classification of dragging modalities, that can be efficiently used to observe, describe and analyze students' processes involved in the exploration and solution of dynamic activities.*

*Keywords: Function, variation, dynamic algebra and geometry software, dragging.*

## Introduction and conceptual framework

The concept of function is very important both in secondary school and university mathematics but it also has a central role in everyday situations. For a long time, this notion has been at the core of several studies in mathematics education, and a rich literature has revealed students' difficulties in understanding the concept in all its aspects (Vinner & Dreyfus, 1989; Tall, 1991; Dubinsky & Harel, 1992; Carlson & Oehrtman, 2005). Difficulties in interpreting the dependence relation as a dynamic relation between covarying quantities are widely reported (Goldenberg et al., 1992; Carlson et al., 2002). Falcade et al. (2007) suggest that the use of a dynamic algebra/geometry software, such as GeoGebra, allows students to experience functions as covariation, that is a crucial aspect of the idea of function (Confrey & Smith, 1995; Tall, 1996). According to these assumptions we are interested in studying students' cognitive processes involved in approaching functions represented in a specific dynamic environment.

Our study is an exploratory study aimed at analyzing students' use of movement in the exploration processes of the dynamic functions. We have adopted the idea of analyzing the movement because several studies have revealed that it can support a cognitive analysis of students' reasoning processes.

In order to analyze students' appropriation of movement Arzarello et al. (2002) identified different types of dragging which students use investigating a geometric problem, according to their different purposes. Antonini & Martignone (2009) proposed a similar classification in the case of physical artifacts. They introduced a classification of students' utilization schemes of pantographs, that are particular mathematical machines designed for geometrical transformations. Although the differences due to the different nature of the instruments these two studies concern, there are certain similarities. Especially the common purpose is to identify students' utilization schemes in order to analyze the cognitive processes involved in the investigation of geometric problems.

In this paper we shall present the first steps of our research: a classification of dragging modalities and the analysis of a protocol, that has been carried out through this classification. Some of our descriptions echo the classifications presented in the above-cited studies, but they have been completely transformed in order to suit the use of particular function representations in a specific dynamic environment. This is the original contribution of this paper. Indeed, while in literature we

can also find other studies on the use of dragging (Baccaglioni & Mariotti, 2010; Robutti, 2013) they concern in particular the dynamic geometry.

## Contextualization of the study

We analysed a sequence of classroom activities, 14 hours in total, implemented in an Italian high school for Math and Science, in which students explore the functional relationship in dynamic interactive files (in GeoGebra). The subjects of this investigation are 16 years old students who never met the concept of function before. The activities were led by the teacher and they have been video-recorded by three cameras present in the classroom simultaneously. The analysis is mainly based on the transcripts of the activities and it was led by paying a special attention to the use of dragging, the language employed and the gestures.

In this paper we present one of the activities carried out by two students. The activity selected concerns The Bottle Problem: an open problem about bottles filled with water (the task is reported in Figure 1), which involves coordinating the variations of two quantities. Students are asked to work in pairs so that they can form conjectures and explain their reasoning to each other. They have no time limits and are video-recorded through a camera behind them pointing at the computer screen. They are given the following task with an interactive dynamic file (in GeoGebra) for the explorations and some sheets of paper for the answer.

**Figure 1: The task of the Bottle Problem**

**Figure 2: The dynamic file**

Figure 2 shows a part of the GeoGebra file in which are presented the graphs of five functions representing the height with respect to the volume of water. They are not the “usual” graphs in the Cartesian plane: there is an unnamed horizontal line with a black point attached to it that represents the x-axis and five other horizontal lines, parallel to it and labelled “Bottle1, Bottle2, ...” with blue points moving on them. The motion of the blue points, bounded at the lines, is an indirect motion

because these points can not be dragged directly: they represent the dependent variables so their movement is determined by the dragging of the black point, that represents the independent variable. The height of each bottle is fixed equal to six, for this reason the blue points move in the interval  $[0, 6]$  and there are six notches on the lines which they move on. The black point can be dragged everywhere along the line without the magnetism, that is a property that GeoGebra allows to give to a point and makes it move on the real axis as if it has a magnet that attaches it to the whole numbers; and disabling this tool the dragging of the point is more uniform.

### Dragging modalities

In this section we introduce a classification of dragging observed during students' exploration of dynamic interactive files. It can be efficiently used to observe, describe and analyze students' cognitive processes, involved in the exploration and solution of problems about functions represented in a specific dynamic environment.

The identified dragging modalities are divided into two families: the first one describes the quality of the movement, this type of dragging could be also recognized by a computer that captures how the mouse moves on the screen (Table 1) and the second one describes the use of dragging with regard to an aim, that is associated through the study of the language employed, the sight and the gestures (Table 2).

One of the potentialities of this classification is the fact that the two families of dragging modalities can be combined and, for example, keeping an element from the first one and an element from the second one allows a complete description of a students' process in solving problems.

First of all we observe that in our cases it is always a *bound dragging*, that according to Arzarello et al. (2002) consists of moving a semi-dragable point (a point which it is already linked to an object). Because the only point that students can move is bound to the x-axis, all the other points move depending on it.

	Description
Continuous dragging	Continuous movement
Discrete dragging	Movement with jumps, associated with counting
Impossible dragging	Trying to move a dependent <sup>1</sup> point that can not be dragged

**Table 1: Types of dragging**

	Description
Wandering dragging	Random movement, exploring the construction
Dragging test	Movement aimed at testing a possibly implicit conjecture

<sup>1</sup> We use this term to identify the point but we do not know if the students are aware of this dependence relation.

Handle dragging	Movement of the object as if it was a handle, in order to observe other objects' movements
Guided dragging	Movement aimed at reaching a particular configuration

**Table 2: Dragging with an aim****A protocol**

In this section we present an activity in which two students, Luca and Mara, work together at the bottle problem and we can identify some of the dragging modalities described before.

Their first approach to the problem involves dragging the black point, representing the volume of water filling the bottle, with a continuous movement (*continuous dragging*) and without apparently paying attention to the dragging of such point: it is used as a sort of handle that allows them to see the movement of the blue point, representing the height of the water in the bottle (*handle dragging*). Indeed, as we can see in Figure 3, during the dragging the arrow representing the mouse does not overlap the black point in every moment, suggesting a weak haptic control because the students' attention seems not on the dragged point.

**Figure 3: An example of handle dragging**

The students do not express, through their words and gestures, awareness that as one variable changes, the other variable changes; they seem more concentrated on the differences between the movements of the blue points than on the relation that links the movement of a blue point to the movement of the black point. For example, they look for which one is the fastest in order to associate it to the tightest bottle, because the speed of blue points represents the speed at which the height increases if the water is poured in at a constant volume per time, and the tighter the bottle is, the faster the height increases; in the same way the slowest blue point will be associated to the widest bottle.

For example, the following dialogue takes place while students explore the file, dragging the black point very slowly and trying to keep a constant speed (*continuous dragging*):

- Luca: The bottle three is the steepest in the lower part.
- Mara: The bottle one goes very slow, also the bottle two.
- Luca: Also the fifth, the bottle two is the slowest respect all the others.
- Mara: No the five, the five does not move!
- Luca: Yes and then it is steeper at the end.

What we can infer from this excerpt is that the students' attention is on the blue points and the independent black point is used as a handle (*handle dragging*), they compare the speed of these points, observing for example that the second is the slowest, or probably the fifth. Luca, in the last sentence, says "is steeper" instead of "goes faster" and this suggests that he mixes up the trend of the height of water in the bottle with the shape of the bottle.

Their initial approach changes: when they have to decide which one of the blue points represents the bottle B, shown in Figure 1 (that in the lower part has a cylindrical shape). They search for a point that has a constant speed and, in doing this, they compare the movements of the black and the blue points. So, first of all, they look at the picture of the bottle on the sheet of paper and imagine how the height of the water in the bottle should evolve, then they drag the point representing the volume of water in order to see whether there is a point, representing the height, with the needed properties (*guided dragging*).

In particular, they count how many notches of volume are necessary to let the blue point reach the first notch of height and then to let it reach the second and finally the third and finally they compare these numbers: if they are equal to each other they conclude that the bottle has a cylindrical shape. It is an example in which the two quantities that are varying are coordinated in order to establish the average speed of the blue point. This seems an attempt to make a continuous situation discrete and it is also suggested from their use of dragging: they drag the black point with jumps, while counting the notches (*discrete dragging*).

The following excerpt shows this combination of *discrete* and *guided dragging*. Luca summarizes their idea about how the blue point representing the bottle B should behave and searches for it:

Luca:            So we have to find a point that is constant till the third notch and then it goes faster.  
                     I would see the bottle one, look: first, second, third more or less goes in the same way.

He drags the black point counting 1,2,3 and stops, 1,2,3 and stops, finally 1,2,3 and stops and during this process the mouse makes some jumps (*discrete dragging*).

Luca:            We could say that it is constant till the third notch and then...

He drags the black point again, this time with a continuous movement and an almost constant speed (*continuous dragging*).

Luca:            Then it goes faster!

The last part of the analysis reports students' explorations and conjectures when they have to draw the bottle looking at the movements of the points: the black point seems no longer to be only a handle for them. Indeed, as the next excerpts show, the students relate the changing values of height and volume in order to find whether the speed of the blue point is constant; their question is: how many notches of volume are necessary to have one notch of height? They fix the amount of change of the height (uniform increments) and find out the relative rate of change of the volume. In doing this, they consider the average rate of change locally, for a specific interval of the domain of the function.

It is not so clear how they conclude that "it is constant till the first notch" and this could be considered as an advanced statement because it requires an awareness that the instantaneous rate of change results

from smaller and smaller refinements of the average rate of change. From what they say it seems that at the beginning they observe a constant speed from the zero to the second notch:

Luca: Slowly at the beginning, it is wide, then it seems a constant velocity, then it is tighter and then wider again: this is a clepsydra. But a clepsydra that in the upper part is wider than in the tighter part. Wait, go back for a moment (she goes back with the black point onto the zero again: *dragging test*). How many notches of volume do you have to do, to have one notch of height?

Mara drags the black point very slowly and they count how many notches it crosses till the blue point reaches the first notch.

Luca: Five and a half, say five. Are these (notches) five again to reach the second notch?

The black point is dragged slowly again and they count how many notches it crosses till the blue point reaches the second notch. They count five notches, more or less. Therefore they conclude:

Luca: Yes, at the beginning it has a constant velocity.

Then by a similar process (*discrete dragging*) they observe that from the first to the second notch the average speed of the blue point is greater than from the zero to the first notch; so they decide that the bottle has to shrink at the first notch of height and before that point it has a cylindrical shape.

Luca: Now, count how many notches of volume: one, two, three, four, five let's round off (for a moment he stops dragging the black point, the blue point is on the first notch). Then from the first notch: one, two, three, four so it is tighter (for a moment he stops dragging the black point, the blue point is on the second notch), I mean the lower part is bigger than...

Finally, they check what they found out and they start drawing the bottle on the sheet of paper:

Luca: Therefore, constant till the first notch, then it is tighter and the third notch is the point in which it is the tightest. So: the first notch constant like this (he draws a vertical segment) then it starts to be tighter (he draws an oblique segment) up here. This is the tightest point (indicating the third notch on the sheet of paper).

Mara drags the black point (*continuous dragging*) without apparently paying attention to its movement, indeed the arrow representing the mouse is far from the point (*handle dragging*). She probably wants to find out where the blue point moves faster, because she puts the point on the second notch and explores a neighborhood of the third notch, that is the point suggested by Luca (*dragging test*).

Mara: It is in this passage that it is steeper (she stops dragging and indicates with the arrow of the mouse an interval between the third and the fourth notch).

Therefore they agree that the bottle has a choke point at half height. They conclude that in the upper part the bottle widens and it is wider than in the lower part because the height increases ever slower.

**Figure 4: Luca's drawing of the bottle**

## Discussion

The studies on the interaction between a subject and a software have to take into account a variety of aspects because several components are involved. In this paper we have presented a study to better understand the explorations of functional dependence in a dynamic algebra and geometry environment: in particular, we have identified different dragging modalities and we have shown an analysis carried out through this classification. The analysis highlights how the proposed description of dragging modalities allows an insight into students' problem solving processes.

We noticed that the *handle dragging* is often recognizable through the observation of the mouse's position: if the attention is placed on an object that is not draggable, it is possible that the arrow representing the mouse does not overlap the dragged point in every moment, suggesting a weak haptic control of the solver. But this is not a generalization, because there could be some cases of *handle dragging*, recognizable for example from student's words, in which the student seems to reveal a good haptic control. We observe that there are two types of *continuous dragging*, in some cases it reveals a movement of the object trying to keep a constant velocity, in other cases the object is dragged with a continuous movement, without jumps, but with a variable velocity, for example a point that is dragged back and forth on a line. In the selected protocol there are no examples of *impossible dragging*, probably because the task says explicitly that the only draggable point is the black one; but we identified various examples of this type of dragging in other activities that we analyzed.

One of the potentialities of this classification is that, in order to better describe students' problem solving processes, it is possible to combine two dragging modalities, one indicating the quality of the movement and the other associated with an aim. It could be interesting to develop this study to investigate how a description of students' use of movement in a dynamic algebra and geometry environment is intertwined with the processes involved in conceptualization of functions, that could give an insight into covariation in the concept of function.

*This paper examines the potential of using screen casting with an iPad to enhance learning in mathematics. Data are presented from two seven-year-old students as they use the Explain Everything app to solve a division with remainder problem (DWR). A social semiotic perspective was used to interpret students' use of multiple modes as they represented the mathematical ideas within the context of the problem. We consider how a social semiotic perspective has the potential to draw attention to the students' interests and emerging expressions in representing mathematical relationships. We further consider how the use of representations in the app might relate to student learning.*

*Keywords: Mobile technologies, multimodality, primary mathematics, representations, social semiotics.*

## Introduction

Several decades ago, Kaput (1987) predicted that the opportunities afforded by new digital technologies would mean “students of the near future ... will be choosing how to represent given relationships” (p.21), and that students' choice in building and interpreting their own representations would be seen as important as the calculations themselves. With the recent introduction of mobile devices into mathematics classrooms, student choice in creating, selecting, and using representations has continued to widen and such new media has been seen to have the potential to “augment and enhance” student learning (Clark & Luckin, 2013, p. 2). In this paper we present data from part of a larger project that examined teacher and student use of iPad apps in primary mathematics classrooms in New Zealand. In particular, we focus on *Explain Everything*, a screen-casting app, with two students (aged seven years old) as they represented their solutions to a problem involving division with remainder (DWR).

Screen casting involves the use of a digital white board screen, which the user can write or draw on. The user can also add images and text. The digital board can then be recorded to capture the images, static or dynamic, along with a vocalisation of the user's thoughts. As such, in mathematics, students can create and present their solutions in real time and in a multi-modal format using text and images along with voice recording. Such apps are generally used as a tool for students to show their explanations in solving problems (Soto, 2015) as they have the appeal of exposing the students' thinking.

Screen casting enables multiple modes of communication, and can provide teachers with further insight into students' thinking and identification of misconceptions (Soto & Ambrose, 2015). Hence, their use as a tool for formative assessment. But might the creation of a screen cast go further than providing insight into thinking? Students can select from a range of modes, including writing, drawings, downloaded images, mathematical symbols, spoken and written language, so there is the

potential for choosing, creating and interpreting different representations for a given relationship (as predicted by Kaput). Furthermore, the use of the screen interface on iPads means that the students can manipulate representations by touch and hand actions (Sinclair & de Freitas, 2014). If the students are choosing to build and create their own representations along with hand actions, can such use go beyond the reporting of solution strategies? We also query whether screen casting, as an example of new media, has the potential to augment and enhance learning.

### **Theoretical framework: Social semiotics and multimodality**

In order to understand the potential for learning with this new media we require a way of understanding how representations are selected and used by students in creating their screen casts. Whilst previous representational theories in mathematics education have been based on an epistemological view of learning as a constructive activity (e.g. Janvier, 1987), further theorising on representations in mathematics has focused on semiotics as intrinsic to mathematical thinking (Duval, 2008; Ernest, 2006). Ernest proposed that a study of mathematics teaching and learning from a semiotic perspective follows sociocultural Vygotskian theories in studying the appropriation of cultural signs and the underlying meaning structures that embody the relationships between signs.

In mathematics, signs are related to mathematical relationships and can only be understood as part of a complex system; there is a “pull towards abstraction” (Ernest, 2006, p.71). If mathematical signs become isolated as purely structural systems they lose meaning. A fundamental view of semiotics refers to representations, as sign production in a broader sense, standing for something else in order to make meaning. Ernest referred to such sign production as “primarily an agentic act” that “often has a creative aspect” (p.69). The students’ use of representations in a screen cast may indicate this agentic, creative act, where the sign relates to a form that “strongly suggests the meaning [we] want to communicate.” (Kress, 2010, p. 64). Rather than using a sign that pulls to abstraction, the student may choose a representation that indicates what he or she sees as critical in regard to their ‘bit of the world’ and the mathematical relationship in the context of a problem. As such, we can determine the interest and agency of the sign-maker, and what they attended to, in order to make meaning.

Drawing on both Ernests’ theorisation in relation to semiotics in the teaching and learning of mathematics, and to broader theorists, such as Kress and social semiotics, students’ choices of representations (text, image, verbal explanations, and hand actions) could be interpreted as sign-making with the potential to make meanings of mathematical relationships within their view of their world. These new meanings may then have the potential to change their understanding of mathematical relationships within a given problem. If we see learning from a social semiotic perspective as generating meaning through sign making (Kress, 2010) then screen casting may have the potential for students’ representations to have a role as social and material resources “in and through which meaning is made and by which learning therefore takes place” (Kress, 2010, p.178).

Furthermore, direct interaction with the screen of an iPad allows students not just to choose representations, but to manipulate them through hand actions. The screen cast app also enables students to record verbal explanations. As such, the use of the app allows for students to be agentic in creating signs across a multiplicity of modes. In this paper we consider how a multimodal social semiotic theoretical perspective (Jewitt, 2013) can inform the interpretation of students’ choices and dynamic use of symbols, and images along with their use of language. Social semiotics has been used

as a theoretical tool to explain phenomena by revealing things, which might not be evident otherwise (Jewitt & Oyama, 2001). In this paper, the intention is to examine the students' choices of representations, how they manipulate them, and to consider what they see as critical between their world and the mathematical relationship in the context of the problem.

In following a social semiotic theoretical perspective, the intention was to interpret the students' syntactic positioning of images as a source for representational meaning as well as temporal components (Jewitt & Omay, 2001). That is, how the students placed images on the screen. For example, how the centrality of their placements and connections of objects showed some elements as held together, in contrast to more marginal or disconnected elements. In addition, the intention was to interpret the students' narrative and hand actions as syntactical temporal components. For example how the students' verbal explanations related to how they moved images or drew on the screen.

## The study

Two seven-year-old students' use of the *Explain Everything* app are presented in this paper. These data come from a larger research project investigating how iPads apps were used in primary mathematics classrooms. The project involved researcher observation and the collection of video data over one year with three teachers experienced in using iPads in their mathematics classrooms. Further data was collected through student and teacher interview to investigate their views of using the apps. The research team met with the three teachers throughout the year for collaborative analysis and critical reflection of classroom practice and student learning. The use of screen-casting apps such as *Explain Everything* featured several times in the teachers' classrooms and in comments made by students and teachers as they were seen as beneficial for reporting solution strategies.

The data presented here come from one class of seven-year-old children. The problem was set by the class teacher and regarded sixteen dog biscuits shared equally among three dog bowls. The students were given five options, as shown in Figure 1. They were asked to determine which option gave the correct solution, and to explain their reasons using the *Explain Everything* app. The teacher projected the problem onto the screen in the classroom. The students took a photo of the problem to insert into a screen on their iPad, so that they could refer back to the five options.

**Figure 1: The division with remainder problem**

Students worked individually on the problem with the intention to create a screen cast of their solution process for the teacher for her assessment. As they worked in the classroom, six students were selected at random by the researchers to explain more fully their solution strategies in relation to the representations on the screen cast they were developing. As Soto and Ambrose (2016) suggested, the completed screen casts of students may not “capture all the intricacies of students’ explanations”

(p.282). As the research team was interested in gaining as much insight as possible, the researchers asked the students to elaborate on their thinking in representing their solutions in the screen cast. These elaborated explanations were videoed to show the iPad screen and students' hand actions, and to capture the students' explanations and responses to the researchers' questions. In this short paper, data from two of the students are presented. These two students are presented here because they showed contrasting approaches in relation to their mathematical solution using partitive and quotitive models. In the partitive or sharing model, the divisor indicates the number of groups and the quotient indicates the number of objects in each group. In the quotitive or grouping model, the divisor indicates the number of objects in each group and the quotient indicates the number of groups (Roche & Clarke, 2009).

### Student 1: Fred

Fred downloaded images of dog bowls and biscuits from the internet and positioned five dog biscuits onto each bowl, see Figure 2.

**Figure 2: Fred's screen with his solution (a sketch is also provided as the iPad screen is not clear)**

Fred: This shows that the answer is (d) because five and five and five is fifteen with one more it's sixteen. So this is the one up here left over. (Fred circled the biscuit in the top right hand of the screen.) So they each get five. (Fred circled the five written above each dog bowl). So that makes it fair and there's one left over for nobody, so nobody has that because they're all full.

Researcher: Did you try any other questions using the bowls? Did you try (a) with the bowls?

Fred: No, I basically knew it was (d) from the start because there were three bowls and you have sixteen biscuits and you have to have one left over.

Fred chose to use realistic images. The dog biscuits were piled onto the dog bowls in a realistic fashion. Fred had also given different names to the dogs. Fred wrote the numeral five above each dog bowl as if in a 'bubble,' and placed the left over biscuit in the top right hand corner of the screen. As Fred said, the dog bowls were "full and fair" and the remaining biscuit was for "nobody." When talking to the researcher Fred used dynamic recordings and hand actions in circling the five numerals and the one biscuit left over in the top right hand corner.

### Student 2: Jan

Jan had drawn three circles at the top of the screen. She downloaded images of dog biscuits from the internet and grouped them at the bottom of the screen. Then Jan moved each biscuit one by one to line up underneath each circle (see Figure 3).

Jan: I'm doing five and then I've got one left over. (Jan moved the left over biscuit around the screen with her finger.)

Researcher: Why do you think that is?

Jan: Ummm, I don't know. (Jan scanned back to the screen with the original problem and the options). Because (a) and (b) are not going to be right, but I haven't tried six (referred to the last option). So if I put six...

**Figure 3: Jan's screen with her solution**

Jan placed six biscuits under two bowls but then moved one biscuit from the middle line to the line of four to make five in two of the lines. She then counted the third line as six and moved the sixth biscuit away. Jan then moved the left over biscuit around the screen (Figure 3).

Researcher: What could you do with the spare one? What would you do if they were your dogs?

Jan: Ummm... I'd probably cut it in half so they'd have equal numbers.

Researcher: If you cut it in half how many pieces would you have?

Jan: (Jan used her finger to draw two lines on the left over biscuit) I'd have three halves. One for that one, one for that one, and one for that one (Jan indicated with her finger to the three lines of biscuits).

Jan used realistic images of the dog biscuits but drew circles for the bowls, and placed the dog biscuits in a vertical line underneath each bowl. Jan did not use any numerals, but she referred to the numbers in her oral explanation. Jan seemed in a quandary about the one left over, to the extent that she tried six biscuits, only to find she needed to redistribute them. Jan also moved the left over biscuit around the screen. She then marked the biscuit into three "halves" in order to share the remainder, pointing to each line as she did so. Whilst she used the term 'halves' incorrectly she was attempting to further divide the left over biscuit between the three dogs.

## Discussion

In relation to the students' use of models of division, Fred used repeated addition to explain his solution; "five and five and five is fifteen with one more it's sixteen." Fred's solution demonstrated a quotitive model, in that he focused on the quotient as the size of the subset from one of the solutions in the options (i.e. five in each bowl). Jan, on the other hand, used a partitive strategy to share out the dog biscuits. Jan focused on the divisor as the number of subsets, that is the three dog bowls, and so she shared out each of the dog biscuits by counting. Jan then moved to the use of rational numbers by including fractions in further dividing the left over biscuit, although maybe she was influenced by

the reviewers' question. It is noted that neither of the students wrote their solution using mathematical symbols formally, such as  $16 \div 3 = 5$  remainder 1, and this may have been due to the way the problem was set where the options were stated verbally.

In relation to the use of representations, Fred used realistic images and features, along with the mathematical symbols. Fred's 'bubbles' over the dog bowls with the number five suggested a close connection between the number symbol and the quantity of dog biscuits in each bowl. Furthermore, he centralized the dog bowls, piled the dog biscuits onto the bowls and then positioned the left over dog biscuit in the corner of the screen, stating it was for nobody. Interpreting the positioning of the representations from a spatial syntax perspective, it could be said that Fred marginalized the left over dog biscuit both in positioning it on the screen and in verbally stating it was for no one and so indicating his own perspective of the remainder in the context of this problem. Interpreting the temporal syntax, Fred's hand actions in circling each of the five numerals and the left over biscuit, along with his explanation, suggested an emphasis on key features, and mirrored a formal recording of the solution.

Jan also used realistic images for the dog biscuits, but used drawn circles for the dog bowls. These circles represented a container in a more general sense, focusing on the shape but not the features. Jan did not include any number symbols, although she referred to the numbers in explaining her solution. Jan also centralized the circles and dog biscuit images as key features of the problem but she placed the circles at the top of the screen and aligned the biscuits under each bowl. This positioning was not as realistic as Fred's as he piled the biscuits onto the bowls. Interpreting the temporal syntax, Jan's movement of the biscuit around the screen suggested a dynamic visual 'doodle' as she thought about the remainder. Her uncertainty in where to position the dog biscuit was reflected in her comment "Ummm I don't know." Unlike Fred she did not seem satisfied that the left over biscuit should be for no one. In the end, Jan solved this problem in a realistic context that made sense to her, and used hand actions in drawing lines to show how the biscuit could be cut into three pieces.

In interpreting the students' use of representations in creating the screen cast, the intention was to see further into the students' placing of different semiotic modes (symbols, images and drawings) alongside temporal narrative and dynamic movements. As the students chose to use mathematical symbols and 'made up' the signs, they were being critical in relating the mathematics with their 'bit of the world', in order to make meaning. Fred already knew the solution and selected realistic representations to show this solution, tying the key mathematical signs, the chosen images and the quotient closely together. The remainder was redundant and hence placed marginally representing his understanding of the relationships in regard to his bit of the world. Jan chose a less real life representation of the problem but appeared to explore the solution with these representations. Her exploration then led her to the use of fractions in relation to sharing as her bit of the world.

## Concluding remarks

The interpretation of the students' use of representations in relation to spatial and temporal syntax may provide further insight into what students attended to in order to make meaning of the mathematical relationships. In this regard, this paper has, arguably, presented an illustration of Kaput's prediction that students will choose to build and interpret their own representations, and that

their choice of representations will be seen as important as the calculation. However, how these choices relate to or augment learning is less clear.

It has been possible to consider how Jan was ‘settling’ an understanding of the mathematical ideas in solving a problem, maybe by virtual ‘doodling’ with the remainder. Her use of the representations was agentic and indicative of how she related to the problem, but they also appeared to change her understanding of the mathematical relationships in the problem. For Fred the representations were used to explain thinking that was already formed. He knew the solution. It is not clear that the use of these representations, whilst agentic and indicative of his bit of the world within the context of the problem, changed his understanding of the mathematical relationships. Although, they may have helped him explain or report his thinking.

In these examples it would seem that for Fred, as an example of a student who appeared to understand the mathematical relationships within the problem, the meaning making of the representations in the screen casting referred to an explanation or reporting of a solution strategy, and that this would relate to studies by Soto (2015) and Soto and Ambrose (2016). However for Jan, as an example of a student less certain of the mathematical relationships within the problem, the meaning making of the representations in the screen casting may also have changed her understanding and hence may have augmented her learning about the mathematical relationships in the given problem.

The intention of this paper was to consider whether screen casting, as a way of agentic sign making across multiple modes, has the potential for students’ representations to make meaning and hence augment learning. Only two examples are presented here, and whilst a social semiotic approach may shed light on what the students attended to, the use of the screen casting app as new media to augment learning needs further investigation.

# Interactive Virtual Math: A tool to support self-construction graphs by dynamic events

Sonia Palha<sup>1</sup> and Stephan Koopman<sup>1</sup>

<sup>1</sup>University of Applied Sciences of Amsterdam, The Netherlands; [s.abrantes.garcez.palha@hva.nl](mailto:s.abrantes.garcez.palha@hva.nl); [s.a.h.koopman@hva.nl](mailto:s.a.h.koopman@hva.nl)

*An essential condition to use mathematics to solve problems is the ability to recognize, imagine and represent relations between quantities. In particular, covariational reasoning has been shown to be very challenging for students at all levels. The aim of the project Interactive Virtual Math (IVM) is to develop a visualization tool that supports students' learning of covariation graphs. In this paper we present the initial development of the tool and we discuss its main features based on the results of one preliminary study and one exploratory study. The results suggest that the tool has potential to help students to engage in covariational reasoning by affording construction and explanation of different representations and comparison, relation and generalization of these ones. The results also point to the importance of developing tools that elicit and build upon students' self-productions.*

*Keywords: Visualization, virtual reality, interactive tool, mathematical modeling, reasoning.*

## Introduction

Students' difficulties with constructing graphs that model dynamic events are well documented in literature (e.g. Thompson, 2011; Carlson, Jacobs, Coe, Larsen, & Hsu, 2002; Carlson, Oehrtman, & Engelke, 2010). When modeling a dynamic situation into a graph (e.g. the speed varying with time or the height of water in a bottle varying with volume), it has to be conceptualized as a covariation relation, that is a relationship between two variables that vary simultaneously (Thompson, 2011; Carlson et al., 2002). However, students have a tendency to view functions in terms of symbolic manipulations and procedures rather than as relationships of dependency between two variables. These students might encounter difficulties imagining how the output values of a function are changing while imagining changes in function input values. And therefore they might fail in successfully construct a graph of a function modeling a dynamic situation.

Research has revealed that traditional approaches have not been successful in overcoming the above described difficulties. Technological tools can however afford alternative approaches to the subject. Also, most of the research that provides insight in students difficulties with understanding graphical situations is done in clinical environments. We need to develop a better understanding of students learning in classroom settings.

In our research we developed a tool that intends to provide an alternative way to approach the learning of graphs by dynamic events and an opportunity for examining its learning in the classroom. The tool Interactive Virtual Math (IVM), which can be found at <https://virtualmath.hva.nl>, is designed to support 14-17 years old students at secondary school to understand the graphical representation of relations between variables in dynamic situations. IVM supports this process by addressing the visualization of these relationships. The aims of this paper are to introduce a prototype of the tool, its

main features and design and, to discuss its added value for students' learning based on the results of one preliminary study and one exploratory study.

## Theoretical framework

### Covariational reasoning

An example of a mathematical task that requires understanding of covariational reasoning is Task A from Figure 1. The task is about a dynamic situation involving the height of water in a bowl and the volume and, it was taken from Carlson et al. (2010), who used it to diagnose students' understanding of graphs of this type of events.

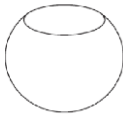

**Figure 1: tasks used in preliminary study**

**Task A**

Imagine this bowl is steadily being filled with water.

Sketch a graph of the water height in the bowl as a function of the amount of water in the bowl.

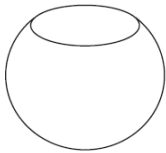

Explain the thinking you used to construct your graph.

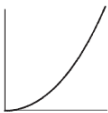

**Task B**

Assume that water is poured into a spherical bowl at a constant rate.

- Which of the following graphs best represents the height of water in the bowl as a function of the amount of water in the bowl?
- Explain the thinking you used to make your choice.

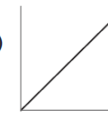

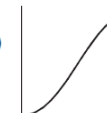

← Spherical Bottle

a) 

b) 

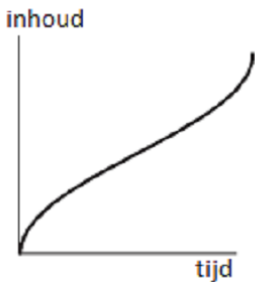

c) 

d) 

e) 

**Task C**

Assume that water is poured into a bowl at a constant rate. The graph in the figure represents the height of water in the bowl as a function of the amount of water in the bowl. Describe the filling in of the bowl in words,

- Explain the thinking you used to make the description.
- Draw a possible bowl

To solve task A, students will need to consider how the dependent variable (height) changes while imagining changes in the independent variable (volume). The coordination of such changes requires the ability to represent and interpret relevant features in the shape of the graph (Carlson et al., 2010).

Carlson et al., (2002, 2010), developed a framework that allows to investigate students' covariational reasoning abilities when responding to dynamic function tasks. The framework describes covariational reasoning as entailing five mental actions, which are successively more complex: (M1) coordinating the value of one quantity with changes in the other; (M2) coordinating the direction of the change; (M3) coordinating the amount of change of one quantity while imagining successive changes in the other quantity; (M4) coordinating the average rate of change of the function with uniform increments of change in the input variable; (M5) coordinating the instantaneous rate of change of the function with continuous changes in the independent variable for the entire domain of the function. We used this framework to evaluate the quality of students' graphs and explanations in our study.

### **Guiding principles and main features of the tool**

There are many technological tools available for learning graphs from dynamic events, but very few request students' own productions. They are often simulation-tools, which involve whole figures or part of figures that have to be moved, changed or dragged. When students are asked to construct a graph with these kind of tools, construction actually means using representations that are already given or can be synthesized by putting parts together. In this case there is not a true visualization of students' concept image (Vinner, 1983), since part of the representation is already given. A distinguishing feature of the IVM is that it builds solely on students' graphical productions.

The tool Interactive Virtual Math allows students to draw, analyze and compare graphs for themselves and improve the graphs if they conclude this improvement is needed. At CERME 10 we presented a second prototype version of the tool in which the students work on an assignment involving a single graphic situation: the dynamic event described in task A (Figure 1). In later versions we expect it to be possible to use more contexts and varied assignments so that all students can practice at their own level. In Table 1 we present a short description of the main features of the tool: *Self-construction*, *Contrast*, *Help 1 and Help 2*, *Reward* and *flow*. These features are based on general learning principles that include building on students' previous knowledge, interaction and feedback. We expect that the use of the tool will challenge students to create their own graphs and explanations, to make assumptions, conjectures and to reflect upon these (feature *Flow*).

The tool was also built according to topic specific learning principles. Thompson (2011) states that it is critical for students to first engage in mental activity to visualize a situation and construct relevant quantitative relationships prior to determining formulas or graphs. Therefore, the graphs in the tool must be drawn by the student themselves and the tool elicit students to imagine relationships from scratch, without presenting any (partial) graphical representation that has not been drawn by the student themselves (feature *Self-construction*).

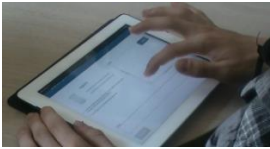

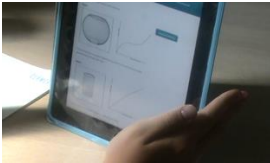

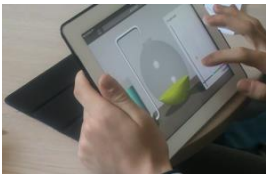

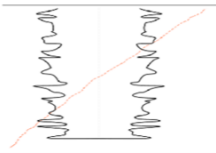

A second guiding idea behind the tool-design is the focus on visualizing quantities. Results from Ellis (2007) indicate that instruction encouraging a focus on quantities can support generalizations about relationships, connections between situations, and dynamic phenomena. To help students to focus on the relation between the height of the water and the volume we provide two kinds of help with the tool: the features *Help* and *Help 2*. In *Help 1* the student visualizes the increasing height of the water in the bowl and he can start and stop the water falling in bowl. In *Help 2* students must assume the height of the water in the bowl and represent it in the graph with dots. We expect that the students,

while guessing where to put the dot for the height, will notice that the difference in height between consecutive dots (values of the height) decreases in certain situations and increases in others.

Another guiding principle was to provide constructive feedback to the students' final graph and to give them a way to evaluate their production. The students get to see, after submitting their graph, the corresponding bowl-figure to the graph they draw (feature *Reward*).

Finally, the tool also includes the use of Virtual Reality (VR), which is still limited to Help 1. Here the use of VR (sound, movement, interaction) is expected to improve the experience of the graphic situation.

**Table 1: main features of Interactive Virtual Math**

Feature	Description
	<p><b>Self-construction</b></p> <p>The student is given two assignments. The first assignment is task A from Fig.1 and the second assignment is a variation of the same task with a cylinder instead of a bowl. In both assignments they are requested to draw a graph that describes the relationship between two variables in the corresponding dynamic situation. The student constructs the graph with a finger, a digital pen or a mouse.</p>
	<p><b>Contrast</b></p> <p>The student compares her/his own graph and explanation of the two situations, referred to as <i>a</i> and <i>b</i>. The student can then submit the graphs or improve them.</p>
	<p><b>Help 1</b></p> <p>The student visualizes the increasing height of the water in the bowl. He listens to the water he moves the platform with the ball and he can start and stop the water falling. Using a mobile device and a cardboard, Help 1 can be experienced as Virtual Reality</p>
	<p><b>Help 2</b></p> <p>The student connects the graphical representation to the context representation. A Cartesian coordinate system in the plane and the bowl appear next to each other. The student must construct a dot graph that represents the height of the water in the Cartesian graph. He does this by dragging and dropping dots into the graph.</p>
	<p><b>Reward</b></p> <p>The student gets the corresponding form of the bowl.</p>

## Methodology

### Preliminary study

Previous to the development of the first version of the IVM tool, we conducted a preliminary study to explore students' knowledge, skills and difficulties with constructing covariation graphs. The study (February-March 2016) involved  $N=98$  students from 4 classes age 15-17 years old and we used three versions of the same task with different questioning (Figure 1). The students in each of the four classes were divided into three groups and each group was presented with one of the three versions.

Analyses of students' written answers showed that the majority of the students (64%) failed to successfully solve task A (see also Table 2). Nineteen of them presented an increasing but incorrect graph, suggesting that they understand that the water increases or that the height increases with the amount of water but they don't have a consistent concept image of this process. Most of these students (13 out 19) produced one straight line (9 students) or a combination of two/three straight lines (4 students). These findings point that the majority of students that solved the self-construction tasks (tasks A and C) could not construct for themselves an acceptable representation. These results motivated the importance of engaging students in self-construction assignments and the development of the IVM-tool.

**Table 2: results of preliminary study**

	Task A (self-construction graph)	Task B (multiple choice )	Task C (self-construction bowl)
Acceptable	12 (36%)	<b>25 (66%)</b>	3 (11%)
Incorrect	<b>19 (58%)</b>	11 (29%)	<b>22 (79%)</b>
No answer	2 (6%)	2 (5%)	1 (4%)

### Exploratory study about the first version of the tool

The first version of the tool was developed in February –April 2016 by a team composed by one researcher-math educator (first author), a high school teacher (second author) and ICT -designers. We decided to use task A (Fig.1) that we considered suitable to explore students' understanding of covariation and within a broad age group. To explore its learning potential and usability we investigated through a small qualitative study the learning of four students age 14-15 years old (two boys and two girls) with different school performance for mathematics. Kevin<sup>1</sup> has high grades for mathematics, Lisa and Anton have average grades and Wilma has low grades. We observed and interviewed the students while working with the tool. The aims of the exploratory study were: (i) to understand how the students construct a graphical representation with IVM; (ii) to identify features of the tool that support or constrain students' successful construction; (iii) to get a better understanding about how the guiding principles work and can be used to develop later versions of the tool. The collected data consisted of video records and students' written work and it was collected at two different moments in April 2016. In both situations the students were asked to go first through the whole application on their own. Lisa was the first student to be interviewed; she used the application on a computer. The other three students Kevin, Wilma and Anton were interviewed together at their

<sup>1</sup> The real names of the students were modified

school. Wilma and Anton use a tablet and Kevin a mobile device. The data was first organized chronologically with relation to each student's attempt to construct the graph and use of the tool. Secondly, a global description of how each student attempted to construct and transform the graph was made and how they used the main features of the tool. We used the covariational framework (Carlson et al., 2002) to get insight in students' covariational reasoning abilities. A summary of the results are presented in Table 3. These results and the data were shared and discussed with the ICT-team and used to evaluate the tool and to make decisions for the development of a next version.

## Results and discussion

As we can see in Table 3, all four students improved their graphs on basis of the tool. Kevin produced in the first trial an incorrect graph with three straight lines and he improved it in second trial after comparing the form of the bowl he got in the *Reward* with the bowl in the bowl-assignment. Wilma produced in the bowl-assignment, in the first trial two incorrect graphs: a straight line and afterwards a raising curve. She 'improved' the graph after seeing the cylinder- assignment (*Contrast*). Through consulting *Help 1* and *Help 2* she constructed in a second trial a final acceptable graph. Anton produced in the bowl-assignment several incorrect graphs. His final graph in the first trial is a curve raising slowly. He consulted *Help 1* several times and, based on that, he produced a graph with three straight lines and adapted the length of the line segments. Anton's improvement did not lead to a final acceptable solution and the student remained in doubt whether the pieces of the graph should be curved or not.

**Table 3: students' use of the features of the tool during the exploratory study**

Features	Kevin	Wilma	Anton	Lisa
<b>Construction</b> (round bowl)	Acceptable final graph after two trials	Acceptable final graph after two trials	Incorrect final graph after two trials	Acceptable final graph after two trials
<b>Construction</b> (cylinder bowl)	All students have produced an acceptable graph at first trial (straight line)			
<b>Contrast</b>	First, all students draw a straight line at assignment one but improve their drawing after constructing the graph of assignment two.			
<b>Help 1:</b> Bowl is being filled up	Doesn't consult help 1 in first trial	changes a straight line into a rising curve	changes the middle line of the graph,	Consults but doesn't improve the graph
<b>Help 2:</b> relation figure - graph	Doesn't consult Help 2 in first trial	changes a rising curve in an acceptable curve	Consults Help 2	Does not understand how it works
<b>Reward</b>	Improves straight line to a curve.	Not observed	Not observed	Does not understand the reward
<b>Flow</b>	Constructs graphs without consulting Help 1 and 2.	Consults Help 1 and Help 2	Consults Help 1 and Help 2 several times	Consults Help 1 and Help 2
<b>VR (Help 1 with cardboard)</b>	Not used	Not used	Not used	rich experience

Based on the analyses of students reasoning while constructing and explaining their graphs, we identified a number of aspects through which students could be brought to a better understanding of

graphical situations, while working with the tool. One aspect is students engagement in covariational reasoning and their progression through the mental actions (Carlson et al., 2002). For instance, Wilma identifies and represents the two quantities changing together (M1). She draws initially a straight line which suggests that she attends only to the direction in which the height changed while imagining increases in the amount of water (M2). *After consulting help 1* she changes her straight line into a rising curve and then into a curve-down followed by a curve- up graph and she is able to explain how changes in the amount of water were related to changes in the height of the water at various locations in the bottle (M3).

Another aspect is students' involvement in actions that underpin mathematical reasoning such as the construction and explanation of different representations and, comparing, relating and generalizing these ones. Examples that we observed include students *comparing* their own graph and bowl filling up with water, which was the case of Wilma when she used Help 1 or Anton switching from Help 1 to his own graph several times; students *evaluating the relation* between the reward and initial graph. Visualizing the bowl of the reward made Kevin to think about the relation between the form of the bowl and the form of the graph. He used the reward to improve the smoothness of the graph curve; students *contrast* the relation between graphical situations of assignment one and two. For instance, Anton switches between one and two and adapt the graph one after seeing assignment two.

As Table 3 shows, different students used different features to improve their graph, which suggests that tool with possibilities to choose to view additional help or not and to be able to switch between the graphical situations, allows for diversity. Furthermore, all students had difficulty with constructing a graph, even with the tool support. This result suggests that self-construction tasks are needed to reveal these difficulties, which can remain unnoticed when using simulation-tools or tools in which the representations are already given.

A final aspect concerns the usability of the tool. Students valued the opportunity of choice and the interactivity of Help 2 (one can drag and decide where to put the point). And, one student (Lisa) who view Help 1 in VR with the cardboard valued this experience as a more enriching one.

There are also some critical issues with regard to the methodology of the study and the tool design. The small amount of students involved in the use of the IVM tool allowed for a fairly detailed study of their interaction with the tool. But, we should carefully interpret our findings since they regard only 4 students. We need to experiment more with the tool in classrooms, in combination with other tasks and forms of interaction and teacher support to better understand its potential and to what extend these findings can be generalized. With regard to the tool design, a number of aspects should be improved in follow up versions. One challenge concerns the self construction- and reward-features. It is left to the tool to decide what is an acceptable representation and how accurate it can be. We programmed the tool to accept any sketch of concave up followed by a concave down graphs starting at the origin. And, for the graph to be considered accurate, the line must be smoothly drawn. Sometimes the tool rejects answers that are accepted by the researchers and teachers. Another concern is the amount of variables involved in the assignments (height, accumulated volume, time, volume per unit of time, shape of the bottle). It is reasonable that the students should focus on one or two variables but not so many that are changing simultaneously. At the CERME conference we also received useful suggestions to improve the tool. For instance the time-counter in Help 1 can be replaced by a volume-counter and, students could fill the bowl by adding themselves cups of water.

This could help students to focus on the relation between height and volume rather than height and time. Another suggestion was allowing students to change the shape of the bottle as this might afford students' awareness of the phenomenon.

Concluding, this paper reports on the experiences of students learning graphical representations by dynamic events with the aid of a new learning technology (IVM); a topic which many students struggle to understand. We have learned that the prototype-tool has potential to engage students in covariational reasoning and we identified a number of aspects that could bring the students, while working with the tool, to a better understanding of graphical situations. Namely, the tool affords construction and explanation of different representations and, comparison, relation and generalization of these ones. The results also point to the importance of elicit and build upon students self-productions.

*Starting from Silver's (1997) approach for the importance of the interplay between problem solving and posing in the agenda of creativity, a new kind of e-book, aiming to promote creative mathematical thinking to students, in which its designers enriched the posing element with a constructionist approach, is used and examined in a real classroom. The paper follows a pair of Grade-8 students while they are working on this book. The contribution of this new interplay in the meaning-generation process around the concept of covariation is examined and the change in the creativity landscape by the analogy between problem posing and constructionism is discussed.*

**Keywords:** C-book technology, meaning making process, constructionism.

## Introduction

According to Silver (1997) deep flexible knowledge is closely related to creativity and emerges during the interplay between problem solving and problem posing. On the other hand, new exploratory and expressive digital media provide users with access to and potential for engagement with creative mathematical thinking and meaning-generation activities (Hoyles & Noss, 2003). However, education systems fail to rise this challenge due to restrictions stemming from the emphasis given on conformity and standardization in testing (Chevallard, 2012). So, new designs are needed to support students' engagement with dynamic digital media that aim to foster creative mathematical thinking. In this spirit, a pair of students are working collaboratively to solve a problem using a new digital medium, we call 'c-book', ('c' for creativity), a new genre of authorable e-book, extending e-book technologies to include diverse dynamic widgets, interoperability and collective design. In this paper we draw on end-users' interactions examining their interplay between problem solving and constructionism as enabler of meaning-making and try to analyze the effect of this affordance of the medium to the meaning making process of the pair as well as to comment on this new role of Constructionism as facilitator/substitute of problem posing.

## Theoretical framework

The close connection of mathematical knowledge with the interplay between problem solving and problem posing flows from the fact that most of the mathematicians do their research, mainly by formulating their own questions and problems and then trying to solve them, rather than solving problems posed for them by others (Borwein, Liljedahl, & Zhai, 2014). In this sense, the generation of new mathematical meanings for students, as an action, may be related with this kind of interplay. Cai and Cifarelli (2005) further refined this link between problem solving and problem posing, considering the posing and solving process to be mathematical exploration structured by this

recursive process. In the context of technology Abramovich and Cho (2015) found that a technological environment facilitates problem posing and turns it into discovery experience. And it is possible for meaning-generation processes to take place during such experience. Obviously, the affordances of the digital environment determine so much the kind of interplay that takes place as well as the meaning-generation process. Papadopoulos, Diamantidis and Kynigos (2016) describe how specific affordances of an expressive digital medium (c-book) led students to meaning-generation process around the concept of angle. However, in their study a possible relation between constructionism and posing is hardly examined. Constructionism is a theory that examines design and learning processes focusing on the ways in which these are part of individual or collective construction of digital artefacts. It illuminates how the representations, the affordances, the rules behind the behaviour of digital objects and the fields in which they reside and the ways in which these representations can be manipulated can all constitute representational registers around which meanings are generated, shared and developed (Kynigos & Psycharis, 2003). It thus provides an analytical lens to study the design and construction process in close interaction with the changes made to the artefact in question and the meanings those changes carry (Papert & Harel, 1991). In the case of a jointly constructed artifact by a group of students, the changes made to the artefact constitute externalization of the group's knowledge. Microworlds are such environments, allowing at the same time personal construction of objects and new meaning. C-books exploit half-baked microworlds which are incomplete by design, challenging students to fix them fostering thus learning through tinkering (Healy & Kynigos, 2010). Students have to solve problems that they encounter, in between and may come up, as a result of students' efforts to make new constructions, in order to fix the initial bug of the microworld. So, the question now is: How the affordance of the c-book technology to support the interplay between problem solving and problem posing/'Constructionism' might contribute to a process of meaning-generation?

### **The digital medium and the Don Quixote c-book unit**

C-book is a new expressive medium that affords the design of modules named c-book units. Each c-book-unit is based on a storyline, and includes diverse 'widgets' between the lines of the narrative. The term 'widgets' is used for objects, such as hyperlinks, videos and mostly instances, or activities, from a range of educational digital tools such as Geogebra and MaLT2, a web-based Turtle Geometry environment that affords Logo-mathematics symbolic notation and dynamic manipulation of 3D geometrical objects, using sliders as variation tools. Most of the widgets refer to mathematical inquiries, constructions and problems. Students can navigate through the pages of the c-book unit and be involved in the included tasks through experimentation, reconstruction and problem solving.

The c-book unit used in this study presents a different twist of Don Quixote's story. It begins with Don-Quixote confronting 30-40 windmills he mistakenly considers giant enemies (first pages of the c-book unit). But, after being close to them he realizes that they are damaged windmills and he wants to repair them. Half-baked logo codes in MaLT2 represent the windmills' fans and sails in various geometrical figures and Don Quixote has to modify the codes so as to repair and reconstruct the fans and the sails.

## The study

This study presents an educational intervention designed and implemented in a classroom. Adopting the methodology of “design experiments” (Collins et al., 2004) the focus was on seeking relationships between the learning process and the use of digital media used by the students during the implementation phase. Twenty-four students (18 from Grade-8 and 6 from Grade-9) from a public Experimental School in Athens participated in the study which took place in the pc-lab of the school during after-class mathematics courses for totally eight teaching hours within four weeks. The students were divided into pairs. Most of them were familiar with the usage of 2D E-slate Turtleworlds. Two teachers served as facilitators for technical issues, when necessary, whereas two researchers undertook the role of observers recording instances of the students’ interactions with the digital medium. Voice recorders and a screen-capture software (HyperCam2) were used to record students’ interactions with the c-book unit tools and their discussions, since both of them constituted our data. The students’ interactions were transcribed and the protocols were parsed into episodes with emphasis on the transitions between episodes since these were the points at which the change from solving problems to creating new ones used to happen (Schoenfeld, 1985).

**Figure 1: The ‘buggy windmill’s fan’ task in the c-book unit environment**

In this study, we follow two students as they are coping with a task asking them to fix a broken windmill. A Logo program was already developed producing a buggy and half-complete fan of windmill (Figure 1, left). It was needed to make changes in the Logo program, to fix the bug and shape up the fan.

## Results

The students initially had to fix the bug on the windmill (Figure 1, left). The fan was ill-constructed since its wings had not been joined in a proper way. So, they started using the variation tool to observe changes and identify the role/function of each slider/variable. The initial Logo-code construction contained three variables  $a$ ,  $b$  and  $k$ , for the ray of the fan, the angle between two consecutive wings of the fan, and the total number of wings, respectively (Figure 1, right).

There are two procedures in this code. The “wing” which uses variable “ $a$ ” to make an equilateral triangle with side length “ $a$ ”, and the “sail” (main procedure) which constructs the whole fan using “wing” as sub-procedure. Fixing the bug, is an open-ended problem with a variety of solutions (for example, for a polygon-shaped fan a feasible solution would be to replace  $b$  with  $360/k$ ).

After some back-and-forth of changing dynamically the values of all variables in the code, and examining the results of their actions on the screen the students found a pair of values that made the figure to look like a windmill's fan:

- S1-23: We managed to make it well shaped, but only for a certain pair of values; 12 for k and 30 for b. We must put certain values instead of variables.
- S2-24: It is not a fair solution; we should find a way to keep the fan well shaped, for any set of values. Is there a possibility that a, b and k vary analogous to each other?
- S1-25: What do you mean by “analogous”?
- S2-26: I mean that the change of only one value through the variation tool, results to changes for all of them, without our intervention.
- S1-27: Let's see [*she changes dynamically the value of a*]. It is not worth dealing with a. It only changes the length. We should find a relation between k and b.

In the extract above, it seems that according to Student-2 the specific pair of the variable values cannot be considered as a proper solution. The references to “analogous” and “without our intervention” are indicative of the student's confidence that a more generic solution such as a relation between the variables, is needed. Therefore, they started actually talking about covariation.

**Figure 2: Three pairs of values that make the shape look like a fan.**

Thus, in order to find the relation between “b” and “k”, students went on with their investigation through dynamic manipulation, identifying pairs of values for b and k that made their construction to look like a proper fan (Figure 2). Their investigation resulted to the conclusion that “b” and “k” might be inversely proportional. Although they reached a conclusion about the kind of relation between “b” and “k”, they did not take the next step to express this finding as a formula, so as to use it for fixing the bug, reducing thus the number of the necessary variables. On the contrary, they decided to go on with their investigation, adding a new variable in the sub-procedure “wing”:

- S1-33: We found the solution. But I think that we must go further. You see, in the program “wing”, there is a right turn by 120 degrees, which means that our solution works only for this amount of turning.
- S2-34: Yes, we should put a variable instead of 120, let's use the letter “k” again, in order to find out what is going on, and solve the problem for every case of turning right.

**Figure 3: The role of right turn by  $120^\circ$  (left) and by  $k^\circ$  (right)**

Variable “k” now refers to the right turn for each new wing (instead for the total number of wings). Students made their own construction, by adding a variable in the ‘wing’ sub-procedure, which actually made the problem more complicated. The choice of a constant right turn by  $120^\circ$  is crucial for having the wings evenly delivered across the fan, since right turn by 120 degrees means that the sails will be equilateral triangles. Substituting the constant right turn by the new variable “k”, has an impact on the angles of the triangular wing (Figure 3). Technically, this choice results to a fan even buggier than the original one. However, students did not see it as an obstacle. On the contrary, they accepted the challenge to solve a new problem that seemed to be more challenging to them:

- S1-46: Let’s use the same variable k, for both, the number of wings in ‘sail’ and the amount of right turn in ‘wing’. [They ran the program and moved hastily the slider that stands for k. This action changed not only the number of wings, but the shape of each wing of the fan as well.] What a strange shape!
- S2-47: Are b and k still inversely-proportional or proportional amounts? [They moved the sliders, in order to find pairs of values, as they had done before (Figure 4).]
- S1-48: Variables b and k do not seem to be proportional.
- S2-49: Nor inversely proportional. This is not fair!
- S1-50: Is it possible that there is no connection, no relation between b and k?
- S2-51: What other kind of relation other than proportional and inversely proportional may exist between them?

This question became the starting point for the students to be engaged in a new inquiry, about a new meaning that seemed to emerge. They started speaking about the notion of covariation in a more abstract sense than before (S1-25, S2-26). The spirit of this negotiation is mirrored in the final remark they made in order to solve the problem: “We think that there must be a relationship between b and the new k. We found that for  $b=30$ , if k equals to 120 or 240 or 480 or 960 the sail stays well-shaped, so there is a relation like  $k=120 \cdot 2^x$ . We also discovered a pattern for the values of b that is much more complicated.” They refer to their observation that if for example  $b=45$  then the most ‘acceptable’ shapes are the ones with k multiple of 5 (Figure 4).

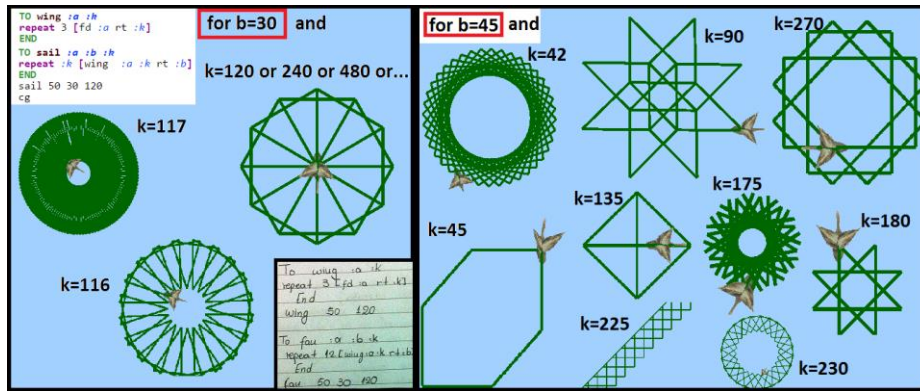

Figure 4: Snapshots for pairs of values of  $b$  and  $k$

## Discussion

The Don Quixote c-book unit is designed in alignment with the view that creativity lies in the interplay between problem-solving and problem-posing, an idea which is very much in accordance with Silver's approach (1997), arguing that it is in the interplay of formulating, attempting to solve, reformulating, and eventually solving a problem where creative activity may lie in. Indeed, as Papadopoulos et al. (2016) describe, students who used this c-book were able to show creative mathematical thinking that did not emerge instantly but was the result of the above mentioned continuous interplay combined with the provided affordances. In this paper we focus on the meaning-generation processes that took place before the creative moment, relating them with the entrance of constructionism in the agenda of creativity. The members of the designing team of the c-book unit showed an inclination to connect creativity with constructionist activities due to their background and familiarization with this theoretical tradition (Papadopoulos et al., 2015). This resulted to a fostering of the problem-posing element by a constructionism view. So, in this c-book unit the students were working in a context that enabled a continuous and more distinct interplay between problem solving and posing/constructionism and this interplay is examined in relation to whether it operates as enabler of meaning-making in mathematics. As we presented above, the students had initially to explore the problem of an ill-structured windmill and find the part of the problem that is ill-defined. The problem seemed to be solved for a specific set of values (S1-23, S2-26) but this does not ensure the generality of the solution. So, the new problem was to keep the fan well-shaped for any set of values. To solve this task, it was deemed necessary to identify the role of each variable in the solution of the problem which resulted to the knowledge that variable 'a' is not related to the bug (S1-27). This actually transformed the last problem to a new one, asking for the relation between variables 'b' and 'k'. This new problem contributed to the shift of the focus towards the notion of covariation. In order to find the relationship between the variables, a series of new constructions took place. They resulted to a collection of pairs of values for 'b' and 'k' that made the fan look like a proper one. This made the students think that the two variables were inversely proportional. However, the formula was still missing and this became their next problem. Therefore, a new variable was added to the code (S1-33, S2-34). A new, more complex construction took place. The feedback on their screen from their constructions made them doubt their claim for the proportionality of the variables (S1-48, S2-49) and the phrase "This is not fair!" (S2-49) opened the discussion about possibly another kind of relationship (S1-50, S2-51). That was the new

problem which resulted to the more focused discussion on covariation and the possible formula that might fix the bug.

It seems that students made a step further. They tried to answer two interim questions they themselves posed and which came up as they tried to fix the buggy windmill, reconstructing it in a way consistent and meaningful for them. So, they reformulated the initial problem, starting from their reconstructing efforts and came back to solve it anew in a process where new and perhaps more creative aspects of mathematical knowledge were expected to emerge. Thus, the interplay between problem solving and constructionism was apparent, while the interplay between problem solving and posing was not direct. The formulation of new inquiries by students indicates that constructionism facilitated problem posing. Actually, this view of constructionism is close to what Brown and Walter (1990) argue about the problem-posing process: the solver first makes a list of all attributes included in the statement of the original problem, and then, he proceeds in negating each of them formulating thus an alternative proposal, a new problem. However, negating an attribute makes the original problem ill-defined (or ‘half-constructed’), and so the solver is challenged to proceed to the ‘construction’ of a ‘new’ problem. It is in this sense, we argue, that an interesting connection between problem-posing and the Constructionism perspective arises within the context of the c-book technology and c-book units, never having been identified in the literature so far. At the same time there is evidence that during this interplay a meaning-generation process takes place. The problem of finding the bug of an ill-structured windmill’s fan, which seemed to be mostly related to spatial observation and Geometry, turned to be investigated by the students through algebraic procedures, use of symbols and looking for relationships between variables. Students while trying to understand what was going on with the shape of the fan by reconstructing it, actually moved back and forth between processes of problem solving and construction. It was during this interplay that students started moving from the specific notions of proportional and inversely proportional variables to the more abstract notion of covariance.

## Conclusions

The problem solving and posing approach in creativity (Silver, 1997) attributes creative moments in the interplay between them. The entrance of Constructionism in the agenda of creativity seems to have an impact in the creativity landscape and perhaps opens new research challenges. The new c-book units that aim to foster creative mathematical thinking in students are based on a design principle that is characterized by ‘Constructionism fostering/substituting problem posing’. Then the whole story is evolved around the continuous interplay between problem solving and posing/constructionism. So, on the one hand some new research questions arise about the role of Constructionism in fostering creative mathematical thinking. On the other hand, there is evidence that this interplay between problem solving and posing/constructionism in the path towards creative moments facilitates meaning-generation processes by the students.

# Three ways that use ICT to enlarge students' roles in learning

Jean-Jacques Salone

Centre Universitaire de Formation et de Recherche de Mayotte, France

Institut Montpellierain Alexander Grothendieck, CNRS, Université de Montpellier, France

[jean-jacques.salone@univ-mayotte.fr](mailto:jean-jacques.salone@univ-mayotte.fr)

*How can the academic success of students be better ensured? Many math teachers ask this question. Educational researchers have proposed multiple solutions. In our own works we have considered three of them: diversifying the taught knowledge's sources of references and re-contextualize it, involving students in their learning process by giving them various responsibilities, enriching the class's didactical "milieu" with resources and digital tools. In this report we will focus on the second and third propositions with one main question: how can information and communication technologies help increase students' responsibilities in learning? We will expose three examples of how this aim could be achieved.*

*Keywords: Cooperative learning, teaching methods, computer assisted instruction, students' topos, anthropological theory of didactics.*

## Focus and rationale

Giving responsibility to students for their learning is a concern that educational researchers have taken for many years. For example Barnes (1977) or Lee and Smith (1996) show that achievement gains are significant when teachers enhance collective responsibilities, Scardamalia (2002) explores some possibilities of computer-supported environments and Coffman (2003) proposes strategies to increase students' roles. Theories also exist that give a frame to this issue, such as the Joint Action Theory in Didactics (Sensevy, 2010) or the Cooperative Learning theory (Slavin, 1995). Our purpose in this paper is to expose three examples of how web resources and digital intelligent systems allow math teachers to involve their students in cooperative activities where they are authors of the lesson tracks, where peer learning is promoted and where curricula are individualized. The intelligent system that will be used in the classroom is the web platform LABOME ( <http://www.labomep.net/> ). We will show that it is a tool likely to foster student-to-student monitoring, autonomous training and self-evaluation.

## Theoretical framework

We will use in this paper concepts from the Anthropological Theory of Didactics (ATD) (Chevallard, 2006; Wozniak et al., 2008; Winslow, 2011). In ATD, learning and teaching are interpreted as ordinary human activities that can be described and analysed through the general concept praxeologies: "A *praxeology* is, in some way, the basic unit into which one can analyse human action at large." (Chevallard, 2006). At first a praxeology is built around a *type of task* which is usually expressed by a verb and a precise object. For example, "to climb a staircase" is a type of task, but to climb, short, is not one" (Chevallard, 1998, our translation). Secondly a praxeology precise a *technique*, a way to realize the type of task, a know-how. This technique is then often justified and lightened by a *technology*, a reasoned discourse which states that the technique is suitable for the type of task and explain how to perform it. "At his turn, the technological discourse contains some

statements, more or less explicit, for which one can ask the reason. We then reach a higher level of justification-explanation-production, the theoretical one” (Ibid.).

Another theoretical concept on which we rely in this paper is that of *topos*:

In some contexts, didactic tasks actually are *cooperative*, meaning that they must be performed *together* by *several* persons  $x_1, \dots, x_n$ , the *actors* in the task. It will be said that each of the actors  $x_i$  must in this case perform certain *gestures*, the whole of which constitutes its *role* in the fulfillment of the cooperative task  $t$ , these gestures being both differentiated (according to the actors) and coordinated by the collectively implemented technique  $\tau$ . Some of these gestures will be seen as separate tasks,  $t'$ , in the accomplishment of which  $x_i$  will act (momentarily) in a *relative autonomy* compared to the other actors in the task. The set of all these tasks, which is a subset of the *role* of  $x_i$  when  $t$  is performed according to  $\tau$ , is then called the *topos* of  $x_i$  in  $t$ . (Chevallard, 1998, p. 108, our translation)

A student's *topos* is thus the set of all of the gestures he will have to accomplish in didactic autonomy. In his dictionary of didactic, Chevallard (1996) describes at least three types of student's or teacher's *topos*: 1/ the math disciple/pupil who just listens and observes what is done by the master/teacher; 2/ the math practitioner who masters some techniques in order to realize some tasks and is guided by the animator/teacher; 3/ the math student/researcher who masters the theoretical and technological parts of the praxeologies and has a relative didactic autonomy when studying research question under the direction of its director/teacher. A way to look at the students' *topos* is to focus on what happens with their public speeches or texts. Most of time, these discourses are just communicated and appear in the milieu (Brousseau, 1997), but they are not included in the shared praxeologies which constitute the lesson and that is here termed the *class's praxeological equipment* (Salone, 2015b). Writing the *class's praxeological equipment* is usually a type of task reserved to the teacher; it is an element of his *topos*. The *topos* of the students relatively to the *class's praxeological equipment* is then just to copy and memorize it. But, in some contexts, it may be a cooperative work, so we proposes a four levels scale to analyse how students' public discourses evolve in a classroom: 1/ they are communicated; 2/ they are discussed; 3/ they are included in the *class's praxeological equipment*; 4/ they program the study. At first level, students' public discourses exist in the class' milieu. At second level, they become a local reference: students and teachers refer to them when debating. At third level, excerpts of the students' public discourses constitute the *class's praxeological equipment* and excerpts of them are directly inserted, with no rewording by the teacher; at fourth level, their function is to organize the study

In order to give the teachers some tools to go through these for levels, we develop some *didactic plans*. A *didactic plan* is a teaching technology, a way to conduct the study in a classroom. Chevallard (2006) proposes some examples: a lecture course is “teaching by giving a discourse on some subject”, a seminar is “a small group of advanced students [...] engaged in original research or intensive study under the guidance of a professor [...]”. Thus a *didactic plan* aims to shape the didactic relation between the teacher's *topos* and the students's *topos*; in this respect it contributes to the evolution of the didactical contract (Brousseau, 1997).

In this paper we describe *didactic plans* where students are involved in cooperative tasks with a relative autonomy, where they have a math practitioner *topos* and where their public discourses are at second and third levels (see above).

## Methodology

Our research was conducted from 2010 to 2016 in math classes ranging from primary school to high school levels. It began with a team of three teachers, including myself, and twelve classes in middle school (students aged from 11 to 15 years), with two classes per grade (from grade 5 to grade 9). Later the team was joined by three more teachers from middle school (four classes per teacher), two teachers from high school (grade 10 to 12, three classes per teacher) and five teachers from primary schools (grade 4 and 5, one class per teacher). In addition two teacher's trainers joined the team. All the teachers involved in the research project agreed to implement *study and research activities* on specific topics and various *didactic plans* designed by an upstream engineering in order to diversify knowledge's sources of reference and to open classes on their surrounding world (Salone, 2015a). Teachers remained free to adapt and insert these activities and plans into their own mathematical progressions. For the research needs, they collected data in their classes: lectures, students' documents, teacher's online textbooks<sup>1</sup>, students' notebooks. Twice or three times a year, we visited one of these teachers (that means we observed their classes without interacting) in order to make audio recordings of sessions, to take photographs of the classrooms and to interview some students that were chosen randomly. We did informal interviews with open questions on how the students appreciated the course and where notes were taken. From 2014 to 2016, the whole team also met twice a year in order to share teaching experiences. This was an opportunity to improve the *didactic plans* and to realize informal interviews of the teachers or to refine some of our *a posteriori* analysis.

## Learning the Pythagoras' theorem

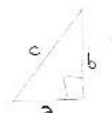

In France, the Pythagoras' theorem is studied in grade 8. The Ministère de l'Éducation Nationale (2008) imposes two abilities: 1/ to characterize the right-angled triangle with the Pythagorean equality; 2/ to calculate the length of a side of a right-angled triangle from the lengths of the two others. It states also that the direct theorem must not be distinguished from its reciprocal (nor from its contraposed form). The case we report here concerns a class at third level of the middle school, with pupils aged 13-14 years (grade 8). The objective was the study of the Pythagoras' theorem. The teacher's online textbook shows his progression: 1/ a survey, at home, of the Pythagoras' theorem; 2/ group works to product synthesis on what is the Pythagorean theorem and its uses; 3/ a tutored training with Labomep; 4/ a selection of exercises' models

## Exploration of the theorem and of its uses

As already said, the study began with an exploratory survey conducted at home, on the web and by asking the close family. In the first session students had realized written presentations on Pythagoras and his theorem (Salone, 2015a, p. 323):

---

<sup>1</sup> In France, teachers are required to write each day a summary of what they have taught in an online textbook. This textbook can be consulted by the students and their parents.

<p><u>Les questions</u> que l'on se pose sur le théorème de Pythagore</p> <p><u>A quoi sert-il?</u> Il sert à calculer la longueur d'un côté d'un triangle rectangle, il sert aussi en architecture.</p> <p><u>Qui l'a inventé?</u> Pythagore de Samos a inventé le théorème de Pythagore.</p> <p><u>Qu'est-ce que c'est?</u></p>  <p><math>a \times a + b \times b = c \times c</math> donc: <math>a^2 + b^2 = c^2</math></p>	<p>The questions we ask about Pythagoras' theorem</p> <p><u>What are its uses?</u></p> <p>It is used to calculate the length of a right-angled triangle. It is also used in architecture.</p> <p><u>Who invented it?</u></p> <p>Pythagoras from Samos invented the Pythagoras' theorem</p> <p><u>What is it?</u></p>
---	--

**Figure 1: Excerpt of a presentation on Pythagoras (left) and our translation (right)**

Four of these presentations were exposed on the blackboard and orally presented by their authors (10 minutes). The teacher then asked some questions: “Does someone have found some more information about Pythagoras?”, “Do you agree with these statements of the theorem?”, “What the Pythagoras' equality allows us to calculate or to do?” Then he invited the students to freely constitute six peer groups (4 to 6 students per group) to answer these questions and to produce a shared synthesis. In the groups, the students collected and compared their presentations. Their works lead to the emergence of shared statements of the theorem, some uses of it and some problems in line with the official programs. After 30 minutes, the teacher ordered each group to copy one single statement on the notebooks. He had a glance to these statements but, since they all were right, he did not reword them. His first teaching objective was thus reached. In addition, he exposed five of the students' synthesis on the classroom's walls. In this session, the students' *topos* was thus quite unusual; indeed they were first responsible at home of their own first encounter with the theorem (Chevallard, 1998); second they produced a synthesis in peer groups, by reviewing collaboratively one another's works, while the teacher facilitated their work; third they were the authors of the theoretical part of the *class's praxeological equipment* (third level on the *students' public discourse* scale). In this *didactic plan*, the ICT were a tool to access web resources. In the interviews, some students reported being pleasantly surprised by all the uses of the theorem.

### **Tutored training with a digital media**

During a second session, the teacher animated a computer training shaped by a *didactic plan* we call a “tutored training” (Salone, 2015a). It's a moment where students perform training exercises and where they help each other and self-evaluate. In this *didactic plan* a digital media, here the web platform for math teachers Labomep (<http://www.labomep.net>), provides series of type of tasks. The teacher has to subscribe and then he is allowed to access and deposit resources to organize his courses. Many exercises are thus available, sorted by school grades, chapters and themes. Students may access Labomep freely, without subscription. But the teachers of our team preferred to enrol their students

so that they could control their works (see further). At first the teacher video-projected one problem from the series (Figure 2, left). Each student then individually sought an answer for it. Then the first students who had one consulted with the teacher who evaluated them. After a few minutes, some of the students who had correct responses were invited to help others. At this moment, these students had a *topos* enlarged with teaching task: they gave technological-theoretical explanations and methodological advices, they realized assessments. Meanwhile the teacher too had a specific *topos*: he regulated the activity, reminding some rules, giving some advices. When everyone had come to an answer techniques were finally discussed by the whole classroom and a common solution was chosen and copied in the notebooks (Figure 2, right). The process could then start again with a new exercise from the same set or from another one. In a third session, not observed, the students had also to gather in a file the problems along with their solutions (one problem from each Labomep series). Thus in these sessions several types of mathematical tasks associated with the Pythagoras' theorem appeared through problems and techniques gradually emerged. The students' *topos* was enlarged with monitoring tasks usually reserved for teachers and with writing tasks in order to constitute the *class's praxeological equipment*. ICT were at the heart of this *didactic plan* as they provided sequences of problems and allowed the existence of a joint action. In interviews, students often reflected the feeling they had that tutored trainings, with peer to peer exchanges, improve their understanding of mathematics. Teachers also highlighted that a long-term regular use of such a *didactic plan* enables students with learning difficulties to keep up with their classmates.

The figure consists of two side-by-side screenshots from the Labomep website. The left screenshot shows an interactive exercise titled "Appliquer le théorème" (Apply the theorem). It contains a question about a right triangle RHO and a diagram. The right screenshot shows a handwritten solution for a similar problem involving triangle ABC, with steps for question, response, and conclusion.

Figure 2: An exercise from Labomep (left) and a shared one (right)

### Self-training and assessments

Websites as Labomep are not only resources for interactive exercises. They are also intelligent systems that assess the performance of individual students. In several of the classes involved in our research, teachers took advantage of this potential to develop training sessions in relative autonomy.

Each student had a personal account on Labomep and trained alone or with a classmate. The sets of exercises are either freely decided or defined in advance by the teacher. At the end of a series, Labomep assigns a score and suggests trying again if needed. Video animations reminiscent of technological-theoretical elements are also directly accessible or proposed. The greatest advantage of this *didactic plan* is that it can be continued outside the class. Indeed each student can extend the studies conducted in classroom by training, revision or exploratory sessions at home. Figure 3 shows an example of individual assessment which is made by Labomep and which the teacher can view. The first column is the name and first name of the student (here a generic one), the second column contains the title of the series, the third one is a score, the forth and the fifth ones are day and time. In the third column, the score is at first a mark (1 over 5 here) and the five rectangles corresponding to the five exercises of the series are coloured: when the colour is red, that means the student didn't succeed at all (he had two attempts to succeed), when it is light green he succeeded at the second try, when it is green he succeeded at the first try, and when it is blue he didn't answer the exercise.

**Figure 3: An individual assessment with Labomep**

To go back to Pythagoras' theorem, Figure 4 shows the activity of two students on it and on the Pythagorean triples. This is an extract from a page with global statistics generated by Labomep that informs us about the different issues they addressed, adding scores or achieved grades, and the dates, times and durations of sessions. The two students, which we will call here Ali and Ame, had different profiles: Ali was ranked among the top students in his class, whereas Ame was facing some learning difficulties. Data on dates and hours show that both have used Labomep 3 times: twice during classroom sessions, on 24/09/2012 and 01/10/2012, and once outside the classroom on 03/10/2012. In class, within an hour and forty minutes of activity (rows 1 to 7), Ali mastered the first two types of tasks (applying the theorem and showing that a triangle is not right-angled). For the first type of task (rows 1 to 4), his score is three times 0/5 and then it becomes 5/5. For the second task (rows 5 and 6), his scores are 1/5 and 5/5. But he only achieved a score of 1/5 for the third type, at row 7 (use the Pythagorean triplets). Within the same time frame, Ame successfully completed the first two types of tasks, with a maximum score of two out of five for the first one (rows 13 to 18) and one out of five for the other (row 19).

**Figure 4: Excerpt from statistical assessments of students in Labomep**

Out of the classroom the path differences are even more marked. Ali returned to Labomep, two days later, more than two hours in the evening (rows 8 to 12); he trained himself to solve the third type and didn't succeed (his best score is 2/5). After that he went on working on two other types of more complex problems (rows 11 and 12). Ame just spent a quarter of an hour taking the first two types, in the afternoon one day after the second session (rows 20 and 21). He partially succeeded the second type of tasks, reaching a score of three out of five. Thus, with intelligent digital systems such as Labomep in such a *didactic plan*, courses and students' paths can be individualized. According to teachers, it is very beneficial for learning: it consolidates the skills of all students. Those who have difficulties have tools to progress at their own pace and perform better evaluations, those who already have a good level complement their knowledge. Some teachers have also chosen to look at these individual activities outside the classroom so that everyone's work is rewarded regardless of the initial or achieved levels in mathematics. Quarterly average scores are thereby increased, which greatly helps to maintain students' motivation.

## Conclusion and perspectives

Through these examples we have therefore tried to identify some benefits on learning induced by the use of *didactic plans* including ICT and which enlarge students' *topos*. The first one concerns the *class's praxeological equipment*: students become authors of the lecture, of its content and its programming. The second benefit is related to the joint action: ICT facilitate peer exchanges in *didactic plans* where students endorse teaching tasks that are usually assigned to teachers. The third benefit is the differentiation of learning: intelligent tutoring systems such as Labomep allow tasks to be performed in individualized ways and to be continued at home. Can we conclude that students are more motivated when using ICT? And does this improve their learning of mathematics? The general consensus amongst the participating teachers and students was yes. But there are other factors that might explain this conclusion. First we worked with an extremely motivated team of teachers who were very dynamic and keen on interesting their classes. Second today's students easily understand and appreciate ICT related activities. So it is not sure that these methods would ensure success for all students. Our research objectives are now to study the conditions and constraints of implementing such *didactic plans* in regular classes.

# Nature and characteristics of digital discourse in mathematical construction tasks

Florian Schacht

Universität Duisburg-Essen, Didaktik der Mathematik, Germany; [florian.schacht@uni-due.de](mailto:florian.schacht@uni-due.de)

*This paper introduces the concept of digital discourse in Mathematics using a philosophical framework by Alexander Galloway. The notion of the digital is discussed and the concept of digital discourse is elaborated on that basis. The empirical data shows its value by reporting on transitions in language when working with digital tools on geometrical tasks. Existing research findings show effects of DGS on language changes referring to geometrical objects and actions. The present study analyses qualitatively both students' language referring to mathematics as well as to the digital tool in the context of geometrical constructions. The empirical results give insights into processes and transitions in the language use (by students) from a tool-oriented language (e.g. referring to buttons) to a mathematical-oriented language (referring to mathematical concepts) and aim to explore the nature and the characteristics of digital discourse.*

**Keywords:** Language, digital tools, geometry, discourse.

There are substantial research results concerning the changes in language used for describing mathematical actions and objects when working with DGS (Kaur, 2015; Sinclair & Yurita, 2008). This paper shows results focusing on empirical phenomena concerning a language that students use in order to describe actions and objects referring to the digital tool. The interplay between these two layers referring to the tool as well as to the mathematics is analyzed in detail. The analysis will give empirical insights into the transition-process between the language of mathematics and technology and, by doing so, will examine a central facet of digital discourses.

## Etymological and philosophical aspects of digital discourse

What is digital discourse? Initially one might think of SMS-chats, of instant messaging via Skype or WhatsApp, of blogging or the like of tweets, of posting messages on social network sites, or of video-based online-discussions (e.g. Llinares & Valls, 2009). There is no doubt that all these forms of discursive practices have their roots in the way new media is used. But is it adequate to use the predicate *digital* for such discursive practices? For the examples above, this paper will rather use the term discourse “in the New Media” (Thrulow & Mroczek, 2010) to differentiate it from the term digital. But what is the *digital*? This paper wants to stress the notion of the digital in the mathematics classroom, especially the notion of what can be seen as digital discourse in mathematics. To do so, we will follow a philosophical path drawing on a work by the philosopher Alexander Galloway (2014), in which he gives an introduction to the work of the philosopher François Laruelle and—by doing so—tracing back the notion of the digital in philosophy to Plato and Sokrates and, especially, to Hegel's work. For Galloway, rather than distinguishing zeros and ones (the digital) compared to continuous variation (the analog), the “digital is the basic distinction that makes it possible to make any distinction at all. The digital is the capacity to divide things and make distinctions between them. Thus not so much zero and one, but *one and two*.” (Galloway, 2014, p. xxix) In that sense, the digital is closely connected to the notion of difference. This philosophical perspective on the digital is used here to discuss its value for the mathematics

classroom and especially for discursive practices and processes of concept formation in it. By doing so, this approach does not claim to adopt Galloway's perspective on philosophy and his non-standard philosophical approach drawing on Laruelle (c.f. Laruelle 2010). It rather uses perspectives he offers to introduce the concept of digital discourse in mathematics and to better understand its nature and characteristics.

The understanding of discursive practices and the underlying norms have been a major subject of study in mathematics education. And yet there is a need for reactivating such analytical approaches in the light of the use of digital tools since digital tools “give rise to new ways of thinking that may conflict with the established discourse of formal mathematics” (Sinclair et al., 2016a). In their analysis, Sinclair and Yurita (2008) outline the way in which the use of dynamic geometry changes discourse, e.g. transitions from static to dynamic forms of discourse. Also, Schacht (2015a; 2015b) reports on shifts in language regarding student's documentations, in which the students use a language that clearly refers to the digital tool and not to mathematics. Both examples show—in different ways—that the digital tool affects the discursive practices in class. And still we know little about normative rules affecting the discursive practices: the conceptual (mathematical) norms involved, the social- and socio-mathematical norms, the norms established and the norms brought in by the technology in use. By introducing the concept of digital discourse, this paper approaches an understanding of discursive processes by using Galloway's perspective on the digital in order to distinguish different discourses referring to the tool or to mathematics with specific underlying norms. Therefore, we will first briefly highlight Galloway's (2014) notion of the digital, then introduce the definition of digital discourse in mathematics before applying it to the empirical data.

### **What is *the digital*?**

Building on the broad definition of the theoretical concept of the digital that points at the notion of difference (see above), Galloway describes the operation of the digital as follows: “the making-discrete of the hitherto fluid, the hitherto whole, the hitherto integral. Such making-discrete can be effected via separation, individuation, exteriorization, extension, or alienation. Any process that produces or maintains identity differences between two or more elements can be labeled digital.” (Galloway, 2014, p. 52) Although the digital can be seen as an archetype of philosophical thinking in general (tracing it back to Plato and Sokrates), Galloway (2014) describes the digital as fundamental to the dialectics of Hegel with its two moments: “the (digital, F.S.) moment of *analysis*, where the one divides in two ( $1 \rightarrow 2$ , F.S.), and the (analog, F.S.) moment of *synthesis*, where the two combines as one ( $2 \rightarrow 1$ , F.S.)” (Galloway, 2014, p. xxix). Galloway also attributes analog and digital to both moments (p. xxxi). Although Galloway (2014) does not focus on computers or new media in this work but rather on discussing the theoretical concept of the digital in general, the (digital) process of discretization and of computation however, of extending *the one* (or, in a mathematical context: the mathematical concept) “beyond its own bounds, thereby branching the one, splitting it” (Galloway, 2014, p. 52) is inherent to computers and hence to digital tools. In this sense, the dialectic idea is existentially present and closely related to the digital: “Hegel is dead, but he lives on inside the electric calculator.” (Laruelle, Introduction aux sciences génériques, 28, cited in Galloway, 2014, p. xxxiv)

## Digital discourse in mathematics

Following Galloway's discussion of the digital, the following definition is used here: Any discourse that produces or maintains differences between two or more elements can be labeled digital. This definition does not necessarily focus on technology. Also, the notion of digital discourse presented here certainly differs from studying discourses in the new media (Llinares & Valls, 2009). As a theoretical concept, this notion can be applied to any discursive practice. However, the analysis of the empirical data will demonstrate that the concept of digital discourses can be used to structure and describe conceptual processes and transitions underlying the work with digital tools because the (*digital*) distinction between expressive reference to the mathematics and to the digital tool and, in line with that, the corresponding underlying norms seem to play a central role in these processes. In this sense, the approach follows the "need to study the transition phases in the progress of geometrical concept formation" (Sinclair et al., 2016b, p. 696).

The term discourse is used here in a pragmatic (more precise: from an inferential) perspective (Schacht & Hußmann, 2015): Individual conceptual processes and mastering mathematical concepts is understood as being able to give reasons for the use of concepts within discursive practices (=master the inferential relations), similar to Wittgenstein's idea of mastering the rules of the language game. In this perspective, individual conceptual acting is highly normative since the individual acknowledges the reasons one has for applying a concept to be true or at least to be adequate in a certain situation. Hence, it is one of the tasks of this analytic approach to reconstruct the (normative) rules that the individuals (as concept-appliers) follow. Discursive practices, in this perspective, give access to individual conceptual processes and the underlying social and individual norms. Galloway's notion of the digital is used here for digital discourses to differentiate between different (normative and conceptual) discursive layers, and especially between the following two layers discussed in this paper concerning the mathematics and the tool. In this sense, it is the aim of this paper to introduce the concept of digital discourse and to better understand its characteristics and nature when working with digital tools exemplified by an example from geometry class.

## Language, written documentations and digital tools in geometry

Before analyzing the digital discourse in the empirical example from a dynamic geometry environment (DGE), this paragraph will briefly highlight research findings on the changes in language when working with digital tools. Such tools affect the conceptual thinking and acting with the mathematical objects as well as the written solutions (Ball et al., 2005; Weigand, 2013). In geometrical contexts, DGS can support the grasping of both the geometrical objects as well as the actions conducted with these objects (Jore & Parzysz, 2005). Also, the use of DGS changes language and discourse in various ways. Hölzl reports that students tend to use active verb forms while working with the dragging mode (Hölzl, 1996) which mirrors the movement and the dynamic actions. Also young children (ages 7–8) tend to change forms of reasoning using action verbs influenced by dynamic and temporal elements of the DGS like the dragging tool (Kaur, 2015). In line with that, changes in discourse and vocabulary could be observed regarding the transition from static to dynamic forms of discourse about geometrical objects: "[S]hapes were discussed as if they were a multitude of objects, changing over time, rather than as a single object" (Sinclair & Yurita,

2008). Hence, not only the understanding of the objects and actions change, but also the language used in order to make actions and objects explicit.

Whereas most of these findings report on transitions of language regarding *mathematical actions and objects* when working with DGS, Schacht (2015) shows that students also use a rather naturalistic language to describe the *manual actions* precisely to get to their solution as well as *objects referring to the tool* like buttons or commands. This paper focuses on the way in which students describe actions and objects both referring to the mathematics and referring to the digital tool as well as on the transitions between these layers when working on geometrical constructions. These different referential units—the mathematics and the digital tool—each reflect certain conceptual—and, following the pragmatic approach, also normative—layers e.g. it makes a difference whether one describes the solution process in terms of the mathematical process or in terms of the manual actions conducted with the digital tool.

This paper studies the transitions of using *tool language* to using *technical language*. This paper reports on results of a qualitative study, in which processes like these were studied based on students' involvement on construction tasks using DGS (GeoGebra) with respect to the following underlying research question and the overarching interest to explore the nature and characteristics of digital discourses: *Which language transitions can be observed between a tool- and a maths-oriented language when working on construction tasks?*

## Methods and design

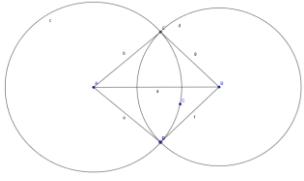

The empirical study was conducted with N=20 students (age 13–15) from different schools. All students worked in pairs with GeoGebra within clinical interviews. This paper uses some of the data of this bigger project in order to demonstrate the potentialities of digital discourses as a way to understand lexical transition processes better. A systematic analysis of such lexical processes is given in Schacht (in revision). All pairs that did the construction tasks were videotaped during the construction and afterwards. The interviews were analyzed qualitatively focusing on the oral and the written language by using lexical categories (Schacht, 2015). The written documents were also analyzed. Three to four geometrical tasks were given to each pair; the duration of working on these tasks ranged between 40 and 80 minutes. All students were introduced to the DGS first and they were encouraged to explore some main functionalities since most of the students had not have much experience working with GeoGebra. Most tasks had an explorative character, meaning for example that the students were asked to construct certain objects and try to formulate a description. Within a task aiming at exploring the concept of symmetry, the students were asked to describe and give reasons for their findings. In this sense, the information the experimenters were trying to obtain from the interviews focused on the way the students work on such geometrical tasks and the language they use when speaking and writing. A detailed description of the tasks relevant to this paper is given below.

## Results and discussion: Transitions in language

The pairs of students were given a geometrical configuration and they were first asked to (reconstruct) the given Figure 1 with ruler and compass (on a sheet of paper) and formulate a written description of the given construction by using ruler and compass for themselves (line 1

below shows the description of student 1 (S1)). After that the students worked in pairs with a DGS. They were then asked to construct the same figure with GeoGebra and then formulate a description of the construction together (lines 2 & 3 shows the common description of S1 and S2 with the DGS).

Line 1	S1 (r&c): Draw a 5,7cm straight line (German: Linie) from A.	 <p>Figure 1: The given geometrical configuration</p>
Line 2	S1&S2 (DGS): Click on the button “segment” at the top.	
Line 3	S1&S2 (DGS): Segment from the center to each point of intersection.	

The analysis focuses on the language the students use to describe the objects they deal with. Using ruler and compass, S1 refers to a term from everyday language (line (German: *Linie*)) which is—in the German translation—not considered to be a proper mathematical term. When the students work with the DGS, they document their manual action (line 2) precisely by describing which button to click on. In this case, they choose the segment-button. In the version of GeoGebra they use, the name of the button “segment” is shown. Hence, the term *segment* refers to a *button* (c.f. Schacht 2015a) which is an object that refers to the digital tool. It is important to note that although *segment* can be considered as a mathematical object, the students describe a button, hence an object referring to the tool. On the other hand, in line 3 the students refer to the segment from the center to the intersection points. This description refers to the mathematical object of segment.

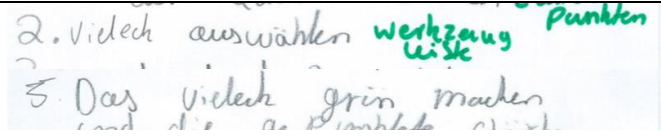

This analysis shows two transitions in the students’ language within their documentations. First, there is a change from the description of a given object in everyday language (line 1) to the description of a certain button (line 2). For the students in line 2, *segment* is a signifier of the button that they use for their documentation. The second transition shows in which way this signifier is used as a mathematical term to refer to the mathematical object of the *segment* (line 3). The students do not refer to a button. They rather use the term segment within a mathematical description. Hence, the analysis gives insights into the process of the description of buttons (as objects referring to the tool) to the description of segments (as mathematical objects). This is a central characteristic of digital discourses: The distinction between the tool-oriented and the mathematical language offers a possibility for the students to use terms common in mathematical discursive practices. The example shows that digital discourses can follow a linear structure in which the difference between the tool oriented layer and the mathematical layer can even be bridged by the digital tool since it offers expressive resources that students adopt.

This first example has limitations though: The students can easily adopt the term *segment* because it connects to a colloquial use of the term. As the following contrasting example will show, obstacles may occur when students use terms that do not connect easily to a colloquial understanding. In this task, the students explored the phenomenon of symmetry. The students were given a GeoGebra file with two quadrilaterals, where one quadrilateral was the image of the other under a line reflection. The line itself was not depicted. By dragging the one quadrilateral, the other one moves according to the line reflection. The students were asked to construct a new geometrical figure by starting with the two rectangles (Figure 2) and the two students S3 and S4 formulated a description for a construction he made with the DGS afterwards.

Figure 2: Exploring the properties of a line reflexion. By dragging ABCD (left) the image moves correspondingly

In the next step, only the written description was given to the other student who then had to (re-)construct the original figure with the DGS. In the following example, student S3 draws a triangle by using the *polygon-button*  Polygon. He had seen the signifier of the button during his construction. In both descriptions below the student S3 refers to the triangle using the term *polygon*.

	<table><tr><td>line 2</td><td>S3 (DGS):</td><td>2. Choose polygon (toolbar)</td></tr><tr><td>lines 6-8</td><td>S3 (DGS):</td><td>5. Colour the polygon green</td></tr></table>	line 2	S3 (DGS):	2. Choose polygon (toolbar)	lines 6-8	S3 (DGS):	5. Colour the polygon green
line 2	S3 (DGS):	2. Choose polygon (toolbar)					
lines 6-8	S3 (DGS):	5. Colour the polygon green					

Transcript of the oral description:

Turn 1 S3 (DGS): By pulling at the left polygon, here at the points, coordinates, in order to have three rectangles.

First, the student refers to the polygon-button (line 2) in order to describe a manual action precisely and the objects (referring to a *button*) needed in order to handle the DGS. Next, the student adopts the signifier in order to refer to the mathematical object (lines 6–8). In lines 6–8, the polygon is seen as a static object that has to be colored in green. Third, this mathematical object is used dynamically since the student describes how to pull at it (turn 1). Hence, this example shows a transition from the description of an object that refers to the tool (*polygon button*) to the description of first a static and then a dynamic mathematical object (*polygon*).

Although this transition seems to mirror the process that could be observed in the first example, there are significant differences. It is important to note that student S3 does not refer to the term *triangle* at all. Instead he sticks to the term *polygon* throughout the interview. When (his partner) S4 has difficulties with the description and asks S3 to describe precisely what he meant by *choose polygon*, S3 does not refer to the three points that his specific polygon (as a triangle) has (turn 1). Hence, this example shows that although S3 uses the signifier to deal with the mathematical object, he has difficulties with grasping the concept to distinguish between a polygon and a triangle since he has no conceptual understanding of this term. This analysis shows interesting obstacles. First, S3's description to *choose a polygon* is viable, but it is not precise enough for S4 to understand that he has to create a triangle. There are several other scenes in this interview, which lead to the conclusion that S3 does not grasp this concept as he cannot connect it to other mathematical concepts. Especially, it is not obvious for S3 that a triangle is a certain polygon. This example raises the question of how it is possible to support a *semantic* connection to the students' knowledge by using the digital tool and the given signifier. In terms of the characteristics of the digital discourse, the student does not manage to make the mathematical concept explicit by giving reasons for it in the course of the interview. He rather incorporates the expression *polygon* offered by the user interface. The second example gives insights into a divergent digital discourse because there is no mediation between the two layers in order to establish a commonly shared mathematical

understanding of the construction. The reason for that is the missing conceptual transition between the two layers mathematics and tool.

## Final remarks

The two examples discussed in this paper show similar transitions in students' language when working with digital tools and give insights into digital discourses. They give insights into the process of the descriptions from objects related to the tool (e.g. buttons) to mathematical objects. Regarding the research question, the examples show different lexical phenomena when working on construction tasks. Example 1 reveals that digital tools can support lexical processes by adopting the signifiers' names in the description of the construction. The students manage the shift from a language that focuses on technology to a rather mathematical language. In other cases this can lead to obstacles which show the need for a conceptual connection to concepts the students already know (example 2). These different lexical transitions show that the use of a rather calculator-oriented language has potentialities as well as limitations. Although it is important for the mathematics classroom to support the use of both language referring to the tool (e.g. in exploration situations) as well as to the mathematics, it remains a challenge to develop means to bridge and support language processes in a way that students not only adopt signifiers but rather grasp a conceptual notion of the mathematical objects and actions. Hence, studying language processes like these shows the importance of a lexical consciousness of the different lexical norms of adequacy when language is used in specific situations (Schacht, 2015).

Studying such language transitions illustrates the role of the notion of difference in discursive practices when working with digital tools. The two examples in this paper show two different digital discourses, understood as discourses that produce or maintain differences between the mathematical and the technological discursive layer. On the one hand, a digital discourse can have a linear structure in which the difference between the mathematical and the technological discursive layer is bridged. On the other hand though, that difference between these two layers maintains throughout the discussion. Regarding the characteristics of such digital discourses, the examples show that it makes a difference if the students use expressions referring to the mathematics or to the digital tool. On the one hand, each layer implies specific underlying norms and specific conceptual aspects, which refer either to the mathematics or to the digital tool. On the other hand, the processes above show the dynamic of such discourses and the way in which these—linear or divergent—transition processes can have implications on the individual concept formation processes.

The results also show possibilities for further studies of the digital discourses in respect (i) to the underlying conceptual processes, (ii) to a deeper insight into the nature and characteristics of digital discourses and (iii) to the potential for classroom practices to foster digital discourses within conceptually supporting environments.

*Mathematics education researchers have been interested in students' understanding of the equality as equivalence relations. Doing so, they pointed out that the notion of equality is difficult for students to perceive. We provided one pair of 16-year-old low-achieving students with a productive environment (technological tool, supportive teacher and an authentic activity) to support their learning of equality sentences as equivalence relations. We examined the pair of students' routines in this environment. The research results indicated that the students followed a sequence of routines where the teacher and the technology had an effective role. Moreover, students' substantiation routines relied on empirical argument that utilized concrete realizations afforded by the applet.*

*Keywords: Commognition, dynamic technology, low-achieving students, equation, equivalence.*

## Introduction

The mathematics education of low-achieving students has attracted educators' attention for a long time. To support the mathematics learning of these students, one of the recommendations is to conduct a classroom environment that is conducive to learning (Leone, Wilson, & Mulcahy, 2010). This can be done, among other things, by giving students authentic tasks and dynamic tools (National Council for Curriculum and Assessment, 2003; National Council of Teachers of Mathematics, 2000), and, at the same time, by maintaining effective teaching (Ball, 2003), for example through questions. By authentic tasks we mean, tasks that are situated in meaningful contexts that reflect the way tasks might be found and approached in real life. In the present research, we tried to follow these principles by giving low-achieving students authentic activities related to equivalence relations. At the same time, the students worked with an applet suited for learning equations as equivalence relations; issues that have been indicated as critical to algebra (e.g., Stacey & Chick, 2004).

## Students' understanding of the equivalence relations

Mathematics education researchers have been interested in students' understanding of the equivalence relations (e.g., Kieran, 1981, 1992; Knuth, Alibali, Hattikudur, McNeil, & Stephens, 2008). Knuth et al. (2008) argue that the notion of equality is often complex, and thus difficult for students to perceive. Furthermore, Kieran (1992) considered the equivalence relations as a pre-requirement for understanding structural representations such as equations.

Knuth et al. (2008) examined middle school (grades 6-8) students' definition of the equal sign. They found that those students had three types of conceptions: a relational conception (when the student expressed the idea that the equal sign represented an equivalence relation between two quantities), operational conception (when the student expressed the idea that the equal sign meant "add the numbers" or "the answer"), and other conceptions; for example, when the student used the word

"equal" in the definition. Several researchers expressed the view that helping students acquire a relational conception of the equality sign would help them succeed in algebra and beyond (e.g., Hunter, 2007; Knuth et al., 2008). Generally, this concept, together with the related concepts, as equivalence and equation, are complex ones and difficult for students to understand (Hunter, 2007; Kieran, 1981).

### **A productive environment for students' learning of the equivalence relations**

Students' difficulties in understanding the equivalence relation could be lessened in a learning environment that includes authentic tasks (Taylor-Cox, 2003), technology (Jones & Pratt, 2006) and teacher's guidance. As to the use of technology to assist the learning of the equivalence relations, Jones and Pratt (2006) report an experiment in which two students connected an onscreen '=' object with other arithmetic objects, which supported them in developing relational conceptions of the equal sign. As to the use of authentic activities to assist the learning of the equivalence relation, Taylor-Cox (2003) describes the Pan Balance scales as a tool to demonstrate equality, where students need to use and make scales. As to the teacher's guidance as means to facilitate students' learning of the equivalence relation, researchers have indicated the importance of the teachers' role and guidance in learning mathematics in general (NCTM, 2000), and learning the equivalence relation in particular (e.g., Taylor-Cox, 2003). Taylor-Cox (2003) describes the mathematics teacher's role in enhancing students' learning, for example by asking questions that promote mathematical dialogue and understanding. The mathematics teacher's actions are part of the classroom routines (using Sfard's terms) that assist the students in their mathematics learning.

We designed the learning environment taking into consideration the role of technology, the role of the teacher, and the type of the tasks. To better understand the students' learning in this environment, we analyzed this learning using Sfard's commognitive approach. Especially, we concentrated on the evolution of routines' use. In the following section, we briefly outline the commognitive approach.

### **Routines in the mathematics classroom**

Sfard (2008) presents four components of the mathematical discourse that help analyze it: words, visual mediators, narratives and routines. *Mathematical words* are used by the participants in a mathematical discourse to express and communicate with the other participants about mathematical ideas. In this discourse, a student learns new uses of previously encountered mathematical words, but may also learn new mathematical words. *Visual mediators* are visual objects and means with which participants of mathematical discourses identify mathematical ideas. They include symbols such as numerals, algebraic letters, tables, graphs and diagrams. A *narrative* is a spoken or written text that describes objects, or relations between objects or activities with or by objects, and that could be accepted or rejected within the mathematical discourse. Mathematical examples of narratives could be theorems, definitions and equations.

Sfard (2008) defined *Routines* as "repetitive patterns characteristic of the given discourse" (p. 134). They characterize the use of mathematical words and visual mediators or the creation, substantiation or change of mathematical narratives. Examples on typical mathematical routines are methods of calculations and of proof (Sfard, 2008). She divides routines into explorations that aim to further discourse through producing or verifying endorsable narratives (as verifying a mathematical conjecture or proving a mathematical relation); deeds that aim to change the actual objects, physical

or discursive, not just the narratives; and rituals that aim to create and sustain social approval with other participants in the mathematical discourse. Furthermore, rituals could involve imitations of other participants' routines (Berger, 2013). Sfard further divided explorations into three types: construction that aims to create new endorsable narratives, substantiation that aims to decide whether to endorse previously created narratives, and recall that aim to summon narratives endorsed in the past.

Previous research has used the commognitive framework in different ways to examine the four components of the mathematical discourse, or just some of them (e.g., Berger, 2013; Viirman, 2012). Little research has been done on students' routines while learning the equality sentences as equivalence relations, where most of the research was done on students' word use or narratives related to these concepts. The present research intends to study the routines of low-achieving students while learning equations as an equivalence relations between quantities. The main research question is: what are the characteristics of low-achieving students' routines in the course of learning equations as an equivalence relations between quantities in a productive learning environment?

### The design of the study

To answer the research question we analyzed approximately three hours of learning by Noha and Maha, one pair<sup>1</sup> of 16-year-old low-achieving students in the math class taught by the third author.

The experiment took place in a school of low-achieving students who want to graduate as car mechanics or house/car electricians. The students volunteered to participate in four after-school meetings that aimed to teach the equations as an equivalence relations. In this study, we concentrated on the third meeting, which dealt with learning the equivalence between the two sides of an equation when performing arithmetic operation. The students who participated in this study had prior knowledge in operator precedence and the substitution of numeric values in algebraic expressions. They were not familiar with using technological software in learning mathematics. The two students shared a single computer, and the third author briefly introduced them to the functions of the software.

The students were video-recorded and their computer screens were captured. The video recording was performed with a computer program that captured the footage in two different windows; one for the computer screen and the other for the student's body. The third author conducted the learning activity. His main role was to ask clarification questions. The pair of students carried out four tasks presented in Figure 1.

#### Task 1

- Enter the expression  $6x$  in the red pan and 18 in the blue. What happened to the pans? Why?
- Change the slider until the pans have equal values. Why do the pans have equal value?
- Add the value 2 to the red pan. What happened and why? What should you do now to make the pans balanced?
- Subtract the value 2 from the red pan. What happened and why? What should you do now to make the pans balanced?

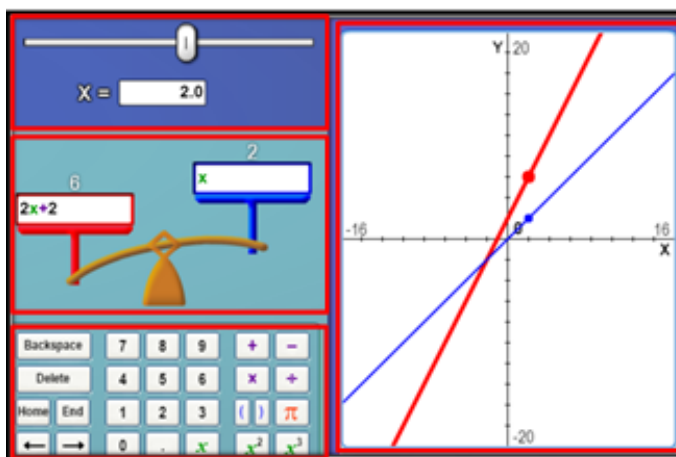

<sup>1</sup> For reasons of space, we decided to perform the micro-analysis of the learning process with one pair of students from the three pairs participating in the research project.

**Figure 1. Example of a task given to the students****The technological tool used in the experiment**

The technological tool used in our study is the interactive applet [Pan Balance Expressions](#) (PBE; NCTM, 2015; Fig. 2). The interactive applet PBE allows numeric or algebraic expressions to be entered and compared. Students can "weigh" the expressions they want to compare by entering them on either side of the balance. Using this interactive applet, students can investigate the equivalence of equation. PBE consists of four main windows: a) the slider window, which allows the student to vary the  $x$ - values; b) the pans window, which contains symbolic expressions entered by the users; c) the keyboard window, which enables the student to enter and edit expressions in the pans; d) the graphic window, which represents the graphs of the expressions entered in the pans.

**Data analysis**

To analyze the data, we categorized the routines, as suggested in Sfard (2008). We considered a routine to be an exploration when the student's goal, from performing the routine, was to arrive at a narrative. More specifically, we considered a routine to be an exploration of the type 'construction', when its goal was to arrive at a mathematical relationship. Moreover, we considered a routine to be an exploration of the type 'construction', its goal was to verify a relationship that was arrived at or conjectured. Other categories that we found are: teacher's request (when the teacher requested the students to do an action), and students' actions with the applet (when the students worked with the applet for different reasons).

**Results****Figure. 2: The interface of the Pan Balance applet**

The pair of low-achieving students worked with three groups of narratives; (a) Solving the equation  $Ax=B$  using the applet; (b) constructing the equivalence equations resulting from performing the same allowed operation on both sides of the equation; (c) solving linear equations using the equivalence principle. In the present paper, we will present students' routines related to constructing the equivalence concept resulting from performing the same allowed operation on both sides of the equation.

Transcript 1 describes the pair of students' work while adding the same number to both sides of an equation. At this phase, the expression  $6x$  was in the red pan and 18 in the blue one. The slider was at  $x=3$ , which mean the pans were in balance.

- 25 T: Add the number two to the blue pan  
 26 N: (*she added two to the blue pan causing the red pan to rise*)  
 27 T: What did you see?  
 28 N: Eighteen plus two  
 29 T: What happened?  
 30 M: It rose.  
 31 N: It is not equal; the red pan rose and the blue fell.  
 32 T: Why did this occur?  
 33 M: (*Looking at the Pan Balance*) Because we added the number two to the blue pan. They are not balanced; one pan is higher than the other.  
 34 T: Could they balance now?  
 35 M: (*adds 2 to the red pan*)  
 36 M: Yes, if we added the number two to the red pan.  
 37 N: Yes they are balanced now.  
 38 T: Why are they balanced now?  
 39 N: Previously there were 18 on both sides. Thereafter, we added two to the blue pan. It totaled 20. Now I added two to the  $6x$  and it also totaled 20. It is now equal.

### Transcript 1: Adding the same number to the two sides of an equation

This transcript illustrates the pair of students' routines, which led to the endorsement of the narrative "*Yes, if we added the number two to the red pan*" [36]. Students' routines started with a teacher's request [26] with an overall intention to allow the student to construct a narrative related to adding a number to an equation. The students got engaged in actions with the applet [26]. The teacher then started a construction routine, with the intention to make the students aware of the effect of adding a number on one pan [27-31]. Then the teacher started a routine of substantiation [32-33]. It can be seen that the students' exploration constituted of the following sequence of routines: teacher's request, students' actions with the applet, students' construction of a narrative, teacher's questioning, and students' substantiation of the narrative. The pair of students performed again the same sequence of routines to explore how to make the two pans equal: teacher's request [34], students' actions with the applet [35], students' construction of a narrative [36-37], teacher's question [38] and students' substantiation of the narrative [39].

In their exploration of the narrative related to subtracting a number from the two sides of an equation, the pair of students needed just one sequence of routines. Moreover, in their exploration of the narrative related to multiplying the two sides of an equation by the same number, the pair of students skipped performing actions with the applet to construct the narrative. However, and as transcript 2 shows, they performed these actions with the applet to substantiate the narrative about the equivalence of an equation under multiplication.

- 86 T: What would happen if you multiplied the expressions in the pans by the same number?
- 87 N: When multiplying, the balance of the two pans would remain unchanged.
- 88 N: [*she inserted the expression  $6x$  on one pan and 18 on the other; thereafter she fixed  $x=3$  to balance the pans*].
- 89 N: I will multiply both sides by 2.
- 90 N: [*She multiplied both sides by 2*].
- 91 N: I got it right.

### Transcript 2: Multiplying the two sides of an equation by the same number

This transcript illustrates a modified sequence of routines: teacher's request [86], conjecture (as a part of a construction) [87], actions with the applet [88], substantiation [89-91].

The data analysis revealed some characteristics of students' routines. First, routines started with a teacher's request or questioning. It seems that one of the teacher's routines in the low-achieving classroom was to start the learning process by requesting the students to act or to answer. Second, the pair of students followed a sequence of routines to arrive at each of the narratives. This sequence consisted of teacher's request, students' actions with the applet, constructing a narrative, and substantiating it. This sequence of routines was not kept as is for every narrative, but a variation of it was followed. Third, students' actions with the applet, what we could call *deed routines*, supported the low-achieving students in their exploration routines, whether they were constructions or substantiations. Fourth, the data analysis revealed a pattern of evolution of the routines associated with the successive narratives, where the number of routines needed for the students to endorse narratives was decreased for each group of narratives.

### Discussion

The goal of the present research was to examine the routines of a pair of low-achieving students, while learning the equivalence relations in a productive learning environment. The students worked with the Pan Balance, which illustrate the equation concept. Working with it, they actually worked with visual mediator which signifying the mathematical objects and relations (Sfard, 2008, p. 224). Moreover, the students' routines regard using the visual mediator were visual and dynamic, where they could scan the Pan Balance and manipulate it, and consequently watch the effects of this manipulation on the equivalence relations. It could be claimed that these visual and dynamic routines helped the low-achieving pair of students to signify the equivalence relation through construction and substantiation routines. Furthermore, the applet constituted for the pair of low-achieving students a prompt for construction and substantiation routines.

It was observed that the pair of low-achieving students used a sequence of routines: teacher's request, students' actions with the applet, students' construction of a narrative, teacher's questioning and students' substantiation of the narrative. Moreover, students' use of the sequence of routines satisfied the variability and flexibility principles (Felton & Nathan, 2009; Sfard, 2008, pp. 202-205), i.e. the students varied their use of the sequence to meet their needs. This happened for example, when they engaged with multiplying the two sides of an equation by the same number. Constructing the appropriate equivalence narrative, they skipped performing actions with the applet, but performed these actions to substantiate the narrative.

The sequence of routines described above shows the effect of the teacher's routines and of technology affordances on students' routines. It seems that the teacher's initiation of students' construction and substantiation routines was a prompt for them to follow routines that supported their successful construction of equivalence narratives. As for the technology affordances, the Pan Balance applet allowed the pair of low-achieving students to perform actions that supported them in their construction and substantiation of the equivalence narratives (e.g., scanning the equilibrium of the Pan Balance). Moreover, we argue regarding the pair of students' substantiation routines, that they relied on empirical argument that utilized the "concrete realizations of the focal signifiers and relies on their perceptually accessible features" (Sfard, 2008, p.233). This type of substantiation is probably expected of low-achieving students.

The present research reports the routines of one pair of low-achieving students. It shows that a productive learning environment that combines teacher's initiation and questioning, technology and authentic tasks will support these students' routines for arriving at mathematical narratives. Research that engages more low-achieving students' is needed to confirm this research findings regarding their routines in similar environments.

# Students' reasoning on linear transformations in a DGS: A semiotic perspective

Melih Turgut

Eskisehir Osmangazi University, Eskisehir, Turkey; [mturgut@ogu.edu.tr](mailto:mturgut@ogu.edu.tr)

*The aim of this paper is to analyze students' reasoning on linear transformations while using a Dynamic Geometry System (DGS) from a semiotic mediation perspective. Considering design heuristics of Realistic Mathematics Education and the semiotic potential of certain tools and functions of DGS, I have developed a hypothetical learning trajectory and have designed a task for inventing fundamental properties of linear transformations. The task was field-tested in a case study with pair of undergraduate linear algebra students. An analysis of the task-based interviews, with a semiotic mediation lens, shows that the students managed to (re-)invent the fundamental properties of linear transformations.*

**Keywords:** *Semiotic mediation, linear algebra, DGS.*

## Introduction

One major issue in the teaching and learning of linear algebra is providing students with ready-made mathematics using different representations and different contexts (Dorier, 1998) without considering the students' intellectual needs for learning (Harel, 1998). An example might be to introduce the notion of linear transformations with two fundamental properties as in numerous textbooks, where such introduction to the topic could trigger epistemological issues for students' conceptualization of non-linear transformations (Dreyfus, Hillel, & Sierpinska, 1998). In this paper, I acknowledge a contrary introduction to the topic and consider a research question: Is it possible for students to (re-)invent fundamental properties of linear transformations? To answer this question, I consider a dynamic geometry system (DGS), which invite students into a progressive process of epistemic exploring, conjecturing and generalizing (Leung, Baccaglini-Frank, & Mariotti, 2013). Consequently, I focus on specific tools and functions of GeoGebra, such as dragging and grid functions, ApplyMatrix command and slider tool of the DGS as a tool of semiotic mediation for students' reinvention of proposed mathematics.

## Theoretical Perspectives

In this work, I consider two theoretical insights: (i) Realistic Mathematics Education and (ii) Theory of Semiotic Mediation, for designing instructional activity and analyzing the teaching-learning process.

### Realistic Mathematics Education (RME)

RME is a domain-specific instructional theory developed by Dutch researchers (Van den Heuvel-Panhuizen & Drijvers, 2014). The word *realistic*, here, does not directly refer to real-world task situations, but to paradigmatic situations that invite the development of meaningful mathematics. The problem situations do not necessarily come from real life directly, they can be related to an imaginary world or to real mathematics that students experience as meaningful: task situations have to be *experientially real* (Gravemeijer, 1999) to students. In parallel to such views, RME offers three interacting design heuristics for curriculum developers and educational designers

(Freudenthal, 1983; Gravemeijer, 1999; Van den Heuvel-Panhuizen & Drijvers, 2014): guided reinvention, didactic phenomenology, and emergent modelling. Guided reinvention means providing students with an environment for their exploration, elaboration and inventing of mathematics. Didactic phenomenology refers to finding certain experientially real phenomena, which might form an environment where students create mathematics. The objective of emergent modelling is to enable students to shift from informal task situations to formal mathematics through support, enabling them to create their own informal mathematics.

### Theory of Semiotic Mediation (TSM)

TSM was presented by Bartolini Bussi and Mariotti (2008) with the following main idea: to construct mathematical meanings, the teacher intentionally uses *artefacts* as a tool of semiotic mediation, which are used in carefully-designed tasks. The aim of the TSM is to transform students' personal meanings to mathematical meanings. The teacher exploits the *semiotic potential* of the artefact, in which he or she uses an epistemological and didactical analysis to picture out possible learning steps from personal meanings to shared conventional mathematical meanings. Here, taking into account the didactic goals, the teacher considers what students know, what their experience with the artefact is and how they will accomplish the task by using the artefact. As a next step, the teacher designs a *didactic cycle* for classroom interventions.

Students' interaction with the artefact produces a complex semiotic process. Artefact signs (aS) appear when students who use the artefact relate in some way to the activity; specifically, to the use of artefact. Mathematical signs (mS) appear, when the students make a definition, conjecture, generalization or proof corresponding to didactic goals. Pivot signs (pS) have an interpretative link between personal meanings and mathematical signs and can appear in the accomplishment of the task. In the application of the didactic cycles, the teacher's role is orchestrating students' learning.

### Methodology

This paper, in which I focus and present the results of a single task, is part of an extensive Design-Based Research (project) (Bakker & van Eerde, 2015). Due to page limitation, I will present a case limited to a pair of students (A male, B female), who were sophomore level undergraduate linear algebra students, aged twenty. The students had experience solving linear equations, matrix algebra, (geometric) vector spaces and subspaces, and they had learned that every linear transformation can be represented through matrices. They also had experience in the use of GeoGebra's main functions, specifically forming a slider and a matrix, and applying the ApplyMatrix construction tool from previous task sequences, where they constructed meaning of a transformation and linear transformation. However, the students did not know the fundamental properties of linear transformations. Task-based interviews were video-recorded and lasted around half an hour. The data was analyzed through a semiotic lens using categories of signs (Bartolini Bussi & Mariotti, 2008): aS, mS and pS.

### Mathematical context, semiotic potential of DGS and task design

A linear transformation is a specific transformation between  $V$  and  $W$  can be represented as  $T:V \rightarrow W$  for vector spaces  $V$  and  $W$ , where  $T$  satisfies: (i)  $T(\mathbf{u} + \mathbf{v}) = T(\mathbf{u}) + T(\mathbf{v})$  for all vectors  $\mathbf{u}, \mathbf{v} \in V$ , and (ii)  $T(k\mathbf{u}) = kT(\mathbf{u})$  for all  $\mathbf{u} \in V$  and all scalars  $k \in \mathbf{R}$  (Lay, 2006). Here, I

took  $V = W = \mathbf{R}^2$  because of DGS availability (for example as in GeoGebra) and considered the semiotic potential of the following tools and functions of DGS for students' (re-)invention of the fundamental properties above: (i) the *dragging* function allows the user to manipulate figures and explore independency–dependency of drawings and constructed objects, (ii) the *grid* function activates specific lines for integer values on the  $x$  and  $y$  axes and this function enables the user to observe variations of the coordinates of the objects in different windows, (iii) the *slider* tool offers a means to define a parameter and this may evoke meaning for dynamic (co)variation (Turgut & Drijvers, 2016), (iv) the *ApplyMatrix* tool works through an input line that enables the user to apply certain matrix transformations to geometric figures. I postulate that students' dragging sliders connected to a matrix and applying matrix transformations to arbitrary vectors could provide an understanding for a meaning: matrix (and therefore linear) transformations preserve vector addition and scalar multiplication.

The synergy between the definitions of guided reinvention and didactic phenomenology heuristics and the notion of semiotic potential in TSM implies the construction of a possible learning route, in other words, a Hypothetical Learning Trajectory (HLT) (Simon, 1995) which has to be elaborated on by the designer before the experiment by following four points (Bakker & van Eerde, 2015): (i) learning goals, (ii) students' pre-knowledge, (iii) assumptions for students' learning, and (iv) the teacher's role (also in our case, the role of artefacts). Therefore, in Table 1, I express (i), (ii) and (iii) points of a HLT for invention of fundamental properties of linear transformations in a DGS.

Associated Concepts	Expected Steps in the DGS	Exemplary Task	Epistemic Artefacts in DGS	Expected Mathematical Meanings
<ul style="list-style-type: none"> <li>–Geometric vectors</li> <li>–Addition of vectors</li> <li>–Multiplication with scalars</li> <li>–Matrix transformations</li> <li>–Fundamental properties of linear transformations</li> </ul>	<ul style="list-style-type: none"> <li>–Exploring the effects of sliders on (arbitrary) linear transformations of arbitrary vectors</li> <li>–Comparing the initial and final versions of vectors while moving sliders or dragging the objects</li> </ul>	<ul style="list-style-type: none"> <li>–Form sliders</li> <li>–Construct <math>2 \times 2</math> matrix</li> <li>–Form arbitrary vectors</li> <li>–Use Apply Matrix command</li> <li>–Move the sliders and drag the objects</li> </ul>	<ul style="list-style-type: none"> <li>–Dragging</li> <li>–Grid function</li> <li>–Apply Matrix construction tool</li> <li>–Slider tool</li> </ul>	<ul style="list-style-type: none"> <li>–Comprehending that the situation is independent from matrix entries or vectors</li> <li>–Formulating the first rule situation, <math>T(\mathbf{u}+\mathbf{v})=T(\mathbf{u})+T(\mathbf{v})</math></li> <li>–Formulating the second <math>T(k\mathbf{u})=kT(\mathbf{u})</math></li> <li>–Proving such results in terms of matrix representations</li> </ul>

**Table 1: HLT for the inventing of fundamental rules for linear transformations**

As aforementioned before, students worked on GeoGebra interface in the previous didactic cycles, which were about transformation of geometric vectors, figures, and constructing meaning for linear transformation. Consequently, the tools and functions of GeoGebra and proposed concepts were experientially real for them. Following Table 1 and considering guided reinvention heuristic, the task was formulated as follows (a possible interface for the task steps is presented in Figure 1), and also for students' making their own models (cf. emergent modeling).

*Step 1:* Open GeoGebra and activate grid function. Next, form two sliders  $a$  and  $b$  and, using  $a$  and  $b$ , form an arbitrary  $2 \times 2$  matrix. *Step 2:* Form two arbitrary vectors  $\mathbf{u}, \mathbf{v}$  and construct  $\mathbf{u} + \mathbf{v}$

through an Input line. *Step 3:* Apply matrix transformation to  $\mathbf{u}$ ,  $\mathbf{v}$  and  $\mathbf{u} + \mathbf{v}$ . Name these vectors, respectively:  $\mathbf{u}'$ ,  $\mathbf{v}'$  and  $\mathbf{w}$  respectively, and then calculate  $\mathbf{u}' + \mathbf{v}'$ . Move the sliders and drag  $\mathbf{u}$  and  $\mathbf{v}$  in itself. Discuss with your pair and explain your observations. *Step 4:* Form a new slider  $k$ . Now, obtain matrix transformation of  $k\mathbf{u}$  and also compute  $k\mathbf{u}'$ . Drag the vector  $\mathbf{u}$  and explain your observations, and make conjectures. What happens when you move the sliders?

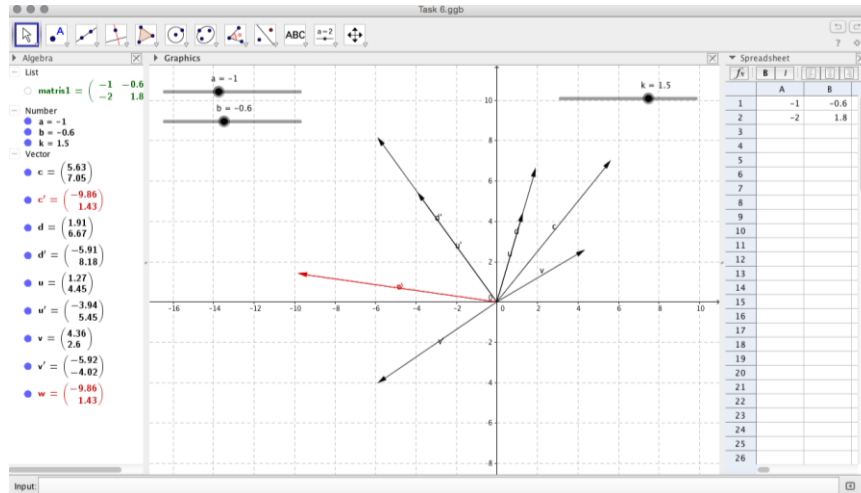

Figure 1: An expected DGS interface for the task

Teacher's (possible) underpinning questions in the interview are: *What is the role of sliders here? What is the role of the matrix? What are the relationships between initial vectors and transformations? How do you prove this?* [In case they make a generalization with matrix notation]. Within this task, I hypothesized that students would observe that the transformation of  $\mathbf{u} + \mathbf{v}$ , denoted by  $T(\mathbf{u} + \mathbf{v})$ , always overlaps on the  $T(\mathbf{u}) + T(\mathbf{v})$  vector and similarly,  $T(k\mathbf{u})$  also always overlaps on  $kT(\mathbf{u})$  vector, where situations were independent from the choice of matrix and/or choice of vector. This could be made possible through the semiotic potential of the aforementioned functions and tools of DGS and teacher's (T) guidance role for reinvention of the mathematics.

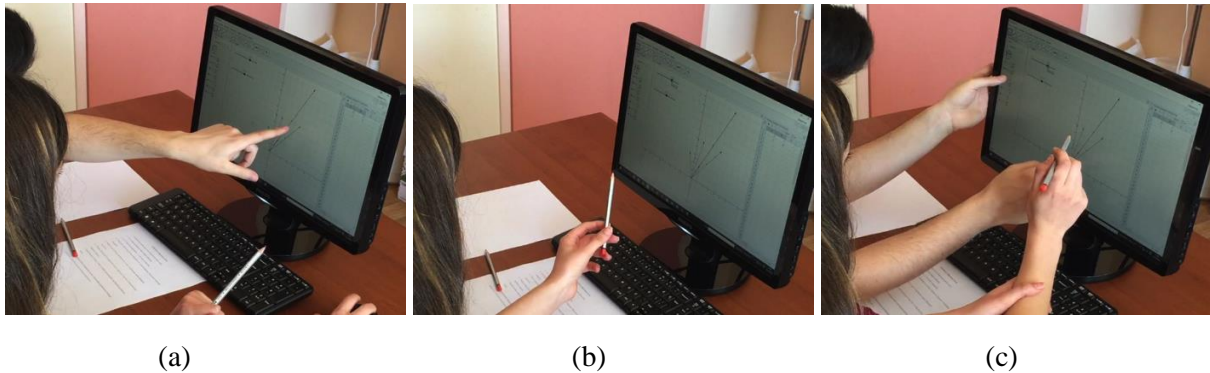

### Analysis: Emergence of signs

Students followed the line of the task. First they constructed two sliders,  $a$  and  $b$ . Next, using such values in the spreadsheet window of Figure 1, they defined a  $2 \times 2$  matrix as  $\mathbf{A} = \begin{pmatrix} a & b \\ b & a \end{pmatrix}$ . Through the Input line, they formed two vectors  $\mathbf{u} = (1, 2)$  and  $\mathbf{v} = (-1, 3)$ . They first obtained the sum of the vectors and thereafter applied matrix transformation by the ApplyMatrix command. The software assigned  $\mathbf{u}'$  for  $T(\mathbf{u})$ , similarly,  $\mathbf{v}'$  for  $T(\mathbf{v})$ , and  $\mathbf{u} + \mathbf{v} = \mathbf{w}$  and  $\mathbf{u}' + \mathbf{v}' = \mathbf{d}$ . For a while, the students discussed the steps of the task to determine which matrix application is the first, the second or the third, which seemed rather confusing for them. After they had completed the three steps, while dragging the sliders, they were surprised because a number of vectors and some transformation vectors overlapped. At this moment a few aS appeared (see 18–20):

- 18 A: ... [pointing on the grid (see Figure 2a)] look, how this happened, these are overlapping...
- 19 B: No. I think, it is because of matrix, look, [dragging sliders and pointing matrix entries with pencil (see Figure 2b)] it is changing.

- 20 A: Let's analyze them, which is which and why overlaps... [*They are trying to separate the vectors (see Figure 2c) and taking notes*]

**Figure 2: a, b, c Emergence of aS during analyzing the overlapping situation**

Next, the teacher intervened to make the students focus on the transformations of the vectors, because they had spent a lot of time dragging sliders, changing matrix entries (i.e., trying a unit or zero matrix and so on) to figure out why some overlapped (see Figure 3a). Then students re-checked the steps and wrote up the findings in their own way. Some pS appeared here, reflecting the students' new meanings through the semiotic potential of the artefact (37–38), and also appeared on the students' productions (Figure 3b).

- 26 T: ... what about the transformations of vectors? What did you observe?
- ...
- 37 B: ... I think we will find a relationship between these [*pointing on the notes (see Figure 3b)*]. Here, we have the sum vector's transformation and sum of each vector's transformation.
- 38 A: However, this could be dependent on the choice of matrix? What will happen for the matrices where their determinants are zero? ...

$$\begin{bmatrix} a & a \\ a & a \end{bmatrix} \Rightarrow \det = 0 \text{ iken}$$

$$\begin{bmatrix} a & b \\ b & a \end{bmatrix} \Rightarrow a = b \text{ iken}$$

(a)

$$\begin{matrix} f(u) + f(v) = d \\ \downarrow \quad \downarrow \\ u + v = w \end{matrix} \xrightarrow{\text{don't know}} w'$$

(b)

**Figure 3: a, b Students' productions as pS**

Interestingly, once more, they focused on the entries of the matrix, because in the previous step they had employed a unit or a zero matrix, and they began to check other possibilities for the cause of the overlapping situation. Consequently B figured 'they always overlap'. Here, aS 'overlaps' in the previous analyses, and can now be considered a pS (see 63, 86), because it is mediating the transformation of personal meanings to mathematical meanings.

- 63 B: It is clear that they always overlap ... Why is this happening?
- 64 A: Exactly... but why?
- ...

86 B: **d** and **w'** always overlap and they are the same. I could not analyze the others.

87 A: ... because of matrix transformation, I think.

As a next step, aS and pS interlaced with the students' personal meanings associated with matrix transformations. They re-analyzed their findings, and finally, mS corresponding to students' reinvention of the fundamental properties appeared (93-97).

93 B: Just a second. What was the meaning of **w'**? It was a transformation of **u + v**? ... [moving sliders and thinking]...

94 A: We also applied matrix transformation to **u + v**?

95 B: Because, they are overlapping, this means, we have obtained the same vector. ... Does transformation of the sum vector [meaning **u + v**] equals the sum of the separate transformations?

96 A: Absolutely, right. ...

97 B: ... [First, she is writing her conclusion, but not mathematically (see Figure 4a), then she is trying to write it mathematically with her partner's help (see Figure 4b)] ...

2 ayrı vektörün toplamının dönüşümü ile  
Vektörlerin ayrı ayrı dönüşümlerini topladığımızda  
aynı vektör çıkıyor.

(a)

(b)

**Figure 4: a, b Students' conclusions for the first fundamental property as mS**

Next, while trying to express the situation mathematically, which was under the teacher's orchestration, the students reinvented the first fundamental property (see Figure 5a). However, the teacher was orienting students to prove their result considering their pre-knowledge on representing linear transformations with matrices. Student B immediately related the situation with her pre-knowledge and proved her conclusion (119 and Figure 5b).

114 T: Ok right. Please remember the matrix representations of linear transformations. Considering this, how do you prove your result?

...

119 B: ... [She is writing matrix representations (see Figure 5b), then explains], yes ... I now realize why this is happening. We can show every linear transformation with a matrix and matrix algebra has distribution property. Then I can do like this [writing expressions in Figure 5b]...

$$\begin{aligned}
 u' + v' &= d, \quad f(u) + f(v) = d \\
 w' &= d \\
 f(u) + f(v) &\longrightarrow w' \\
 f(u+v) &= w' \\
 f(u) + f(v) &= f(u+v)
 \end{aligned}$$

(a)

$$\begin{aligned}
 A \cdot \vec{u} + A \cdot \vec{v} &= A(\vec{u} + \vec{v}) \\
 A(\vec{u} + \vec{v}) &= A\vec{u} + A\vec{v} \text{ or } d. \\
 f(u+v) &= f(u) + f(v) \text{ dir.}
 \end{aligned}$$

(b)

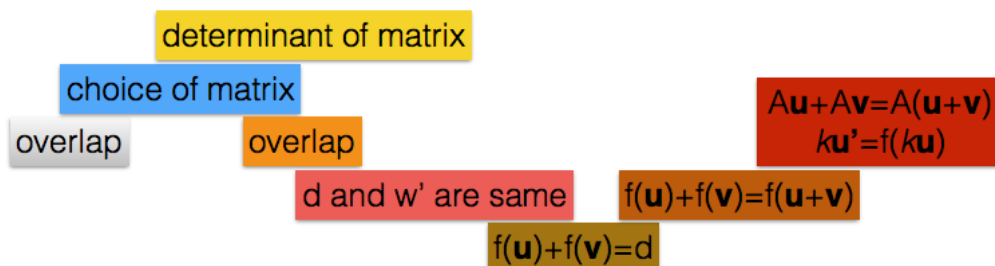

**Figure 5: a, b Emergence of mS in relation to the task's goal**

As a final step, the teacher asked the students to consider Step 4. As expected they placed a slider for  $k$ , and applied a matrix transformation to  $k\mathbf{u}$  and also computed vector  $k\mathbf{u}'$ . As soon as one student saw that the transformation of  $k\mathbf{u}$  and  $k\mathbf{u}'$  overlapped and were exactly the same, by the help of the first property she invented, B expressed her views. The final mS emerged in the discourse (129).

- 129 B: ... Oh yes, I think this is obvious; this is also a result of property of matrix algebra. For a matrix,  $k$  can be multiplied with each entry of a matrix or it can be expressed a factor [writing  $k\mathbf{u}' = f(k\mathbf{u})$ ]. Therefore, their [meaning  $k\mathbf{u}$  and  $k\mathbf{u}'$ ] transformations are the same.

## Conclusions

In this paper, I consider the research question, ‘Is it possible for students to (re-)invent fundamental properties of linear transformations?’ Students work on the task formed through the design heuristics of RME and the semiotic potential of some tools and functions of GeoGebra provide an affirmative answer, but with some doubts and limitations. For instance, the students spent much time determining vectors when they overlapped. This issue to be considered is the students’ frequent analysis of matrix entries, where they think that an overlapping situation depended on this. I think that such frequent analysis of matrix entries stems from previous experience, where the students were continually trying to find matrices of linear transformations. Interestingly, in the students’ analyses for characterizing the matrix, different semiotic resources beyond aS, pS and mS appeared; for instance, gestures and mimics attached to students’ analyses process. A multimodal perspective (Arzarello, 2006) could provide a detailed view for our case. However, in the present case within a TSM perspective, I observe a semiotic chain (Bartolini Bussi & Mariotti, 2008), which shows the connection between semiotic resources of students’ learning, for inventing fundamental properties of linear transformations as follows (Figure 6).

**Figure 6: A semiotic chain for inventing fundamental properties**

## Acknowledgment

This paper is part of an on-going post-doctoral project, which is supported by the Scientific and Technological Research Council of Turkey (TUBITAK), under 2219-International Post-Doctoral Research Fellowship Programme. I would like to thank my supervisor Paul Drijvers for his kind contributions to the paper and also thank TWG16 reviewers for making constructive comments.

# Research on the language barriers of students who use Khan Academy as a mathematics homework platform

Jiří Vančura

Charles University, Faculty of Mathematics and Physics, Czech Republic; [jivancura@gmail.com](mailto:jivancura@gmail.com)

*Homework is a routine practice in maths classes, and research has shown that the immediate feedback and acknowledgement of effort is important for students. Unfortunately, the traditional classroom setting does not allow for this degree of feedback. Khan Academy offers a free tool that allows teachers to monitor students' activity and provide them with feedback and guidance. In this study, we investigated one Czech high school's use of Khan Academy as a homework platform, focusing specifically on language barriers and their impact on the ability of non-native English-speaking students to benefit from Khan Academy. We found that students who faced a lower language barrier were able to make better use of Khan Academy's educational resources. Surprisingly, we also found that a reported language barrier does not significantly correlate with a student's English grades.*

*Keywords: Homework, online assessment, language barrier, electronic resources.*

## Introduction

Every student does maths homework during his or her high school studies. I remember doing most of mine on the way to school or during the break before my maths classes. At the beginning of each maths class, my teacher would walk around the classroom, checking some notebooks randomly to see if there was anything that looked like homework. Since I really enjoyed maths, I did most of my maths homework by myself and then lent it to others to copy. We did not receive much feedback on our homework, so it was no wonder that many students were not very motivated to do their homework on their own. Unfortunately, maths teachers in large classes did not have much of a choice back then. Today, however, new online technologies, such as Khan Academy (KA), offer individualisation, guidance and immediate feedback for students, as well as a great amount of data about student activity for teachers (Khan Academy, 2016a).

The Khan Academy (KA) is a non-profit organisation that runs the website [www.khanacademy.org](http://www.khanacademy.org). Since 2008, it has undergone a great deal of development. What started as a list of instructional maths videos has developed into a network of vast educational resources, including interactive exercises covering mathematics, the natural sciences and more, from the elementary to the undergraduate level. Thanks to generous donors, KA is able to provide all of its content for free, and it probably will not be cancelled or monetised any time soon. At the moment, KA's exercises and most of its educational videos are offered in English only, as is the case with many other online resources. We therefore decided to investigate the effects of language barriers on the preferences and attitudes towards KA of students who practise maths using KA exercises.

## Theory

### Homework and feedback

Homework assignments are routine in most mathematics classes, including those in high schools in the Czech Republic. There is a great deal of evidence suggesting that monitoring students' work and acknowledging their efforts is very important for students, as it increases the effort they put into their homework (Strandberg, 2013). When teachers do not grade a homework assignment and return it promptly, students report feeling like they have wasted their time on this activity (Strandberg, 2013; Wilson & Rhodes, 2010). Students need to believe that their homework is meaningful and that teachers value their efforts (Bempechat, Neier, Gillis & Holloway, 2011).

When it comes to feedback, there are still important gaps in our understanding (Shue, 2008). There is some evidence suggesting that when a task requires material or procedural understanding and analytical problem solving (e.g. mathematics), providing hints and allowing multiple attempts may lead to a greater increase in student performance than simply revealing the correct solutions (Clarina & Koul, 2003; Attali, 2015).

Students benefit greatly from timely and meaningful homework feedback. Unfortunately, it is often beyond a teacher's capacity to provide this to every student in a traditional classroom setting. However, technology might be able to help teachers with this. Moreover, technology can prevent misunderstandings between students, teachers and parents about the amount of time students spend on homework, as accurately estimating this can be difficult for teachers in the traditional classroom setting (Strandberg, 2013).

### Language barriers

We did not find many recent studies investigating English language barriers in terms of learning mathematics or learning in general. There have been some studies that have investigated non-native English-speaking students in an English-speaking environment, both at the high school (Adams, Jessup, Criswell, & Weaver-High, 2015) and university (Variawa & McCahan, 2012) levels. However, these are not very relevant to our investigation, as they study foreign students in English-speaking communities and focus on different subjects (e.g. chemistry, engineering).

For the purposes of this study, we define a language barrier as English language difficulties, as perceived by students when interacting with the Khan Academy website.

### Khan Academy

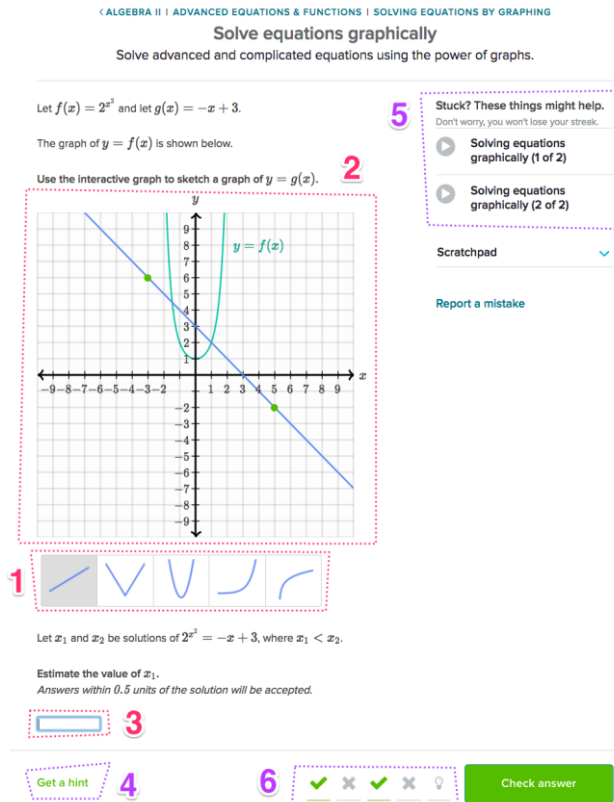

KA has been providing interactive exercises for only a few years, so it has not yet been heavily researched. However, videos have been used for educational purposes for decades. Two recent studies have investigated data from several Massive Open Online Courses to determine the attributes of the more engaging videos (Guo, Kim, & Rubin, 2014; Kim et al., 2014). In our previous study, we concluded that KA's videos align well with most of the aforementioned recommendations (Vančura, in press). Our investigation into the possible impact of KA as a homework platform on student attitudes towards mathematics demonstrated that negative impacts are very unlikely (ibid).

A large study was also conducted concerning the implementation of KA in U.S. classrooms (Murphy, Gallagher, Krumm, Mislevy & Hafter, 2014). The results revealed that only 45% of

American students reported being able to learn new skills using KA without teacher assistance. We found similar results (46%) in our previous study (Vančura, in press).

## Context

In this study, student participants were assigned homework on a weekly basis in the form of KA's interactive exercises.

**Figure 1: Interactive exercise (Khan Academy, 2016b)**

Every exercise consists of a series of problems related to very specific topics. In the exercise shown in Figure 1, students are asked to practise estimating equation solutions using graphs. Specifically, students are required to select the shape of the graph for function  $g$  [1]; to graph the function  $g$  using the interactive graphing tool [2]; and to estimate the lower solution of equation  $f(x) = g(x)$ , where function  $f$  is given by the graph. Students cannot move on to the next problem until they solve the exercise correctly. If they cannot solve the problem, there are hints [4] that demonstrate step-by-step solutions. Even after the whole solution is revealed, students are still required to graph the function  $g$  and estimate the solution correctly. Only then can they continue on to the next problem. Students can also watch instructional videos that explain the solutions to a sample problem in detail [5]. Each student's progress is captured and displayed at the bottom of the screen [6]. Students receive a check mark for solving the problem correctly on the first try without any hints. They get an x mark for entering the wrong solution and a light bulb icon for solving the problem correctly on the first try with some hints.

In order for students to successfully finish an exercise, they must get five (or sometimes three) check marks in a row (i.e. solve five problems on the first try without any hints). This multiple-try

mechanism aligns well with the findings on feedback (Attali, 2015). However, this feedback does not tell students where they have made their mistakes, and it usually provides only one way to solve a problem. Some exercises consist of multiple-choice answers, and students might be tempted to guess the solutions—although the requirement of solving five problems in a row makes guessing time consuming. For example, even if students were able to narrow the choices down to two, they would still need to answer 62 questions on average in order to get 5 in a row correct. If students guessed blindly from 4 choices, they would need to answer 458 questions on average.

Another important tool that KA offers is the teacher dashboard, which allows teachers to monitor student activity. Teachers can see when students work on exercises, which exercises they work on and how well they solve the problems. Teachers can even see the amount of time students spend on each problem, as well as the total time they spend on KA. This data allows teachers to monitor, acknowledge and assess students' homework objectively and meaningfully. Moreover, in our study, these attributes allowed teachers to grade homework on a weekly basis.

Based on the results of one SRI study (Murphy et al., 2014), student participants were not required to learn new skills on KA; rather, they had to practise skills they had already acquired.

## **Methodology**

### **Research questions**

1. Does a student's language barrier influence whether he or she prefers KA homework over homework from traditional textbooks?
2. How does the language barrier influence students' attitudes towards KA and their ability to learn maths while using it?

As the research progressed, we saw that language barriers did play an important role, which made us add a third question of interest:

3. Can the language barriers of individual students be easily and reliably estimated (i.e. by asking the student's English teacher)?

### **Data collection**

We developed two surveys based on the surveys used in the SRI study (SRI, 2015), although we added some questions about English language usage and omitted some questions that were irrelevant to our investigation. The first survey was administered in December 2015, and the second was administered in June 2016. Both surveys contained several pairs of verification questions to detect inconsistencies or carelessly filled-out surveys. To measure the language barrier, we used Likert-scale questions, such as, "My limited English knowledge prevents me from using Khan Academy effectively." To measure the preference for the KA homework platform, we used Likert-scale questions, such as, "I prefer to solve examples from common textbooks rather than from Khan Academy." Surveys were administered during an ordinary maths class so that the students had no reason to hurry. We also collected students' midterm and final grades in mathematics and English for the 2015–2016 school year.

At the beginning of September 2016, we asked the students' English teachers to estimate the reading and listening abilities of the participating students, as well as the effects of the students'

language barriers when using English mathematical software. The teachers were asked to use the Common European Framework of Reference for Languages (A1–C2) for their estimations (Council of Europe, 2016), which were then recoded on a scale of 1–6.

### **Participants and criteria of analysis**

The first survey was administered to 141 non-native English-speaking students aged from 15 to 20 years old from 7 maths classes in 2 Prague high schools. For the second survey, the participants included 83 students from 5 out of the 7 classes that participated in the first survey. All of the students were learning English as their second or third language. A total of 64 students participated in both surveys. The students in our study were taught by six different English teachers, who were asked to estimate the students' language barriers. The author of this paper was the maths teacher for two of the seven classes. Therefore, we looked for relative patterns (i.e. connections between the students' language barriers and their learning independence) rather than for absolute results. When investigating absolute results, such as student preference for KA over traditional textbooks, we also considered the differences between the students who were taught by the researcher and those who were not.

To measure the language barriers, we required Cronbach's alpha to be greater than 0.7, which is generally considered to be an acceptable level of consistency. When it came to correlations and hypothesis testing, we used the 5% significance level.

### **Results**

In the first survey, students reported a strong preference for KA over traditional textbooks (Vančura, in press). This preference decreased significantly in the second survey, although KA was still preferred. In both surveys, the students who were taught by the researcher did not report a stronger preference for KA than the other students. Students' preference for KA was significantly correlated with reported language barriers (see Figure 2). Students with greater language barriers tended to prefer KA less. Even so, students who reported significant difficulties with English preferred KA over traditional textbooks.

Both surveys revealed a significant connection between the students' reported language barriers and several other factors. In both surveys, students with lower language barriers

- a. found KA videos and exercises to be more helpful for them (correlations 0.18–0.45);
- b. reported higher autonomy when learning new skills using KA (0.17–0.28); and
- c. reported a more adequate understanding of their skills while working in KA (0.22–0.29).

The reported levels of language barriers decreased slightly between the two surveys, but this decrease was not statistically significant. Surprisingly, the reported language barriers did not significantly correlate (-0.02, 0.14) with the English grades. We assumed that different teachers would have different grading strategies and standards, so we normalised the English grades within the groups of students taught by each teacher. The resulting correlation increased slightly to 0.16, which is still insignificant in our case. We also calculated the correlation between English grades and the decrease of language barriers between the two surveys; again, the correlation was insignificant (0.02).

**Figure 2: Student preference for the KA homework platform by language barrier in the first survey**

Driven by these results, we asked the English teachers to evaluate the students' English listening and reading skills, which correlated moderately (0.45, 0.48) with the language barriers reported by the students.

## Conclusions and discussion

Homework remains an important part of mathematics education in the Czech Republic. KA can provide students with guidance and immediate feedback, which we believe is the main factor that leads students to prefer KA over traditional textbooks. The decrease in KA preference over time may be attributed to the novelty of this new system wearing off. Still, it is worth noting that even six months (and many working hours) later, KA remained the preferred choice of the majority of the student participants.

We found that language barriers play an important role in both preference and reported utilisation of KA. Students with greater English-language capabilities reported a higher ability to use KA learning resources, which we believe to be a strong factor behind their stronger preference for KA over traditional textbooks. We can assume that similar patterns would appear with other online educational resources—the number and quality of which continues to grow rapidly, and which would take a great deal of time to translate into Czech. Notably, KA is one of the most-translated educational resources in the Czech Republic. However, despite great effort from the non-profit organisation Khanova Škola (Khanova škola, o.s., 2016), only about 35% of KA's videos have subtitles, while fewer than 1% have Czech dubbing. If we want students to benefit from these growing resources, then we need to prepare our students for learning in English.

The last result of our study was that students' English grades did not significantly correlate with their reported language barriers (i.e. the 'best' English students did not typically feel better able to overcome their language barriers than the struggling students). This pattern held true even after six months of using KA. We assumed that the students would learn to overcome these barriers over time, as they used the English resources over the course of the study. Our study did indeed show that the reported language barriers decreased slightly, albeit insignificantly.

The teachers' evaluation of the students' English reading and listening skills correlated significantly (0.45, 0.48) with the language barriers reported by the students, so such evaluation could provide a

very rough estimate of the language barriers faced by a group of students. However, this correlation was not strong enough to provide a reliable estimate of the barriers faced by the individual students, as it only explained about 23% of it ( $0.48^2 = 0.23$ ). Ultimately, we were unable to find a quick and reliable way to estimate the individual students' self-reported language barriers.

## Limitations and future research

The small size of our sample made it impossible for us to find small correlations or inconspicuous patterns. Larger samples would have also allowed us to verify our results at a higher confidence level. The disconnection between the reported language barriers and the students' English grades could also be a local phenomenon, since every Czech school has its own curriculum.

In this study, we relied mostly on students' opinions, which might not have been completely accurate (i.e. even though students reported that they could make good use of KA resources, that does not necessarily mean that they did).

The results also showed that the English courses currently being offered to students might not be sufficient to prepare them to learn mathematics in English using tools like KA. Therefore, determining how to help students learn in English might be an interesting question for researchers and a challenge for both maths and English teachers.

While KA offers a great variety of exercises, its narrow focus (i.e. graphing quadratic functions in vertex forms) and repetitive nature might produce very formal knowledge that cannot be transferred. In future study, we would like to investigate what students actually learn using KA and how it might be affected by their language barriers.

As with every digital resource, KA sometimes experiences technical problems. Exercises can fail to load properly and data might not show up in the teacher dashboard. Therefore, it is a good idea to consider possible technical problems before judging students too quickly.

<sup>2</sup>University of Namur, Faculty of Computer Science, Namur, Belgium;  
[Marie-Ange.Remiche@unamur.be](mailto:Marie-Ange.Remiche@unamur.be)

*Keywords: Podcast, didactic contract, complete praxeology.*

In 2012, the University of Namur (Belgium) launched the PUNCH project ('PUNCH', 2012). Within this framework, many experiences to rethink our teaching practices were sponsored. Among many others, the POD-EN-MATH project aims to help students in computer science to complete praxeologies (Chevallard, 2006; Winslow, 2008) when learning mathematical concepts and doing this with the help of high-quality podcasts. Students will gain experience by analyzing step-by-step our own procedure to make the link between theory and technics. Doing so would permit us to make the didactic contract more explicit (Brousseau, 1984). Indeed this procedure is not documented but only transmitted orally. The next step of the project is that students themselves provide content to our podcast database. This experience put into evidence the difficulty we had to help students to communicate, to teach their own knowledge focusing on a more didactic point of view.

## Podcast we proposed

At the end of their graduate program, Computer Science students should be able to model the customer's need, compute the complexity's program (in terms of number of needed operations to perform) and prove that proposed program architecture fulfills the customer's demand. Discrete mathematics is mandatory as a corner stone to reach these outcomes. However, our students have great difficulties in building up the connection between theory and practice due to, among others, our ex cathedra teaching habit, as mentioned by Winslow (2008). Our podcasts aimed at filling this gap. We proposed high-quality podcasts of five to ten minutes. Our objective is to explain step-by-step, the reasoning that permits us to obtain the solution of a problem. Indeed the difficulty they often mention is to translate the problem into a mathematical model that needs to be solved, and not the theory they should use once the mathematical model is obtained. As proposed in Houston (2009), we want them to build up their mathematical reasoning and one way to do it is by viewing our own podcasts. As future analysts, the mathematical reasoning is of crucial interest for our computer scientists. Indeed they will have first to analyze the customers' needs and next to rephrase them in terms of programming objects and methods to programmers they manage. Mathematical reasoning is using the same skill.

## Podcast they had to build

Our final objective was that students should be able to build up their own podcast in the second level of discrete mathematics program. They were expected to build these podcasts, with the same level of quality and accordingly contribute to the podcast database. The problem they have to solve is on building up a podcast explaining their proof using the so-called recursive method. A specialist in

mathematics education was available to answer all their questions via personal meetings. Our students did present almost all the difficulties reported by Grenier (2012) as explained in the poster. In the light of the personal didactic supervising, some have been corrected and others have unfortunately not. The question then arises on how to improve our methodology to give them the ability to discuss about how to build up an inductive proof.

## Return on experience

None of the submitted podcasts reached our didactic quality requirements and could not be shared between peers. However, students greatly enjoyed producing podcasts as well as the personal coaching. They mentioned their understanding of the recursive approach increased in quality. Grades obtained at the final examination confirmed their belief.

This experience has highlighted to us the difficulty students have when building up their own expertise independently, as well as the difficulty they have to explain to their peers how to build up their own mathematical reasoning. The question that remains is to decide what kind of approach should be used to let our students become more and more autonomous in their learning of mathematics.

## Introduction/Literature review

Previous studies of courses with both face-to-face lectures and online lectures/videos (Inglis, Palipana, Trenholm, & Ward, 2011) have identified clusters of students based on their resource engagement. They found that students who attended face-to-face lectures or the maths support centre achieved higher grades than students who predominantly used online lectures. Inglis et al. (2011, p. 490) furthermore discuss how “what remains poorly understood is the overall pattern of study choices made when students are presented with many options”, and comments on how valuable research into examining student choices would be. Other studies have made suggestions as to why students might opt for a particular engagement pattern including: performance in course to date; proficiency of IT; convenience; and personality type (Bassili, 2006). Bassili found that both promotion and prevention factors influence students' engagement decisions. This study seeks to expand on the literature by explaining reasons behind students' choices. Subsequently, the research questions for this study are:

- Which resources do students engage with when studying the course content?
- Why do students choose to engage with these resources?

## Method

This study took place in University College Dublin (UCD). Data was collected from a large first year undergraduate module, Maths for Business. This is not a traditional, blended or e-learning course. Maths for Business is a unique course in that students have a choice of whether to complete the course material through lectures, online videos or a combination of both. The e-learning segment of the course consists of 68 short videos with average length of 7.6 minutes. The module co-ordinator has chosen to offer online support for students in response to: the large class sizes; acknowledging differences in learning styles and abilities of students; and additional support needed by ‘weaker’ students. This form of online learning is particularly suited for procedural mathematics courses of large mixed ability cohorts. For our study, we combine quantitative and qualitative survey data to identify engagement clusters based on resource usage, and explain the reasons behind students' engagement clusters.

In order to develop a complete understanding of students' engagement, the data for this study broadly covers three areas: survey response data, background information of students, and engagement data. Students' data was linked together from each of the sections. The first stage was cluster analysis. Rather than cluster students under total videos and lectures, we decided to cluster students based on what resources they engaged with for the lecture material they covered. We developed three variables to describe this; lecture usage, video usage and overlap of resources. Subsequently, cluster analysis was performed on the three variables; lecture usage, video usage and overlap of resources using model-based clustering. Qualitative data analysis is currently being

performed under the Braun and Clarke (2006) framework. Themes are considered to be semantic as students' responses are direct.

## Initial results

Cluster analysis has identified four distinct clusters: high lecture usage cluster; high video usage cluster; a cluster with high lecture, high video usage and high overlap between resources; and a cluster which features both lecture usage and video usage but with little overlap. Initial qualitative analysis has suggested the high lecture usage cluster is formed by students who perceive videos as a secondary tool; they find the lecture content has more depth, and enjoy the interactive lecture environment. In comparison, the high video usage cluster is formed by students who have issues with the lecture environment, and find little if any benefit from lectures. Videos offer these students an efficient and flexible method to study. The third cluster, the cluster with high overlap, has occurred owing to weak students accessing all available resources and needing extra support. The final cluster with little overlap of resources is formed by students who have switched from lectures to videos during the semester or are avoiding a specific lecture every week owing to the inconvenience of the timetable.

Mathematical procedural courses differ in their nature and design from other disciplines. Maths for Business use of e-learning allows 'stronger' students to progress at a fast, flexible pace while supporting the 'weaker' students through providing access to multiple resources which can be repeatedly used. Students can choose their resources to suit their learning. Overall there is an opinion from students that "[online learning] works very well for maths however [students] don't know if it would work well for other modules". Understanding students' reasons for choosing their engagement pattern may help in the future design of resources, and identifying whether online resources are particularly beneficial for large mathematics classes of mixed abilities.

The poster will expand on the initial qualitative analysis of the survey responses by explaining in detail the reasons behind each engagement cluster. We would like to thank UCD IT services for providing the Virtual Learning Environment data.

# Using tangible technology to multimodally support algebra learning: The MAL project

Thomas Janßen, David Reid, Angelika Bikner-Ahsbabs, Anke Reinschlüssel, Tanja Döring,  
Dmitry Alexandrovsky, Rainer Malaka and Estela Vallejo

University of Bremen, Germany; [janssent@uni-bremen.de](mailto:janssent@uni-bremen.de)

*Keywords: Algebra, learning modalities, smart objects.*

## Scope and objective of the presented project

Based on the assumption that activity (as opposed to the passive consumption of verbal instruction) supports learning, and accompanying the rise of learning theories that take into account the bodily grounding of the brain and its development, the usage of *manipulatives* – tangible learning materials – enjoys widespread trust among algebra teachers. Over the last two decades a variety of virtual adaptations of such manipulatives on personal computers and touch devices has been developed. The potential of such programs lies in the possibility to discover a range of configurations that would not be feasible in the real world, and to get automatic feedback about the correctness of the chosen manipulations. However, these qualities come at the price of abandoning the materiality of the manipulatives. The miniaturization of existing technologies and the creation of new input and output channels raise the question if and how manipulatives in mathematics education could be conceptualized as *smart objects* or *tangibles* – manipulatives that have the ability to interact with its users. Such objects have already been designed for learning purposes in other domains (Marshall, 2007). For the field of school algebra, the possibilities and challenges of their implementation is to be investigated in the MAL (*Multimodal Algebra Learning*) project, a collaboration between mathematics education and digital media researchers, experts in data collection and evaluation, and commercial enterprises. This contribution focuses on the didactical conceptualization that underlies the work of the consortium.

## Theoretical framework

Many theoretical approaches assume bodily action to be beneficial or even defining for learning processes. Bruner's well-known model proposing the distinction between enactive, iconic and symbolic action offers a starting point. Following Nakahara (2008), a distinction can be made at the enactive level (between hands-on manipulation and other real(istic) settings) and at the symbolic level (between natural and mathematical symbolic language). Although neither Bruner's nor Nakahara's terminology implies a strict proceeding order, the progression from concrete action with the smart objects to symbolic algebraic language follows from the pedagogical setting at hand.

## Design ideas and questions for investigation

Because research regarding traditional manipulatives suggests that only prolonged engagement with such objects reliably supports learning (Sowell, 1989), the MAL project wants to design *one* set of smart objects that can be used for a whole range of topics (e.g., for the generation of algebraic expression from pattern sequences, for transforming expressions, building relations, and for solving

equations). To achieve this, we turn to *algebra tiles*, which are already integrated in some North American algebra textbooks (e.g., Dietiker, Kysh, Sallee, & Hoey, 2010).

Marshall (2007) offers a framework that allows for the systematic design analysis of tangibles in learning environments. For example, he points to possible learning benefits: the playfulness that can be designed, the potential novelty of links, enhanced accessibility, chances of collaboration, and the learning benefits that may arise from physicality itself. Furthermore, he proposes a distinction between *expressive* and *exploratory* activities, which reminds of the more algebra-related work by Drijvers, Boon, and van Reeuwijk (2011), who distinguish between (technological) *tools for doing algebra* and *tools for learning algebra*, with the latter being subdivided into *practicing skills* and *developing concepts* (p. 185). It seems that the existing implementations of algebra tiles are more in the expressive realm of doing algebra, as they always start with a given definition of variables as unknowns, opposed to the possible exploration of their potential in describing change. It is a central goal of the MAL project to bring these two together. In the process, the following questions can be addressed: How do the physical and technical features of the designed objects interact with the didactical goals? To what extent is the integration of many algebraic concepts into one system of smart objects helpful in creating a multi-faceted image of the role of variables in algebra? What are limitations of the smart algebra tiles that could be resolved by either returning to traditional manipulatives or going virtual?

## Acknowledgments

The research reported on in this document is funded by the German Federal Ministry of Education and Research in the grant program “Erfahrbares Lernen” (experienceable learning). The initial research proposal was developed by some of the authors together with Gerald Volkmann.

# **Self-assessment and achievement in mathematics education: The influence of immediate feedback included in a computer-based learning environment.**

## **Concept of a research study**

Elena Jedtke and Gilbert Greefrath

University of Münster, Germany; [e.jedtke@uni-muenster.de](mailto:e.jedtke@uni-muenster.de)

## **Theoretical background**

Roth (2015) defines computer-based learning environments based on mediawiki software as a structured pathway with a well-matched sequence of tasks. Central contents are interactive materials like for instance GeoGebra-applets. Roth adds that learners are encouraged to work self-regulated, self-reliant and activity-oriented within these pathways. In Germany suchlike learning environments are for example available on the website of ZUM-Wiki (<https://wiki.zum.de/wiki/Hauptseite>), a web page that is called on to yield a well-kept surrounding in which everybody is invited to add something (Vollrath & Roth 2012). In our study, we will focus on quadratic functions. The area of functional relationships is a central theme during secondary education in Germany in which commonly occur some learning difficulties as for example on figuring out the meaning of parameters (Nitsch 2015). A computer-based preparation is called to promote the understanding of the parameters due to the option to easily include dynamic and interactive visualizations (Vollrath & Roth 2012). Furthermore, the importance of feedback for learning is mentioned in several publications (e.g. Black & Wiliam 1998; Vollrath & Roth 2012; Hattie & Gan 2011). Hattie and Gan (2011) for example identified feedback as one of “the top 10 influences on achievement” (Hattie & Gan 2011, p. 249). Thereby the dimension of this influence would vary depending on different kinds of feedback. Apart from this, we are interested in the influence of feedback on self-assessment as a specific component of metacognition (cf. Ibabe & Jauregizar 2010). More specific we will look at students’ self-rating ability. In our study, we will focus on feedback, which is typically encountered in computer-based learning environments. Suchlike feedback concerns the right answer and, in some cases, comments on how to get to this conclusion. Beside it “help me”-buttons with hints about how to proceed are added. Both the right answer and the hints can be activated by mouse click.

## **Research questions**

1. Is students’ self-assessment better if they work with a computer-based learning environment, including immediate feedback, than it is when they get the feedback outside the learning environment (research based on quadratic functions)?
2. Does a computer-based learning environment, including immediate feedback, have greater benefit on students’ math achievement in comparison to their achievement when they get the feedback outside the learning environment (research based on quadratic functions)?

## Method

We are currently conducting some preliminary studies, including a qualitative (pre-study I) and a quantitative part (pre-study II). The quantitative pilot study includes testing the self-assessment scales and the achievement test. Within this study, self-assessment is used in a context of self-rating the expected performance in the upcoming achievement test. The achievement test includes items about functional thinking as anchor items and items about linear functions (pretest) alternatively quadratic functions (posttest). In the qualitative pre-study, we are proving the designed computer-based learning environment about quadratic functions. Our aim is to reveal problems and misunderstandings and thus to rework and improve the learning environment.

The main study will be a quantitative research study with a quasi-experimental between-subject design. Students will work with the computer-based learning environment. The experimental group receives the learning environment including immediate feedback and hints for the tasks. The control group gets the same learning environment with absent feedback. Instead, this group gets correct-answer-feedback in outlying paper-sheets. Students' self-assessment as well as math achievement will be measured in a pre- and posttest design. The achievement test will measure the students' prior knowledge about linear functions (pretest) and their concepts on functional thinking (pre- and posttest) as well as their increase of learning after the self-regulated learning with the different types of feedback (posttest). As further research interest, we are going to compare the self-assessment ability of both groups related to the passage of time.

*Keywords: Technology enhanced resource, formative assessment, first year mathematics, evaluation.*

## Introduction

The aims of this project are to design and develop formative assessment resources for first year undergraduate mathematics modules and to evaluate the impact of these resources. The types of resources that have been developed to date include: targeted Khan Academy playlists and mastery challenges, a smart phone based audience response system that allows mathematical input, Moodle lessons, student generated screencasts and interactive tasks using Geogebra. The mathematical topics which are the focus of these resources were chosen based on the results of surveys of staff and students (Ní Shé, Mac an Bhaird, Ní Fhloinn, & O'Shea, 2016). In this poster we will present a snapshot of the resources, the evaluation methods and initial results. Augmented reality software and/or QR Codes are used in the poster to demonstrate the resources.

## Theoretical framework

The National Research Council (National Research Council, 2001, p. 116) defined mathematical proficiency as comprising of five interwoven and interdependent strands: conceptual understanding, procedural fluency, strategic competence, adaptive reasoning, and productive disposition. This description of mathematical proficiency guided our design of resources. We used the Black and Wiliam (Black & Wiliam, 1998, pp. 7–8) definition of formative assessment: 'encompassing all those activities undertaken by teachers, and/or by their students, which provide information to be used as feedback to modify the teaching and learning activities in which they are engaged' to advise our implementation of formative assessment techniques. We used technology to design and deliver the formative assessment in this project. This is not a new idea; according to the JISC report (JISC, 2010, p. 9) the benefits of using technology in assessment include allowing a greater range of types of assessments, a greater flexibility on timing and location of assessment; improved student engagement especially with interactive tasks which incorporate instant feedback, timely evidence on the effectiveness of course design and delivery.

## Methodology

The resources were developed by researchers affiliated to five different higher education institutes in Ireland who lecture on first year undergraduate mathematics. The resources were trialed in the 2015/2016 academic year. According to McKnight et al. (Mc Knight, Magid, Murphy, & McKnight,

2000, p. 10) mathematics education research is 'inquiry by carefully developed research methods' that provides evidence of the nature of teaching and learning. For the evaluation we chose to conduct student surveys, resources usage, student grades and think aloud interviews. The questionnaires, developed from similar questionnaires (MacGeorge et al., 2008; Zaharias & Poylymenakou, 2009) contained 4 dimensions; confidence when learning mathematics; impact on engagement, impact on learning and usability of the resource.

## Results, analysis and conclusions

Students were generally positive about the use of the resources, though there were differences between students' opinions on the different resources. For example students using the audience response system found that the resource encouraged them to engage more in class (over 80%) whereas only 32% of students using the interactive tasks reported accessing the extra resources when not assigned on homeworks. Based on the results of this analysis the resources are currently being modified for use in the next academic year, 2016/2017. The data from the evaluations will be further analysed to answer the research questions that we have: What are the benefits of using technology in formative assessment design? How effective are the resources in developing mathematical proficiency?

# Real materials or simulations?

## Searching for a way to foster functional thinking

Michaela Scheuring and Jürgen Roth

University of Koblenz-Landau, Landau, Germany; [scheuring@uni-landau.de](mailto:scheuring@uni-landau.de)

*Keywords: Real materials, simulation, functions, functional thinking.*

### Relevance

Living in a world strongly influenced by intelligent technology, it is indispensable to know in which contexts this technology can be beneficial and in which contexts the ‘real world’ should be used for teaching mathematics. Considering the topic of functional relationships, the need to foster pupils’ functional thinking (FT) from the very first beginning arises. Even though the topic is important for mathematics education in every grade, pupils show a lot of misconceptions (Leinhardt et al., 1990). Therefore and because of our multimedia life, we need to ask, if FT should be fostered with computer-simulations (GeoGebra) or real materials (like cubes, pencils...).

### Theoretical background

FT consists of three fundamental aspects: mapping, covariation, and function as object (Vollrath, 1989). Previous research shows that the use of real materials as well as the application of computer-simulations can lead to a learning progress in this complex topic. On the one hand, real materials make it possible to experience functional relationships physically (Ludwig & Oldenburg, 2007). Learning in such a setting has long-lasting effects, i.e. pupils can recall results and working methods better (Vollrath, 1978). On the other hand, simulations enable pupils to explore functions in different ways. Pupils can vary variables systematically and use the multiple-representation system (Balacheff & Kaput, 1997). Thus, e.g. covariation gets perceptible. Summing up, simulations become a mediator between pupils and mathematical phenomena (Hoyles & Noss, 2003).

### Methodology

After constructing a test to measure FT we derived topics that can be used to foster FT with real materials and simulations from theory: the relationship between volume and fill height of vessels, edge length and volume of a cube, diameter and circumference of discs, rotation-number while sharpening a pencil and its remaining length.

**Figure 1 Interfaces of the used simulations done with GeoGebra**

Then we designed an intervention-study (pre-post-control-group-design, randomized experimental-groups) that was implemented in grade 6 (age 11-12, N = 282). During the intervention (4 lessons) pupils had to work on learning-tasks individually to foster their FT. They were not instructed or

supported by a teacher. While part of them were using real materials (experimental-group 1,  $N = 111$ ) the others worked with computer-simulations (experimental-group 2,  $N = 123$ ). The learning-tasks in both groups were equivalent, only the medium differed. The control-group ( $N = 49$ ) worked on pre- and posttest, only. Data analysis was done with item-response-theory (IRT). First, we estimated item difficulties by use of virtual persons. Then we did a 2-dim. Rasch-model (dim. 1: pretest, dim. 2: posttest) with fixed item difficulties to estimate the person ability FT. Finally, a mixed ANOVA (Field et al., 2013) using 10 sets of plausible values to compare pupils' FT in pre- and posttest was conducted.

## Results

The mixed ANOVA (between: intervention, within: time) leads to the result, that there is a significant main effect of time ( $F(1, 22.71) = 68.16$ ,  $p < .001$ ,  $\eta^2 = .089$ ) and also a significant interaction effect of time and intervention ( $F(1, 23.69) = 7.65$ ,  $p = .003^{**}$ ,  $\eta^2 = .044$ ). A pairwise t-test showed that real materials as well as computer-simulations lead to a significant increase of FT (real materials:  $p < .001$ , Cohen's  $d = .49$ , computer-simulations:  $p < .001$ , Cohen's  $d = .83$ ). In contrast, the control groups' FT increases not significantly ( $p = 1$ , Cohen's  $d = .22$ ). Thus, it needs to be concluded that FT can be fostered by use of real materials as well as computer-simulations. Nevertheless, effect sizes show that computer-simulations should be the method of choice for fostering FT.

## **The development of the mathematics curriculum in basic education with technology**

Manuela Subtil<sup>1</sup> and António Domingos<sup>2</sup>

<sup>2</sup> *Universidade Nova de Lisboa, Faculdade de Ciências e Tecnologia, UIED, Monte da Caparica, Portugal; [amdd@fct.unl.pt](mailto:amdd@fct.unl.pt)*

*Keywords: Technology, curriculum development, activity theory.*

This poster refers to a project concerning an educational teaching experiment that focuses on the development of the curriculum on the 7th grade of basic education, by integrating technology. Using a learning environment with an exploratory nature, based on diversified tasks involving the use of graphing calculator, we aim to create an innovative curriculum in this level of education.

The teacher is the mediator of all the curricular decisions, having the responsibility to reorganize the main curriculum proposal, adapting, transforming, innovating and setting methodological teaching strategies that foster motivation and improve student outcomes (Pacheco, 2001).

According to several authors, the implementation of technology in the teaching of mathematics, namely computers and calculators (Domingos, 1994; Lee & McDougall, 2010; Tan & Tan, 2015) influences the way in which it is taught and enhances students' learning, for they build themselves their knowledge by premise creation. There are several benefits that emphasize the incorporation of technology in learning environments, namely, the increase of motivation, involvement, cooperation, hands-on learning opportunities, confidence and technological skills of students (Costley, 2014). In addition, those tasks are tools that generate activity in an interactive form, supporting the mathematical knowledge (Ainley et al., 2013).

This study is supported by the Activity Theory and seeks to understand how students, in solving specific tasks with the aid of the graphing calculator, builds their mathematical knowledge embedded in a learning community. Being the activity system within the classroom the unit of analysis, the third generation of the Activity Theory (Engeström, 2001) allows us to understand what happens when different activity systems interact. More specifically we seek to understand the instrumental genesis (Rabardel, 1995) and the semiotic potential played by technology in a student's activity system, developing the process of semiotic mediation (Bussi & Mariotti, 2008). In this sense, we intend to investigate how the graphing calculator influences, reinforces and facilitates the quality of teaching and learning and promotes the processes of instrumental genesis and semiotic mediation in the performance of tasks in curriculum development. We seek to get answers to the following research questions: Which are the instrumental action schemes created by students when they use a graphing calculator? How does the teacher promote the process of semiotic mediation? How does the graphing calculator act as semiotic mediation tool? How does the integration of technology in the curriculum influence the process of teaching and learning? What is the quality of the achieved learning?

Based on research of an interventionist nature, using innovative practices that aim to promote new ways of learning, enabling improvements on an educational level, a qualitative paradigm based on a Design Research process will be adopted. The techniques used to collect the data shall be based on the planning of the study units, the elaboration of reports by the students as a result of completing the tasks and reports resulting from the participant observation of the teacher as a mediator. We will

also consolidate the structured observation of lessons, using a logbook, photographs of the graphic representations in the calculator, videos and audio recordings, during the performance of the tasks (Cobb, Confrey, diSessa, Lehrer, & Schaube, 2003). Empirical data will be collected in the school year of 2016/17 in a public school in the district of Setúbal, in Portugal.

We therefore intend to present an innovative curriculum development project, that integrates a strong technological component in an educational level where traditionally this kind of approach is not commonly used. The use of tasks permeated by graphic technology seek to highlight the semiotic dimensions present in the instrumental genesis that are activated in different activity systems.

### Line of thought of the previous working groups in CERME5 to CERME9

Since CERME4 in 2005, theoretical approaches and perspectives have been the topic of an ongoing CERME working group. The idea of the “networking of theories” emerged at CERME 4 and was explored in the subsequent conferences. At CERME 5 (Arzarello et al., 2007), the diversity of theories in the field of mathematics education was regarded as a source of richness, and the networking of theories as a multi-theoretical approach which preserves theoretical identity but also while allowing to bridge the boundaries of theories for a better understanding of teaching and learning. Thereby, the effort was made to make hidden assumptions and relationships of theoretical approaches visible. Principles and heuristics of handling the diversity of theories in empirical research were explored as a new possibility to better grasp the complexity of empirical situations of teaching and learning mathematics, such as the interplay between the individual and the social. Typical heuristics to network theories were to relate different approaches based on research: bottom-up on the one hand and starting from theoretical views top-down on the other, but also mixed types were presented. One interesting result was that not only theoretical principles may be hidden in the use of theories but also the view on the nature of mathematics can be an implicit but relevant feature in the specific theoretical approach.

The central theme of TWG 9 of CERME 6 (Prediger et al., 2010) was investigating how the use of networking strategies may lead to a more comprehensive understanding of the empirical world, what kind of limits have to be faced, and what kind of difficulties have to be considered. In this respect, the questions of commensurability and complementarity of theories came into play. Radford’s conceptualizing of theories (2008) as a triad of principles, methodologies and research questions built as a cultural entity of research practice in the semiosphere, a cultural-semiotic space of research as activities, was applied to structure the way networking strategies were used as guiding heuristics which link different aspects of theories. Examples showed that through the networking of theories new questions of ‘balance’ can be posed, concepts at the boundary of theories may become relevant to solve problems, and theoretically “zooming-in and zooming-out” can be a strategy when theories of different grain size are coordinated. The discussion in this TWG was captured by a dynamic view on theory “as a ‘living entity’ embedded in the researchers’ social, cultural and institutional heritage” (Prediger et al., 2010, p. 1533).

Two years later, the TWG 16 at CERME 7 (Kidron et al., 2011) re-addressed meta-theoretical views on the networking of theories and recognized the need for a meta-theoretical frame for the networking of theories. Projects began to implement the networking of theories as a research practice following the new research aim of building a relationship between corresponding concepts of different theories. Besides the semiosphere (Radford, 2008) which was re-used in the paper presentations as a space where the networking of theories may be conducted, Artigue, Bosch and Gascón (2011) applied the Anthropological Theory of the Didactics to investigate the networking of theories as a research praxeology leading to specification of the relevance of problems and phenomena. Monaghan (2011) described Theoretical Genesis as an analogy to instrumental genesis on the part of the researcher adopting a theoretical view. It is a meta-view on the process of theorizing through the practice of “writing, learning, engagement with research and other voices” (ibid., p. 2498). The interesting point was the insight that also meta-theoretical views on theories largely depend on the cultural-semiotic way (meta-)theories are considered in the specific community. The contributions and discussion of this TWG substantiated the view that the networking of theories may advance the quality of research and lead to more linked and comprehensive results of research.

Whereas teaching and learning mathematics has been the main focus before, in TWG 16 of CERME 8, teacher education provided new directions of considering theories that involve new ways of theorizing on new research objects. This new topic also renewed the understanding of theories as epistemological tools: “the theoretical approaches need to be considered by what they enable researchers and practitioners to do, the questions raised, the regularities identified and described, that is, in a sense the results obtained” (Kidron et al., 2013, p. 2788). Besides addressing goals and practices of networking theories in research, the aspect of time as an additional dimension was emphasized; for example, because the networking strategy of coordinating theories may be executed as an intermediate step in time when theoretical elaborations have reached a particular status, or because coordinating theories may be executed fruitfully in a sequential way.

Although the networking of theories has also been an ongoing topic in TWG 17 of CERME 9, the main focus of this working group was on the notion of theories (Bosch et al., 2015). The discussions once more emphasized that theories are living entities that develop through processes of theorizing in research, beginning with local models, and developing towards more global entities dependent on the requirements of research. These processes result from exploring specific research questions, which may or may not broaden the theories’ scope in mathematics education and beyond.

### **The Thematic Working Group 17 of CERME 10**

The TWG 17 of CERME 10 continued the discussion on multi-theoretical approaches (the use of more than one theory in research, see the paper of Chan and Clark in the proceedings), particularly on the networking of theories, but also shifted its attention towards multi-theoretical approaches in design research and the problem of transfer inherent in the tension between home-grown and borrowed theories. The latter aspects have been an ongoing theme, already addressed by Steiner in the conferences on Theory of Mathematics Education of 1985 (Steiner, 1985). The description of the call of TWG 17 of CERME10 showed what kind of contribution was expected:

This networking of theories approach is also addressed in the TWG 17 of CERME 10. With this working group we want to build on previous work of the group but this time we also want to address more specific topics: theories as prerequisite and result of design research, theorizing in research which involves technology, theories involved in interdisciplinary research with mathematics education. We want to explore how theories are used and built to better understand their role in and beyond mathematics education and the use of theories to inform practice.

Twelve papers and five posters were presented in the TWG 17. All but one poster abstract are published in the proceedings. They are grouped in three topics, the essentials of which will be extracted in the subsequent summary.

### **Networking of theories approaches**

As in previous CERMEs, the discussion within this TWG has addressed the question of how to deal and work with theories, particularly concerning multi-theoretical approaches, which respect the theories' identities and at the same time are able to connect them fruitfully to solve problems in the field and understand the complexity of teaching and learning mathematics better. In terms of the networking of theories approach, the subsequent contributions witness a growing methodological maturity of handling the diversity of theories in research. This maturity is strongly related to deepening and broadening insight about the complex nature of the teaching and learning settings on two intertwined levels, the level of data analysis as well as the level of methodological and theoretical considerations and decisions, both being intertwined.

For example, Tabach, Rasmussen and Dreyfus conduct research to understand how learning in inquiry-based classrooms takes place individually and collectively and how these two learning planes are linked. They *coordinate* two theories, namely Abstraction in Context and Documenting Collective Activity, in a way that represents an innovative methodological step of research within the networking of theories strand that allows to identify how specific ways of coordinating may lead to in-depth insights into the functioning of inquiry-based learning, individually and collectively.

The effect of using networking strategies is directly investigated by Shinno, who has undertaken two case studies following two consecutive networking strategies; namely, coordinating and locally integrating. His research reveals: While coordinating preserves the meanings of the concepts involved as parts of theories, locally integrating theory elements changes the meanings of concepts. The reason for this seems to be that the concepts were *integrated* into a new theoretical framework, with new kinds of issues, questions, and aims. This result substantiates the fact that the meaning of a concept is deeply determined by the theory to which it belongs.

The mathematical workspace (MWS) presented by Nachache and Kuzniak even *requires* to be networked with further theory elements. The MWS originates in practical work with teachers, preserving its pragmatic character in linking semiotic, epistemic and cognitive genesis. Kuzniak et al. illustrate the plasticity of the model by connecting it to several theories or models for teaching mathematics. The reason why this connection is possible is the empirical load: The mathematical workspace model is empirically empty, and therefore allows models with high empirical load to complement it according to the three components offering ways to navigate through them.

Chan and Clarke's purpose in using a multi-theoretical approach is to explore the notions of complementarity and commensurability in an empirical way, a theme that has repeatedly been

addressed in previous working groups. They have instantiated a research project allowing to clarify the concepts of complementarity and commensurability based on analysis of the same data sets of problem solving activities from three different theoretical perspectives. Thus, the common data sets function as boundary objects (Star, 2010), objects that can function in different practices for different purposes, even without the need for consensus (Star, 2010).

In the fifth example, Behrens and Bikner-Ahsbahr add the perspective of the indexicality of signs to their theoretical framework for analyzing gestures related to speech, representations, and a technological tool. This choice is driven by the need to better understand the development of gestures from hand movements on the iPad's digital place value chart towards epistemic gestures, contributing to build knowledge. They show that the process of conceptualizing decimal fractions proceeds as an epistemic shift from *gesture-of* towards *gesture-for*, thus justifying their choice by a methodological result: The indexical nature of signs is a fruitful theoretical perspective for the analysis of epistemic processes as it allows tracing these processes back to their origins.

### **(Multi-)theoretical approaches in design research**

The call explicitly asked for examples of theory use; specifically, in design research. This is particularly challenging because the purpose of theory use in this area is different from that in studies considered before in the networking of theories cases in the previous CERME-TWGs and the previous section. What is special about design research is that the justification of an educational goal requires normative theories, and the ways in which means are implemented to reach the goal – for example in design principles – require prescriptive theories. Finally, there is also a need for theoretical tools to analyze the empirical data of the implementation of the design, using descriptive or explanatory theories (Prediger, 2015). The normative and prescriptive theories developed, for example in the form of design principles, conjecture maps or hypothetical learning trajectories, raise the issue of methodology in relation to theory (cf. Radford, 2008). Kelly (2004) challenged design researchers to come up with what he calls an argumentative grammar – the reasoning from methods via analysis to warranted conclusions, which in the case of randomized controlled trials largely relies on the structure of argumentation.

Bakker takes up the challenge and argues that in design research, as in many other qualitative and mixed methods approaches, scholars cannot rely purely on the structure of argumentation. They need to account for the content too (content of the learning goals, content of core concepts used, context etc.). Bakker argues that design research may need several argumentative grammars and proposes elements of an argumentative grammar that he proposed to experts in design research during an interview study.

Given the multi-theoretical focus of the TWG, it was interesting to see how theories could play different roles in the design of curriculum or learning activities. For example, Johnson and colleagues used different theories for the design of their learning activities and for analyzing the resulting learning processes. The authors show how making theories of different grain sizes — grand theories (Piagetian theory), intermediate theories (Marton's variation theory), and domain specific theories (Thompson's theory of quantitative reasoning) — interact with each other allows designing effective dynamic computer environments and tasks to promote students' learning. Kourapatov and Dreyfus, on the other hand, used two theories for the design of a task-based

curriculum and for analyzing resulting learning processes to feed back into improved design. The two theories – Abstraction in Context and Proceptual Thinking – were of different grain size and had different focuses, which made them complementary. The authors argue that in the process of designing learning units, the different theories have been interwoven while keeping different roles from stage to stage.

Simon and his colleagues, building on constructivist theory and their empirical research, developed an elaboration of Piaget's construct of reflective abstraction for the purpose of undergirding an instructional design theory for promoting mathematical concepts. In conjunction with this elaborated construct, they have articulated an instructional design approach that fosters reflective abstraction of particular concepts. In doing so, they have afforded a change in design research (i.e., teaching experiment methodology) from a focus on students' mathematical reasoning and operations to a focus on the conceptual learning process and designs for promoting that process.

### **Transfer of theory elements: The tension between home-grown and borrowed theories**

The tension between home-grown and borrowed theories was one question previous working groups have dealt with by several contributions. In this working group, the discussion focused on two main interrelated issues. On the one hand, home-grown concepts may bear with them meanings specific to the social and cultural context or the field in which they have been elaborated, and that raises the question how to transfer them into a foreign context or field. Research is needed to address the viability of adapted concepts. On the other hand, theoretical tools or perspectives which are borrowed from other fields must either be adapted to mathematics education or particularized or complemented with content-related theoretical tools in order to be fruitfully put to work. Some of the contributions presented in the working group faced one of these two issues.

For example, Roos' contribution shows how a home-grown concept which emerged in specific cultural context may be difficult to transfer or translate into a different one. More specifically, Roos presents an overview about the concept of *Grundvorstellungen*. This concept emerged in German-speaking countries as a practical tool for teaching. It is impossible to translate and even difficult to explain in English, even if one can recognize the existing links with the notion of *concept image* or with Vergnaud's *theory of conceptual fields*. This difficulty raises the question of how ideas, or even entire theories, which emerge within a specific cultural context and therefore bear cultural-historical meanings, can be communicated on an international scale.

In other cases, home-grown concepts seem to have the potential to be more easily transferred and adopted in foreign contexts. This is shown in Liljekvist's contribution. She uses the concept of *prosumer*, which stems from sociological research, to understand mathematics teachers re-sourcing and using social media in a Web 2.0 world, linking the two activities of consuming and producing. Even if the concept of *prosumer* bears meanings and values from its native context and has to be further developed for mathematics education purposes, it has the potential to be easily translated and spread outside as it carries its 'origins' in the term itself.

Adapting borrowed concepts and theories from other fields is not only a question of translation. Mathematics and mathematics education have their own specificities, which must be taken into account when borrowing theoretical tools and concepts from other fields. How that can be done is at the core of the tension between home-grown and borrowed theories. For example, Haspekian and

Roditi faced the issue of adopting general concepts from the field of assessment research in education to a specific research study in mathematics education. The authors developed a methodological tool for analyzing teacher-student interactions in mathematics classes as an adaptive dynamic process. The discussion on their uses of concepts from the assessment field illustrates a way of locally connecting research areas via a shared methodological tool.

Similarly, Georget and Sabra draw on general sociocultural theories to investigate the professional development process occurring in mathematics teachers' communities; however, their study emphasises the need to resort to a complementary theoretical focus addressing specifically the place of mathematics in such communities in order to account effectively for the dynamics which take place in the community. The same tension is also present in the contribution of Zerafa. Zerafa developed an intervention programme addressed to children experiencing mathematics learning difficulties. The design of this programme relies upon the adoption of a large number of borrowed theoretical tools. That raises the question of how to complement borrowed theoretical framework in order to take into account the specific mathematical content at stake.

Researchers can also meet problems concerning the adaptability of theories in context or for purposes different from those in which and for which theories have been developed, even within a given specific field. For example, Benedicto, Gutiérrez and Jaime faced such a problem when applying an existing model, developed to analyse cognitively demanding tasks in the areas of arithmetic and algebra, with the aim to analyse tasks in different mathematical topics. In fact, the original model revealed not to fit adequately their research needs. Their contribution illustrates the processes of analysing the model and the difficulties emerged. Thus, they adapted the model to the new needs and obtained an improved model that did not lose its core meaning while being more widely applicable.

## Issues to be considered in future meetings

For future development, several participants expressed the wish to make progress on broader themes that superseded individual presentations. One way to do so is by proposing themes that participants commit themselves to for the next TWG, as was done in previous groups. This would allow the working group to continue working by themes, and discuss the studies in relation to a central theme (say one per day). This can make each author's contribution a case of a more general issue, and allows us to do cross-case analyses in the working group. However, the challenge of this theory group is to balance concreteness and generality in the discussions to make the huge number of theories (48 theories in TWG17) being presented in this working group accessible to all the participants even if they are familiar with some of them. Suggestions for central themes are:

1. **Progress and quality:** On what grounds can we decide whether the networking of theories is a contribution to the field? Concepts often used are: complementarity, commensurability, consistency, usability, and fit to purpose. What **methodologies** for research with networking theories are suitable? What **criteria** are suitable for selection and adaptation when networking theories? Criteria may be different for researchers who have a fundamental interest than for educators who work with models that teachers need to work with. Theories can be placed in a framework of different levels (diSessa & Cobb, 2004); are there any heuristics we can derive on good practices of how to coordinate multiple theories; and what

do disciplines outside mathematics education have to offer us in this respect (history and philosophy of science?)

2. What **work** do you do with theories to be able to use them for your purposes? In what respect do you have to adapt a theory or combine it with others? What is the nature of theories used: Describing and explaining learning processes versus offering design heuristics or guidelines? The incompleteness of theoretical models (discussed by Kuzniak et al.) can be an advantage because generality or emptiness can make a model or construct easy to transport (transportable). However, there are also risks when there is a lack of specificity. An issue raised was how theories are insensitive to differences that may matter.
3. What are appropriate **argumentative grammars** for types of research that explicitly have a normative and/or prescriptive element, such as design research? How do we ensure that design embodies theoretical ideas, and how to study the resulting learning as a consequence of the design?
4. How can we deal with concepts that are hard or even impossible to **translate** into English (*milieu*, *Grundvorstellung*, *Stoffdidaktik*, types of participation in Asian countries, ...)? The Lexicon Project will have a lot to offer in this respect.

To deepen the understanding of theory and methodology in European research, this thematic working group of CERME should in the future address the issues of quality of the networking of theories in research practice, of the specificities of theories, of identifying different argumentation grammars and scientific ways of communicating culturally bound concepts and theories on the international plane.

*In this report we advance the methodological and theoretical networking for documenting individual and collective mathematical progress. In particular, we draw together two approaches, Abstraction in Context (AiC) and Documenting Collective Activity (DCA). The coordination of these two approaches builds on prior analysis of grade 8 students working on probability problems to highlight the compatibility among the epistemic actions that ground each approach and drive the respective methodologies. The significance of this work lies in its contribution to coordinating what might otherwise be viewed as separate and distinct methodologies.*

*Keywords: Methodology, theories coordination, individual cognition, collective meaning making.*

## Background

In this report we advance the methodological and theoretical networking (Bikner-Ahsbahr, & Prediger, 2014) of two different approaches, the Abstraction in Context (AiC) approach with the RBC+C model commonly used for the analysis of knowledge construction by individuals or small groups; and the Documenting Collective Activity (DCA) approach with its methodology commonly used for establishing normative ways of reasoning in classrooms. In previous work related to this goal (Hershkowitz, Tabach, Rasmussen, & Dreyfus, 2014; Tabach, Hershkowitz, Rasmussen, & Dreyfus, 2014) we demonstrated how this coordination can illuminate the processes by which ideas shift from individuals and small group to the classroom community as a whole or vice versa. This combination revealed that some students functioned as “knowledge agents,” meaning that they were active in shifts of knowledge among individuals in a small group, or from one group to another, or from their group to the whole class or within the whole class.

We take the coordination between AiC and DCA a step further by explicating theoretical and methodological commonalities between the two approaches. These commonalities, which we first pointed to at CERME9 (Tabach, Rasmussen, Hershkowitz, & Dreyfus, 2015), drives further the integration of the two approaches, including what we refer to as environmental, underlying, and internal commonalities. The analysis in the present case led us to enhance the theoretical commonalities with data driven ones. We explicate these commonalities to set the stage for the analysis of students’ work, but first begin with a brief summary of the AiC and DCA approaches.

## Abstraction in Context and the RBC+C model

Abstraction in Context (AiC) is a theoretical framework for investigating processes of constructing and consolidating abstract mathematical knowledge (Hershkowitz, Schwarz, & Dreyfus, 2001). Abstraction is defined as an activity of vertically reorganizing previous mathematical constructs within mathematics and by mathematical means, interweaving them into a single process of

mathematical thinking so as to lead to a construct that is new to the learner. According to AiC, the genesis of an abstraction passes through three stages (ibid): (i) the arising of the need for a new construct, (ii) the emergence of the new construct, and (iii) the consolidation of that construct. AiC includes a theoretical/methodological model, according to which the description and analysis of the emergence of a new construct and its consolidation relies on a limited number of epistemic actions: Recognizing, Building-with, Constructing, and Consolidating (RBC+C).

These epistemic actions are often observable as they are expressed by learners verbally, graphically, or otherwise. Recognizing takes place when the learner recognizes a specific previous knowledge construct as relevant to the current problem. Building-with is an action comprising the combination of recognized constructs in order to achieve a localized goal, such as the solution of a problem or the justification of a claim. The model suggests Constructing as the central epistemic action of mathematical abstraction. Constructing consists of assembling and interweaving previous constructs by vertical mathematization to produce a new construct. It refers to the first time the new construct is expressed by the learner. Recognizing actions are nested within building-with actions, and recognizing and building-with actions are nested within constructing actions. Therefore, the model is called the nested epistemic actions model of abstraction in context, or simply the RBC+C model. The second “C” stands for Consolidation. The consolidation of a new construct is evidenced by students’ ability to progressively recognize its relevance more readily and to use it more flexibly in further activity.

### **Documenting Collective Activity**

The methodological approach of documenting collective activity (DCA) is theoretically grounded in the emergent perspective (Cobb & Yackel, 1996), a basic premise of which is that mathematical progress is both an individual constructive process and a process of enculturation into the emerging norms and practices of the local classroom community. That is, the personal and collective mathematical progress can be seen as two sides of the same coin. Collective activity of a class refers to the normative ways of reasoning that develop as students work together to solve problems, explain their thinking, represent their ideas, etc. These normative ways of reasoning can be used to describe the mathematical activity of a group and may or may not be appropriate descriptions of the characteristics of each individual student in the group. A mathematical idea or way of reasoning becomes normative when there is empirical evidence that it functions in the classroom as if it is shared. The empirical approach makes use of Toulmin’s model of argumentation (1958), the core of which consists of Data, Claim, and Warrant. Typically, the data consist of facts or procedures that lead to the conclusion that is made. To further improve the strength of the argument, speakers often provide more clarification that connects the data to the claim, which serves as a warrant. It is not uncommon, however, for Rebuttals or Qualifiers to arise once a claim, data, and warrant have been presented. Backing provides further support for the core of the argument.

The following three criteria are used to determine when a way of reasoning becomes normative: 1) When the backing and/or warrants for particular claim are initially present but then drop off, 2) When certain parts of an argument (the warrant, claim, data, or backing) shift position within subsequent arguments, or 3) When a particular idea is repeatedly used as either data or warrant for different claims across multiple days (Cole et al., 2012; Rasmussen & Stephan, 2008).

## Environmental commonalities

The use of both methodologies, RBC+C and DCA, requires quite specific classroom social norms (Yackel & Cobb, 1996). First, they require classrooms in which students routinely explain their thinking, listen to and indicate agreement or disagreement with each other's reasoning, etc. If such norms are not in place, then evidence is unlikely to be found of challenges, rebuttals, and negotiations that lead to ideas where knowledge is constructed and starts functioning as if shared by the whole class. We call such classrooms "inquiry-oriented classrooms" (Rasmussen & Kwon, 2007). Second, these classrooms require the intentional use of tasks designed to offer students opportunities for constructing new knowledge by engaging them in problem solving and reflective activities allowing for vertical mathematization. Both methodologies focus on the ways in which mathematical progress is achieved and spreads in the classroom. RBC+C focuses on individuals or small groups working in the classroom and DCA focuses on group or whole class discussions. In this sense, the two methodologies complement each other in analyzing a sequence of lessons including individual and group work and learning in whole class discussion and in tracing how knowledge is constructed and becomes normative.

## Underlying commonalities

Other characteristics of a classroom culture in which DCA and RBC+C methodologies might be enacted together are that the tasks are designed to afford inquiry and the emergence of new constructs from previous constructs by vertical mathematization (Treffers, & Goffree, 1985); such learning materials allow for interweaving collaborative work in both small-group work and whole-class discussions, where the teacher adopts a role that encourages inquiry in the above sense. Another underlying characteristic relates to the centrality of the shared knowledge. RBC+C characterizes shared knowledge as a common basis of knowledge which allows the students to make further progress. We find its counterpart in sociological terms, in the phrase "function as if shared" used by the DCA approach. What is common between the two constructs is the point that each operationalizes when particular ideas or ways of reasoning are, from a researcher's viewpoint, beyond justification for participants. At the collective level, ideas or ways of reasoning that function as if shared have the status of accepted mathematical truths for the group. At the individual level, consolidation results in individuals accepting something as a mathematical truth.

## Internal commonalities

DCA analysis helps illuminate what is happening on the social plane, while RBC+C analysis helps illuminate what is happening on the cognitive side. To elaborate, we highlight relationship between constructs suggested by the cognitive RBC+C analysis and their sociological counterparts suggested by the DCA analysis. We do that from a theoretical perspective and from an empirical perspective. To achieve this goal we begin with the following excerpt 1, used also in Hershkowitz et al. (2014) but for different purposes. It is a discussion between Noa and Gil, two eighth grade students working on a probability problem (see turn 95) during a group work period taken from the third lesson on this topic, and a bit of whole class discussion. This excerpt includes a DCA analysis, in particular classification of the marked parts of students talk (*shaded*) according to Toulmin's model as data [D], claim [C], warrant [W], backing [B], rebuttal [R] or qualifier [Q]. In addition, RBC+C actions were identified in students' talk (*italic*), and marked as recognizing (R), building-with (B),

end of the constructing action (C) or consolidating (CC) with respect to two knowledge elements:  
 $E_{xp}$  - experiment is needed in order to determine the chances and  $E_{xd}$  – experiment detailed.

No.		Utterance [DCA analysis]	RBC +C
95	Noa	(reads) ‘Is it possible to determine without experimenting what the chances are that we will take out a defective match from a matchbox? If yes, what is it?’ <i>You can’t know!</i> [D1] <i>Unless ... you have to experiment</i> [C1]! <i>You can’t know!</i> You need to experiment! I’m writing “You need to experiment!”	RB
96	Gil	<i>You don’t have to!</i> [C2, counterclaim]	B
97	Noa	Of course you do!	
98	Gil	“What the chances are of taking out a defective match from a matchbox?” <i>It’s 1 out of the number of matches in the box.</i> [D2]	R
100	Noa	<i>Right, so you take many boxes, how many, if, in the box</i> [W1]...	B
101	Gil	<i>Noa, it depends on how long you have been using the box, if you used it once then maybe it will be less ...</i> [Q1]	B
102	Noa	<i>No! If it’s defective! You have to take many boxes</i> [D1] <i>and see in each one if there is ... if there are let’s say 50 matches in each box and 1 is defective so it says on the box 1 out of 50</i> [W1], <i>so you have to experiment!</i> [C1, referring back to turn 95]	B
103	Gil	<i>So it’s 1 per the number of matches in each box</i> [W2].	R
104	Noa	<i>Not 1, there may be 2 defective matches in the box</i> [R2].	B
105	Gil	But what are the chances?	
106	Noa	But with 2 defective ones?	
107	Gil	But Noa, you are speculating ... <i>you can say 50 out of 50</i> [R to 104].	B
108	Noa	<i>But you can’t say 1 out of 50! Out of ... whatever!</i> [W to 104] What is the probability? It’s not correct what you are saying!	B
109	Gil	What isn’t correct?	
110	Noa	<i>Because just like you can’t say 2 out of the matches because you don’t know that it’s 2 or that it’s 1</i> [W1 = R2].	B
111	Gil	(writes) “ <i>can’t determine without experimenting.</i> ” [C3]	$C_{xp}$
112	Noa	<i>We can, if we experiment.</i> [C, slightly new claim of how to do the experiment]	$CC_{xp}$
113	Noa	<i>Ok, so what is the probability? It’s, we have to write that we won’t know</i> [D1] <i>until we experiment</i> [C1].	RB
114	Noa	Let’s write at the bottom, that <i>we need a few boxes</i> [D4], <i>suggest an experiment (dictates: “we need to take a few boxes of matches and see out of them</i> [D4]...” [Dictate together].)	B
115	Noa	No, wait! <i>How many matches does the box contain, and see how many defective matches are in it</i> [D4]... [Dictate together].	B

116	Gil	(continues to dictate) “ <i>then, check how many defective matches are in the box</i> [W4]” [Dictate together].	B
117	Noa	Then we will write “ <i>the probability is the number of defective matches in the ...</i> [C4, together with turn 123]” [Dictate together].	C <sub>xd</sub>
...			
122	Gil	Noa, <i>each box will come out differently.</i>	R
123	Noa	<i>So it's average</i> [C, note Data is previous argument], <i>not precise</i> [Q4]!	CC <sub>xd</sub>
		<b>Back to whole class discussion</b>	
135	Noa	In my opinion <i>you need to experiment</i> [C10]!	
136	T	Why?	
137	Noa	I don't know. I can <i>suggest an experiment</i> [Q10]	
138	T	Friends, listen, you need to express your opinion on what they said	
139	Gil	[addressing Noa] Why can't you say why you need an experiment, <i>you can't know how many matches there are in the box</i> [D10].	B <sup>1</sup>
140	T	Let's say I can reveal to you that there are 45 matches in the box.	
141	Gil	<i>And inside you have to [check].</i>	B
142	Noa	[you need to <i>take some</i> ] matchboxes [D11], you need to see <i>how many matches are in each box, and how many of them are defective</i> [W11].	
143	T	Let's say we know that information, what do I do with it?	
144	Noa	So ...	
145	Gil	So I do <i>the average</i> [C11, with 147]	B
146	T	What average?	
147	Gil	<i>Of the defective matches in each box</i> [C11, with 145]	C <sub>xd</sub>
148	T	And how is that going to help us know what the probability is that we take out a defective match?	
149	Noa	Let's say we have 2 defective matches in a box with 50 matches, so it's 2 divided by 50.	
150	T	2 to 50, what do you think?	
151	Gil	We are saying that <i>you can't do it without an experiment</i> [C10]. <i>You can't know how many defective matches there are because we don't know how many matches are in the box and we don't know either ... We can't speculate how many defective matches there are</i> [W10]. <i>We wrote that we need to take a number of matchboxes and see how many matches they contain, then count how many out of them are defective and do an average of how many defective matches in each box</i> [C11]. If we got 3 then it's 3 divided by 50.	CC <sub>xd</sub>

Table 1: Excerpt 1, Transcript from the class

<sup>1</sup> From this point on it is Gil who does the B and C actions

## RBC+C and DCA analysis

We begin by relating elements of the RBC+C and DCA analyses to each other, and then we relate the three criteria of the DCA approach to consolidation.

*Relationship between Recognizing and Data.* Theoretically, we argue that Recognizing actions are largely associated with Data. One uses some piece of information as Data because that piece of information makes sense to him/her. That is, this piece of information is relevant for the person; it is what the person selects for use (as Data). In the above excerpt, we see that Recognizing actions are primarily associated with Data. In some cases (e.g., turn 103), Recognizing actions can be associated with Warrants. In carrying out the DCA analysis, disentangling Data and Warrant is at times non-trivial, in which cases Recognizing actions can be sensibly associated with Warrants.

*Relationship between Building-with and Warrants.* Theoretically, Warrants establish a connection between data and claim; in order to establish such a connection, one needs to build-with what one has recognized. In the above excerpt this commonality is largely the case with some exceptions that need clarification. In turns 95/96 we had claims associated with building-with. These are the first building-with actions of this excerpt and thus the first ones of the part where the students are working on the present task. As a consequence, the building-with actions are somewhat shallow and make only claims without really warranting them. As such, this example does not pose a substantive threat to the theoretical conjecture. Similarly, turns 114 - 116 and 139 do not pose a substantive threat to the conjecture. These are the final utterances belonging to a constructing action; as such, they complete the constructing by explicitly stating the claim that was constructed. As we noted above, at times data and warrant are difficult to disentangle with certainty, hence building-with can be associated with data. Empirically, this is the case for turns 114 and 115.

*The relationship between Constructing and Arguments as a whole.* Constructing requires vertical mathematization. Constructing actions are usually much more extended than Recognizing or Building-with actions; they incorporate sequences of interweaving Recognizing and Building-with actions (plus the 'glue' between them). Similarly, arguments interweave data-claim-warrants and backings as a whole. Hence, in a line by line coding it is not feasible to indicate the holistic nature of an argument and it is typically indicated after a line by line coding (see for example Tabach et al., 2014). Moreover, arguments are usually co-constructed by several participants over several turns. Such interaction is also frequent in constructing actions.

*Consolidating and the three criteria for identifying function-as-if-shared ideas.* In consolidating actions as well as across the three DCA criteria for identifying when an idea functions as if shared, repetition, reuse, revisiting, or repurposing of earlier ideas frequently occurs. To clarify, in Criterion 1 there is a repetition, but the repetition is partial in the sense that some parts of the argument (Data, Warrants) cease to be explicitly stated. In Criterion 2 there is repurposing of previous part of an argument (e.g., Claim) as either Data or Warrant. In this sense there is a repeating and reusing, but for a different purpose. In Criterion 3 there is a revisiting of either Data or Warrants to establish new Claims. In consolidation, previous constructs are recognized as relevant (i.e., revisited), and then built-with, which means they are reused, often for a new purpose such as a new constructing action. Hence there are strong parallels between consolidation and the three DCA criteria. For example, in 151, DCA analysis shows that W10 (the warrant for Claim 10) turns into D11 (i.e. the

data for Claim 11); hence Criterion 2 is satisfied: the same part of the argument is reused with a different function. RBC+C analysis shows that knowledge construct *xd* is consolidated by being used again, and at the same time elaborated.

Further commonalities between consolidating and the DCA criteria can be seen by considering the characteristics of consolidation: awareness, self-evidence, flexibility, immediacy, and confidence (Dreyfus & Tsamir, 2004). Self-evidence links to Criterion 1 because the evidence is the Data, which drops off in subsequent arguments. The subsequent argument also then relates to immediacy and confidence in the validity of the idea. Flexibility links to Criterion 2 because components of an argument are being reused and repurposed (as sign of flexibility) in subsequent arguments. Similarly, Criterion 3 relates to flexibility, but in a different way. Here the flexibility lies in the fact that one is able to use an idea (e.g, Build-with) as Data or Warrant for a variety of different Claims. Hence close relationships exist between the criteria and characteristics of consolidation.

We conclude this report by returning to vertical mathematization, which was highlighted as an Environmental commonality. We also see vertical mathematization as an Internal commonality. Both methodologies work from the premise that vertical mathematization is core to mathematical progress. In the RBC+C approach, consolidation is vertical mathematization and, as we argued above, the consolidation is closely linked to the three criteria.

## Conclusion

We now turn to discussing some implications for research. In addition to offering a theoretically and empirically grounded approach for coordinating methodologies for individual and collective mathematical progress, there exist specific ways in which this coordination can play out. For example, one could choose an individual student within the classroom community and trace their constructing actions for the ways in which they contributed to the emergence of various normative ways of reasoning. Alternatively, when considering a normative way of reasoning, a researcher could investigate who the various individual students are that are offering the claims, data, warrants, and backing in the Toulmin analysis used to document normative ways of reasoning. How do those contributions coordinate with individual student constructions? For instance, does a student ever utilize an utterance that a different student authored as data for a new claim that they are authoring, and in what ways may that capture or be distinct from other students' individual mathematical meanings? Future research could take up more directly the role of the teacher in relation to individual and collective level mathematical progress. More generally, however, this report contributes to an emerging discourse on theories and ways in which different theoretical approaches can be profitably networked (e.g. Bikner-Ahsbabs & Prediger, 2014).

## Networking strategies and the present study

In the past decade, strategies for connecting theories have been intensively discussed (e.g., Prediger et al., 2008). According to Prediger et al. (2008), the networking strategies are structured as follows: *understanding* and *making understandable*; *comparing* and *contrasting*; *combining* and *coordinating*; and *integrating locally* and *synthesizing*. The purpose of this study is to show my/our two case studies related to the networking theories in order to consider some meta-theoretical aspects of these studies. I will briefly introduce the two case studies, which have been developed by myself (Shinno, 2016) and by a Japanese research group (Shinno et al., 2015). The first study is concerned with combining and coordinating, and the second study is concerned with locally integrating.

By reflecting the researchers' practice on the two case studies at meta-theoretical aspects, I attempt to reconsider different treatments of theoretical terms in different strategies. This may allow us to analyse transition between pre/post statuses of the networking, although different strategies can be utilized for different purposes. Comparing the two studies, by focusing on the treatments of terms, I discuss how the elaboration of the original terms may influence the degree of integration.

## The two case studies: Overview

### Case study 1: *Combining and coordinating*

Shinno (2016) aims to characterize the development of mathematical discourses in a series of lessons in terms of the model of semiotic chaining by Norma Presmeg and the *commognitive* framework (Sfard, 2008). One of the research questions of this study is as follows: In what ways can the model of semiotic chaining be combined with the *commognitive* framework in the analysis of reification in the learning of square roots? For gaining multi-faceted insight of the reification phenomenon, Shinno (2016) attempts to coordinate the *commognitive* terms (such as *keywords*, *visual mediators*, *endorsed narratives*, and *routines*) with the semiotic terms (such as *signifier*, *signified*, and *interpretant*). By doing so, Shinno (2016) intends that the implicit meta-discursive rule (*routine*) may become explicitly identified as the semiotic component (*interpretant*).

### Case study 2: *Integrating locally*

Shinno et al. (2015) aims to construct a theoretical framework for curriculum development for teaching proof by means of integrating different theoretical constructs related to proof. In developing a framework, the notion of Mathematical Theorem comprised of the three elements – *statement*, *proof*, and *theory* – is used as the foreground of the framework. Some other theoretical constructs, such as *mathematical proof* by Nicolas Balacheff and *local organization* by Hans Freudenthal, are locally integrated into the framework in order to consider the wide range of contents and levels of

*statement, proof, and theory* in curriculum. As a result, Shinno et al. (2015) elaborate some additional categories by introducing new terms, for example, *real world logic*, *local theory*, and *quasi-axiomatic theory*, which are included in a category of ‘nature of system’ based on the concepts of *local organization*.

### **Discussion: Meta-theoretical aspects**

In the first study, when coordinating the semiotic and discursive terms, it seems that a theoretical term is interchangeable with another term (e.g., “an interpretant” with “a routine”). Therefore, even after the coordinating, it seems that the treatments of the terms can be preserved in both theoretical contexts. In other words, the results of the empirical studies can feedback to the original theories. In the case of Shinno (2016), it allows to analyse the reification phenomenon from the two different perspectives and to gain a deeper understanding of the phenomenon. In the second study, it seems that the basic constructs to be networked are ‘concepts’ rather than ‘theories’. Some original concepts such as *local organization* can be elaborated and integrated locally into new terminologies or categorizations in the constructed theoretical framework. Since elaborated terms have a consistency within the new framework and these can create new meanings, such terms cannot preserve their original senses. Thus, this networking strategy may contribute to establish a new theoretical discourse rather than to understand a certain empirical phenomenon. It seems that this strategy also can be utilized for developing or elaborating a new theoretical model.

*In this communication, we address the specific relationships between the Mathematical Working Space model (MWS model) and practice in the teaching and learning of mathematics. The strong and positive interactions existing between these two aspects are illustrated with two examples from geometry and probability teaching. They show how some theoretical constructs as MWS diagram can enlighten practice and, conversely, how studies on practice nourish the model with new tools such as “comics”, “complete mathematical work” or “emblematic tasks”.*

*Keywords: Mathematical work, MWS model, emblematic task, mathematics teaching.*

A decade ago, the Mathematical Working Space (MWS) model has been introduced as a theoretical and methodological framework dedicated to identify and shape the mathematical work in schooling. Developed by researchers working collaboratively in various countries with, sometimes, very different educational approaches in Europe (France, Spain, Cyprus), Latin America (Chile, Mexico...) and North America (Canada), the model is deeply rooted in the teaching of mathematics in real classrooms. This communication aims at showing dynamics and dialectics between the MWS model and relevant questions to education practice. After a short presentation of the MWS model, we show first how it can be used to deal with the question of planning series of tasks in the teaching and learning of geometry. That leads us to introduce two new constructs: the methodological tool of “comics” used to describe the evolution and circulation of the mathematical work and the more theoretical idea of “complete mathematical work” which allows qualifying the final nature of this circulation within the diagram. Then, these two new tools are used for the study of the teaching of probability and statistics. In France, this teaching is relatively new and it is now initiated on modeling tasks with use of technological tools. This leads us to check the relevance of the above constructs and identify two kinds of incompleteness of mathematical work and, in addition, to draw out certain specific tasks, named “emblematic tasks”. Designed on these former results, our present research aims at tracking transformations made by teachers when they adapt these “emblematic tasks” to their classrooms.

## A short insight in the MWS model

Extending the research work developed by Houdement and Kuzniak (2006) in didactics of geometry, the MWS model emerged during the last decade. The model, especially in geometry, had already been presented during former CERME meetings (Kuzniak and Nechache, 2015). A recent issue of ZDM-Mathematics Education (48-6, 2016) is devoted to this model and we refer the reader to this issue for further details and discussions about the MWS model. Some elements of the introduction (Kuzniak, Tanguay and Elia, 2016) to this issue are used to present the framework.

The theoretical model of Mathematical Working Space (MWS) provides a tool for the specific study of the mathematical work in which students and teachers are effectively engaged during mathematics sessions. The abstract space thus conceived refers to a structure organized in a way that allows the mathematical activity of individuals who are facing mathematical problems. It establishes the reference to the complex setting in which the problem solver acts. In this approach, the crucial function of educational institutions and teachers is to develop a rich environment which enables students to properly solve mathematics problems. To describe the specific activity of students solving problems in mathematics, the idea of organizing the MWS into two articulated planes is retained: one of an epistemological nature in close relation to the mathematical content in the field being studied; the other of a cognitive nature, related to the thinking of the individual solving problems. Three components in interaction are characterized for the purpose of describing the work in its epistemological dimension, organized according to purely mathematical criteria: a set of concrete and tangible objects, the term *sign* or *representamen*<sup>1</sup> is used to summarize this component; a set of *artifacts* such as drawing instruments or software; a *theoretical system of reference* based on definitions, properties and theorems.

The second level of the MWS model is centered on the subject, considered as a cognitive subject. In close relation to the components of the epistemological level, three cognitive components are introduced as follows: *visualization* related to deciphering and interpreting signs, and to internally building (psychological) representation of the involved objects and relations; *construction* depending on the used artifacts and the associated techniques; *proving* conveyed through processes producing validations, and based on the theoretical frame of reference. Furthermore, the development by communities or an individual, whether generic or not, of appropriate mathematical work is a gradual process by which a suitable MWS is settled through a progressive approach and fine tuning. Therefore, analyzing mathematical work through the lens of MWSs allows tracking down how meaning is progressively constructed, as a process of bridging the epistemological plane and the cognitive plane, in accordance with different specific yet intertwined genetic developments, each being identified as a genesis related to a specific dimension in the model: semiotic, instrumental and discursive geneses. This set of relationships can be described proceeding from the elements of the following diagram (Figure 1) which, in addition, shows the interactions between the two levels with three different dimensions or geneses: semiotic, instrumental, and discursive:

- The Semiotic genesis is the process associated with representamen (or signifiers), and accounts for the dialectical relationship between the syntactic and the semantic perspectives on mathematical objects, displayed and organized through semiotic systems of representation.
- The Instrumental genesis enables making artifacts operational in the construction processes contributing to the achievement of mathematical work.
- The Discursive genesis of proof is the process by which the properties and results organized in the theoretical reference system are being actuated in order to be available for mathematical reasoning and discursive validations.

The epistemological and cognitive planes structure the MWS into two levels and help to understand the circulation of knowledge within mathematical work. How then, proceeding from here, may one

articulate efficiently the epistemological and cognitive levels in order to make possible the expected mathematical work? How may one organize and describe interrelationships existing between our former three geneses? In order to understand this complex process, the interactions that are specific to the execution of given mathematical tasks will be associated to the three vertical planes, naturally occurring in the diagram of Figure 1: the [Sem-Dis] plane, conjoining the semiotic genesis and the discursive genesis of proof, the [Ins-Dis] plane, conjoining the instrumental genesis and the discursive genesis of proof, the [Sem-Ins] plane, conjoining the semiotic genesis and the instrumental genesis (Figure 2). The three planes are valuable tools for describing the interrelationships between the different geneses, for identifying and characterizing phases in the solving processes, for analyzing the shifts occurring in the course of these processes when specific aspects are, unexpectedly or gradually, either left aside or given more prominence.

**Figure 1: The Mathematical Working Space Diagram**

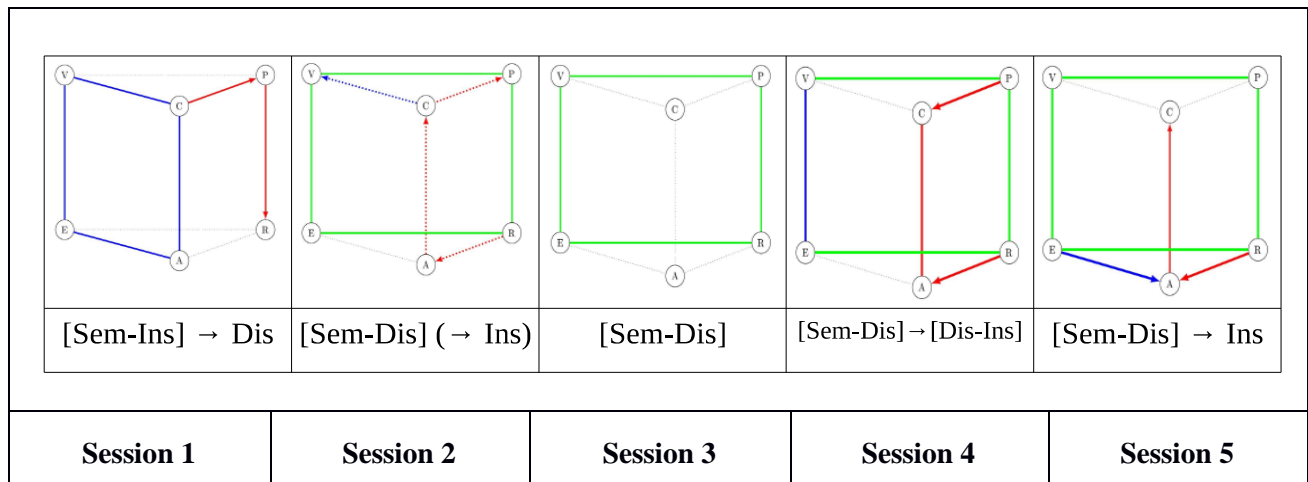

**Figure 2: The three vertical planes in the MWS**

The exact definition and precise description of the nature and dynamics between these planes during the solving of a series of mathematical problems remains a central concern for a deeper understanding of the MWS model. They vary with the mathematical field at issue, with the tasks, with the schooling level, with the type of work promoted or expected, etc.

### Planning of a teaching sequence in geometry at primary school

In France, at primary school level, numerous and interesting tasks in geometry are available and relatively easy to access. By contrast, few resources are available to help teachers to plan a series of geometrical tasks and activities for elementary schools students. To move forward on this issue, the MWS model (Kuzniak & Nechache, 2015) was used to identify some key points in organizing a long teaching sequence on a specific topic. Designed by two well-known French researchers in the domain (Fenichel & Taveau, 2009), the selected sequence “Le cercle sans tourner en rond” is dedicated to Grade 4-6 students. The sequence includes eight sessions from half an hour to one hour. Its main objectives are the introduction of the global notion of circle as the set of all points equidistant from a given point, named the center; to use this property for solving distance problems and make constructions with compass used also to transfer distances. The MWS diagram was used to analyse each of the sessions and to observe various circulations of the geometrical work through the different planes of the MWS diagram (Figure 2). For example, in session 1, the objective is to identify the circle as the set of all points equidistant from a given point, the centre. Students are

asked to place a point A on a white sheet and then a point B (semiotic dimension). After that, they have to place 15 points “situated at a distance from A which is the same as the distance of B from A” (semiotic dimension). They may use various artifacts: blank and tracing paper, twine, square set, compass (instrumental dimension). The geometric work starts in the [Sem-Ins] plane. Then, during a formulation phase, some students’ productions are displayed on the blackboard and discussed. The strategies used by the students to carry out the task are clarified and formulated. The notion of equidistance from a given point is expected to emerge. Some geometric terms are institutionalized and the characteristic property of the circle is given by the teacher and enriches the theoretical referential (discursive dimension) in the MWS. In summary, the geometric work starts in the [Sem-Ins] plane and is concluded in the discursive dimension (Dis). The same analysis has been made on five sessions and allows describing the dynamic evolution of geometric work. This evolution is visualised with the following “comics” which highlight the key-points of the sequence.

**Figure 3: The dynamic evolution of the mathematical work during the five sessions**

The analysis, supported on “comics”, demonstrates a comprehensive circulation through the three vertical planes of the MWS model (figure 2) leading to what we identify as a “complete geometric work”. More generally, a mathematical work is considered “complete” when both conditions (A) and (B) are satisfied:

(A) A genuine relationship between the epistemological and cognitive planes. This aspect means that students, be they generic or not, are able to select the useful tools to deal with a problem and then to use them appropriately as instruments to solve the given task.

(B) An articulation of a rich diversity between the different geneeses and vertical planes of the model. This aspect means that various dimensions of the work related to tools, techniques and properties are taken into account.

### **Identifying blockages and misunderstandings and checking if the mathematical work is complete and coherent**

Identifying blockages and misunderstandings requires observing how teachers implement tasks in their classroom. That allows us to describe what we call *suitable* MWS which depends on the institution involved, and is defined according to the way the knowledge must be taught, in relation to its specific place and function within the institutional curriculum.

## Identifying blockages and misunderstandings through the study of circulation within the MWS diagram

Our analysis is based on a classroom session at Grade 10 (age 15) (Kuzniak, Nechache & Drouhard, 2016) in which a task is given to the students with two questions on the probability values of an event. The statement of the exercise is written as follows in the textbook used by the teacher:

Two identical wallets are at disposal. The first contains 3 banknotes of 10 euro and 5 banknotes of 20 euro. The second contains 2 banknotes of 10 euro and 4 banknotes of 20 euro. One wallet is chosen randomly and a banknote is drawn “blindly” from this wallet. What is the probability of choosing one banknote of 10 euro? One banknote of 20 euro?

The underlying probabilistic model is that of equal probability. This model is not explicit, but the text makes reference to it with the following terms: identical, randomly, blindly. Moreover, this exercise involves a random experiment with two successive and not independent draws. The use of a weighted tree to solve the problem would be the most effective way to solve the problem. But, this particular type of tree only appears officially in Grade 12, the introduction of this kind of tree is something that is left for teachers to do. In the textbook, weighted trees are introduced before the exercise which is not the case in the observed class.

After some time left to search for a solution, a student is invited by the teacher to write his answer on the blackboard. He draws a non-weighted tree semiotic dimension to represent the situation and then gives his answer in the form of a fraction (Figure 4). The student gives numerical results without any justification and the tree is not only used for representing the situation but also as an implicit support for calculation instrumental dimension. His mathematical work starts in the semiotic dimension, which allows him to convert the problem into the form of a tree, the latter being then used to get the solution of the given problem. The student has performed his work in the [Sem-Ins] plane.

Figure 4: The student's tree on blackboard

Unsatisfied with the student's solution, the teacher asks him to explain his answer, and in particular, to explain the two results written on the blackboard (namely 5/14 and 9/14). Arguments given by the student are uniquely grounded on the semiotic dimension and the teacher is expecting one based on the discursive dimension, using properties. Then, asking various questions to the whole classroom, he attempts to shift the mathematical work to discursive dimension in order to develop a discursive proof of the results. The teacher emphasises strongly the importance of justification based on tools coming from the theoretical system of reference and this focus prevents him to notice the non-validity of the results provided by the student (the right results are 17/48 and 31/48). In fact, the mistake is linked to the student's insufficient knowledge about the nature and use of the tool “tree”. The student draws a choice tree which allows counting the outcomes, but which is not a

weighted tree. At this Grade, the teacher avoids the use of probability trees which are spontaneously used by his students. The mathematical work done by students remains in the [Sem-Ins] plane while the teacher confines it in the discursive dimension to promote a discursive proof. Thus, this leads to a misunderstanding and blockages among some students which can be related to the two different forms of mathematical work expected to solve the task.

### Mathematical work: Completeness and mathematical coherency

The following example is based on the analysis of a class session at Grade 9 (Kuzniak, Nechache & Drouhard, 2016) in which students are asked to solve the following task taken from Education Ministry resources:

On a segment  $S$ , two points  $A$  and  $B$  are taken randomly. The following outcome is considered “The length of segment  $[AB]$  is strictly superior to half the length of segment  $S$ ”. What is the probability of this event?

The event “The length of segment  $[AB]$  is strictly superior to half the length of segment  $S$ ” is labelled  $D$ . The solution suggested into the resource document is divided in two parts. In the first part, the reasoning work starts with an visual exploration on the segment (semiotic dimension) which is closely related to the use of an artefact (here a spreadsheet) for calculating numbers randomly with the *random* function (instrumental dimension). So, the mathematical work begins in the plane [Sem-Ins]. Then, based on the results given by the artefacts, an estimated value, closed to 0.25, is given and the estimation process is justified with the law of large numbers. The work done in this phase ends in the plane [Ins-Dis].

In the second part, the exact value (0.25) is justified with a discursive proof. It is first suggested to find all the couples  $(X; Y)$  such that  $|X - Y| > 1/2$ , where  $X$  and  $Y$  are two random variables with a continuous uniform distribution on the interval  $[0; 1]$  (use of the theoretical referential). The inequation is solved graphically (Figure 5) on the square  $[0; 1] \times [0; 1]$  (semiotic use of the square). Thus, the suitable couples  $(X; Y)$  belong to the gray zone (Figure 5), hence the probability of the event  $D$  is equal to  $1/4$  (based on visualisation). The mathematical work, really implemented, is placed in the [Sem-Dis] plane.

Figure 5: Geometric solution

In summary, the analysis, with the MWS model of the solution given by authors, of the resource document, serves to identify a circulation of the mathematical work through the three vertical planes of the diagram (Figure 2). Thus, a priori, the mathematical work can be regarded as potentially complete and mathematically coherent.

Figure 6: The evolution of the mathematical work

In the session we observed, the *suitable* MWS implemented by the teacher, and, thus, the resulting mathematical work, is really different from the potential one described above. The teacher asks the students to realize the random experiment first. They have to draw a segment with a given length, place two points randomly on this segment and, measure the distance between this two points and, compare the measure to half the length of segment  $S$ . Then, the teacher engages students to use a discrete model of the experience with throws of two six-sided dice to get an experimental value of the probability of  $D$  and, they get 0,3. Finally, the teacher gives the students a table ( $6 \times 6$ ) with 36 cells to complete and asks them to calculate the probability of  $D$ , which is equal to  $1/3$ .

In figurative terms, we can say that each phase favors one of the MWS vertical planes (Figure 2) moving from the [Sem-Ins] plane to help the understanding of the random experiment, to the [Ins-Dis] plane to obtain an experimental value of the probability, and finally to the [Sem-Dis] plane to give a theoretical validation based on counting numbers. In summary, the mathematical work proposed by the teacher provides an articulation between the various working contexts and can be considered complete. But, the probability of  $D$  in the model chosen by the teacher is  $1/3$  and is different from that expected in the official resource, which is  $1/4$ . This difference is due to the fact that the teacher wants to adapt the task to his classroom and changes the initial task by using a discrete model instead of a continuous model. This difference highlights the contradiction between the reference MWS expected by the authors of the resource document and the suitable MWS developed by the teacher. The consequence is that the mathematical work is not mathematically coherent according the expectations of the reference MWS, at this level, even if the mathematical work can be considered complete.

### **On mutual influence of theory and practice on the MWS development**

In this paper, we intend to show how analysis of tasks and teaching-learning sessions can benefit from and participate in the development of the MWS model. Is it possible to generalize our results to other theoretical approaches? We cannot assert, because the MWS model is still an emerging and growing model that is difficult to compare with mature theories. As Artigue (2016) underlines, one of the current characteristics of the model is precisely its plasticity and adaptability that, according her, big and mature French theories do not have. Moreover, conceived to describe and ensure the dynamics of mathematical work, the MWS model cannot be improved without a close and dialectic link with researches on tasks and activities favoring the tuning of the mathematical work.

### **Research perspective: Teaching trajectory and mathematical work**

In the previous section, we have shown how, in some cases, teachers have transformed tasks in such a way that students have been blocked or engaged in mathematical work far from the intended one. In our present research and using the MWS model, we address the following questions: When do some blockages arise in the mathematical work? How can they be characterized? What is their origin? Which kind of teachers' adaptations and changes allows keeping (or not) a complete and mathematically coherent mathematical work? The research objective is to identify misunderstandings or resistance points or, instead, favorable rebounds which allow that an activity goes on nicely in the classroom. It is also possible to focus on tasks transformations leading to

denaturing when the intended mathematical objective is lost and questions of reproducibility and didactic obsolescence can be addressed.

To do this, some specific tasks, named “emblematic tasks” and verifying several conditions, are chosen. They must benefit first from an institutional recognition which ensures their compatibility with the intended mathematical work. Then, they are already provided by textbooks and, above all, implemented in some regular classrooms. Lastly, they may convey a complete mathematical work as defined above. We make the assumption that adequate and solid learning can result from the implementation of these tasks in classrooms if they are not too distorted through the teaching process. To study this assumption, these emblematic tasks are first implemented in pre-service teachers training by experienced teachers trainers and their transformations by the pre-service teachers are studied. The teachers training framework helps us to monitor the development and implementation of tasks in classrooms and makes easier the study of teaching trajectories according our research objectives. Moreover, two other specific objectives related to teacher training can be added to our research program: the use of “emblematic tasks” may initiate students to new and interesting forms of mathematical work for those who are not familiar with; the assessment of the impact of this approach on students' belief by analyzing the different transformations and adaptations of the tasks. In a way, emblematic tasks can help to understand the link between teaching and learning.

# The Mathematical Working Space model: An open and adaptable theoretical framework?

Charlotte Derouet, Alain Kuzniak, Assia Nechache, Bernard Parzysz, Laurent Vivier

Université Paris-Diderot, LDAR (EA 4434), Paris, France; [alain.kuzniak@univ-paris-diderot.fr](mailto:alain.kuzniak@univ-paris-diderot.fr)

**Keywords:** *Activity theory, cognitive approaches, MSW model, networking theories*

For more than a decade, a theoretical approach focusing on mathematical work in schooling has been developed by an international community of researchers. Grounded on geometry education research, the Mathematical Working Space (MWS) model emerged from this collaborative work and has been developed during symposia, the fifth of which being held in Florina in July 2016. Recent publications in English, French and Spanish (Relime 17(4), 2014; Bolema 30(24), 2016) and in English (ZDM-Mathematics Education 48(6), 2016) may be helpful for discovering this model and its current state.

This poster aims at illustrating and discussing one of the specificities of the model, which means that it was conceived to interact with other approaches. As Artigue (2016, p. 938) underlies:

But the MWS construction is an object of a very different nature, at least in its current state. Its logic seems more that of an assembly that would incorporate, possibly with adaptation, a diversity of constructs and perspectives developed in the field, without privileging any of them. This gives the MWS structure a plasticity that big theories (...) do not have, and certainly contributes to its accessibility and attractiveness.

Conversely, this plasticity and attractiveness pose the challenging question of the real nature of its relationships with other theoretical approaches, which may be grounded on very different epistemological and methodological principles. In this poster our purpose is to address this question through some examples. For that reason, some key-points of the model will be presented and, in particular, how the study of mathematical work in schooling is framed. Then, some examples will be given to illustrate possible interactions with other theoretical and exogenous frameworks. All the examples come from special issues on MWS model and MWS symposia. The list of examples is not complete and other frameworks have been used, although they do not appear in the poster (Didactical Situation Theory, Anthropological Didactical Theory, Semiotic registers, etc.). Naturally, all the examples cannot be considered in detail but the fact that the model is supported on a diagram assists to illustrate interactions. The poster is organized around diagrams showing the findings of the different papers and questioning the openness and adaptability of the MWS model.

**Combining the model with Drouhard's epistemography.** Drouhard's epistemography use has changed the view on tool and instrument in the MWS model (Kuzniak, Nechache & Drouhard, 2016). Depending on their nature and on the way they are being exploited to solve the problem, tools may be situated in any of the three poles of the epistemological plane. In the cognitive plane, one speaks of an instrument whenever a subject interacts with a tool in order to tackle a task effectively. Thus, a tool is associated with a corresponding instrument in the cognitive plane.

**Interactions with Activity Theory.** Hitt, Saboya and Cortés (2016), investigate the articulation between arithmetic thinking and early algebraic thinking, through the analysis of an experiment

which focuses on secondary school students' spontaneous productions. The experiment is conducted within a research methodology based on Activity theory. The MWS model, used as a framework, is here adapted into an 'Arithmetic-Algebraic Working Space' (A-AWS), whose cognitive plane displays an articulation between arithmetic and algebraic thinking.

**Completing APOS theory with the MWS model.** Camacho Espinoza and Oktaç (2016) provide a study, using APOS Theory, on an University teacher in Mexico solving a task in linear Algebra. APOS helps to understand the work at a micro level using the mental mechanism of desencapsulation of an Object into a Process, and the authors use the MWS model to understand the global logic of this work at a macro level.

**Integrating the MWS model in cognition and affect studies.** In a technological (with Dynamic Geometry Software) collaborative setting, Gómez-Chacón, Romero Albaladejo and García López (2016) study the interplay between cognition and affect in geometrical reasoning. Their study integrates the MWS frame to enable a detailed exploration of the transitions from instrumental to discursive geneses of reasoning, within teacher-student and student-student interactions, and also of the cognition-affect dynamics in this process, with a focus on mathematical attitudes.

**Coordinating the MWS and MTSK model to understand teachers' knowledge and the role of the teacher in the classroom.** The MWS model describes the mathematical work development by teachers through the teaching implemented. Carrillo et al. (2016) suggest an articulation between the MWS model and the MTSK theoretical model (Mathematics Teacher's Specialised Knowledge) to emphasize the specific role of Teacher's Knowledge in this learning process.

*The utilisation of multiple theories in a single research study requires careful consideration with respect to the complementarity of the theories and the commensurability of the associated research accounts in relation to the specific setting or research site. This paper proposes that commensurability is constructed to facilitate the comparison that researchers are trying to make. The Social Unit of Learning project is conducted in a laboratory classroom facility equipped with 10 built-in cameras and up to 32 audio channels allowing structured, rigorous, fine-grained investigation of the social aspects of classroom practice. The rich and detailed data generated allows parallel analyses predicated on different theories. Complementarity of theories is distinguished from commensurability of research accounts, which requires the identification of operationalised constructs (e.g., categories or measures) common to the accounts generated.*

*Keywords: Classroom research, video technology, research methodology, research design.*

## Comparability as a challenge in learning research

With the abundance of theories and perspectives that have been generated through research over the years, a continuing challenge that researchers face relates to the difficulty of navigating the multitude of theories available (Bikner-Ahsbahr & Prediger, 2014; Cobb, 2007). In this paper, we consider the conditions under which multiple theories might be deployed for the simultaneous, parallel analysis of a single social setting, with a specific focus on the roles of complementarity and commensurability in undertaking comparison of either the theories or the analytical accounts arising from any such multi-theoretic research design.

Clarke and his colleagues (e.g., Clarke, Emanuelsson, Jablonka, & Mok, 2006) have advocated “complementarity” as central to the contemporary conceptual management of theory and methodology, particularly in their use of “complementary accounts” (Clarke, 1997). In the same way that two research accounts of a social situation may be different but equally legitimate and informative, so two theories may be complementary in their foregrounding of different constructs. Like the accounts, both may be simultaneously “true” within their own coherent conceptual framework so that they are disjoint but separately coherent. Tensions between theories emerge when we juxtapose the analytical accounts derived from two different theories in relation to the same research setting and the coherent body of practice that occurs there. A specific difficulty with juxtaposing and connecting existing theories and their associated constructs is the possible incommensurability of the accounts generated by their application, particularly because theories arise historically from observations based on different research designs, settings and participants.

Direct comparison of analyses employing different theories, without considering the contexts or settings in which the theories are being applied and the intended purpose of their application, empirically undermines the integrity of the comparison and the legitimacy of the conclusions drawn

from the comparison. Consideration of “the right to compare” (cf Stengers, 2011; Clarke, 2013) must take into account differences between findings or interpretive accounts that relate to different physical spaces, different times, and/or involve different actors, activities, or cultural contexts. Clarke (2013) expressed an analogous concern regarding international comparative research, where a single theory is applied across multiple culturally distinct settings for the purposes of comparison with respect to a specific construct (e.g., student achievement). In such studies, researchers can risk compromising the validity of the comparison made in their study by misrepresenting the valued performances, school knowledge, classroom practice, etc. that are differently conceived by the communities being compared. A construct such as “student participation” can be conceived so differently (both theoretically and in practice) in different cultural settings that it cannot be employed as a “boundary object” (Akkerman & Bakker, 2011), that is, as a point of connection by which classroom practice in the different settings might be compared. In the application of a single theory across different cultural settings, it is the questionable validity of application of the same construct in the compared settings that renders the accounts incommensurable.

We are employing commensurability in the sense of the construction of common points of distinction<sup>1</sup>, which can be seen as related to the notion of boundary objects. *Boundary objects* have been described as “artifacts that live in different practices, but can be used in different ways” (Bakker, 2016, p. 272). Consistent with Akkerman and Bakker (2011), we caution against the identification of a boundary object simply on the basis of similarity of name without an empirical grounding suggesting functional equivalence. In the case of “participation,” such assumed functional equivalence can conceal profound differences in nature. To illustrate the extent of such differences, the significance attached to student talk as facilitative of learning in Western theories (and practice) is contested by theorists writing from a different cultural and theoretical position (e.g., Kim & Markus, 2004), leading to entirely different theorisations of the constitution of student participation. Attempts to connect theories in which definitions of student participation were predicated on such different epistemologies would lead to accounts that not only lacked comparability, but were in fact incommensurable, since the connecting construct “student participation” would admit no common points of distinction in the application of the two theories to any setting. In this sense, one might describe the two *theories* as being incommensurable *in their application*, but we suggest that the theories are better thought of as complementary (disjoint, but separately coherent), and it is the *accounts* arising from their application that are incommensurable. Accounts, like theories, can be complementary (disjoint but separately coherent), but commensurability is an attribute of accounts alone, implying consideration of context and purpose.

We argue that the commensurability of two theories cannot be meaningfully examined except in so far as they are “put to work” in the analysis of data. The interpretive accounts generated by such analyses (whether qualitative or quantitative) can then be compared and assessment made of the points of correspondence or dislocation in the accounts (e.g., through the identification of common points of distinction). Such points of correspondence take the form of operationalised constructs

---

<sup>1</sup> Our usage of “points of distinction” draws on the comments of John Mason during a conversation on 10 February 2017.

having similar meaning within both theories and which therefore serve to align the interpretive accounts for the purposes of comparison and connection. Such operationalised constructs may be thought of as boundary objects (Akkerman & Bakker, 2011). A “boundary object” in this discussion is an operationalised construct that has conceptual legitimacy and similar meaning in both theories being applied, connected, and compared. Where no such constructs exist, the theories are disjoint and each may be applied independently of the other to investigate the same or different settings (Clarke et al., 2012). In such a case, the disjoint theories are complementary, although incommensurable with respect to any setting to which they might be applied analytically, sharing no constructs by which comparison of the resultant accounts might be undertaken.

How might different theoretical perspectives be juxtaposed and connected in a way that allows the commensurability of the analytical accounts to be examined? This paper proposes as one solution the construction of research designs that involve the generation of data, which are complex and rich in detail, while sufficiently structured to allow systematic investigation of both the research setting and the multiple theoretical perspectives employed. The affordances of such research designs are illustrated with examples from the Social Unit of Learning Project, which utilises the newly established laboratory classroom facility to generate data amenable to multi-theoretical analysis.

### **The Social Unit of Learning Project**

The recent development of a laboratory classroom at the University of Melbourne (see <https://pursuit.unimelb.edu.au/articles/high-tech-classroom-sheds-light-on-how-students-learn>) has made possible research designs that combine better approximation to natural social settings, with the retention of some degree of control over the research setting, task characteristics, and possible forms of social interaction. Such designs allow conclusions about connections between interactive patterns of social negotiation and knowledge products (learning) to be made with greater confidence. The Social Unit of Learning Project used the Science of Learning Research Classroom (SLRC) at the University of Melbourne to examine individual, dyadic, small group (four to six students) and whole class problem solving in mathematics and the associated/consequent learning. The project aims to distinguish the social aspects of learning and, particularly, those for which “the social” represents the most fundamental and useful level of explanation, modelling and instructional intervention. The project conforms to an experimental rather than a naturalistic paradigm. The caveats for the experimental approach are discussed in greater depth elsewhere (Chan & Clarke, in press). The SLRC has the capability to capture classroom social interactions with a rich amount of detail using advanced video technology. The facility was purposefully designed to allow simultaneous and continuous documentation of classroom interactions using multiple cameras and microphones. The project collected multiple forms of data for analysis including student written products and high definition video and audio recordings of every student and the teacher in the classroom. This allows the examination of data from multiple perspectives by multiple researchers as well as the reciprocal interrogation of the different theoretical perspectives through answering research questions such as the following:

1. What commonalities and differences in process and product are evident during problem solving activities undertaken by learners as members of different social units (individual, pairs, small groups and whole class groupings)?

2. Which existing theories best accommodate the documented similarities and differences in process and product and in what ways do the accounts generated by parallel analyses predicated on different theories lead to differences in instructional advocacy?

The following presents work currently being carried out to lay the foundation for considerations of complementarity and comparability in a multi-theoretic research project.

### **Data generation**

The SLRC is equipped with 10 built-in video cameras and up to 32 audio channels. Intact Year 7 classes were recruited with their usual teacher in order to exploit existing student-student and teacher-student interactive norms. Two classes of Year 7 students (12 to 13 years old; 50 students in total) provide the focus for this report. Each of the classes participated in a 60-minute session in the laboratory classroom involving three separate problem solving tasks that required them to produce written solutions. The students attempted the first task individually (10 minutes), the second task in pairs (15 minutes), and the third task in groups of four to six students (20 minutes).

The problem solving tasks used in the project were drawn from previous research (e.g., Sullivan & Clarke, 1991). All three tasks had multiple possible solutions, included symbolic or graphical elements, and afforded connection to contexts outside the classroom. These features can make the thinking and/or social processes of the problem solving activity more visible, as the students can express their thinking through multiple modes (e.g., verbal, graphical, textual, etc.) and approach the task using different strategies or prioritise different forms of knowledge or experience. Nonetheless, despite sharing some similar features, the content foci of the three tasks were deliberately disconnected to avoid carry-over effects between tasks.

Task 1 provided students with a graph with no labels or descriptions with the following instructions: “What might this be a graph of? Label your graph appropriately. What information is contained in your graph? Write a paragraph to describe your graph.” Task 2 was specified as follows: “The average age of five people living in a house is 25. One of the five people is a Year 7 student. What are the ages of the other four people and how are the five people in the house related? Write a paragraph explaining your answer.” Task 3 stated that “Fred’s apartment has five rooms. The total area is 60 square metres. Draw a plan of Fred’s apartment. Label each room, and show the dimensions (length and width) of all rooms.”

The resulting data collected in the project include: all written material produced by the students; instructional material used by the teacher; video footage of all of the students during the session; video footage of the teacher tracked throughout the session; transcripts of teacher and student speech; and pre- and post-lesson teacher interviews.

### **Parallel data analyses**

As an entry point for analysing the project data, the written solutions, transcripts, and video record are used to understand the social process that took place to produce the written solution. The instructional material and teacher pre- and post-lesson interviews provide insights about the class capabilities and social relationships that the researchers would not otherwise be able to access.

Several parallel analyses are currently being undertaken drawing on the established research expertise of classroom research communities in three countries. For example, in Australia, Clarke

and Chan are conducting an analysis which identifies the negotiative foci of the students' social interactions during collaborative problem solving taking the social negotiation of meaning as a key constitutive element of learning (e.g., Clarke, 1997); in Spain, Díez-Palomar is conducting an analysis of the dialogic character (Mercer & Howe, 2012) of the spoken interactions of students working in collaborative groups; and in Finland, Tuohilampi is carrying out an investigation of the affective enablers and disablers of student participation in collaborative group work that uses Goldin's motivating desires (Goldin, Epstein, Schorr, & Warner, 2011) to explore the extent to which a group of students established a productive affective micro-culture. A theory is recruited to this study for its capacity to address constructs, artefacts or situations distinct from those addressed in other theories being employed – that is for its capacity to complement those already selected.

Connection of these three analyses is made possible by their application to a common set of social events occurring in the same research setting. The validity of any connections between the parallel analyses is heightened by their grounding in data from the same source and their application to a common interactive sequence. For example, consider the following excerpt when Anna and Pandit were writing up their response to Task 2 (pair task):

- Anna: Okay. So let's explain it here.  
 Pandit: So - so 7 ... //One kid...  
 Anna: //Because we have to write it in words. (Note. // indicates overlapping speech.)  
 Pandit: So one kid has to be four... 17.  
 Anna: No, no, no. So ...  
 Pandit: (Laughs)  
 Anna: I'm going to write it.  
 Pandit: One kid has to be 17.  
 Anna: So ...  
 Pandit: So wait, no, no, no, no.  
 Anna: ... because ...  
 Pandit: Oh a seven - a Year 7 is 13.  
 Anna: I'm ignoring you.  
 Pandit: You can't - So - So sad. I'll draw.

From the excerpt, we can examine the focus of the students' negotiation on the task requirements or sociomathematical focus (Anna: "Because we have to write it in words."), the coordination of the mathematical components of the task or mathematical focus (Pandit: "One kid has to be 17."), and the social obligations of the participants or social focus (Anna: "I am ignoring you"; Pandit: "You can't.").

At the same time, the transcript allows the investigation of the dialogic character (García-Carrión & Díez-Palomar, 2015) of the participants, where the excerpt began with Pandit offering information to Anna for her writing up of the results and ended with Anna rejecting Pandit's contribution. The conversation shifted from the dialogic interaction initiated by Anna ("So let's explain it here ... because we have to write it in words.") to non-dialogic or authoritarian talk (Anna: "I'm ignoring you."; Pandit: "You can't.").

From an affective perspective, Anna and Pandit both appeared to share the same motivating desire to “Get the Job Done” (Goldin et al., 2011, p. 553). However, Pandit appeared to also appeal to the motivating desire of “Let Me Teach You” (p. 554) by dictating the information to be written down by Anna (“So one kid has to be four... 17 ... One kid has to be 17. ... Oh a seven - a Year 7 is 13.”). Her attempt to take on the higher epistemic role did not appear to be well received by Anna. Upon being rejected by Anna, Pandit’s desire quickly changed to “Don’t Disrespect Me” (p. 553) by being disengaged from the task and switched to off-task drawing.

Although all three analyses focus on the same interactive episode during collaborative problem solving, each analysis highlights different aspects of the social interaction. The multitheoretic research design of the project provides the context for the consideration of how commensurability may be conceptualised in relation to the parallel analyses.

## **Discussion and conclusion**

This paper presented three analyses that are currently being applied to the data that have been generated from the laboratory classroom concerning the same interactive episode of collaborative problem solving. The approach allows direct comparisons to be made between the applications of the three analyses (negotiative foci; dialogic theory; and motivating desires) in terms of what constitutes evidence within the realm of each analytical framework, the unit of analysis, and the conclusions that can be drawn from the analyses, all of which could form the basis for the evaluation of the commensurability of the separate analyses. In the case of the project, commensurability can be evaluated in relation to a common construct with respect to which each of the analyses might be employed to make comparative distinctions (either descriptive or evaluative).

For example, for the purpose of distinguishing between different interactive episodes with respect to the construct of “student engagement”, the analytical accounts derived from dialogic theory and the theory of motivating desires can be seen as commensurable, whereas it is more difficult for an analysis with respect to negotiative focus to make useful distinctions with respect to engagement. The analyses based on dialogic talk (in terms of the ways in which students put forward their arguments) and on motivating desires (in terms of the fulfilment of goals or beliefs through social interactions) can each be seen as potentially capable of distinguishing between interactive episodes in terms of some conception of the quality of “student engagement” during collaborative problem solving, even though the premises on which the two analyses might make such evaluative distinctions would be different. On the other hand, the consideration of the negotiative foci of particular interactive episodes distinguishes between types of “student engagement” in a descriptive but non-evaluative way. In this sense, the account provided by the analysis of negotiative focus does not suggest any points of evaluative distinction in terms of student engagement, in the way that is possible with the accounts provided by the other two analyses. This renders it incommensurable with the other two analyses with respect to the construct “student engagement”.

We want to emphasise that commensurability between theoretically-grounded analytical accounts should not be seen as “an ideal state” but as a reference point for examining the connections between theories. Stengers (2011) makes the essential point: “Commensurability is created and it is never neutral, always relative to an aim” (p. 55). In the case of multi-theoretic research designs, researchers are obliged to construct commensurability to facilitate the comparison that they are

trying to make between theoretically-grounded analytical accounts. The utilisation of multiple theories is enhanced through the identification of shared operationalised constructs (such as “student engagement”), intrinsic to or derivable from the interpretive accounts in question, the existence of which is prerequisite for their commensurability. Complementarity between the theories discussed can be accommodated independently of arguments concerning commensurability. The emphasis on complementarity removes the obligation that interpretive accounts should converge to a single truth. We posit that theories can be complementary in their conceptual totality (having different epistemological and ontological bases) but nonetheless invoke operationalised versions of specific constructs common to both theories which could be used to interrogate the setting, and form the basis for interpretive accounts which can then be juxtaposed with respect to their implications for practice. The viability of multi-theoretic designs does not demand that all accounts be commensurable. Some accounts may be simultaneously coherent and consistent with the data, but disjoint, in that they employ different operationalised constructs.

In conclusion, this paper argues for the importance of considering the roles of complementarity and commensurability in multi-theoretic research designs. We suggest that the consideration of complementarity resides between theories while commensurability can only be examined in relation to the interpretive accounts arising from the application of the theories. By juxtaposing theories applied analytically to data generated from the same setting, the research design of the Social Unit of Learning Project accommodates the complementarity of theories and affords an informed judgement of the commensurability of the parallel interpretive accounts. The consideration of commensurability obliges researchers to articulate the nature of the comparability between theoretically-grounded interpretive accounts when juxtaposing theories. We feel that the explication of complementarity and commensurability in this paper should contribute to the further theorisation of multi-theoretical research approaches.

# The perspective of indexicality: How tool-based actions and gestures contribute to concept-building

Daniela Behrens<sup>1</sup> and Angelika Bikner-Ahsbabs<sup>2</sup>

<sup>1</sup>University of Bremen, Germany; [daniela.behrens@uni-bremen.de](mailto:daniela.behrens@uni-bremen.de)

<sup>2</sup>University of Bremen, Germany; [bikner@math.uni-bremen.de](mailto:bikner@math.uni-bremen.de)

*In this paper we apply the theoretical perspective of indexicality to gesture use on a digital place value chart on the iPad and show that this perspective allows for explaining how mathematical meaning is accumulated linking specific gestures to the actions performed on the digital device. Thus, practical dragging leads to structural dragging via operational dragging, resulting in a shift of the representational function of gesture (gesture-of) to the epistemic function of gesture (gesture-for).*

**Keywords:** Digital tool, indexicality of gesture, gesture-of and gesture-for, modes of dragging.

## Introduction

De Freitas and Sinclair (2013) have proposed to adopt a new materialistic view in research on learning mathematics, specifically for technology use. In this respect, the indexicality of signs is relevant (Sinclair and de Freitas, 2014). This paper investigates the added value of the theoretical perspective of indexicality while adopting it to the analysis of technology-based epistemic processes in the design project DeciPlace, to understand more deeply how acting based on a multi-touch surface contributes to building mathematical knowledge.

DeciPlace is a design-based research project. Its main goal is to develop a task sequence for conceptualizing decimal fractions as structures in small groups of students by the use of a digital place value chart (DPC) on the iPad (Behrens, 2016; Behrens & Bikner-Ahsbabs, 2016). The core approach is to act tool-based with the DPC. Thereby, conceptualizing is not considered as a pure individual cognitive process but as a collective communicative process of constructing mathematical structures in an embodied and multimodal way (see Krause, 2016). For this kind of learning, the instrumental approach (see Drijvers, Kieran & Mariotti, 2010), which is often used for research on technology learning settings, fails to attain insight into the epistemic process in all its aspects. Our focus is on tool-based acting and interacting. However, the way this contributes to knowledge construction is not yet understood in-depth. In this paper, we will first present the tool, then outline what we mean by indexicality and finally apply this perspective in the analysis of some episodes from the DeciPlace data corpus to show how the adoption of this perspective deepens insight into tool-based collective learning.

## The digital place value chart (DPC)

The digital place value chart on the iPad (designed by Ladel & Kortenkamp, 2013; iTunes-App: “Place Value Chart”) can represent a number on three different levels in parallel: In the bottom row of the chart tokens can be displayed by tapping on the screen. In the upper row the name of the place value as well as the number of tokens in each column of the place value chart is indicated. Additionally the standard notation of the represented number can be displayed above the chart. When the user drags a token to the next (after next) column to the right, the token is de-bundled

automatically into ten (hundred) tokens and so on (see Figure 1). The other way around, by dragging a token to the next (after next) column to the left, either nine (99) tokens move along with the dragged token bundling together to one token in the new column or – if there are not enough tokens to come along with – the dragged token slides back to its origin. Hence, in contrast to traditional place value charts (paper and pencil or material tokens) this digital version de-bundles and bundles (if possible) automatically, while the represented value is kept constant, and it gives feedback if the intended manipulation is impossible.

**Figure 1: De-bundling a token from ones to tenths in the digital place value chart**

### **Recent results: Three modes of dragging**

In the analysis of activities on the DPC by a pair of grade 6 students who were introduced to the extension of the place value system from natural to decimal numbers, we noticed a shift in the students' activities from dragging-actions on the iPad to dragging-gestures (incorporated by the characteristic movement to the right or left), becoming more and more independent from the representation on the screen during the course of interaction with the DPC (see Behrens & Bikner-Ahsbahr, 2016).

Using an epistemic analysis based on ideas developed by Krause (2016) we were able to distinguish three modes of dragging:

- *Practical dragging* comprises actions of dragging tokens performed directly on the digital place value chart, when students use the function of bundling or de-bundling by dragging with a practical aim without scrutinizing the underlying principle.
- *Operational dragging* can be observed when students are able to foresee the result of bundling or de-bundling or when they want to test something by dragging a token intentionally in the chart, so that they use both transformations to fulfil a particular goal. This mode of dragging can be manifested either as a direct act of dragging in the digital place value chart or as a dragging-gesture referring directly to the chart.
- *Structural dragging* becomes apparent, when a particular mathematical structure is being described generally and the movement of dragging is represented in a gesture from left to right or vice versa performed independently from any concrete representation.

### **Aim of this paper**

Using these three modes of dragging, we were able to describe the epistemic role of gestures in processes of building the decimal fractions' concept, which is mainly based on the principle of bun-

dling and debundling (see Behrens & Bikner-Ahsbahs, 2016). However, we were not able to understand in detail how these three modes of dragging contributed to processes of learning based on the digital artifact. In this paper, we will address this topic by answering the following research question:

*How do actions and gestures “regarded as indices” contribute to conceptualizing the decimal fractions’ concept based on the digital place value chart on the iPad?*

## **Describing the theoretical approach: Actions and gestures regarded as indices**

In this paper, we focus on the connection between the digital place value chart and a pair of individuals interacting with each other with regard to the device. To examine this interaction we focus on signs which are produced in the setting, such as gestures, inscriptions, tokens on the display, the artifact itself and so on.

The students’ collective epistemic process is manifested in their actions (based on the tool), their verbal utterances and other semiotic resources. These actions can be analyzed in a multimodal way based on the concept of the semiotic bundle (Arzarello, 2006), which consists particularly of gestures, speech, inscriptions and relations among each other. To emphasize the influence of tool-based actions on speech, gesture and inscriptions, we adapt the perspective of the indexicality of actions on multi-touch devices described by Sinclair and de Freitas (2014). This perspective draws on Peirce’s notion of semiotics, “in which signs (icons, indices and symbols) differ in terms of the nature of the relationships between the signifying sign and the signified” (Sinclair & de Freitas, 2014, p. 355). According to Peirce, a sign is defined by a triadic relation between sign, object and interpretant:

A sign, or *representamen*, is something which stands to somebody for something in some respect or capacity. It addresses somebody, that is, creates in the mind of that person an equivalent sign, or perhaps a more developed sign. That sign which it creates I call the *interpretant* of the first sign. The sign stands for something, its *object*. It stands for that object, not in all respects, but in reference to a sort of idea, which I have sometimes called the *ground* of the representamen. (Peirce, 1932, 2.228, emphasis in the original)<sup>1</sup>.

As a consequence, a sign comes into being when there is an individual who produces an interpretant according to the relation between the sign and the object. This relation distinguishes a sign to be an icon, an index or a symbol (Peirce, 1994, p. 239).

While an icon is characterized by producing the idea of resemblance of sign and object in individuals and symbols are defined to be conventionalized signs, an index

refers to its object not so much because of any similarity or analogy with it, [...] as because it is in dynamical (including spatial) connection both with the individual object, on the one hand, and with the senses or memory of the person for whom it serves as a sign, on the other (Peirce, 1932, 2.305, cited in Sinclair & de Freitas, 2014, p. 355f.).

---

<sup>1</sup> This refers to Peirce in terms of ‘(section/page)’, where 2.228 stands for ‘volume 2, paragraph 228’.

By this, indexical signs “show something about things, on account of their being physically connected with them” (Peirce, [1894] 1998, p.5; cited in Sinclair & de Freitas, 2014, p. 355).

Sinclair and de Freitas (2014) emphasize that also the action that resulted in the emergence of another sign may be included in the concept of indexical signs:

For instance, the chalk drawing of a parallelogram on a blackboard is often considered to be an iconic reference to a Platonic conception of parallelogram, but it is also an indexical sign that refers to the prior movement of the chalk. This latter indexical dimension is usually not emphasized in the semiotic study of mathematical meaning making, since we tend to focus on the completed trace and dislocate it from the labour that produced it. (Sinclair & de Freitas, 2014, p. 356)

Taking this assumption into account, we can further assume that every process of producing a sign is an indexical sign referring to the sign and the sign itself refers indexically back to the effort which produced it.

They conclude that “indexation becomes part of an experience that exceeds itself, and is thus self-generative” (p. 359). Thus an action on multi-touch screens leaves traces, hence, these traces as well as a hand gesture may refer to the original action when this gesture is produced in a similar way to the action on the device. Taking up this theoretical perspective we want to examine the above described modes of dragging with respect to “how they function as indexical, material actions” (p. 360) trying to explain how dragging movements contribute to build the concept of decimal fractions.

### **Applying the theoretical approach: Indexicality in dragging modes**

We are re-analyzing episodes of our design-study DeciPlace (Behrens & Bikner-Ahsbahr, 2016) in order to answer the above posed research question. This way we will investigate the added value of this indexicality perspective.

As described above, practical dragging takes place when tokens are dragged directly in the digital place value chart from one column to the other either to the right or to the left without observable intention. The digital place value chart reacts to this practical dragging of one token to the next column on the right by de-bundling this token into ten tokens. Likewise, the DPC can bundle ten tokens to one in the next column, when one token is dragged into the next column on the left. Bundling and de-bundling by dragging keeps the value of the decimal number the same. This way, dragging can be linked to bundling or de-bundling in a material way being performed as an action of dragging from right to left or vice versa on the DPC. According to Sinclair and de Freitas (2014) an action of dragging leaves traces – e.g. the new arrangement of tokens within the chart – which refer back to the original action of dragging and vice versa.

In the following scene, two students are asked to find different representations for the number 101 in the place value chart:

- 1     Bella:        I’ll just try (*drags a token from hundreds to tens within the digital place value chart on the iPad (in the tens’ column ten tokens emerge)*, see Figure 2) Woah
- 2     Hanna:       Ten and One.

**Figure 2: De-bundling as dragging from hundreds to tens**

In this scene of practical dragging the newly emerged bunch of ten tokens in the tens' column can be seen as an iconic sign representing ten tens and therefore the number 100. Additionally the bunch of ten tokens refers back to the action of dragging a token from the hundreds' column to the tens' column on the DPC and at the same time to the DPC's reaction by letting the token explode into ten tokens without changing the represented number (concept of de-bundling). Thus, a new sign emerged by indexation linking the action of dragging on the DPC with a visual representation of de-bundling. This in turn produced a reaction of astonishment expressed by Bella ("Woah"), again referring back to the DPC's reaction on her dragging.

When the students get more and more familiar with the DPC in phases of practical dragging, they may apply movements of dragging intentionally for a specific purpose, for example while making a conjecture or predicting what will happen in the case of dragging directly in the DPC. Operational dragging can take place as an action of dragging *on the surface of the device* and also as a gesture *directly above the surface* referring to the DPC but without touching it (the so-called potential level, see Krause, 2016, p. 134–139). Because of the material link between dragging actions and dragging gestures both being performed by a similar movement from left to right or vice versa, dragging gestures may refer to previous actions of dragging and what is already linked with them. In this respect, operational dragging being conducted as a gesture on the potential level of reference is materially linked to the performance of dragging in the DPC and at the same time linked to the traces which are potentially and materially produced by that.

In the following situation the place value "tenth" is just introduced by the interviewer adding the new column named "tenth". The students are asked to find further representations for the number 4. At first, the students tap in four tokens into the ones' column of the DPC.

- 3 Bella: Can I drag over one (*moves her right hand at the bottom of the iPad from the ones' column to the tenths' column; see Figure 3*) and see what gets out?
- 4 Interviewer: Try.
- 5 Bella: (*drags a token from the ones' to the tenths' column, where ten tokens emerge; see Figure 4*)
- 6 Hanna: Ohh.
- 7 Bella: So ten are (1 sec.) one one (*pointing to the ones' column*) are ten tenths (*moves her hand to the right flexing and extending her index finger pointing to the tenths' column*).

**Figure 3: Dragging-gesture to the right from ones to tenths above the chart**

**Figure 4: De-bundling ones to tenths by dragging**

In this scene Bella intentionally exploits the DPC's function of de-bundling to get insights into the relation between ones and tenths (lines 3 & 7). Thus, the two dragging-gestures (lines 3 & 7) as well as the dragging-action (line 5) represent operational dragging. From the perspective of indexicality, both dragging-gestures from left to right (acc. to the view of the students) can be assumed to be linked to previous actions of dragging from left to right on the DPC and their traces, because of the close resemblance between gesture and action. By this, dragging-gestures become indices of dragging-actions including the experiences and assumptions that have been made by dragging tokens on the DPC from left to right, e.g.: "when I drag a token to the right, the number of tokens changes / increases" or "when I drag a token to the right, the represented number remains the same".

Although both dragging-gestures are executed more or less equally, in relation to speech they function differently. The first dragging-gesture seems to focus on the movement of dragging to the right from ones to tenths specifying "what" and "where" (Krause, 2016, p. 125) to "drag over" (a wording frequently used by the students). In contrast, the second dragging-gesture adds the way by which the insight that "one one are ten tenths" (line 7) was gained, referring back again to the experiences and assumptions made by the action of dragging rightwards on the DPC just before (line 5). Similar to the notion of model-of and model-for (van den Heuvel-Panhuizen, 2003, p. 14) we have identified the development from a gesture-of (representing the action of dragging) to a gesture-for (representing the procedure of arriving at this particular conclusion) mediated by operational dragging.

Structural dragging is done when a dragging-gesture is conducted in the gesture space without visible references to any concrete representation of a place value chart. This was used particularly when describing the concept of bundling within the digital place value chart, which is a main step of conceptualizing the decimals' structure. Assuming that the characteristic movement from left to right or vice versa indicates the material link between dragging-actions and dragging-gestures, we can con-

sider structural dragging to be an indexical sign on the traces left by practical and operational dragging including all experiences, intentions, and conjectures made before.

During the whole design experiment, the two students established a shared context where they observed the other student dragging and negotiated shared answers to the tasks. In the first situation here, Bella performs the dragging (line 1), while Hanna sums up the emerged result (line 2). In the second scene Hanna reacts to Bella's dragging on the chart (line 5) and the chart's reaction by astonishment (line 6) and is therefore likewise involved in conceptualizing de-bundling. Thus, a dragging-gesture of one student can also be taken as an index to previous dragging-gestures by the other student. This way, both students and the device constitute an ecology of tool-based interaction to build the concept of decimal fractions.

### **Discussion: Reflections and consequences**

Applying the theoretical perspective of indexicality we have reconstructed how the action and the gesture of dragging can accumulate more and more aspects about bundling and de-bundling. This process of mutual reference between indexical actions and gestures brought forward the conceptualization of bundling and de-bundling as the basis for the concept of decimal fractions. At the same time the dragging-gestures detached more and more from the concrete dragging-actions on the DPC and became shared signs by enriching indexical references.

Similar to the shift from model-of to model-for (van den Heuvel-Panhuizen, 2003, p. 14), a shift from gesture-of to gesture-for was observed, that is: A dragging gesture first represents the action of dragging (gesture-of), later the dragging-gesture is used as an epistemic means to structure the description of the base-ten structure (gesture-for). Operational dragging can be considered as an intermediate state. It produces a change of view from dragging tokens to bundling and de-bundling as the underlying concept. Hence, adding indexicality to gesture analysis may improve our understanding in how epistemic processes progress.

Whether or not this theoretical perspective keeps being fruitful for tool-based learning in general can only be answered by further empirical research. The main issue will be how this perspective can be fruitfully linked with local theories and models for learning specific contents, such as expanding natural numbers to decimals fractions. For that, we will apply the indexicality perspective to additional data from design experiments with another 15 student pairs in the DeciPlace project, attempting to prove our results and gain further insight into the role of tool-based dragging-actions and -gestures for contributing to conceptualize the decimal fraction's structure.

# Towards argumentative grammars of design research

Arthur Bakker

Bremen University, Germany; Utrecht University, the Netherlands; [a.bakker4@uu.nl](mailto:a.bakker4@uu.nl)

*Design research is considered a valuable but demanding methodological framework that continues to generate theoretical and methodological reflection. An important topic to address is that of argumentative grammar, the logic guiding a method and supporting warranted claims, because critics consider it a weak spot of design research. With reference to the history of logic, I challenge these critics' demand of an argumentative grammar that relies solely on structure rather than also on content. The purpose of this paper is to think through what argumentative grammars of design research could look like. Because the literature is so limited on this topic, I draw on interviews with experts in design research to evaluate and discuss my own attempt to formulate an argumentative grammar in relation to possible research questions. One conclusion is that design research requires multiple argumentative grammars depending on the design and the research focus.*

*Keywords: Design-based research, expert interview study, methodology.*

## The need for an argumentative grammar of design research

In a special issue on design research, Kelly (2004) argues that design research (DR) is a valuable emerging set of methods in education, but he has methodological concerns. In his view, “[t]he next task is to establish the logos of design research so that we can argue, methodologically, for the scientific warrants for its claims.” (p. 105) For design research to become a methodology (method + logos), he proposes, we need an “argumentative grammar,” which he defines as “the logic that guides the use of a method and that supports reasoning about its data” (p. 118).

A methodology that already has a clear argumentative grammar is that of randomized field trials as introduced by Sir Ronald Fisher in the 1920s for agriculture. In such trials, also called randomized controlled trials, researchers randomly attribute objects or subjects to an experimental or control condition so that they can assume that these two groups are equal on average except for receiving the treatment or not. Any differences between these two groups as measured by means of pre- and posttests can therefore be attributed to the difference in treatment. One advantage of this methodology is that its argumentative grammar is a structure that can be

described *separately* from its instantiation in any given study so that the logic of a proposed study and its later claims can be criticized. Thus, many reviewers reject studies not on the choice of method (procedure), but on their violation of the underlying logos that one expects to see with that choice of method. (Kelly, 2004, p. 118, emphasis in the original).

Kelly and other critical friends such as Shavelson et al. (2003) thus push design researchers to make warranted claims and go beyond purely narrative accounts. With Cobb et al. (2014), I think design researchers should indeed work towards an argumentative grammar (or grammars) to increase DR's methodological quality. However, drawing on the history of logic, I problematize the preference for a *separate* logical structure for design research (DR) that is irrespective of content. The purpose of this paper is then to think through what an argumentative grammar for design research could look like instead. Because the literature is so scant on this topic, I decided to interview experts in DR on a provisional grammar that I formulated myself.

## Problematizing the need of a separate argumentative structure

This section first addresses randomized field trials (RFTs) as the best known example of a methodology with an argumentative grammar that relies on the structure of argumentation. Next I use the history of logic to argue that logic that is based only on the structure and not on its content is of limited scientific value. I argue that DR requires argumentative grammars that acknowledge content as part of their logic, where content can refer to many things including key concepts used in the research, information on local circumstances (context), and the content of what is learned or aimed to achieve.

### Randomized field trial

With respect to RFTs, I highlight three themes to prepare the discussion of an argumentative grammar of DR. Theme 1: In an RFT the design of an intervention and the evaluative research are separate. From some theoretical perspective or hypothesis, educational design with particular characteristics is developed and then evaluated. When the effects of its implementation are positive, these are attributed to characteristics of the design, operationalized in particular variables. Where does this leave the design researcher who typically intertwines intervention and evaluation?

Theme 2: Typical research questions reveal the type of knowledge that RFT are often after: What are the effects of intervention I on D? Is intervention I1 better than I2? The design researcher typically asks how particular learning can be supported or how some problem can be resolved (of course RFTs can also focus on mechanisms rather than just effects).

Theme 3: RFTs have a clear argumentative structure that is separate from the content of what is researched. This allows the audience, even those who may not have the expertise to engage with the content of the studies (e.g., key concepts, learning content, situation, mechanisms) to judge the structure of the procedure and the scientific reasoning. What could an argumentative grammar of DR look like if it, as I argue later, cannot depend on structure alone?

Despite their power, RFTs also have their limitations (MRC, 2000). To know “what works” in general is of little value if it is unknown “how and under what conditions things work” or what the mechanisms or “active ingredients” are that make an intervention work (Biesta, 2007). It is further acknowledged that valid measurement is difficult and that RFTs typically have good internal but not necessarily good external validity (cf. Shavelson, 2008).

### Logic: Content matters as much as structure

I now use examples from logic to clarify that Kelly’s (2004) and others’ focus on the *structure* of argumentation may hold back educational research. The discipline of logic started in Aristotle’s *Prior Analytics* with syllogisms such as “All men are mortal; Socrates is a man; therefore Socrates is mortal.” This logic purely depends on the structure of the inference: The non-logical terms such as “mortal,” “Socrates,” and “man” can all be replaced by other terms without loss of validity. The interpreter does not even need to know the meaning of these terms to judge the validity of the reasoning. This reasoning is thus rigorous but irrelevant in scientific reasoning:

This kind of logic based on syllogisms came into disrepute in the seventeenth century when science was born. Scientists like Descartes found that all interesting propositions, all interesting inferences are in fact nonsyllogistic. (Lakatos, 1999, p. 39)

Logic has developed in multiple ways. One nonsyllogistic type of reasoning relevant to science is what Brandom calls non-monotonic. This means that new conditions can turn a valid inference into an invalid one. Brandom (2000, p. 88) gives an example from physics:

1. If I strike this dry, well-made match, then it will ignite. ( $p \rightarrow q$ )
2. If  $p$  and the match is inside a very strong electromagnetic field, then it will *not* ignite."  
( $p \& r \rightarrow \neg q$ )
3. If  $p$  and  $r$ , but the match is in a Faraday cage, then it will light. ( $p \& r \& s \rightarrow q$ )
4. If  $p$  and  $r$  and  $s$  and the room is evacuated of oxygen, then it will not light. ( $p \& r \& s \& t \rightarrow \neg q$ )

Scientific reasoning in educational research is clearly non-monotonic: There are overwhelming numbers of factors that can influence learning. Any relevant positive factor can probably be counteracted by a negative one. Given the pragmatic nature of education, it is also worth mentioning progress on pragmatic reasoning: Walton et al. (2008), for example, identified 96 argumentation schemes that people use in reasoning. It has also become evident that valid argumentation does not depend purely on structure but also on content (and context). So-called material inferences even purely depend on content rather than on their structure. Brandom (2000, p. 85) uses the inference from “Pittsburgh is to the west of Philadelphia” to “Philadelphia is to the east of Pittsburgh,” as an example of an inference that is materially valid because it depends only on the content of the concepts of east and west.

These brief observations from logic suggest that scientific progress relies not only on the structure of argumentation but also on content. Why then should research methodology in education be judged by the separate structure of its argumentation? But what would an alternative look like? Design researchers are faced with the challenge to come up with an alternative grammar or, more likely, grammars. One attempt is that by Cobb et al. (2014):

1. Demonstrating that the students would not have developed particular forms of mathematical reasoning but for their participation in the design study.
2. Documenting how each successive form of reasoning emerged as a reorganization of prior forms of reasoning.
3. Identifying the specific aspects of the classroom learning environment that were necessary rather than contingent in supporting the emergence of these successive forms of reasoning. (p. 490)

The function of such grammars is that they “link research questions to data, data to analysis, and analysis to final claims and assertions” (p. 489). Given that little has been written about this, I formulated an argumentative structure myself based on discussions with Karel Stokking and my own experience with doing and supervising DR. The most efficient and sensible way to gauge its quality seemed to be an interview study with expert design researchers. In this way I could explore what they thought about the need for an argumentative grammar of DR, what they thought of my attempt, and how it could be improved.

### **Method: Interview study with experts**

I interviewed eighteen well-known international design researchers on argumentative grammars of DR and related themes for about 60-90 minutes. These experts represent a variety of different

disciplines and traditions in DR (seven were mathematics educators). Before presenting my own grammar proposal, I asked them about issues that might elicit their view on the logic accompanying DR and the type of claims it renders. First, I asked about the intertwinement of design and research because it can make particular claims difficult: In line with the argumentative structure of RFTs and thinking in terms of variables, many researchers prefer to keep design of an intervention and the (evaluative) research separate. Second, I asked experts' views on Kelly's (2004) claim that DR has no clear argumentative grammar. Third, I asked if they had a preference for types of research questions (what- vs. how-questions). An example of a what-question I showed to the interviewees is: "What are characteristics of a valid and effective teaching and learning strategy to teach students about correlation and regression in such a way that they experience coherence between mathematics and the natural sciences?" (Dierdorp, 2013). A how-question I presented is: "How can students be fostered in their connecting of gene as a molecular-level concept to phenomena at higher levels of biological organization?" (reformulation of Van Mil's, 2013, question). Fourth, I asked experts about the argumentative grammar I propose in the next paragraphs.

The focus on *how* to support learning in DR implies that in my view at least four things need to be captured in an argumentative grammar of a DR project. First, learning goals need to be underpinned (or a problem or needs analysis should be done). A design criterion could be relevance and a research criterion content validity (Plomp & Nieveen, 2013). Several existing methods (review study, expert interviews, Delphi study) can be used to this end. Second, a design (e.g., tool, teaching-learning strategy, or program) could be described in relation to theoretical and empirical considerations. Criteria here can be "empirically and theoretically underpinned" and "innovativeness," but some may want to emphasize "feasibility or practicability." Third, only if intentions are realized, particular intended phenomena can be studied (e.g., whole-class scaffolding; Bakker & Smit, 2017). In RFTs, the criterion would be formulated as "implementation fidelity," necessary to check if any effects can be attributed to the intervention having particular characteristics (cf. Sandoval, 2014). Fourth, information about to what extent learning goals are achieved, or a problem solved, needs to be given in order to answer the main question. The main criterion here is effectiveness.

The structure of a DR project presented to all interviewees for their feedback was the following:

*How can goal X be achieved for a particular group of learners (in particular conditions or under particular constraints)?* To answer this main question, a sensible list of research questions could be:

1. What is an appropriate learning goal for....?
2. What is a design that would help students/teachers to achieve this goal?
3. How well was this strategy/trajectory implemented?
4. What were the effects of this intervention?

In discussing this structure, several topics arose that are related to aspects of argumentative grammar such as links between different parts of research (data, claims), in particular in contrast to RFTs. I summarize the experts' responses in three themes.

## Theme 1: Intermingling design and research

A key feature of DR is that design and research progress hand in hand. In response to this issue, the interviewees noted the following points. First, any natural scientist knows that scientific practice, in particular the context of discovery, is much messier than presented in textbooks or reports of experiments. Of course, there is a place for experiments, but a large part of science—even in physics—is trial and error with set-ups, designing new arrangements, philosophizing, thought experiments et cetera. In certain disciplines, take astronomy, experiments are even impossible. Serendipity (e.g., the discovery of penicillin) also points to the importance of the context of discovery. The relative importance of RFT as a methodology rests on the side of justification. Several experts said that RFT-type research often produces “false security” or that it struggles with similar issues as other types of research, but somehow it has become common practice to ignore particular problems or trust researchers on doing it well (e.g., validity of measurement, identifying relevant variables). However, many noted there is also a place for RFT as it helps for example policymakers to decide between various well-established options to be implemented.

Second, two interviewees emphasized that DR is about how education *could* be. Where much research is about current educational practice, and some about its past, DR is about its future. Design researchers may argue that educational goals should be different from current educational practice, and design for these new goals. Such DR is thus after proofs of principle, not proof of doing better than current practice which may have very different goals. Comparison with a control group that worked towards different learning goals would be unfair. The argumentative grammar of this type of “proof of principle” DR is thus clearly different from DR that aims for causal claims about effectiveness of particular means of support. This points to the need for multiple grammars.

Third, several interviewees noted that DR conceptualizes learning environments as ecologies rather than systems that can be captured with a few manipulable and unmanipulable variables. Attributing an effect to particular variables then becomes challenging. Rather the focus should in the experts’ view be on design principles, hypothetical learning trajectories, or mechanisms of learning, in line with DR’s intention to produce knowledge about *how* things work (cf. Sandoval, 2014).

## Theme 2: Research questions

Most interviewees considered the examples of what- and how-questions presented to them as too broad. Some did not have a strong preference for either formulation: The researcher wants to know similar things in both cases. However, most experts preferred the how-questions because these emphasize the process of achieving particular learning goals or solving a particular problem. In terms of Cobb et al. (2003), DR typically aims to provide insight into how particular means can support particular learning. This hints at the type of knowledge claims that DR purports to deliver.

A view, expressed by Abrahamson and diSessa, was that DR is a methodological framework (not a method or a strategy) that provides a generative context (about how education could be). Because new types of learning are promoted, new phenomena may emerge and thus in turn become objects of investigation. This view fits with the image of DR as a context of discovery for researchers. Once such phenomena are implicated and objectified, they can be studied as interesting in their own right, with little or no reference to the broader design research context (e.g., Abrahamson et al., 2016). In

line with the generativity of DR, many interviewees emphasized that interesting research questions often emerge rather late in the research process. They are hard to formulate in advance.

### **Theme 3: Argumentative grammar**

The interviewees were overall positive about the proposed grammar. The elements of learning/educational goals, design, implementation, and effects are key to DR, and can be studied empirically, perhaps even in separate publications. One interviewee expressed some resistance to categorizations and structures in research because each project is unique and requires flexibility and creativity. Yet structures could be useful to early career researchers as a starting point.

The experts' further comments were matters of detail. With regard to the learning goals, diSessa noted that he sometimes preferred learning goals that colleagues thought were impossible to achieve with certain age groups (e.g., comprehending velocity and acceleration as vectors in Grade 6). McKenney pointed out that design researchers often encounter obstacles that can become the topic of research. She tends to do a lot of “front-end” work in the early phases of DR in areas where too little is known to arrive at effective designs.

Judging the quality of implementation was considered a good idea, although several experts noted that the implementation process could be interesting to study even without judging its quality. diSessa remarked that failure can be interesting from a design perspective. In his experience, many colleagues respond with surprise when he reports failure, but as long as important lessons can be learned, contributions to the knowledge base can be made.

The terms “interventions” and “effects” elicited some resistance due to connotations with the RFT paradigm of thinking in terms of variables. Several experts preferred to talk in terms of learning ecologies instead. However, some found it important to measure what was achieved and thought that design researchers had measured too little in the past. Many noted that there is certainly a place for RFTs, as well as for quantitative measurement, in DR. Some indicated that RFT ideally gives insight into mechanism too, and can be part of DR.

Ruthven suggested a fifth element, namely an improved re-design, which is indeed in line with DR's emphasis on the hypothetical status of any claims. Citing Cronbach, Plomp emphasized this holds for any type of research: “When we give proper weight to local conditions, any generalization is a working hypothesis, not a conclusion” (Cronbach, 1975, p. 125).

Plomp noted that although he did not write about argumentative grammar, his approach with Nieveen (Plomp & Nieveen, 2013) has such a function. For each phase of a DR project one criterion was central: relevance for the exploratory phase (e.g., problem analysis), consistency (of the design), practicability (of using the design), and last effectiveness.

An issue raised was whether different criteria were needed for DR than for some other research approaches. Because many readers and reviewers are used to different commissive spaces, experts such as Cobb stressed that DR has to become clear on the criteria on which it wants to be judged. For example, we have to acknowledge that design researchers are part of the research, and that their qualities as designers and researchers matter. As Confrey noted in the interview: “You build a reputation for doing good work (...), but that's not great for newcomers because they don't have the track record yet.” It certainly goes against the more conventional norm of reliability that research

should be independent of the researcher. Hence it seems necessary to think through the criteria by which design researchers want to be judged. However, McKenney preferred the research part of DR to be treated with the same criteria as other qualitative or mixed-methods approaches. Kelly suggested DR can learn from other research approaches such as single-subject and repeated-measures designs.

Not only the design researcher, but the audience has to make judgments as well. Where RFTs can yield results that sometimes seem to require little understanding of the topic at hand, DR asks for an audience that can appreciate the relevance of the educational goals chosen, the innovativeness of the design, and the learning processes reported. diSessa noted that the typical reasoning in DR is to show what types of reasoning can be promoted in a particular way, for instance by using particular software. Any well-informed domain-specific educational researcher with knowledge of the disciplinary (e.g., mathematical) content will know how rare or relevant such types of reasoning are for particular age groups, so will appreciate qualitative examples of even small samples.

## Conclusion

In this paper I have argued that it is unreasonable to expect that educational research including DR should use an argumentative grammar that depends solely on structure rather than also content (key concepts, mathematical learning content, context etc.). Examples from logic illustrate the importance of types of reasoning that are also based on content. Argumentative grammars for DR should thus acknowledge content too. Cobb et al. (2014) offered an argumentative structure that can help convince readers about the development of students' mathematical reasoning and the aspects of the learning environment that supported them (see also Sandoval, 2014). My own proposal focused on the grammar of a DR project with the aim to contribute to knowledge about how particular educational goals could be achieved in general (or problems solved). Based on the interviews with experts, my proposal—after some modification—seems to make sense as a starting point for design researchers when they write a proposal or want to demarcate phases in their overall project (cf. McKenney & Reeves, 2012; Plomp & Nieveen, 2013) with criteria that are central in each phase. However, there is a need for more explicit argumentative grammars, for instance for “proof of principle”-type DR and for smaller-scale design studies that focus on interesting phenomena that are discovered during a larger DR project.

*We explicate how we used different theories of learning to design dynamic computer environments and tasks to promote secondary students' discernment of covariation—central to students' study of fundamental mathematical ideas such as rate and function. Using Marton's variation theory, we designed task sequences to foster students' discernment of the critical aspect of covariation. Using Piaget's constructivist theory, we defined the critical aspect, covariation, in terms of students' conceptions of a relationship between attributes whose measures vary. Using Thompson's theory of quantitative reasoning, by quantities we mean attributes of objects that students can conceive of as being possible to measure. We provide data to demonstrate how a student's discernment of covariation advanced during her work on a task sequence. We discuss implications for the design of dynamic computer environments and tasks focused on the mathematics of change and variation.*

*Keywords: Secondary school mathematics, instructional design, computer simulation, learning theories.*

By drawing on more than one theory of learning, researchers can combine tools and lenses to investigate complex phenomena (e.g., Cobb, 2007; Sfard, 1998; Simon, 2009). Cobb (2007) recommended that researchers “act as bricoleurs by adapting ideas from a range of theoretical sources” (p. 29). Sfard (1998) argued that researchers should not assume that theoretical “patches of coherence” somehow would combine to form a single, unifying theory of learning. Yet, using multiple theories can pose challenges, particularly if researchers view theories as competing, rather than complementary (Simon, 2009). To address challenges, it is useful for researchers to take into account the grain sizes of different theories (Kieran, Doorman, & Ohtani, 2015; Watson, 2016).

By distinguishing between the grain sizes of theories, researchers can more effectively interpret and use theory for task design purposes (Kieran et al., 2015; Watson, 2016). Broadly, grain sizes include grand theories (e.g., Piaget's constructivist theory), intermediate theories (e.g., Marton's variation theory), and domain specific/local theories (e.g., Thompson's theory of quantitative reasoning). Furthermore, it is useful for researchers to acknowledge interrelationships between theories of different grain sizes. Theories of smaller grain size depend upon or address particular aspects of theories of larger grain size (Watson, 2016). For example, Thompson's theory of quantitative reasoning depends upon Piaget's constructivist theory to define quantities in terms of students' conceptions. By drawing on theories of different grain sizes, researchers can adapt and interpret grand theories for task design and implementation (e.g., Cobb, 2007; Kieran et al., 2015; Thompson, 2002; Watson, 2016).

When researchers engage in task design, they should make explicit how their theory choice informs their task design (Watson, 2016). Using Marton's variation theory (2015), we designed task

sequences to engineer opportunities for students to discern critical aspects central to fundamental mathematical ideas, such as rate and function. We posit that one such critical aspect is covariation. Using Piaget's constructivist theory (1985), we define covariation in terms of individuals' conceptions. Using Thompson's theory of quantitative reasoning (1994, 2002), we articulate the conception; by covariation we mean a conception of a relationship between attributes whose measures vary. Students' conceptions of covariation impact their understanding and use of function (Thompson & Carlson, 2017).

We build on the work of researchers who have designed dynamic computer environments and tasks to foster students' study of the mathematics of change and variation (e.g., Kaput & Roschelle, 1999; Saldanha & Thompson, 1998; Thompson, 2002). In this paper, we explicate how we used theories of different grain sizes to design dynamic computer environments and tasks to promote secondary students' discernment of covariation. To avoid remaining only in the abstract, we provide data to demonstrate the utility of our approach in fostering students' discernment of covariation.

## Theoretical and conceptual framework

We use Piaget's constructivist theory to orient our research. We foreground students' conceptions to explain how researchers might design dynamic computer environments and tasks to foster students' development of difficult to learn mathematical ideas such as function and rate. We focus on students' mental operations, which refer to actions that individuals can enact in thought or in the physical world (Piaget, 1985).

We use Marton's variation theory to guide the design of our dynamic computer environments and related task sequences. Broadly, Marton (2015) argued that instructional designers should develop task sequences that provide students opportunities to discern critical aspects. The task sequence should involve patterns of variation, then invariance in the critical aspects (Marton, 2015). We draw on Piaget's constructivist theory to orient our interpretation of the critical aspect that we intend for students to discern. By critical aspect, we mean a conception. The critical aspect—covariation—refers to a conception of a relationship between attributes whose measures vary.

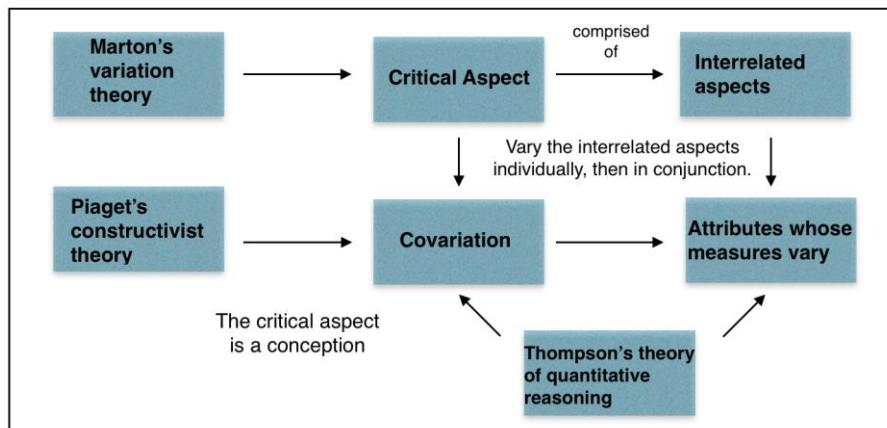

When using variation theory it is important for instructional designers to determine if the critical aspect is comprised of a single aspect or of interrelated aspects (Marton, 2015). For example, suppose a designer intends for students to discern the color blue, which students could conceive of as being comprised of a single aspect. A task sequence should begin with variation in color and invariance in some unrelated feature (e.g., blue ball, green ball, red ball), then invariance in color and variation in the unrelated feature (e.g., blue ball, blue block, blue cone), and then variation in both. In contrast, if a designer intends for students to discern the *depth of blue color*, students would need to conceive of interrelated aspects (depth, color) that comprise the critical aspect. In this case, the task sequence should include variation and invariance in each interrelated aspect (e.g., different colors of the same depth, then different depths of the color blue), then move to variation in both aspects. A conception of covariation necessitates a conception of a relationship between interrelated aspects (attributes whose measures vary). For example, in a situation involving the varying height and distance of a car in a turning Ferris wheel, the height and distance are the interrelated aspects, and students' conceptions of a relationship between measures of height and distance (covariation) is the critical aspect.

We found Marton's variation theory and Piaget's constructivist theory to complement each other for the purposes of our task design. From a constructivist perspective, we do not assume that a relationship between attributes whose measures vary (covariation) is something that is "out there" for students to perceive. Marton (2015) argued that researchers should not assume that students already attend to the critical aspect prior to encountering a task sequence; therefore, task sequences should include variation in critical aspects (contrast) prior to variation in noncritical aspects. To foster students' discernment of covariation, we incorporated variation in the types of interrelated aspects (height, width, distance) prior to variation in the representation of those aspects.

We use Thompson's theory of quantitative reasoning to explain what we mean by the attributes whose measures vary—the interrelated aspects comprising the critical aspect of covariation. Drawing on Piaget's constructivist theory, Thompson (1994) defined quantities in terms of individuals' *conceptions* of attributes of objects. Therefore, quantities are not "things" that exist in the physical world. Following Thompson (1994), we claim that an individual conceives of some attribute as a *quantity*, if the individual can conceive of the possibility of measuring that attribute. For example, we would claim that a student conceived of "height" as a quantity if the student provided evidence of envisioning the possibility of measuring the height of some object.

We selected Thompson's theory of quantitative reasoning because we found it to be useful for interpreting Piaget's constructivist theory. Accordingly, the mental operations on which we focus are quantitative operations, which involve actions on attributes that students can conceive of as measurable, or in other words, actions on quantities (Thompson, 1994). Specifically, we focus on students' conceptions of covariation, which entail the quantitative operations involved in forming and interpreting relationships between attributes whose measures vary. For example, a student conceiving of covariation could form and interpret relationships between the varying measures of height and distance for a Ferris wheel car traveling around one revolution of a Ferris wheel.

The diagram in Figure 1 illustrates how we used different theories to inform our task design.

**Figure 1: Relationships between the different theories we used to inform our task design**

We placed Marton's variation theory at the top to foreground our intention to design a task sequence to foster students' discernment of a critical aspect comprised of interrelated aspects. We placed Piaget's constructivist theory in the center to communicate how we used this grand theory to define the critical aspect, covariation, in terms of individuals' conceptions. We placed Thompson's theory

of quantitative reasoning at the base to show how we used this local theory to explain what we mean by covariation—a conception of a relationship between attributes whose measures vary.

### Ferris wheel dynamic computer environments

Using Geometer's Sketchpad software, Johnson developed two dynamic computer environments for use with the task sequence. The environments consisted of a Ferris wheel animation and linked graph, each of which students could control separately or in conjunction. The environments related either the *height* of a Ferris wheel car from the ground or the *width* of the car from the center to the *distance* traveled around one revolution of the wheel (Figure 2 shows height and distance). See Johnson (2015) for more details about the environments.

**Figure 2: Ferris wheel dynamic computer environment, distance and height**

The Ferris wheel environments contained three affordances particularly relevant to our use of variation theory. First, students could vary each of the interrelated aspects (e.g., height and distance) individually by dragging or animating the dynamic segments on the vertical and horizontal axes. Second, the environments included different interrelated aspects—height and distance (Figure 2), and width and distance (not shown). Third, the environments included variation in the axes used to represent the interrelated aspects on the Cartesian plane (e.g., height and distance represented on the vertical and horizontal axes [Figure 2], then horizontal and vertical axes, respectively [not shown]).

Our use of Piaget's constructivist learning theory and Thompson's theory of quantitative reasoning informed our choices about the types of quantities to include on each of the axes. Specifically, we included quantities measurable with linear units, because it is less difficult for students to conceive of using linear units to measure quantities (see also Piaget, 1970). Furthermore, Thompson (2002) recommended students use their fingers as tools to represent change in individual quantities. In the Ferris wheel environments, students could use either their fingers or the dynamic segments on the vertical and horizontal axes to represent change in individual quantities.

## The Ferris wheel task sequence

### Purpose and setting

We view tasks as problems designed for particular audiences and settings (see Sierpinska, 2004). Johnson designed the Ferris wheel task sequence to provide students opportunities to discern covariation. In a small neighborhood school in an industrial region of a large U.S. city, Johnson conducted a series of small group interviews with five ninth grade students (~15 years old), enrolled in an introductory algebra course. Interviews occurred approximately once per week. During the interviews, students completed the Ferris wheel task sequence (see Table 1). Johnson designed the task sequence for a small group interview setting; however, teacher/researchers could adapt the tasks for use in different settings (see Johnson, Hornbein, & Azeem, 2016).

### Variation and invariance in the Ferris wheel task sequence

To foster students' discernment of critical aspects comprised of interrelated aspects, Marton (2015) recommended that instructional designers begin with task sequences containing variation in individual interrelated aspects, then variation in the both interrelated aspects, against a background of invariance. In the Ferris wheel task sequence, we intended for the situation of a turning Ferris wheel to provide a background of invariance. Furthermore, Marton (2015) recommended variation in features (or dimensions) of those interrelated aspects. We provided two types of variation in features: the type of interrelated aspects (width, height, or distance), and the representation of each aspect on the Cartesian plane (horizontal or vertical axis). Table 1 shows the Ferris wheel task sequence, including variation in interrelated aspects and representations on the Cartesian plane.

Task	Interrelated aspects	Representation on axes on Cartesian Plane
1	Height, Distance	Distance – horizontal, Height – vertical
2	Width, Distance	Distance – horizontal, Width – vertical
3	Height, Distance	Height – horizontal, Distance – vertical
4	Width, Distance	Width – horizontal, Distance – vertical

**Table 1: Ferris wheel task sequence: Variation in interrelated aspects and representation**

### Covariation and quantity in the Ferris wheel task sequence

When the critical aspect is a mental operation, instructional designers should provide students opportunities to engage in activities in thought as well as action. Each task in the Ferris wheel task sequence contained five parts: (1) Explain what the interrelated aspects measure in the Ferris wheel situation; (2) Sketch a graph relating both aspects; (3) Use dynamic segments to represent change in individual aspects (e.g., height or distance); (4) Predict a car's location on the Ferris wheel given only dynamic segments representing the changing individual aspects; and (5) Compare the computer generated graph to the sketch in (2). Through each of the five part tasks, Johnson provided students multiple opportunities to discuss and represent their thinking about how the interrelated aspects (height and distance or width and distance) were changing individually and together. For example, students sketched a graph relating the interrelated aspects prior to viewing any facets of the dynamic graph. Furthermore, Johnson provided students opportunities to discuss and show the possibility of

measuring interrelated aspects of the Ferris wheel situation (e.g., “height” represents the vertical distance from the car to the base of the Ferris wheel, see Figure 2).

### A case of a student’s discernment of covariation

We use the work of one student—Ana—to demonstrate the promise of this design approach for fostering students’ discernment of covariation. Ana’s work demonstrates the range of reasoning of all five students who completed the Ferris wheel task sequence. Building from Ana’s work, we present a case of a student’s discernment of covariation.

We share data from Ana’s work for Part 2 of Tasks 1 and 3: *Prior to viewing the dynamic graph, sketch a graph relating both aspects.* We selected data from Part 2 to illustrate how Ana’s sketches changed prior to viewing aspects of the dynamic graph. We attribute the changes in her sketches to changes in her conceptions of a relationship between varying measures of height and distance.

Figure 3 shows Ana’s written work for Part 2 of Tasks 1 and 3. For Part 2 of Task 1 (left), Ana drew the curved graph, labeling it “height,” and then drew the line graph, labeling it “distance” (Figure 3, left). When asked what her labels meant, Ana stated: “This (points to the curved graph) would be the graph shape if we were dealing with the height, and this (points to the line graph) would be the shape if we were dealing with the distance.” For Part 2 of Task 3, using one continual motion, Ana sketched a single graph (Figure 3, right). When asked to explain her thinking, she stated that the “distance keeps on going,” but the height will reach “a certain amount,” and then “it goes back down.” To illustrate, she drew an arrow along the left of the distance axis. Next, she drew a small, darkened segment on the graph, and two arrows extending along the graph.

**Figure 3: Ana’s graphs in Part 2 of Task 1 (left) and Part 2 of Task 3 (right)**

For Part 2 of Task 1, we interpret that Ana represented individual variation occurring in the measures of height and distance. Not only did she sketch two graphs, she labeled the actual sketches, rather than the axes. We use Ana’s work for Part 2 of Task 1 to demonstrate that Ana did not enter the Ferris wheel task sequence already conceiving of a relationship between the varying measures of height and distance, or in other words, conceiving of covariation. Moving forward to Part 2 of Task 3, Ana used a single graph to represent a relationship between the varying measures of height and distance. Not only did she sketch a single graph, she annotated the graph to show how the single graph represented variation in the measures of both height and distance. Therefore, we claim that Ana demonstrated discernment of covariation during her work for Part 2 of Task 3

(conceived of a relationship between attributes whose measures vary). Furthermore, Ana's discernment of covariation was not limited to the aspects of height and distance. She also demonstrated discernment of covariation when working with width and distance in Tasks 2 and 4.

## Discussion/Implications

When critical aspects involve interrelated aspects, Marton (2015) recommended that instructional designers develop task sequences that include different backgrounds. In our task sequence, we used only a Ferris wheel situation, and we recommend that researchers designing task sequences to foster students' discernment of covariation also include different situations. However, we provide our recommendation with a caveat—the different situations should include interrelated aspects measurable with linear units. For example, if we were to design a task sequence for a filling bottle situation, we might ask students to relate the height of the liquid in the bottle to the diameter of the liquid in the bottle. Our caveat stems from our use of Piaget's constructivist theoretical perspective. It is less difficult for students to conceive of the possibility of using linear units to measure attributes (e.g., Piaget, 1970). Therefore, we recommend that task sequences designed for students to discern covariation (a critical aspect involving interrelated aspects) should include interrelated aspects measurable with linear units. Researchers have shown that even successful university students have difficulty using graphs to represent relationships between height and volume in a filling bottle situation (e.g., Carlson, Jacobs, Coe, Larsen, & Hsu, 2002). If students have difficulty conceiving of the possibility of using a three-dimensional unit to measure volume, it may impact their discernment of covariation for situations involving such attributes.

By using theories of different grain sizes, we were able to employ multiple, compatible lenses to engage in task design that looked both *across* and *within* the sequence of tasks. By guiding our variance and invariance of interrelated aspects, Marton's variation theory informed design *across* the task sequence. By fostering our choices about the kinds of aspects to vary, Thompson's theory of quantitative reasoning informed our design *within* tasks in the sequence. The ability to view a task sequence from different perspectives—in our research, looking both across and within—is a productive result emerging from the use of multiple theories to do compatible explanatory work to augment the design of task sequences intended to foster students' discernment of critical aspects.

# Combining two theories in the design for learning about integrals

Anatoli Kouropatov<sup>1</sup> and Tommy Dreyfus<sup>2</sup>

<sup>1</sup>Levinsky College of Education, Israel; [anatoliko@gmail.com](mailto:anatoliko@gmail.com)

<sup>2</sup>Tel-Aviv University, Israel; [tommyd@post.tau.ac.il](mailto:tommyd@post.tau.ac.il)

*We show how a combination of two theories, Abstraction in Context and Proceptual Thinking, served as basis for design decisions in the framework of a research study about learning the integral concept in high school via constructing knowledge about accumulation.*

*Keywords: Design of instruction, Abstraction in Context, proceptual thinking, integration.*

## Introduction

Designing learning units involves decisions about the transition from syllabus to curriculum (Dreyfus, Hershkowitz, & Bruckheimer, 1987); Mathematics Education offers home-grown theories supporting this transition; curriculum designers use these theories when design is a main goal.

Here, we present a case study of using theories for the design of a didactical tool – a learning unit intended for students' construction of a specific mathematical notion. This study is part of a larger research project (Kouropatov, 2016) offering a didactic approach supporting high school students in acquiring a conceptual understanding of the integral. For this purpose, we asked ourselves: a) What does "a conceptual understanding of the integral" mean? and b) How can we support students in acquiring such understanding? Answering question (b) required design. The design was preceded by a thorough didactical-mathematical analysis of approaching integration via the idea of accumulation (Thompson & Silverman, 2008). A tight interrelationship developed between the design process and the relevant theories, Abstraction in Context and Proceptual Thinking. In this paper, we exhibit this relationship via the need for and effect of these theories in the design process and hence the contribution of these theories to a basis for the transition from syllabus to curriculum.

## Theoretical frameworks and their influence on the design

We follow Tabach, Hershkowitz, Arcavi, and Dreyfus (2008) in distinguishing

- a pre-design stage involving considerations before starting the actual development and research work with students;
- an initial design-research-redesign stage of sporadic and isolated activities, and the observation, data collection, and analysis of their implementation with a few students;
- a final stage that comprises further redesign, for the creation of a coherent, complete task-based curriculum, and its implementation (limited, in our case, to four pairs of students).

These stages indicate what to do but not how to do it. Design decisions require theories. For our study, we have adopted Abstraction in Context (AiC) because its roots in constructivism and in activity theory make it suitable to design for and analyse the construction of abstract knowledge during the learning process (Hershkowitz, Schwarz, & Dreyfus, 2001). We have also adopted the theory of Proceptual Thinking (PT) because of the proceptual nature of the mathematical notions in focus, in particular accumulation (Gray & Tall, 1994). The theories are compatible but different: PT deals with how students see mathematics; AiC deals with how students acquire knowledge.

## Theoretical considerations at the pre-design stage

### *AiC as basis for design*

AiC takes abstraction to be a learner's activity of vertical (in the sense of Freudenthal) reorganization of previous mathematical constructs in order to arrive at a new (to the learner) construct. Abstraction leads from an initial, vague first form, which may lack consistency, to an elaborated form (Davydov, 1990). The activity is interpreted in terms of epistemic actions performed by a learner, or a group of learners, for a specific purpose, in a particular context. The context includes the social setting as well as the learners' personal background, in particular the previous mathematical constructs resulting from previous processes of abstraction. 'Reorganization' includes establishing new connections between previous constructs, making mathematical generalizations, and discovering new strategies for solving problems. 'Vertical' implies building a new level of abstraction on top of a previous level. For the researcher, the question arises how to support and unveil the processes by which the students' new constructs may emerge as a vertical reorganization of previous constructs in the current context. AiC argues that for this purpose, it is crucial to carry out an a priori analysis. This theoretical content analysis aims at identifying the elements of knowledge (mathematical facts, notions, claims, strategies, representations, etc.) that together constitute 'learning a concept' and have a didactical perspective, namely can be constructed by learners in a suitable context using appropriate didactical tools. The results of the a priori analysis are *descriptions* of the elements of knowledge that belong to the world of mathematics but may be linked to the current context, and operational *definitions* that constitute descriptions of observable student behaviour: utterances or actions that provide criteria for assessing whether a student's constructing action corresponding to the said knowledge element has occurred.

AiC has originally been proposed in the framework of a curriculum development project, in which abstraction was a central concern, and Hershkowitz et al. (2001) have already then expressed the hope that it will be useful not only for analysing students' processes of abstraction but also for designing sequences of activities supporting students in such processes. At the pre-design stage, AiC requires a sequence of activities, each intended toward the construction of an appropriate element of knowledge, while the sequence is hierarchically structured as imposed by verticality. In other words, AiC helps us find a structure of the subject knowledge that is appropriate for implementation in the design. For example, based on the a priori analysis of the mathematical content, we decided that the unit should be designed as a four level vertical structure of the following conceptual components: *Approximation* in the context of given geometrical objects; *Accumulation Value* (the definite integral) in the context of given analytical objects or situations; *Accumulation Function* (the definite integral with varying upper bound); and *Integration-Differentiation interplay*, mainly the Fundamental Theorem of Calculus (FTC). Further analysis of each level provided the vertical structure of the elements of knowledge intended to be constructed by the students. We present two of the four levels in some detail.

For didactical reasons and based on verticality, *Approximation* was interpreted as Geometrical Shapes Approximation (GSA) with the following three knowledge elements:

AP<sub>G</sub> "General approximation": The size of a given object can be approximated by replacing the given object with known objects;

AP<sub>R</sub> "Refined approximation": The approximation can be made more precise by decreasing the size of the replacing objects and increasing their number;

AP<sub>L</sub> "Approximation limit": The size of a given object can be determined as precisely as one wants by continued refinement.

The corresponding operational definitions are that we will say students have constructed

AP<sub>G</sub> if they explicitly (verbally and/or graphically) replace a given object with known objects;

AP<sub>R</sub> if they explicitly (verbally and/or graphically) refine the approximation by decreasing the size of the replacing objects and increasing their number;

AP<sub>L</sub> if they explicitly (verbally and/or graphically) identify a value as the exact size of a given object by continued refinement.

Knowledge elements for the other three conceptual components were similarly described and defined (Kouropatov, 2016; Kouropatov & Dreyfus, 2014). These descriptions and definitions constitute the framework for the design of activities in the learning unit. In other words, by means of the description of the elements of knowledge, AiC informs the decisions of what should be designed and in what hierarchy it should be organized. AiC does not inform how to design for each notion by means of micro-tasks. For that purpose we used PT.

### ***PT as basis for content design***

Gray and Tall (1994) defined the notion of procept as an aggregate of three things: process, concept (or object), and symbol. For example, the symbol  $\int_0^x f(t)dt$  is meant to evoke both the process of

accumulation (integration) and the concept of accumulation function (integral), with the cognitive combination of all three, process, concept, and symbol, being called a procept. This stance has crucial didactical implications: students might first meet a process; later, a symbol is introduced for that process and/or its product, and this symbol takes on the dual meaning of the process and the object created by the process. Proceptual Thinking is then defined as the ability to switch one's focus between these dual roles of the symbols as is useful and efficient in the current context, for example solving a problem. Someone who has the ability to think in this way may be described as versatile (Tall & Thomas, 1991). Versatility includes a global picture of a concept as well as the ability to break it down into a process, seeing each stage as part of the whole concept. According to Hong and Thomas (1998) versatility is critical for comprehension of the integral concept.

We see the integral as a multilevel, hierarchic procept, which is composed of (in the sense of AiC, and hence intended to be constructed by students from) other procepts including function, graph, approximation, sum, and accumulation; hence, we continue the pre-design stage by

- using the result of the above a priori analysis in order to identify and describe the main sub-procepts of the integral procept;
- identifying the hierarchic structure of the integral as an aggregate of procepts.

The main didactical flow of ideas was derived directly from the procept hierarchy of the mathematical notion of the concept of the integral. In particular, the didactical goals are: to create an opportunity for the learners *to carry out a process* that is meaningful for them (e.g., to

approximate an unknown area of some shape by accumulating the known areas of small parts of this shape); to give the learner the possibility *to internalize this process as a concept* (e.g., by quantifying the process, by discussing the characteristics of this process); *to introduce* the learner to the common mathematical *symbol* as encapsulation of the completed process and the internalized object; these considerations became the leading considerations of the initial stage of design. In other words, PT allows us to answer the question of how the learning activities should be designed.

We present two examples from the learning unit that show how we took into account the proceptual nature of the intended elements. The first one, is the initial activity for introducing *Approximation* via GSA. And the second one is from the middle of the unit, and is intended to lead students to constructing the concept of *Accumulation Function*. As mentioned above, these two concepts, together with the *Accumulation Value* and the *FTC*, are the four components of the vertical structure of the suggested design of the unit.

Regarding GSA, students *carried out the process* of approximating the length of a given (sketched) curve (interval, semicircle, non-standard curves) using a ruler, compass, protractor, square paper (with two different mesh sizes) and calculator. Then, students discussed the "quality" of the resulting approximation and were asked to refine it (for example by using more sophisticated measurements) with the intention to lead to *internalization of this process as a concept*. Finally, students were asked to *find the length* as precisely as possible (the existence of such a value was taken as intuitively obvious). This "process, concept, existence" triad constitutes the GSA procept according to the above analysis.

Regarding the notion of *accumulation function*, the activities offered students opportunities to *carry out the process* of co-variational change of the accumulation value according to the value of the right end-point of a certain sub-interval (using approximation or algebraic considerations); students dealt with a table and/or graph and/or verbal representation of this change with the intention to lead to *internalization of this process as a concept*; finally, the symbol  $A(x) = \int_a^x f(t)dt$  was introduced.

This "process, concept, symbol" triad constitutes the accumulation function procept.

### **Theoretical considerations at the initial stage of design**

The influence of AiC and PT on the design of the unit could, in principle, best be demonstrated by the design of activities about the procept of accumulation, the central notion of the learning unit. Because of space limitations, we concentrate instead on a small part of this: When describing a process of accumulation, one should know "how to start accumulating" - in other words, how to calculate an initial quantity. Then, one should know how to calculate further pieces of the accumulating quantity. The general answer to this problem is *approximation*. Here, the proceptual nature of approximation is particularly important: We see approximation as a process, and the result of this process, of calculating (as accurately as required) some unknown value (length, area or volume) by using known values.

While approximation refers to many kinds of quantity, verticality suggests a sequence of activities that starts with concrete geometrical shapes (lines, 2-dimensional and 3-dimensional shapes) followed by geometrical shapes that are given analytically (using elementary functions) in a coordinate plane (space); only then, more general quantities, given analytically, are considered.

Such a sequence allows students to construct their knowledge, starting in a concrete context of geometrical drawings and bodies that is intuitively clear to them, and where all quantities (i.e. length, area, volume) have positive values. This context requires relatively little previous knowledge and allows for rather linear and smooth vertical reorganization. Next, follows a more formal context of analytically given objects or situations (all quantities still having positive values). And finally, students are asked to deal with general quantities. Practically, approximation may be made by measurement, by geometrical consideration (with known formulas), or by algebraic considerations (analysing some algebraic term). In light of these considerations we have designed a sequence of activities, which we now, following an a priori analysis, interpret as focusing on (i) GSA with its three elements of knowledge ‘General Approximation’ (replacing the given object by known objects), ‘Refined Approximation’, and ‘Approximation Limit’; and (ii) parallel elements of knowledge for ‘Analytical Shape Approximation’.

Similar considerations apply to the concept of *accumulation function*. We see the accumulation function as a process of change (e.g. the change of accumulating area beneath the graph of the function while "the upper bound is moving") and the product corresponding to this process (e.g., a graph of this process demonstrating the ability to characterize it). This approach to the accumulation function immediately leads to the following conclusions: for constructing the accumulation function element of knowledge, students should know (even if only intuitively) that if we change the upper end-point of some sub-interval of the function domain, the appropriate value of the given function and the accumulation value of the given function will also change; and they should know how to characterize the process of the changing of the accumulation value. In light of these considerations, we have designed a sequence of activities, focusing on the *Accumulation Function* element of knowledge via its component elements (not specified in this paper).

On the basis of the above we claim that the combination of AiC and PT allows us to make decisions regarding the design of activities for the learning unit.

### **Theoretical considerations at the final stage of design**

As a result of the two previous stages (pre-design and initial design) we developed a sequence of activities that were organized according to the above four component vertical structure. Each of its four components constitutes a hierarchical procept that is vertically composed of sub-procepts. We interpret this whole structure as the procept of Integral.

At the final stage of the design we analysed the developed activities with the purpose of avoiding inconsistent usage of terms, symbols, and visual representations. Another important issue we took into account at this stage was adaptation of the unit to students' previous knowledge. Thus, for example, at the previous stages we had used the number  $e$  for some of tasks. We recognized that this notion is not familiar to the students, so at the final stage of the design certain activities have been changed (e.g., by using  $\pi$  instead of  $e$ ).

The implementation of the unit was organized in the form of learning sessions of pairs of students with in the presence of a researcher. The time interval between the sessions was typically between one and two weeks. We considered that for every part of the unit, students need some introductory and some summarizing activities. These activities aimed to provide a smooth flow of the learning

process and were developed (in the form of a short discussion that was led by researcher) at the final stage of design.

As a result of the final stage, we created a task-based curriculum unit introducing the concept of integral via the idea of accumulation with a fair measure of internal coherence. This unit has been implemented with four pairs of students.

### **AiC as a tool for design evaluation**

An essential component of AiC is the nested epistemic actions model for describing and analysing, at the micro-level, processes of abstraction by which learners construct new knowledge. The model uses the three epistemic actions of Recognizing (previous constructs as relevant in the present situation, R), Building-with (the recognized constructs to achieve a local goal, B), and Constructing (assemble and integrate previous constructs so that a new construct emerges by vertical mathematization, C). In processes of abstraction, R-actions are nested in B-actions, and R and B-actions are nested in C-actions.

Following Dreyfus, Hershkowitz and Schwarz (2015) the core of the method is the analysis, utterance by utterance, of transcripts to identify R, B and C epistemic actions as building blocks of abstraction. The RBC methodology helps making processes of knowledge constructing observable. This claim is based on empirical results regarding many content areas including integration (Kouropatov & Dreyfus, 2014).

RBC analysis of the learning sessions has been successfully used for evaluating the design of the activities by identifying problems with the implementation; this evaluation has uncovered instances where the design (or micro-design) of activities or their sequencing needed to be improved. We present two examples.

The first example concerns the concept of approximation limit ( $AP_L$ ) referred to above. The RBC-analysis of the performance of one pair of students (A and B) supplied empirical evidence about students' constructing processes of  $AP_G$  and of  $AP_R$  but not of  $AP_L$ , which is a crucial component of approximation. Therefore, the design of the activity for the following groups of students has been refined in a way that supports the constructing process of  $AP_L$ . The elaboration consisted of adding questions leading the students to intuitively distinguish between overestimates (decreasing to the exact value) and underestimates (increasing to the exact value) of the approximated value. The revision was successful in the sense that all following student pairs succeeded in constructing  $AP_L$ .

The second example relates to the issue of lacking previous constructs assumed by the design. For example, when constructing the concept of approximation via GSA, students M and N demonstrated a lack of previous constructs such as identifying coordinates of points on a graph, or calculating lengths of segments. For example, in the activity of finding the length of a quarter-circle, the students quickly recognized the relevance of approximation. They replaced the curve with a set of chords but then got stuck because they didn't know how to calculate the chord-lengths. The idea of choosing the segment endpoints according to some division of the given interval was new to them and outside their current grasp. The teacher's intervention was needed and was locally helpful. So, we can argue that there was a need for an additional element of knowledge that our design did not take into account: division of the given interval creating an appropriate division of the graph.

## Conclusions and further questions

We presented a case study of using theories for design decisions; this case dealt with learning the integral concept in high school via constructing knowledge about accumulation. The theories were most significant but not the only resource for decision making. The decisions were inspired by theory (e.g., in the case of verticality of the structure of the elements of the intended knowledge), by practical experience (e.g., in the case of assumption regarding intuitive accessibility of some elements of knowledge for students), or by both (e.g., in the case of building the system of sub-procepts of the procept of the integral or in the case of designing the sequence of learning activities). However, we argue that in the process of designing the learning unit on integrals for high school students, the theories have been interwoven and have played crucial roles in the process of development and implementation of the unit at all stages: the pre-design, the initial, and the final stages, as well as for fine-tuning the design after its evaluation.

The theories that we adopted for the purpose of the design are Abstraction in Context (AiC) and Proceptual Thinking (PT). These theories were adopted on two levels: AiC on a cognitive-epistemological level with the purpose of coming to design decisions regarding the nature and the structure of knowledge to be learned (at a macro-level, which seems to be efficient in a more general context); PT on a didactic-implementation level with the purpose of coming to design decisions regarding how to help learners to achieve this knowledge (at a micro-level, which seems to be efficient in the context of mathematics procepts). The role of the theories differed from stage to stage: AiC was more essential at the pre-design stage while PT was more fruitful at the initial stage. However, the synergy of the theories was more influential than their diversity: Our design aims at supporting students in constructing proceptual knowledge of the Integral that we interpret as a hierarchical procept that is vertically composed of sub-procepts. Our research allows us to follow how students acquire a proceptual view while they construct their knowledge. We speculate that students' behaviour that is coherent with the suggested operational definitions (in terms of AiC) can be interpreted as evidence for the acquisition of a proceptual view (in terms of PT).

Following the research, we find ourselves in a better position to pose two relevant yet unsolved problems, a practical and a theoretical one. The practical problem is how to optimally profit from theory when designing instruction. The findings of the research show that the AiC and PT frameworks can be used for development and evaluation of an important instructional instrument – a learning unit. What about other instructional instruments, such as homework assignments, tests, and so on? Could we also use these theories for the design of such instruments? Additional research and experiments are needed in order to suggest the adaptation of the discussed theories for these types of instrument. The theoretical problem concerns the consistency of theories: Could we have used other theoretical frameworks instead or in addition to AiC and PT, what consistency issues would have arisen, and how different a design would have resulted?

# Learning Through Activity: A developing integrated theory of mathematics learning and teaching

Martin A. Simon

New York University, New York, NY, USA; [msimon@nyu.edu](mailto:msimon@nyu.edu)

*Sociocultural theory (Vygotsky, 1978) has left the process of internalization relatively unexplored. In the Learning Through Activity (LTA) research program, we use basic constructs of constructivism to address this issue. The goal of our empirical and theoretical work has been to elaborate an integrated theory of mathematics learning and teaching. Towards this end and grounded in our empirical research, we have engaged in explicating reflective abstraction for mathematical concepts and developing a design approach for fostering reflective abstraction. The LTA approach is complimentary to a problem-solving approach; learning engendered by the LTA approach is not dependent on the uncertainty inherent in solving authentic problems.*

*Keywords: Constructivism, learning theories, task design, mathematical concepts, learning trajectories.*

In Simon (2009), I argued that different theories of learning can be thought of as different tools for research affording different kinds of work. It is the job of mathematics education researchers/theorists to not only develop and articulate theories, but to specify the work for which they are designed. Such specification allows fruitful discussion about the relationship of different theories and the possibilities of particular multi-theoretical approaches. In this paper, I describe a developing theory and the work for which it is intended.

## Background

In the Learning Through Activity (LTA) research program, we use multiple theories. In particular, we use sociocultural theories to think about cultural factors and the role of artifacts, social theories to think about the norms negotiated in situations of learning and teaching, and cognitive (constructivist) theories to think about the development of particular concepts. The latter has been our primary theoretical tool and the theoretical area to which we have been contributing.

Sociocultural theory views all knowledge as socially constructed. Knowledge development proceeds from a social level to an individual level through a process termed “internalization” (Vygotsky, 1978). Bereiter (1985) wrote, “How does internalization take place? It is evident from Luria’s first-hand account (1979) of Vygotsky and his group that they recognized this as a problem yet to be solved (p. 206). My colleagues and I see constructivism as a theory that has the potential to explicate internalization.

Constructivism, particularly the work of Piaget (1985), is a major theory of learning and has been the basis of important research on the learning of mathematics (Steffe & Kieren, 1994). However, Piaget’s work has not had a comparable effect on mathematics pedagogy.<sup>1</sup> DiSessa and Cobb (2004) observed, “Piaget’s theory is powerful and continues to be an important source of insight. However, it was not developed with the intention of informing design and is inadequate, by itself, to

---

<sup>1</sup> I use “pedagogy” to refer to all contributions to instruction, instructional design, instructional planning, and teaching.

do so deeply and effectively” (p. 81). We believe that it is Piaget’s later work on reflective abstraction, rather than his earlier work on equilibration, that has the potential to be the basis for pedagogical theory development.

The goal of our empirical and theoretical work is to elaborate an integrated theory of mathematics learning and teaching. This involves articulating a theory of conceptual learning that is useful for orienting mathematics pedagogy and building on that theory to explicate mathematics instructional design and teaching. Towards this end and grounded in our empirical research, we have engaged in explicating reflective abstraction for mathematical concepts and developing a design approach for fostering reflective abstraction. This empirical and theoretical work has focused on the learning and teaching of mathematical concepts (as opposed to problem solving or other areas of mathematics learning), and on the generation of hypothetical learning trajectories (Simon, 1995), including the design of task sequences.

The term “mathematical concept” is an underspecified construct. Because it is central to our empirical and theoretical work, I have characterized the construct for research and development purposes (Simon, 2017). I refer to one aspect of that characterization here:

A mathematical concept is a researcher’s articulation of intended or inferred student knowledge of the logical necessity involved in a particular mathematical relationship.

## Elaborating reflective abstraction

### Outline of the theory<sup>2</sup>

One challenge that we accepted in explaining the development of new mathematical concepts was that the explanation must account for building more advanced concepts from prior concepts. Thus, we endeavored to describe a recursive structure in which the result of conceptual development at one level serves as a building block of a concept at the next level. Piaget (1980, p. 90) described reflective abstraction as a “coordination of actions.” We built on this idea in the following way.

1. We specify a concept as a complex of a goal and an action (represented as  $G_n-A_n$ ) constructed through reflective abstraction. We represent the prior concepts of the learner as  $G_0-A_0$  and the concept whose development we are attempting to explain as  $G_1-A_1$ .
2. The learning process begins with the learner setting a new goal (generally in response to a mathematical task) and calling on a sequence of *available* actions to achieve that goal. This sequence of available actions is what we call an activity, represented as  $(A_{0a} \rightarrow A_{0b} \rightarrow A_{0c})$ . An activity is the precursor to a new concept.
3. The actions that are part of the activity do not exist in isolation. Each is part of an existing concept (e.g.,  $G_{0a}-A_{0a}$ ), and each is called upon, because the goal of that existing concept (e.g.,  $G_{0a}$ ) is a subgoal of the activity used to solve the task. Thus, the set of actions that make up the activity are part of a set of concepts that are activated to achieve the goal (solution of the task). Thus, whereas Piaget defined reflective abstraction as a coordination

---

<sup>2</sup> This description has been abbreviated. In particular, there is no discussion of the stages of concept development. For a full treatment of reflective abstraction and discussion of the stages, see Simon, Placa and Avitzur (2016).

of actions, we assert that this coordination takes place in the context of a coordination of concepts. This point is important, because it allows us to explain how concepts build on concepts recursively.

4. The coordination of actions results in a new, higher-level action linked to a goal ( $G_1-A_1$ ). Reflective abstraction results in a learned anticipation. That is, the learner can now solve the task without going through the sequence of actions that was originally necessary, but rather by enacting the higher-level action. (This will be demonstrated in the example.)

### Example from data

The following example is taken from Simon, Placa and Avitzur (2016). The data derived from a single-subject teaching experiment focusing on learning fraction concepts. Kylie was 10 years old at the time of the study. “R” refers to the researcher, Simon, and “K” to Kylie.

In this example, Kylie is developing an abstraction of recursive partitioning (i.e., a unit fraction of a unit fraction). Hackenberg and Tillema (2009) defined recursive partitioning as “partitioning a partition in service of a non-partitioning goal, such as determining the size of  $1/3$  of  $1/5$  of one yard in relation to the whole yard” (p. 2).

• **Task 4.1:** *[Using JavaBars, R draws a bar on the screen.] This is one third of a unit. Make a bar that is one sixth of a unit.* Kylie made it clear that she did not know how to just “cut up” the bar on the screen. She made the whole by iterating the third three times and then cut the first third in half. She indicated immediately that one of the small pieces is one sixth.

• **Task 4.2:** *This is one fifth of a unit. Make one tenth of a unit.* Kylie used the same process. She iterated the one fifth 5 times to make the whole and then partitioned the first fifth into two subparts. She reported, “Here, you have one tenth of a unit.”

• **Task 4.3:** *This is one third of a unit. Make one ninth of a unit.* This time Kylie immediately divided the one-third bar into three pieces (without iterating to make the whole).

K: One of those is one ninth.

R: How do you know?

K: Because, um. How many times does three go into nine? . . . Three times. And it’s one third! So. Three times three is nine, and one of—if you cut it up into thirds again. That is, um. . . . And you take one, it would be . . . one third. . . . But that’s really one ninth of a unit.

Kylie seemed to indicate that she thought about what number of parts would iterate three times to the whole. She therefore knew that one third of the one third would iterate nine times in the whole.

• **Task 4.4:** *This is one fifth of a unit. Make one twentieth of a unit.* She immediately cut the fifth into four pieces. She went on to complete two more tasks in this way. (pp. 77-78)

In this example, Kylie developed an abstraction that taking  $1/m$  of  $1/n$  creates  $1/mn$ , that is, a part that when iterated  $mn$  times recreates the unit. The example illustrates several aspects of the theory discussed above. Initially, Kylie had no way to think about making  $1/mn$  by simply partitioning  $1/n$ . However, she did have knowledge that allowed her to make  $1/mn$ . That is, she had concepts that she

was able to call on producing a sequence of actions (an activity) to achieve her goal. She conceptualized  $1/n$  of a unit as a part that can be iterated  $n$  times to make the unit. She also knew that she could partition the unit to make any unit fraction. In Task 4.1, she called on these two concepts. She sequentially iterated the original part,  $1/3$ , three times to make the unit and then partitioned the unit to make  $1/6$  of a unit. However, because the unit bar that she created was already partitioned into three parts, she called on her concept of partitive division (6 divided by 3) to determine how many times to partition each of the three parts. Thus, Kylie created an activity made up of three actions involving three extant concepts: iterating the part to make the unit, using partitive division to determine the number of subparts per part, partitioning a subpart.

The activity Kylie employed for Tasks 4.1 and 4.2 led to the abstraction that was apparent in Task 4.3 and beyond. In Task 4.3, Kylie no longer needed to go through the sequence of actions used in the preceding tasks. The actions that made up the activity were now coordinated into a single higher-level action. She knew immediately in Task 4.4 that cutting  $1/5$  into 4 subparts allows a subpart to iterate  $5 \times 4$  times to the whole.<sup>3</sup> That is, she had developed an anticipation that the denominator of the part has a multiplicative effect on the number of times the subpart iterates to the unit.

### **Building a pedagogical theory: the LTA instructional approach**

As stated our goal was to generate a theory of mathematics concept learning that can serve as a basis for mathematics pedagogy. In this section, I describe how we have built an instructional design approach on the basis of the explication of reflective abstraction, discussed above.

The first two steps in our design of instructional sequences are part of various design approaches. In Step 1, we specify the prior knowledge needed to engage with the sequence. This is particularly important in our design approach, because it identifies the concepts that students can call upon as components of their activity. In Step 2, we identify specific learning goals for the students, that is, we articulate the particular abstractions we intend to promote.

Step 3 makes direct use of our explication of reflective abstraction. In this step, we specify an activity (sequence of concepts/actions) available to the (actual or hypothetical) students that could serve as the raw material for the intended abstraction. There are two requirements here. First, the students must be able to call on the activity. Second, the researchers/designers must be able to describe how the students could come to the abstraction as a result of engaging in the activity. In our example above, the activity would be iterating the part to make the unit and then partitioning the unit by subdividing each part – the number of partitions determined through partitive division.

Step 4 involves generating a sequence of tasks designed to elicit the activity specified in Step 3 (in our example Tasks 4.1-4.4) and promote reflective abstraction. Sometimes the tasks that promote the activity are sufficient as in the example presented (by the third task, Kylie had made the abstraction). In some cases, subsequent tasks are created that restrict the student's ability to carry out the sequence of actions in the activity – prompting the students to use developing anticipations

---

<sup>3</sup> Although Kylie's justification was given for Task 4.3, I refer to the numbers from Task 4.4, because in Task 4.3, the use of  $1/3$  as both the fraction of the unit and the fraction of the part makes articulation of the ideas confusing.

if available. For example, in our work on promoting a reinvention/abstraction of the multiplication of fractions algorithm, Kylie had developed a reasoned activity beginning with thinking through the effect of the denominator of the multiplier on the denominator of the multiplicand. Her reasoning then included the numerator of the multiplicand and finally the numerator of the multiplier. Each step was dependent on the prior one. To promote and elicit use of a developing anticipation, we gave her tasks with the denominators hidden and asked for the numerator of the product. She was only able to do these tasks when she had developed sufficient anticipation of the effect of the numerator of the multiplicand in the context of her activity. In other cases, particular tasks are sequenced to increase the probability that students will attend to the commonality in their activity. In Simon et al (2010), Erin was reinventing/abstracting a common-denominator algorithm for multiplication of fractions. She had developed diagram solutions to division tasks whose dividend and divisor had common denominators. She had also developed the ability to talk through a diagram solution (without drawing). For example, she was able to talk through  $37/31 \div 17/31$ . However, she also made it clear that without talking through the solution, she could not come up with the quotient. At this point, I gave her consecutively two tasks with the same pair of numerators, but different common denominators (e.g.,  $7/167 \div 2/167$  and  $7/103 \div 2/103$ ). Although she needed to talk through the first, she was able to give the answer immediately to the second. Not only that, she was able to elegantly explain the abstraction she had made and do subsequent tasks (involving common denominators) simply by dividing the numerators.

I have highlighted the first four steps. However, as in other approaches to instruction, these steps might be followed by symbolization, introduction of vocabulary, and institutionalization of ideas.<sup>4</sup>

A couple of clarifications are in order. First, when we refer to a *task*, it includes the resources available to the students for solving it. Second, the goal of our research is to specify a sequence of tasks that can promote a particular abstraction. Thus, the sequence should work without the instructor asking leading questions, telling or showing solutions, or giving hints or suggestions. Also, the sequence should allow students to make the abstraction without needing to hear the solutions of others. This does not mean that there is not a role for teachers. The teacher is important in developing norms for the mathematical work, promoting justification at appropriate times, introducing symbols and vocabulary, and leading discussions that institutionalize the learned abstraction. Also, teachers should be able to monitor student progress and modify task sequences in response to student progress.

### **Affordances of the LTA instructional approach**

To provide a context for discussing the affordances of the LTA instructional approach, I first discuss a commonly used and important approach to instruction, a problem-solving approach. I will then highlight some of the contrasts and complementarities between the LTA approach and a problem-solving approach.<sup>5</sup>

---

<sup>4</sup> See also Simon (2016).

<sup>5</sup> Discussion of contrast with Harel's DNR can be found in Simon (2013).

Although there is no single problem-solving approach, I will discuss some typical features. One of the main strengths of a problem-solving approach is the engagement of students in the critical activity of mathematical problem solving, attacking a problem for which the student has no solution at the outset. I will not highlight here the abilities and dispositions that can be developed through regular engagement in problem solving; these have been well documented. Rather, I will focus on one feature of this approach that provides a contrast with the LTA approach. Problem solving is by definition uncertain. There is no assurance that those who engage in solving an authentic problem will succeed in solving it. When a diverse set of students in a mathematics class attempt to solve a problem, it is likely that only those who are the stronger problem solvers and who have the more powerful mathematical concepts will succeed in solving the problem. The other students must try to *follow* the reasoning (in small groups or whole class discussions) of their more able peers.

The LTA approach is intended to provide a complimentary approach, one in which learning of a concept is not dependent on the uncertainty inherent in attempting to solve authentic problems. If an LTA sequence is designed effectively, students should be successful in solving every task in the sequence.<sup>6</sup> In the LTA approach the learning (the new abstraction) is not the ability to solve the task. Rather it is the insight that is gleaned through the students' solutions to tasks using available activity. In our example, Kylie was successful in solving each of the four tasks. She was not trying to learn anything – just to solve the tasks presented. However, by the third task, she understood something that she had not understood at the beginning of the instructional sequence.

We conceive of the LTA instructional approach as a technology for engendering the construction of particular mathematical concepts on the basis of particular prior knowledge. I call attention to two potential contributions of this approach:

1. For concepts that tend to be difficult to teach and learn, the LTA approach provides a technology for building up those understandings (promoting particular abstractions).
2. For students who have previously been unsuccessful in learning mathematical concepts, it provides a specific methodology for building up their conceptual foundation.

### **Affordances of the LTA theory for research and development**

The elaboration of reflective abstraction discussed above provides a lens for looking at conceptual learning in different situations, not just in situations designed using the LTA instructional approach. For example, the LTA elaboration of reflective abstraction could be used to understand conceptual learning in the context of a problem-solving approach to instruction. How do we explain the success or failure of a lesson for particular students? Of course, the students' prior knowledge and problem solving skills are important. But how can we consider the usefulness of the problem or problems? The LTA elaboration of reflective abstraction allows for analysis of the students' activity and its relationship to the abstraction that they make.

---

<sup>6</sup> Of course, there is no curriculum that works flawlessly for all students. The issue is not whether we can create a sequence in which every student can solve every task. Rather the issue is that we intentionally create tasks that we predict students will be able to solve. This is in contrast to putting them in a problem-solving situation.

In Simon (1995), I postulated the construct of a *hypothetical learning trajectory (HLT)*. An HLT can describe a hypothesized trajectory for a single lesson or for a sequence of concepts in a conceptual area (also referred to as a “learning progression”). Learning trajectories has become a hot area for mathematics education researchers. HLTs are not just a series of conceptual steps through which learners progress, they involve articulation of sequences of learning situations and hypotheses of how these situations will be used by the students to learn the target concepts.

The LTA integrated theory of teaching and learning can provide the framework for learning trajectories in various conceptual areas. As a framework, it provides a basis for selecting and sequencing tasks and for hypothesizing how the students will abstract from their activity in working with those tasks. In our current project, we designed, enacted, and modified in teaching experiments nine trajectories for different concepts involving fractions.<sup>7</sup> This work has been grounded in and contributed to the LTA theory of teaching and learning. Also essential to the design and modification of the trajectories has been (but beyond the scope of this short paper) our work on reversibility (Simon, Kara, Placa, & Sandir, 2016) and on the stages of concept development (Simon, Placa, & Avitzur, 2016). Both build on the theory described in this paper.

*In this article, we discuss the German construct of Grundvorstellungen and highlight the connection with mathematical aspects. After recalling the definition of these terms, we compare it with similar notions used in the literature such as “concept image/concept definition”, and “metaphors”, pointing out some common features and differences. Moreover, we use Grundvorstellungen and aspects for the analysis of the concept of extreme points. Finally, we briefly sketch how it may be used for the discovery and interpretation of students’ misconceptions.*

*Keywords: Grundvorstellung, calculus, extreme point, misconception.*

## **Motivation**

There exists a vast literature on problems, mistakes, and misconceptions of mathematical topics in school. In order to discuss these misconceptions in connection with “correct” ideas, several approaches have been proposed, such as the construct of so-called “Grundvorstellung” (or GV, for short), which is mainly used in German literature (e.g. vom Hofe, 1995; Greefrath et al., 2016b). In this article, we briefly recall this construct and compare it with similar constructs appearing in the literature. In particular, we show how the GV construct can be applied to extreme points, with an emphasis on the transition from school to university. To this end, we give a short overview over GVs for extreme points, which helps us to classify students’ problems concerning extreme points.

## **Theoretical background**

Let us first explain the notion of *Grundvorstellungen*. Grundvorstellungen originate from the traditional German didactical approach of subject-matter didactics and have a long tradition in German mathematics education (see vom Hofe, 1995). Vom Hofe extended the subject matter didactics approach by his understanding of Grundvorstellungen: he suggested to additionally take into account the learners’ perspectives (see Straesser, 2014, p. 569). As a consequence, he distinguishes between GVs from a normative viewpoint, on the one hand, and GVs from a descriptive viewpoint, on the other hand. Vom Hofe (1992, p. 347) recalls the main characteristics of this construct: It gives meaning to a concept by connecting it with already known facts or experiences. It brings along the development of corresponding representations and the ability to use the concept. Scrutiny reveals that it is useful to introduce different types of GVs, which read as follows: A *primary GV* is a GV which gives meaning to a concept by connecting it with concrete experiences and objects from everyday life. A *secondary GV* is a GV which gives meaning to a concept by connecting it with ideas and representations of other mathematical concepts (see e.g. vom Hofe & Blum, 2016, p. 234).

To clarify the connection between GVs and the mathematical content of a concept, Greefrath et al. introduce a distinction between aspects and GVs of a mathematical concept:

“A Grundvorstellung of a mathematical concept is a conceptual interpretation that gives meaning to it.” (Greefrath et al., 2016a, p. 101). However, an *aspect* of a mathematical concept is a part of this

concept, which refers to its mathematical content, like its definition, theorems related to the concept, its properties, or connections to other concepts. It is a part of this concept, which can be used to characterize it (see Greefrath et al., 2016a, p. 101).

Another distinction is given by Greefrath et al. (2016b, pp. 18–19) who introduce the notions *universal* and *individual* GVs: A *universal GV* works as a normative guidance for teachers and answers the question what students should think of a concept, i.e. a universal GV refers to vom Hofe’s normative viewpoint. Universal GVs refer to mathematical aspects. However, there is no one-to-one correspondence between GVs and aspects: One GV can refer to several aspects, and one aspect can be the basis for several GVs (see *ibid.*, p. 17–18). On the other hand, an *individual GV* answers the question what a special student actually thinks of a concept, i.e. an individual GV is related to vom Hofe’s descriptive viewpoint. Individual GVs can be detected by watching students solving problems or by analyzing their explanations with regard to certain questions. Therefore it is a GV that an individual person possesses regarding a certain concept.

For our purposes—to find reasons for students’ misconceptions—it is necessary to introduce yet another kind of GV which we call *partial GV*. A *partial GV* is an idea that gives meaning to a concept in a limited context. It also goes back to mathematical aspects of a concept, and thus to a normative viewpoint. However, it loses its generality through restrictive premises. Depending on the goal, it could also serve as a (preliminary) educational objective. An example is the idea “multiplication makes bigger” which is correct only in certain cases, e.g. the natural numbers (larger than 1). To highlight the differences between these types of GVs, we want to add the following point to the description of a universal GV: “Universal” means that it works in every given context. Consequently, we categorize an individual GV either as a universal GV, as a partial GV, or as a part of them. The following graphic puts the characterization of the GVs in a nutshell:

**Figure 1: Connection of universal, partial and individual GVs**

The notion Grundvorstellung could be translated, loosely speaking, as “basic idea”, “basic notion” or “basic mental model” (see vom Hofe & Blum, 2016, p. 226; Greefrath et al. 2016a, p. 101). However, we decided not to translate the notion to not mix it up with other (mainly in Germany used) constructs like fundamental ideas, universal ideas, central ideas, big ideas, leading ideas (for further details see Vohns, 2016).

GVs are especially interesting regarding misconceptions. These “erroneous conceptions” have different names (preconceptions, alternative conceptions, misconceptions) and are defined in various ways in the literature (see e.g. Leinhardt et al., 1990; Hammer, 1996). We just recall the main facts: They are a repeatable, robust, “well-formulated system of ideas” (Leinhardt et al., 1990, p. 5) and they are cause for errors, although they do not need to constitute a complete theory (*ibid.*, p. 5–6). If one takes a closer look at these, one can categorize some as so called epistemological

obstacles (see e.g. Brousseau, 1989), or overgeneralizations, like in our background as partial GVs used in the wrong context. Vom Hofe (1996, p. 259) describes the importance of GVs regarding misconceptions as follows: Firstly, GVs as a normative guidance should help during the learning process so that individual ideas become individual GVs and not misconceptions (see vom Hofe, 1996, p. 259). In this respect, GVs work as a *prevention* of misconceptions. Secondly, GVs should work as a plausible alternative to already existing misconceptions. If learners already have misconceptions they need not just be dissatisfied with the former idea, but also need to be given an intelligible, plausible and fruitful alternative by the teacher (see Posner et al., 1982, p. 214). In this respect, GVs work as a remedy for misconceptions.

The purpose of this article is to give a survey on universal and partial GVs at university level that refer to aspects of the concept of extreme points. To begin with, let us briefly recall the role of GVs in the existing literature.

### **GVs and concept image/concept definition**

One of the most important and popular works on the properties of concept image, concept definition, and their distinction is due to Tall and Vinner (1981). A *concept definition* consists of the words used to specify a concept. The definition of a concept given by the mathematical community is called *formal concept definition*, whereas the definition given by an individual is called a *personal concept definition*. A *concept image* consists of all non-verbal connections to and connotations inferred by an individual regarding a certain concept. These connections and connotations may include all kinds of representations. There exists some literature describing similarities and differences between concept image/concept definition and GVs: vom Hofe and Blum (2016, p. 237) state that GVs refer to the concept image from both a normative and descriptive level. Greefrath et al. write:

“A concept image may contain several individual Grundvorstellungen that conceptualize different perspectives of that concept. Individual Grundvorstellungen are central components of a valid concept image[...].” (Greefrath et al., 2016a, p. 103)

However, for some learners, also misconceptions may be part of their concept image. The individual GVs can either be partial GVs or universal GVs. As Greefrath et al. write:

“These Grundvorstellungen give meaning to mathematical concepts that may be studied with respect to various aspects. Each of these aspects may be expressed with one of the various [formal] concept definitions that one reads in textbooks. Thus, a [formal] concept definition is a specific realization of an aspect.” (Greefrath et al., 2016a, p. 103)

The personal concept definition could either be similar to the formal concept definition or differ from it. It also has a relationship to the concept image.

### **GVs and metaphors**

Apart from concept image/concept definition tools, metaphors have also been used to describe mathematical cognitive processes (see Lakoff & Núñez, 1997, 2000). First, we recall some facts about the concept of metaphors used by Lakoff and Núñez. They analyze the (conceptual) structure of mathematics and therefore use results of metaphor theory of cognitive linguistics. This theory is about how mathematics is constructed. To describe mathematics, they distinguish several kinds of

metaphors, the two crucial ones being *grounding metaphors* and *linking metaphors*, which are defined as follows:

“Grounding metaphors ground mathematical ideas in everyday experience.” In addition, “[...] linking metaphors allow us to link one branch of mathematics to another. For example, when we metaphorically understand numbers as points on a line, we are linking arithmetic and geometry.” (Lakoff & Núñez, 1997, p. 34)

Let us now point out some similarities and differences between the concepts of GV and metaphor. Both GVs and metaphors reveal several perspectives of one concept through a detailed analysis of it. GVs and metaphors suggest using this analysis for educational purposes. Grounding metaphors resemble primary GVs, since they connect everyday life experiences with mathematics. Linking metaphors resemble secondary GVs, because they connect different domains within mathematics. However, a fundamental difference is the aim of these theories: finding of GVs through a subject matter analysis aims at making the most important aspects of a concept comprehensible and giving them meaning, respectively. Referring to metaphors in the sense of Lakoff and Núñez (1997, p. 31), this educational aim is named “peripheral” for the theory of metaphors. The discussion about metaphors tends more toward revealing the structure of mathematics and unconscious connections to non-mathematical concepts as mentioned above. Metaphors are used to explain our linguistic vocabulary when talking about mathematical contents.

There are also connections with other theories like the theory of conceptual fields of Vergnaud (1996), which also works as a framework for organizing didactic situations. For lack of space we do not go into detail, but just remark that an exact analogue to the GV construct does not exist in the literature, but constructs which exhibit some similarities with GVs.

## **Aspects and GVs of extreme points**

After defining the concept of GVs and comparing it with other concepts from the literature, we are now going to use it for the concept of extreme point, which is the major topic of this article. The following GVs were identified by both discussions with lecturers of analysis courses and a subject matter analysis of the concept of extreme point.

### **Aspects of extreme points**

We will discuss three aspects of the concept of a (local) extreme point:

#### The aspect of “largest/smallest value”

*Extreme points are the points  $(x,y)$  with the largest/smallest  $y$ -value with respect to a neighbourhood of  $x$ .*

This aspect refers directly to the definition of an extreme point. It illustrates the connection of an extreme point (of a graph of a function) with the maximum/minimum of a (totally ordered) set: extreme points are the points, whose  $y$ -values coincide with the maximum/minimum of the range (on a given domain). Already children have some experience with this aspect.

Non-mathematical examples:

- Searching for the highest point (of a mountain)

- Searching for the best object of category (fastest car, most expensive house, highest building)

Mathematical examples:

- Interpretation and discussion of graphs: where is the highest/lowest point?

The aspect of “largest/smallest value” is the most fundamental one for the concept of extreme point.

The aspect of “derivative zero”

*Extreme points are located at points where the derivative becomes zero.*

In this connection, however, one has to be careful and take into account two important points. First, there are points, which are not extreme points, although the derivative becomes zero at these points. Second, since this aspect refers to the necessary condition for the existence of (local) extrema, one has to impose two additional premises: the point must be an interior point of the domain, and differentiability of the function is required. By dropping one of these premises, one can easily find examples of extreme points where the derivative does not become zero (e.g. boundary points of an interval).

Non-mathematical examples:

- From a physical viewpoint: searching for the points where the velocity becomes zero.

Mathematical examples:

- The algorithm for the identification of extreme points most frequently taught at school: find the zeros of the first derivative. Afterwards, check the sign of the second derivative at these zeros to detect maxima and minima.

The aspect of “change of monotonicity”

*Extreme points are located at points where the sense of monotonicity of a function changes, i.e., from increasing to decreasing or vice versa.*

It is, in fact, easy to see that a change of monotonicity always implies the existence of an extreme point. The converse, however, is false: not every extreme point induces a change of monotonicity (consider again extreme points at the boundary of an interval).

Non-mathematical examples:

Change of the direction of movement:

- Activities: mountain climbing (change of uphill to downhill), bike riding (change from pedaling to idling).

Mathematical examples:

- At school (premise: differentiable functions): a table of sign changes for the first derivative (distinguishing extreme points from saddle points).

### **GVs of extreme points**

Let us now study three GVs of the concept of (local) extreme points of a real function (defined on a nondegenerate interval). The first GV is universal, the second and third are partial.

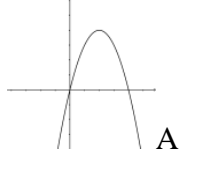

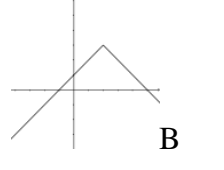

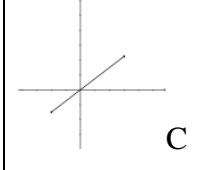

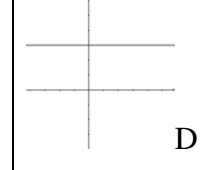

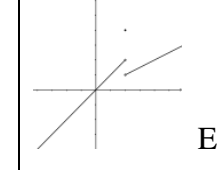

## Universal GV

### The GV of “largest/smallest value”

This GV refers directly to the aspect of largest/smallest value and may be interpreted in a concrete geometrical way: extreme points are the points with the largest/smallest  $y$ -value with respect to a certain neighbourhood. The students should:

- Identify extreme points through analyzing  $y$ -values of points of a function graph algebraically or graphically.
- Demonstrate the connection between a maximum/minimum of a (totally ordered) set and an extreme point of a function by projecting (pieces of) the graph onto the  $y$ -axis.

				
Extrema as hill/valley (differentiable function)	Extrema as hill/valley (not differentiable function)	Extrema at the boundaries of an interval	Extrema of a constant function	Extrema at a discontinuity point

**Table 1: Subcategories of extreme points**

Once the students understand this GV correctly, they can specify different subcategories of extreme points, such as those sketched in the synoptic Table 1.

This GV is universal and should thus be emphasized when introducing the concept of extreme point. For applications, however, it is not that useful: it would take an infinite long time to analyze every point with regard to the value of its  $y$ -component, because the domain of definition is a continuum. However, there exist another two GVs, which are more helpful in applications.

## Partial GVs

### The GV of “slope zero”

This GV reflects the fact that the graph of a function has slope zero at an extreme point. Since this idea is intimately related to the aspect of “derivative zero”, it should be assumed that the function is differentiable at the (interior) point in question. As this is usually the case for functions dealt with at school, it is mainly consolidated as a consequence of math classes. The GV of “slope zero” calls upon the GVs of the derivative of a function like the GVs “Tangent slope” or “Amplification factor” (see Greefrath et al., 2016a, pp. 106–113):

- Tangent slope: slope zero entails the existence of a horizontal tangent at the extreme point in question that approximates the graph locally. This means that the graph is also almost horizontal.
- Amplification factor: slope zero implies here that a change of the independent variable  $x$  leads to almost no change in the dependent variable  $y$ .

The reason, why this is just a partial GV is the fact, that neither the argument “extreme point implies slope zero” nor the converse argument “slope zero implies extreme point” is true.

### The GV “change of monotonicity”

If you look at the graph of a function and see that it is strictly increasing up to a certain point  $x_0$ , and then strictly decreasing, you could intuitively argue that  $x_0$  is a (local) maximal point. This idea exhibits an analogy to the curvature of a graph at inflection points; if a function changes at some point from left curvature to right curvature, or vice versa, this is an inflection point. As far as differentiable functions are concerned, passing from an increasing piece to a decreasing piece can be interpreted as the transition of the first derivative from the upper half-plane to the lower half-plane. The GV of “change of monotonicity” goes back to a specific “dynamical” experience of the students: if you regard the graph as trajectory of a moving particle, the movement changes in the  $y$ -direction precisely at minimal or maximal points. The students should:

- Partition the graph of a function into monotonically increasing and decreasing pieces and identify extreme points as boundary points of the partition intervals.

The reason, why this is just a partial GV is the fact that it works only “in one direction”, because the logical converse is again false: not every extreme point leads to a change of monotonicity.

### **Discussion**

These GVs play an important role when analyzing mistakes of students in their first semester at university concerning the concept of extreme point. The partial GVs especially can lead to mistakes when their restrictive premises are not considered. Our study aims, on the one hand, at finding mistakes and misconceptions of mathematics students after their first analysis course and, on the other hand, at giving insight into possible reasons for these mistakes. It turns out that the concept of GVs helps to find normative education objectives of extreme points, and it supplies—used in a descriptive way—an orientation of what ideas students have of extreme points.

# Mathematics teachers' re-sourcing and use of social media: Can the 'prosumer' concept convey what's going on?

Yvonne Liljekvist

Karlstad University, Department of Mathematics and Computer Science, Sweden;

[yvonne.liljekvist@kau.se](mailto:yvonne.liljekvist@kau.se)

*Keywords: Mathematics teachers, prosumer, social media, theoretical discussion.*

## Poster summary

The interrelated roles of social media as both a platform and a phenomenon of interactivity, invite teachers to produce and consume knowledge of teaching and learning mathematics (e.g., Liljekvist, 2016; van Bommel & Liljekvist, 2015, 2016). The availability and user-friendliness of the social media platform alter the behaviour of the mathematics teacher, and 'stories' of the good mathematics teaching are made (e.g. kinds of curricular material, or kinds of questions raised, see e.g., Liljekvist (2016)). Analysing the affordances of this new environment is necessary to understand how the subject didactical discourse on learning and teaching is simultaneously constructed and consumed in mathematics teachers' digitalized every-day practice. It is a matter of probing the characteristics of the interaction, that is, the ways in which the activity on the Internet supports knowledge development and re-sourcing in mathematics teaching (cf. Liljekvist, 2016; Ruthven, 2016).

The primary aim of this poster is to initiate a discussion in the TWG17 that elaborates on theoretical constructs that may be fruitful in the research of mathematics teachers' digitally extended every-day practice and collaboration. This arena for teacher learning and collaboration is under-researched (see, e.g., Robutti, Cusi, Clark-Wilson, Jaworski, Chapman, Esteley, Gnoos, Isoda, & Joubert, 2016)).

The prosumer concept, that is, people as producers and consumers of products and services (cf. Beighton, 2016; Ritzer, Dean, & Jurgenson, 2012; Zajc, 2015) shows some possibilities to theoretically model mathematics teachers' re-sourcing on social media as it centres on the phenomenon per se (i.e., producing and consuming 'value' for the user). Thus it is closely tied to the *raison d'être* of social media (Zajc, 2015) and mathematics teachers' activities there (van Bommel & Liljekvist, 2015, 2016). However, the concept needs to be operationalized in an educational setting and in a mathematical discourse in order to have sufficient explanatory power for our purposes. Here are some examples; In business and sociology, the driving forces for investigating 'prosuming' is to understand consumers' behaviour (e.g., Ritzer et al. 2012; Zajc, 2015), but in educational research mathematics teachers' performance, for instance, as a learner and as a colleague is of interest (e.g., Liljekvist, 2016; Ruthven, 2016; van Bommel & Liljekvist, 2015, 2016). Further, Beighton (2016) discusses in his article how the prosumerist behaviour can also work as a tool for control, where creativity and knowledge development, and professional learning may not be supported. This aspect of mathematics teachers' online activities is relevant, as it, for instance, may explain some of the quality problems in the curricular material shared (e.g., Liljekvist, 2016).

Mathematics teachers nowadays use social media to re-source and collaborate. This is an arena where the every-day practice of subject didactics is made (Liljekvist, van Bommel, & Olin-Scheller, 2017). Analysing this activity is to understand teachers as both producers and consumers of subject didactical contributions and of peer-learning. The core research question, then, is how we can theoretically describe mathematics teachers' simultaneous processes of producing and consuming subject didactical knowledge on social media.

# Analyzing verbal interactions in mathematics classroom: Connecting two different research fields via a methodological tool

Mariam Haspekian<sup>1</sup>, Eric Roditi<sup>2</sup>

University of Paris Descartes, Sorbonne Paris Cité, France,

<sup>1</sup>[mariam.haspekian@parisdescartes.fr](mailto:mariam.haspekian@parisdescartes.fr), <sup>2</sup>[eric.roditi@parisdescartes.fr](mailto:eric.roditi@parisdescartes.fr)

*This paper presents a small case of junction of two research fields that remained, until recently, relatively cut off from each other. Using concepts of the Assessment field, specified in a didactic approach, we develop and test a methodological tool on the analysis of students-teacher interactions in mathematics classroom. We discuss then its potential in the Assessment field. This illustrates a way of locally connect research areas, via a shared methodological tool.*

*Keywords: Mathematics teaching practices, evaluation, interactions, formative regulation.*

## Introduction

Initially inscribed in a particular research area of the didactics of mathematics field, the Double Approach (didactic and ergonomic) theory (Robert & Rogalski, 2005), our study aims at investigating the teacher's coherence in the processes of information-adaptation, when adjusting the situations, making decisions on the spot. Research on Assessment, a field traditionally cut from didactic ones, though with some exceptions (Vantourout and Goasdoué, 2014; Veldhuis, 2015), handles these questions with concepts as *formative* assessment or *regulations*. How can we describe these regulations and understand the way interactions guide them?

To study these questions, we thus went beyond the specific fields of didactics theories and carried out a literature review on formative interactions in Assessment, a research field in education, with its own models and conceptual frames<sup>1</sup>. Our review briefly summarized in section 1 shows needs for didactic references on learning and teacher activity, and led us to a theoretical and methodological development (reported in section 2) to support our analyses regarding the teacher-students interactions in mathematics as an adaptive dynamic process. The last part tests potentialities and limits of this tool on a short episode, before coming back to theoretical questions.

## Literature in the field of assessment: Needs for a didactic approach

Various theoretical concepts relate to teacher-students interactions, for instance the “diagnosis and responsiveness” of “scaffolding”, (Bakker et al., 2015). In Assessment research, they relate to three overlapping concepts we focus on: *feedback*, *formative assessment* (or *for learning*), and *regulation*.

## Theoretical needs for a didactic approach

The teachers' feedback to learners' activities constitute an element of the process of formative evaluation, and research has been deepened to understand their different effects according to their nature. Yet, Crahay (2007) notes that research on this concept is full of opposed results. He proposes to focus on the processual aspect of the link between teachers' reactions and students' learning considered as an activity rather than a product, and taking into account the characteristics of the

---

<sup>1</sup>This includes research on measurement in education, psychometric and edumetric approaches.

tasks, the school disciplines or the taught objects.

As for the concept of formative assessment, initially restrained to dedicated moments, it has been extended to “*all those activities undertaken by teachers, and/or by their students, which provide information to be used as feedback to modify the teaching and learning activities*” (Black & Wiliam (1998, p.10). Research points out a new concept, that of *regulation*, which can be interactive, retro-active or proactive. In this widened sense, the interactive regulations that may happen in didactic situations make a junction between evaluation and teaching-learning situations. This also fits the idea of “whole-class scaffolding” (Smit et al.). Crahay’s synthesis (2007) or that of Allal and Motier Lopez (2005) evoke a strong dependence between the formative evaluation and the very organization of teaching, encouraging research to integrate didactic issues (task, disciplinary contents...) in the analyses. More recently, Vantourout and Goasdoué (2014, p.142) claim the need for taking into account both didactical and psychological approaches by arguing that willing to foster learning requires understanding students’ cognitive functioning with a task. Although some attempts exist in mathematics education, they stress the lack of research investing in this joint perspective.

The theoretical needs addressed in this review join our didactic concerns, i.e. to pay particular attention to specificities of the taught and evaluated contents by analyzing the teacher-students interactions. In this perspective, the concept of interactive regulation described in research on formative assessment seems an interesting object regarding our didactical concern.

### **Regulation in formative assessment**

Formative assessment research has been driven by two underpinning teaching and learning theories: originally the neo-behaviorism, then the cognitivist one with its strong necessity to consider classroom interactions, particularly real-time regulations. In Allal and Mottier Lopez’s synthesis (2005), the concept of regulation is a process referring to the features of the concept of formative evaluation (collect, interpret, decide). Our didactic concerns relate to one of the five distinguished conceptual forms of regulations they bring out from literature: the online regulations resulting from interactions. Their model of regulations includes the situation; the teachers’ interventions; and the interactions between students based on a Vygotskian approach using the ZPD concept, which makes again a link with scaffolding. Aligned with this, recent research on assessment for learning (e.g., Pryor & Crossouard, 2008) is referring to Activity theory (Leontiev, 1975/84) in order to consider the formative assessment as a cultural historical activity shaped by teachers’ and students’ reciprocal acting, and co-determined by the subject and situation, which should not be considered separately.

The Double Approach also borrows from Activity theory, exploited in the field of ergonomics, but with a different unit of analysis, there the term “activity” focuses on that of an individual subject (Leplat, 1997). This didactic approach considers not only the mathematical knowledge to be taught, but also the procedures and the student’s activity to solve problems. Also considered as cultural-historical processes, the activity of a subject is here again co-determined by the subject herself and the situation carried out, which includes socio-cultural interactions with other subjects (Robert & Rogalski, 2005). In these interactions, we are interested in how the teacher’s activity depends on that of the students; particularly while adapting, adjusting teaching to optimize learning. Activity theory constitutes thus a theoretical link, enabling us to articulate teaching practices and students’ learning. The next part clarifies these links and outlines our theoretical and methodological tool.

## **Connecting with a didactical approach of regulations of students learning**

### **Towards tools for a didactic analysis of the formative regulations**

We consider two “sub-activities” of one activity system, reciprocally influencing each other: that of teacher, whose result is a situation for the students, impacting them; that of the students, co-determined by the students and the situation produced by the teacher. The teachers’ activity therefore involves two levels: the double regulation, resulting from the activity they address to themselves (to teach) and that resulting from the activity they address to the students (to make learn).

As for Crahay, in the Double Approach, teachers’ feedbacks should not be studied independently of student’s activity that creates them. From the didactic point of view, the analysis of the students’ activity needs to consider the situation at stake, including the task and possible elements of the didactic contract; the students’ knowledge and procedures (that are contextual elements), needed to solve the task; and the product (oral or written) of students’ activity (answer and any element on how the task has been realized). Aligned with research on assessment, we consider that the teacher’s activity in class interactions, is formative when he/she takes information on the students’ activity in order to act on the learning. Our analyses of the teacher’s regulations therefore need to specify the nature of information she collects and the actions (in Leontiev’s sense, 1975) she subsequently carries out to reduce the gap she can observe with her learning objectives.

Our research is therefore guided by the principle of identifying what is the gathered information about: a product (answer, result), a procedure, or a piece of knowledge; and what the feedback directly aims at (again a result, procedure or knowledge). Even if we do not have hierarchical assumptions on these types of intervention as for learning, not all interventions are equivalent. In case of an error for example, some interventions aim at correcting by giving the expected result (this lets the student the responsibility to find the underlying mathematical concept). Other interventions address the underlying procedure or knowledge (conforms or not with what was aimed at). All constitute forms of accompaniment of the student’s learning.

### **Results, procedures, knowledge**

Activity theory (Leplat, 1997) distinguishes the result of the activity from the procedure implemented and from the state of knowledge of the subject. This framework adapted to teaching, leads to associate to the student (the subject) a state of knowledge, which allows him to analyze and redefine the task prescribed by the teacher, to implement a procedure leading to an answer, guided by some knowledge (explicit or implicit). This student’s activity (generally carried out in thought, but possibly verbal or written) can thus be observable in what it produces: an answer/ a mathematical result... Among the possible feedback of the teacher, one can also distinguish those addressing the result only (indicating for example that the answer is false), or the procedure (indicating for example that the theorem used does not correspond to the hypotheses of the statement), or the student’s state of knowledge (indicating for example confusion between a theorem and its reciprocal etc.). The choice of a type of feedback depends on various factors (time, prior explanations/examples, teacher’s experience, etc.). In the same way, if the student says he ignores how to apply such theorem, the teacher perceives information on the procedure thought by the student. The possible feedback varies here again. It can remain on the procedure level, for example explain that the rule is not adapted; or change level by giving the solution (or begin the resolution and let the student finish), or it can

approach the student's difficulty by clarifying the mathematical knowledge.

This way of analyzing interactive regulations leads to identify in each student-teacher interaction a couple information-feedback where the information, as well as the feedback, could be associated to a *result* (R), *procedure* (P) or *knowledge* (“*connaissance*”, C), leading to 9 possible types (table 1). A qualitative didactic analysis of each interaction in a class session allows reporting the dynamics at play in these interactions by associating each of them to one of the nine possible types of regulation.

Action Information	Result	Procedure	Connaissance
Result	RR	RP	RC
Procedure	PR	PP	PC
Connaissance	CP	CP	CC

**Table 1: Information-Action: 9 possible pairs**

In some case, the “coding” could depend on what has been previously done, so that there is a need for interviews to support the coding.

The following section implements this tool to analyze an effective classroom episode.

### **A minute of verbal interactions in class of mathematics**

We use a classroom video, collected from the French research project NEOPRAEVAL on evaluative practices in mathematics to analyze there the students-teacher interactions with the “RPC tool”. The extract, situated at the beginning of a one-hour session with Grade 8 (14 y.o.), consists of “Flash”, a series of calculations ritual in this class, intended to be treated quickly. A slide titled “Mental calculus” then five calculations are successively displayed 30sec each, during which the students carry out calculations. Their written answers/calculations are neither collected nor looked at by the teacher. After the fifth calculation, the teaching undertakes a collective correction, questioning students and writing the answers herself on the board. Our analysis concerns the collective 1min dialogue-correction of the very first calculation displayed:  $3 \times 10^{-2}$ . We aim at identifying verbal interactions that can be interpreted as moments of formative regulation, based on an *a priori* analysis of the task, of the knowledge concerned (presented in Appendix), of possible interventions; and an *a posteriori* analysis of the effective interactions (presented in the next section).

#### **Analysis *a priori* of the teacher's interventions**

In situations of interaction, the teacher faces various cases (answers are correct or not, wished or not, expected or surprising...), which could raise various types of regulation (explicitly agree or not, develop the procedure or not, indirectly disapprove by repeating an explanation/ not reacting/ questioning someone else...), depending, among others, on the objectives fixed by the teacher prior to the session and/ or on the spot. In all cases, the intervention is said formative if it enables the student to recognize whether a behavior, answer, is correct or not<sup>2</sup>.

For the calculation  $3 \times 10^{-2}$ , answers *a* or *b*, or even *f* (Annex) would be the acceptable correct ones (expected/not). Answer *a* could bring a simple approval or a development to clarify the procedure, for example by an oral explanation on the product by  $10^{-2}$ , leading 3 at the hundredths digit by a

<sup>2</sup> The exactness of an answer does not prejudice the teacher's reaction. A correct and awaited answer could still draw to repeat the solution, to develop a procedure, take the opportunity to review some concepts, etc.

technique on the rows of the decimal writing, or by using one of the other possible answers  $b, f, g, h, i, j$  or  $k$  as intermediate calculus. As for the answer  $b$ , it contains already a calculative step of procedure, but here again; the teacher could accept it or add an explanation via the answer  $c$ , even  $d$  or  $e$ . These *a priori* reactions not only depend on the mathematics aimed at but are to be adjusted with the context where the task takes place. As already underlined, neither the task alone, nor the students' answers (correct or not) suffice to explain the feedbacks. Here, the mental calculations context, in the “flash” ritual, requires not to spend too much time on the task; therefore answers  $c, d, e$ , or  $j, k$  (fractional answers) are less likely to be acceptable (even if the teacher may want to expose them during the correction). We assume that these answers will lead the teacher to some “negative” feedback, i.e. indicating, by a way or another, that it's not the expected answer in such context.

### Analysis of the 1 minute interactions

Table 2 transcribes the turns to speak that occurred during the minute of this correction. The two last columns indicate whether the information (I) brought by the student's relate to result (R), procedure to obtain it (P), or subjacent knowledge (“connaissance”, C); the same for the resulting teacher's action (A). The coding actually limits the researchers' inferences by addressing the facts: the nature of the feedback (from a mathematical point of view: a result, a procedure or knowledge). This feedback can be done by addressing the result level, others the procedure, still others the knowledge. When the teacher does not react verbally to an answer<sup>3</sup>, we consider this silence an information too about the validity (or not) of the student's answer.

	Turns of speak	I	A
01	P : so / Camélia ?		
02	Camelia : three times one over ten times ten/	P	
03	P : what is ten to the negative two ?		P
04	Camelia : one over ten times ten	P	
05	P : and we know how to calculate it ?		P
06	E2 : one over three hundreds	R	
07	E3 : what's that ?		
08	P : you don't know how to calculate one over hundred??		R
09	Camelia : Ah yes ///		
10	E2 : it makes one over three hundreds. P: --	R	R
11	E3 : it's not possible	R	
12	P : Orlane		R
13	Orlane : one over three hundreds. P: --	R	R
14	E5 : three hundreds... one over three hundreds	R	
15	P : there is indeed a negative here [showing the sign of the exponent – 2 on the statement]		P
16	E5 : bah / negative one over three hundreds. P: --	R	R
17	E6 : zero point zero three	R	
18	P : Yasmine		R
19	Yasmine : zero point zero three	R	
20	P : [writing on board $0,03$ then $10^{-2} = \frac{1}{10 \times 10} = \frac{1}{100} = \frac{1}{10 \times 10} = \frac{1}{100} =$ ] So ten, negative two/ indeed Camélia / this is one / over ten times ten / so / one over hundred / one hundredth / you know how to write this?		P
21	Camélia : yes		
22	E8 : this is one percent !	R	
23	P : [she writes 0,01 after 1/100] It is 0,01 / so if one asks to make 3 times this/ 0,03		P

**Table 2: A minute of verbal interactions**

The pairs (I; A) then constitute basic units of formative evaluation and finally, the analysis of the interactions in this extract results in the following table:

<sup>3</sup> We consider only obvious cases (the student action is clearly audible and the teacher takes a time “not paying attention”) and we count only utterances directly linked to the task as R, P or C, no other ones (as lines 7 or 21).

Information/Action	Result	Procedure	Connaissance (knowledge)
Result	6	3	0
Procedure	0	2	0
Connaissance	0	0	0

Table 3: Synthesis of the interactions

Several observations can be made: 1) a majority of pairs remain on the same level, with a majority of RR among these. Only 3 feedbacks are changing the student's level of information making it pass from result R to procedure P; 2) Very few student intervention are situated at the P level in this particular case; 3) No interactions from students, nor from teacher, directly address knowledge. Many of these remarks could reasonably be explained by the specific nature of this episode: mental calculation, intended to be already mastered by students, the correction of which should be easy and short. Yet, we can notice a swift along teacher's interactions. After a time respecting the students' "result" level, she switches feedbacks towards procedural level. Indeed, the rare RP events occur all at the end of the exchange (line 15/20/23). This can reflect teacher's up-taking of information from the students' speeches. Seeing numerous mistakes instead of the expected answer, she adapts her feedback by entering into a procedural level. She does not always verbally react when the answer is wrong (see E2; repeated twice; or E3; E5); she possibly prolongs the interaction when the answer is acceptable even if not expected (it is the case for Camelia's answer, but not for the answer "1%" of E8) and writes on the board what is correct and acceptable (" $10^{-2}=0,01$  and  $0,03$ "). Thus, when Camelia starts an answer that could lead to  $d$  (fractional expression) or  $g$  or  $j$  (decimal expression), she interrupts her to orient the discourse towards the meaning of the powers of 10 (here  $10^{-2}$ ) that lead to decimal notations (" $0,01$ "). Referring to our *a priori* analysis, we assume that the teacher thus expects the answer  $b$  (direct decimal expression) not  $f$ , nor  $i$  that have intermediate fractional steps. Yet, the student goes on with fractions. The expected answer turns to be long delayed. Students make the classical mistake which is not picked up by the teacher (E5), then an answer using percentage is expressed, not much taken into account by the teacher, who seems to get eager for the expected decimal. Observing the mistakes and students' difficulties, she reconsiders the change of the power of ten into decimal notation via fraction calculation, in accordance with the procedure suggested by Camelia, thus finally accepting to align with the cognitive path taken by her students.

## Discussion and perspectives on didactic regulations

Aiming at analyzing, in a didactic approach, teachers' practices of formative regulation, we reviewed literature, which characterize these practices as both very few and little diversified. We thus looked for a theoretical and methodological tool that enables comparison between teachers and also various contents, in order to agglomerate results from various data and seek correlations. The analysis of the short episode above brings up many questions on the observed session as on the RPC. On the data, it suggests to test longer episodes, other contexts, other mathematical contents, and with other teachers. In the purpose of describing and understanding the teachers' adaptive activities to the students' one, it would be interesting to enrich analyses with various mathematical contents, and various didactical contexts of learning (application of former knowledge, problem solving, institutionalization...). The RPC tool makes possible the determination of trends in the regulating practices (between-variability of teachers or within-variability of teacher). On the theoretical tool, it results in prolonging the use of these RPC tables by devising tables being "average" of many same contex-

tual tables, to characterize the regulation types for a given teacher. One could indeed calculate a table of the variations to the average of the tables corresponding to several sessions for the same teacher (intra-variability, to characterize the regulation practices for a given teacher), or examine the variations to the average for several teachers on a given content (inter-variability to characterize the profession, or how regulating practices depends on the specific knowledge).

Similarly, the other few analyses we have carried out with this tool look quite promising for research on teaching regulations. They confirm the variability of the practices observed in former research. Yet, they also reveal some tendencies: 1) the couples information-feedback observed are not of the same type but distributed among five or six of the nine possible types; 2) these regulations were not numerous in our data; 3) the couples RR are dominant for all the teachers, a result converging with research on evaluative practices quoted in our literature review; 4) the distribution of interactive regulations, for a given type of information (R, P or C) is higher along the diagonal, i.e. pairs RR are more frequent than RP or RC; pairs PP are more frequent than PR or PC. This suggests that teachers generally produce feedbacks on the same level as the students' answers. They rarely turn a R-answer onto a procedure level; or help a student, who is indicating a procedure, to formulate the underlying knowledge C. Therefore, are these specific cases of *regulation* (when the teacher's feedback and received information are not on the same level) fostering the students' learning? And are the ascending ones (RP, RC, PC) more supportive for learning?

In conclusion, the joint perspective taken here led us to a tool to analyze the mechanisms of formative regulation in classroom interactions. If the tool appears fruitful here, could it be applied more largely to other forms of formative assessment in mathematics education? Indeed, "formative" evaluation requires means from the teacher to collect information on the students' learning. Identifying results, procedures or knowledge in interactions could *a priori* be means of taking into account the specificity of the *savoirs* in the forms of formative assessment set-up by the teacher (questioning, discussions, peer/ self-assessments...). Such considerations lead to reflections about the nature of the beginning networking case here. The connection between didactic fields of research and the assessment one is realized here by elaborating a possible common methodological tool that possibly informs both research fields. This case of networking is rather original, although it is justified in Radford's remark: Using the semiosphere's spatial metaphor, theories  $T_i$  and  $T_j$  can be visualized as being "closer" or "further" depending on their own  $(P_i, M_i, Q_i)$  and  $(P_j, M_j, Q_j)$  structures. The connection  $ck$  of  $T_i$  and  $T_j$  requires the identification of research questions  $Q_{ij}$  (tasks, problems, etc.) that guide the enterprise as well as the building of a new methodology  $M_{ij}$  to answer the research questions under consideration. (Radford, 2014, p. 284).

### Appendix: Excerpt of the a priori analysis of the task

**Possible answers and procedures:** Various categories of correct procedures and answers can be discerned following the knowledge used. **I) Use of the scientific notation:** directly move from this notation to the decimal one:  $a. 3 \times 10^{-2} = 0,03$  (note that the lack of explicit calculation can lead students to reject this procedure by didactic contract effect). **II) Use of the decimal notation in calculation:**  $b. 3 \times 0,01 = 0,03$  **III) Use of the fractional notation:** different procedures according to the fractional form applied to ten powers:  $c. 3 \times \frac{1}{10^2} = 3 \times \frac{1}{100} = \frac{3}{100}$   $d. 3 \times \frac{1}{10 \times 10} = 3 \times \frac{1}{100} = \frac{3}{100}$   $e. 3 \times \frac{1}{10^2} = 3 \times \frac{1}{10 \times 10} = 3 \times \frac{1}{100} = \frac{3}{100}$ . **IV) Mix fractional/ notation:** various procedures depending on the forms applied to ten powers:  $f. 3 \times \frac{1}{10^2} = 3 \times \frac{1}{100} = 3 \times 0,01 = 0,03$   $g. 3 \times \frac{1}{10 \times 10} = 3 \times \frac{1}{100} = 3 \times 0,01 = 0,03$   $h. 3 \times \frac{1}{10^2} = 3 \times \frac{1}{10 \times 10} = 3 \times \frac{1}{100} = 3 \times 0,01 = 0,03$   $i. 3 \times \frac{1}{10^2} = 3 \times \frac{1}{100} = \frac{3}{100} = 0,03$   $j. 3 \times \frac{1}{10 \times 10} = 3 \times \frac{1}{100} = \frac{3}{100} = 0,03$   $k. 3 \times \frac{1}{10^2} = 3 \times \frac{1}{10 \times 10} = 3 \times \frac{1}{100} = \frac{3}{100} = 0,03$ .

**Mathematical knowledge at stake:** The task could be legitimately interpreted in multiple ways. Yet, in the context here (a series of quick calculus), short procedures (and short corrections), mentally easy, might be awaited by the teacher, so  $a$ ,  $b$ ,  $c$ ,  $f$  or  $i$ . There, the passage from 10 powers to decimal or fractional form, do not explicitly rely on the definition of the exponent. This is important to interpret her feedbacks taking into account professional constraints as the time factor.

# Networked theories for a didactical study of communities of mathematics teachers

*Existing research about communities of mathematics teachers mainly draws on sociocultural theories. In complementarity, our project consists in studying more deeply the place of mathematics within communities of teachers. We also define the notion of didactical study of communities of mathematics teachers to focus on a general research project on the place of mathematics in teacher community dynamics. We propose a theoretical model to analyze the problems of the community stemming from the network of several theoretical frameworks and approaches. The theoretical model is particularly based on arguments given by the members of the community and mathematics teaching resources. Two contrasted case studies show the relevance of our focus on mathematics.*

*Keywords: mathematics teaching, teacher communities, problem of a community, argumentation, mathematics teaching resources.*

## Introduction

This paper focuses on communities of mathematics teachers. We are particularly interested in the role of mathematics in community dynamics, its epistemological characteristics, its validation modes and its conditions of teaching. We wonder about the singularity of a community of mathematics teachers: in what way the study of a community of teachers in mathematics education is different from the same study in physics education, in geographic education and so on?

In this contribution, we discuss a general question which is the focus of our research project: “What network of theoretical approaches is needed to determine the singularity of communities of mathematics teachers?” We are in an exploratory stage in which we develop theoretical constructs. In the three last CERME workgroups about networks of theoretical approaches, two authors discussed the issue of communities of mathematics: Palmer (2013) and Castela (2013). Palmer notes that Wenger’s (1998) theory of communities of practice does not focus on mathematics education and/or teaching. Castela (2013) stresses the fact that the activity of communities of teachers and different modes of validation of mathematical knowledge in these communities are determined by the institutional conditions and constraints. For instance, teacher’s communities do not have the same role as the researcher communities in the knowledge validation process. These researchers mainly draw on sociocultural theories in order to understand some phenomena. In complementarity to these research works, we aim to determine the singularity of communities of mathematics teachers. Our research also contributes to the French ReVEA<sup>1</sup> project, which concerns

---

<sup>1</sup> ReVEA is a project funded by the French National Agency for Research [www.anr-revea.fr/](http://www.anr-revea.fr/)

the interactions between teachers (individual and collective aspects of their work) and their resources in four disciplines, including mathematics.

Before presenting the kind of networking needed to study the communities of mathematics teachers, we shall define the way we use some words in the following. Many researchers use *communities of teachers* to talk about the forms of collaboration between teachers (Robutti et al., 2016). In the same line, we use the term *community*, loosely defined and not aligned with particular theoretical ideas. A community of teachers designates several teachers engaged together professionally to achieve a common project related to mathematics teaching. We propose also to characterize “*community dynamics*” as the role of the members and their individual projects, the verbal interactions, and the interactions with the resources for teaching.

## **Communities of mathematics teachers: Networking of theories needed**

### **For a didactical study of communities of mathematics teachers**

Several researchers on the practices of mathematics teachers have already studied the issue of communities of teachers (Graven, 2004; Gueudet, Pepin, Sabra, & Trouche, 2016; Jaworski, 2006; Krainer, 2003).

Some researchers explore the place of collective work in teacher training (Llinares & Krainer, 2006; Jaworski, 2006) and more recently its place in online teacher training (Borba & Llinaras, 2012). Furthermore, relying on the theory of CoP, Jaworski (2006) develops the *communities of inquiry* approach. She stresses that developing critical thinking on teaching practice takes place in long-term processes of collaboration between teachers, trainers and researchers. This approach takes the specifics of mathematical epistemology in teaching and learning practices into account. However, from the standpoint of research, the communities of inquiry approach only allows the study of communities determined by the particular operational process of this approach.

Other researchers in mathematics education characterized different forms of communities but the place of mathematics is not always considered as central in the theories mobilized and developed (for example, see Krainer, 2003).

In order to identify the singularity of communities of mathematics teachers, we define the notion of *didactical study of a community of mathematics teachers* as the study of the conditions and the constraints of learning and sharing knowledge related to mathematics education through the design of resources and interaction between members of this community. Let us specify each element of this definition:

- The conditions and constraints of learning and sharing knowledge are those that allow, encourage, restrict or inhibit learning in the community.
- Knowledge related to mathematics education consists of *subject matter knowledge* and *pedagogical content knowledge* (Ball, Thames, & Phelps, 2008) that affect the condition of mathematics diffusion.
- Resources are anything that is developed and used by teachers (and students) in their interaction with mathematics to teach or learn inside/outside the classroom (Pepin,

Gueudet & Trouche, 2013). This element is preponderant in the study of a community and plays the role of a mediation and communication tool.

- By “interaction between members”, we do not only mean simple verbal, oral or written, exchanges but also sharing resources and experiences through online activities.

The next sections discuss the theories and approaches that help us to take into account each of the elements above.

### **Learning and sharing knowledge in CoP: through problems of the community?**

Wenger (1998) proposes a general theory built in the context of knowledge management to study communities of practice (CoP) defined as apprenticeship communities. He emphasizes that learning takes place during the exchanges between members, especially those exchanges related to their joint (community) problems. The treatment of these problems leads to new knowledge emerging from the participation process.

Wenger’s theory does not give specific tools to consider mathematics, though we rely on this general idea proposed by Wenger of considering the problems of the community. We distinguish between *problems of the community* – identified by the researcher – and *community problems* – identified by the members – even if both can sometimes be the same. In this contribution, according to our focus on mathematics, a *problem of the community* is a phenomena or event that prevents or hinders the achievement of the common project and that is linked with mathematics as a science or as a teaching field.

At this point of our contribution, we hypothesize that the study of the problems of a community permits to determine a part of the community dynamics. We propose to realize it by following up the resources and the argumentation process.

### **Resources for teaching mathematics**

The documental approach of didactics (Gueudet & Trouche, 2012) attempts to frame the process of the design of teaching from the point of view of the teachers’ work. It is a socio-cultural approach that permits us to study the interleaving between the community resources and the teachers resources that are involved (Gueudet et al., 2016). The teacher interacts with resources, selects them, and works on them (adapting, reviewing, reorganizing, etc.) in some processes where *design* and *enacting* are intertwined. The intertwining of new resources and interactions with other actors in the educational system creates new teaching knowledge and carries teachers’ professional development (Gueudet & Trouche, 2012).

In order to achieve common projects, the different individual documental geneses interact (Gueudet et al., 2016). The consideration of resources in the community of teachers should take into account: 1) the gathering, creating and sharing of resources in order to achieve the mathematics teaching goals of the community; 2) the result of this process, the shared resources and shared associated knowledge (what teachers learn together from conceiving, implementing, and discussing resources).

In the documental approach, we use the definition given by (Pepin, Gueudet, & Trouche, 2013): “all the resources which are developed and used by teachers (and pupils) in their interaction

with mathematics in/for teaching and learning, inside and outside the classroom”. The advantage of this definition is that it determines the documentation work in terms of interaction with mathematics. In this perspective, the resources of the community could be considered like a highly structured system, where resources are linked according to the level of teaching, the mathematical topic, the teaching mode, and the evolution of the curricula.

The documentary approach is a framework designed to articulate with some other ones. To answer our question, we need a complementary framework to consider the epistemological characteristic of mathematics.

### **Interaction between members: the place of argumentation**

Taking into account the interaction between the members of a community implies taking the oral or written verbal exchanges into account. We have chosen to identify the arguments given by the members during the exchanges and to interpret them with the help of the resources that were mobilized or designed. We define argument as the reason that one presents to defend a certain point of view (Plantin, 1990). It is always oriented toward the decision that speaker wants to take (Ibid.).

Pedemonte (2007) stresses, in the case of mathematics, what can be considered an argument. She notes that it is necessary to look at the proposition and at the context, which allows us to remove misunderstanding. More specifically, she distinguishes between arguments to convince – based on rationality – and arguments to persuade – for example based on authority.

Plantin (1990) and Pedemonte (2007) considered argumentation in the learning processes. Which kind of transfer could we make in the case of teachers? Some aspects need to be developed and clarified in our future work: typology of arguments, impact on the community dynamics.

### **Emerging model for analyzing a problem of the community: criss-crossing of several theories and approaches**

*Problems of the community* that we consider are linked to mathematics as subject matter knowledge and as pedagogical content knowledge (Ball et al., 2008). We hypothesize that the treatment of these problems is related to: (1) the role of members in the community of teachers; (2) the arguments given by members; and (3) the use of resources that the teachers mobilize or produce to support the process of argumentation. We aim to determine the articulation between these components that could emerge (or not) in the treatment of these problems (members, arguments, resources) and the decision-making. We consider two case studies.

### **Problem of the community treatment: two contrasted case studies of a didactical study of a community**

We developed the model on two contrasting cases to: 1) highlight the importance of considering the problem of the community; 2) extend the validity of the model.

We conducted the first case study at high school level. The community is spontaneous. The mathematical knowledge considered is the notion of “function”. The researcher is outside of the community.

We conducted the second case study at the primary level. The community is intentional. The mathematical knowledge considered are research situations and proof. The researcher is within the community.

In both cases, we present some elements of context, the arguments given by the members of the community and their role in the treatment process of the problem of the community. Finally, we present the interpretation of the arguments exchanged by specifying the determining factors in the decision-making. We provided the details of the analysis in another paper (Georget & Sabra, 2015).

### **First case study: grade 10 textbook project**

Sesamath is a mathematics teachers association founded in 2001. It aims to design and disseminate free and open resources. Interactions between the Sesamath members take place on online platforms and by mailing lists. Sesamath is structured around several project communities. We consider one of these communities: the grade 10 textbook project.

The chosen corpus corresponds to a thread of discussion about the progression of the topic “functions” in the textbook it is intended to design. “Functions” is the main topic to introduce in mathematical analysis at secondary level in France. The curriculum introduces functions for the first time at the grade 10 (15-16 years old), which generates a problem of the community that led to a controversy that we formulate by the following words: “What progression of the topic 'functions' must be adopted?”

Three members of the community are mathematics teachers with more than ten years of experience each. They play a particular role in the discussions: Mr W as a designer and a commentator and reviewer of resources, Ms A as a designer and a reviewer and a commentator of resources, and Mr H as a coordinator for several Sesamath projects and coordinator between Sesamath and other external communities.

This first case study illustrates arguments given to treat a problem of the community: (1) mathematical arguments with a discussion on the mathematical contents (connectivity between some concepts); (2) epistemological arguments about “functions” with a level of abstraction, depersonalization, and decontextualization of associated concepts; (3) didactical arguments coming from a personal experience or by consideration of the topic “functions” in the different level of teaching; and (4) arguments mainly linked to the design of resources.

The interpretation of the arguments during the discussions cannot be made independently of the context of the problem (structuring of the "functions" topic in the textbook). The mathematical argument takes importance in the formulation of the decision. We consider some arguments made by Mr H (argument to persuade) as a strong determinant factor in the decision. Mathematical arguments launched by Mr W and confrontation of his proposal with existing textbooks are also a second determinant factor in the decision. The members formulated the decision in terms of mathematical arguments.

### **Second case study: CoP and situations of research and proof at the primary level**

The second case study is about an experiment of an intentional CoP during three years. We implemented a CoP to develop the practice of situations of research and proof between peers in

some classes at the primary level. It was composed of teachers and the researcher-coordinator of the CoP. We proposed several “mathematical situations” on online resources to the teacher and the design of these resources has been a key point in this CoP.

The data analyzed are about an extract of transcription of a meeting at the end of the second year with three teachers and the researcher-coordinator. One of the teachers, Mr D, does not understand the proof of a mathematical problem. He brings the usability of the resources into question by pointing out that the resources do not take his lack of mathematical knowledge into account.

For Mr D, the introduction of the proposed situations in his practice is rather exceptional. Ms S is voluntary in her implication in the CoP and for practicing these situations with her pupils. Mr H is more experienced than Mr D and Ms S, who have also problems of understanding for several resources, especially Mr D about a certain resource which Ms S understands well. Some exchanges help Mr D to understand the proof of the mathematical problem after which Mr H closes the debate implicitly. Mr D and Ms S do not rekindle it. Following some controversies about the usability of several resources, there is therefore an implicit decision not to modify them.

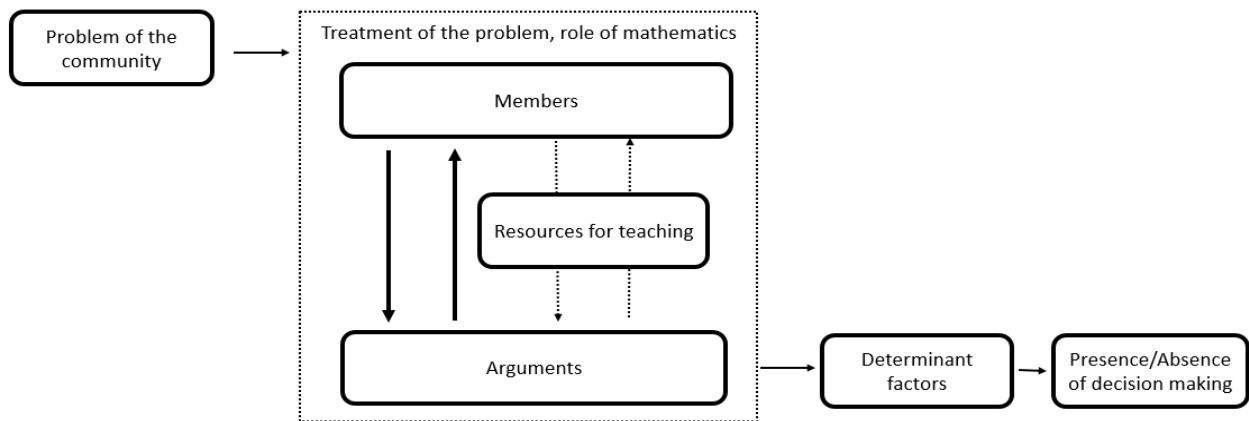

During the interactions, both kinds of arguments are exchanged: (1) resource design arguments about the usability of the teaching resources given by Ms S and Mr D who launch the interactions; and (2) mathematical arguments given by Mr H and the researcher/coordinator that permit the understanding of the proof by Mr D.

At the end of the exchanges, the decision is implicitly validated by mathematical arguments: the proof presented by the resource is valid and understood by the majority of those present at the meeting, so it is not necessary to modify the resource once the explanations have been given.

## **Results and discussions**

In both cases studied, community members use mathematical arguments to validate the final decision. Mathematics appears to have at least two different roles. In the first case, the validation by some mathematical arguments seems to be essential to legitimate the decision-making even if the determining factor concerns the design of teaching resources. In the second case, the decision-making is implicit and validated by mathematical arguments while the common project of the community concerns the design of “pertinent” teaching resources.

Thus, from a methodological point of view, it is relevant to analyze the specific role of mathematics in the exchanges about a problem of a community. From the study of both case studies, a model emerges (see figure 1) as a proposal for understanding the community dynamics. We base this model on three components: (1) The members of the community depending on their role and their implication in the treatment of the problem, (2) the arguments, and (3) the resources for mathematics teaching that support the argumentation. The model gives the opportunity to analyze the problem of all type of communities.

**Figure 1: Model to analyze the role of mathematics (didactical, epistemological, etc.) in the treatment of a problem of the community**

## Conclusion

Existing research about mathematics teacher communities draw mainly on sociocultural theories. In complementarity, our project consists in studying more deeply the role of mathematics within communities of teachers. We propose a model of analysis resulting from articulation of several theories and approaches. We have also defined the notion of *didactical study of communities of mathematics teachers* to clarify the frame of this general research program. We have presented a model based on (1) the identification of a problem of the community, (2) the analysis of this problem in terms of community dynamics, (3) the characterization of the specific role of mathematics among arguments and resources for mathematics teaching. Both contrasted case studies contribute to show the relevance of our proposals. The model of analysis allows us to distinguish two roles of mathematics in the treatment of problems: 1) to explicitly formulate a decision already taken; 2) to implicitly validate a decision that might even be against the goal of the community. However, the model must now be tested on other data and on other kinds of communities. We also aim to test it in the perspective of identifying other roles of mathematics in community dynamics.

# An analytical tool for identifying what works with children with mathematics learning difficulties

Esmeralda Zerafa

University of Malta, Malta; [esmeralda.zerafa@hotmail.com](mailto:esmeralda.zerafa@hotmail.com)

*Keywords: Analytical tool, Vygotsky's perspectives, mathematics learning difficulties.*

As a theoretical framework I chose to use social constructivism on development and learning, mainly Vygotsky's perspectives. As highlighted by Ernest (1998), social constructivist theorists propose that knowledge is constructed through socially situated interactions or conversations. My study is underpinned by social constructivism because in this paradigm:

- The teacher has a fundamental role as the more knowledgeable other in guiding the learner through the learning process;
- Rich social interaction can enhance learning especially through the rich tool of social conversation and other forms of language; and
- Resources and language can be used to facilitate learning and thus to take the learner from the current point of learning to that which s/he has the potential to get to.

In Vygotsky's works the learner's developmental trajectory is often referred to as the Zone of Proximal Development (ZPD), "the distance between the actual development level as determined by independent problem solving and the level of potential development as determined through problem solving under adult guidance, or in collaboration with more capable peers" (1978, p. 86). In this journey, the role of the More Knowledgeable Other (MKO) is thus crucial. Vygotsky frequently makes use of specific terms in his works. In the poster, I intend to provide a brief explanation for each term. Vygotsky's perspective accentuates that a child develops through a transformative collaborative practice which involves cultural tools, cultural influences, and other significant adults (Vianna and Stetsenko, 2006). This process, known as 'cultural mediation' underlies my use of an intervention programme to support learners with MLD. The programme sought to provide the participants with meaningful interactions that would help them to master the ten numeracy components (Catch Up, 2009). Vygotsky (1978) suggests that the analysis of the data collected by himself and his team "accords symbolic activity as a specific organizing function that penetrates the process of tool use and produces fundamentally new forms of behaviour" (p. 24). Therefore, whilst analysing the initial data I looked closely at situations in which the interactions provided would have altered the child's behaviour to such an extent that they now have mastered a specific concept, skill or knowledge vis-à-vis a specific numeracy component being focused on. Dunphy and Dunphy (2003) suggest that there are four stages within the ZPD, the first being that in which performance is assisted by the MKO, hence the choice of a teacher-led intervention programme. Based on Vygotsky's works, Tharp (1993) identifies seven means of supporting the learners to develop within their Zone of Proximal Development. These are: *modelling, feedback, contingency management, instructing, questioning, cognitive structuring "explanations" and task structuring* (Tharp, 1993, p. 271-272). Internalisation might take place through the use of what Vygotsky names as "cultural tools". Vygotsky (1978) distinguishes between technical tools and psychological tools. Technical tools "serve as the conductor of human influence on the object of activity; it is externally oriented" (p. 55). Such tools include the use of a ruler or protractor, for

example. Psychological tools are directed inward and gear the mind and the process of thinking such as language. In my programme I made use of both forms of tools.

### **Poster format chosen**

The study focuses on exploring effective strategies for helping 9 – 10 year old Maltese children struggling with mathematics. Six participants were selected through standardised tests for numeracy and reading. Three children were identified as having only mathematics learning difficulties (MLD) and three having comorbid difficulties in mathematics and reading (MLDRD). In the poster, I present some crucial theoretical perspectives and the process of data collection. Its focus is to present the analytical tool developed to analyse the data collected through the multiple case studies carried out as part of an intervention programme conducted on a one-to-one basis with each of the participants.

### **Possible implications for existing research in the area**

Research about what works with children having MLD is still very limited. Hence the importance of this study and the process of analysing the data gathered from the multiple case studies. Through the data analysed so far some important annotations have been made. These include the observation of two other modes of assistance that had not been mentioned by Tharp (1993). These I decided to label as ‘recapturing’ and ‘role inversion’. Moreover it also seemed evident that interaction between the learner, the MKO and Cultural Tools was fundamental in providing the necessary assistance in guiding the learner within the ZPD to towards the potential zone of development. This means that this interplay was crucial in supporting the internalisation process. Therefore strategies that are effective with learners having MLDRD seem to be those that bring together all these aspects. This is represented in the analytical tool developed, which shows this symbiosis and its facilitation of internalisation.

*Some theoretical models emerged from specific mathematical contents or educational levels, so they are well adapted to the context where they were created but, sometimes, they do not fit well in a different context. Related to the issue of the need to go beyond a specific theory when researching a phenomenon, to solve the tension between home-grown needs and borrowed theories, we present the reasons for and steps of an adaptation we have had to do of the Cognitive Demand model so that it fits the requirements of our research questions, methods and data. We systematized the definition of the model stated by its authors, and completed this definition with some necessary statements. Then, we re-stated some characteristics of the model to avoid inconsistencies when using it. Finally, we particularized the general model to several specific mathematical topics.*

*Keywords: Theoretical framework, adaptation, cognitive demand, mathematical problem solving.*

## Introduction

The choice of a specific theoretical framework is a key decision for researchers when they start working on a new research project. However, sometimes, researchers wish to use a theoretical model in a context that the model does not fit well, and they decide to modify the theoretical model to adapt it to the new requirements. We present our experience of fitting a theoretical model with flexibility so it can be adapted to contexts and used in ways the model had never been used.

We are developing a research project<sup>1</sup> aimed to better understand the cognitive processes of primary and lower secondary mathematically talented students (i.e., students showing mathematical abilities clearly over average students) when solving problems. A characteristic of those students is that they demand problems making them engage in high level of reasoning. A way for teachers to succeed in it is by posing them that kind of problems. Then, we had to find a way to determine the cognitive effort required by problems and done by students when solving them. The *Cognitive Demand model* (Smith & Stein, 1998) fitted our requirements, so we integrated it in our theoretical and methodological research frameworks. However, when we used this model to analyze our data, we found some difficulties in applying it due to ambiguity or inconsistency of results, so we decided to adapt it to our needs. We detail in next pages the steps in the process of adaptation, the reason for each step, and the resulting theoretical model. We present a reconstruction of the main parts of the real recurrent process, which has taken several years and still has not been finished.

The next section presents the characterization of the Cognitive Demand model as stated by its authors. Third to sixth sections present examples of the difficulties we found and the steps we followed to adapt the original model: organizing the original characterization, completing such charac-

---

<sup>1</sup> The results presented are part of the R&D&I research projects EDU2012-37259 (MINECO) and EDU2015-69731-R (MINECO/FEDER), funded by the Spanish Government and the European Fund for Regional Development.

terization with some new statements, re-wording some characteristics of the model to avoid inconsistencies when using it, and particularizing the new general characterization of the model to different specific mathematical topics. Due to space limitations we cannot show the details for all levels of cognitive demand, but only an example of each step for certain levels.

### The starting point: The levels of Cognitive Demand

The Cognitive Demand model resulted after a process of characterization of mathematical tasks according to their “potential to engage students in high-level thinking” (Smith & Stein, 1998, p. 344). It includes four *levels of cognitive demand* that assess the cognitive effort required from students to solve a mathematical task. These levels are labelled (Smith & Stein, 1998) as *memorization*, *procedures without connections* to concepts or meaning, *procedures with connections* to concepts and meaning, and *doing mathematics*, when complex mathematical thinking is required. Each level is defined by a set of characteristics paying attention to different aspects of the solutions of problems. We present in Table 1 the characteristics of two levels that are the ground for the rest of the paper.

---

#### *Procedures without connections*

- 2.1. Are algorithmic. Use of the procedure either is specifically called for or is evident from prior instruction, experience, or placement of the task.
  - 2.2. Require limited cognitive demand for successful completion. Little ambiguity exists about what needs to be done and how to do it.
  - 2.3. Have no connection to the concepts or meaning that underlie the procedure being used.
  - 2.4. Are focused on producing correct answers instead of on developing mathematical understanding.
  - 2.5. Require no explanations or explanations that focus solely on describing the procedure that was used.
- 

#### *Procedures with connections*

- 3.1. Focus students’ attention on the use of procedures for the purpose of developing deeper levels of understanding of mathematical concepts and ideas.
  - 3.2. Suggest explicitly or implicitly pathways to follow that are broad general procedures that have close connections to underlying conceptual ideas as opposed to narrow algorithms that are opaque with respect to underlying concepts.
  - 3.3. Usually are represented in multiple ways, such as visual diagrams, manipulatives, symbols, and problem situations. Making connections among multiple representations helps develop meaning.
  - 3.4. Require some degree of cognitive effort. Although general procedures may be followed, they cannot be followed mindlessly. Students need to engage with conceptual ideas that underlie the procedures to complete the task successfully and that develop understanding.
- 

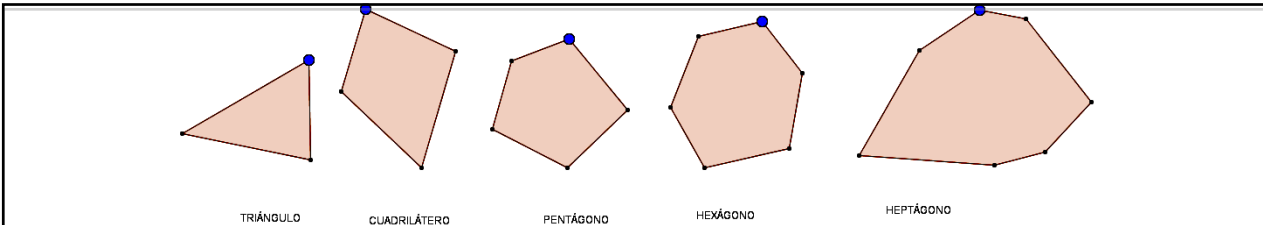

**Table 1: Definition of the levels of cognitive demand of *procedures without connections* and *procedures with connections* (Smith & Stein, 1998, p. 348). Order numbers are added for easy reference**

To attain our research objectives, we created *rich problems* intended to be posed to whole-class groups, consisting of several related questions of increasing complexity, in such a way that all students should be able to solve the first questions but only the more able students could solve all of them. The levels of cognitive demand allow us to classify the questions in a problem and decide whether each question is more appropriate for average students or for talented students.

The Cognitive Demand model was created after the analysis of problems that, most of them, were in the quite algorithmic areas of school arithmetic and algebra (Stein & Smith, 1998; Stein et al., 2009), but we are trying to use the model to analyze problems in mathematical topics very different from the previous ones, as are plane geometry, geometric patterns (pre-algebra) and visualization.

### Identifying inconsistencies between the characteristics of the levels

After using the model to analyze different problems, a difficulty related to lack of consistency between some levels arose. We exemplify it by analyzing a problem consisting of several questions guiding students to discover and prove a formula to provide the number of diagonals of any polygon. The problem has two parts: the first one can be seen in Figure 1; the second part asks students to draw and count all the diagonals of the same polygons and to fill in a table, to calculate the number of diagonals of a 20-sided polygon, to generalize the procedure of calculation of the diagonals to any given polygon, and to prove this relationship. We present our analysis of question 1a (Figure 1) by considering typical average students' solutions that do not go further than what is asked to do.

1a) In each polygon, draw all the diagonals starting from the marked vertex. Change the shape of the polygons by dragging that vertex. Count the number of diagonals. Fill in the table below.

Polygon	N° of sides	N° of diagonals from one vertex
Triangle		
Quadrilateral		
Pentagon		
Hexagon		
Heptagon		

1b) What is the relationship between the number of sides of a polygon and the number of diagonals from one vertex? Why?

**Figure 1: First part of a problem focused to discover the number of diagonals of any polygon**

Regarding the level of *procedures without connections*, question 1a is algorithmic and the statement suggests the procedure to be used, namely to draw the diagonals from a given vertex and count them to fill in the table, so it fits characteristic 2.1 in Table 1. The polygons drawn in the statement guide students to draw the diagonals from a specific vertex, so there is little ambiguity about what they have to do and how to do it (it fits 2.2), and it does not require explanations (it fits 2.5). On the other hand, the procedure to be used has connections with the relationship between the number of sides and diagonals from a vertex of polygons (it does not fit 2.3), although question 1a is focused on producing correct answers, not on developing understanding of that relationship (it fits 2.4).

Regarding the level of *procedures with connections*, question 1a does not fit 3.1, since it is not focused to make students develop understanding of the underlying relationship. However, it fits 3.3,

since, to answer it, students use geometric and numeric representations of information about polygons and diagonals: the numeric representation shows the general relationship between number of sides and diagonals, while the geometric representation may help students understand why it is true. So the question has the potential to let students connect both representations, which would help them develop the meaning for the relationship. Question 1a fits 3.2, since it explicitly suggests a procedure that is closely connected to the underlying concepts, the number of sides and diagonals from a vertex of polygons. Question 1a does not fit 3.4 since its procedure may be followed without need of being mindful, and a correct solution to it does not require understanding the underlying relationship between number of sides and diagonals from a vertex of polygons.

The epistemological conception of the levels of cognitive demand is that they are mutually exclusive. We see that question 1a fits several characteristics of each level *procedures without connections* and *procedures with connections*, so it is unclear to which level of cognitive demand should it be assigned. This happens because some characteristics of these levels, as stated in Table 1, are not precise enough, which can lead to errors when trying to assign a level of cognitive demand to some problems. The most evident vagueness, or contradiction, happens with characteristics 2.1 and 3.2.

### Organizing the characteristics of the levels and filling their gaps

After having identified the difficulty analysed above, we made a detailed comparison of the characteristics of each pair of consecutive levels, to identify possible weaknesses and modify their wording to correct them. We noted that the characteristics of levels (see examples in Table 1) focused on six domains of objectives of a problem or its process of solution. These six domains of characteristics are: *Procedure of solution*, *objective* of the problem, required student's *cognitive effort*, mathematical *contents implicit* in the problem, kind of *explanations* required, and types of *representations* used in the solution. The domains helped us arrange the characteristics of the levels of cognitive demand provided by Smith and Stein (1998) and identify some gaps in the definitions of the levels.

<b>Levels of cogn. demand</b>				
<b>Domains</b>	<b>Memorization</b>	<b>Procedures without connections</b>	<b>Procedures with connections</b>	<b>Doing mathematics</b>
<b>Procedure of solution</b>	1.2	2.1	3.2	4.1, 4.5
<b>Objective</b>	1.1	2.4	3.1	4.2
<b>Cognitive effort</b>	1.3	2.2	3.4	4.3, 4.6
<b>Implicit contents</b>	1.4	2.3	3.4	4.4
<b>Explanations</b>	--	2.5	--	--
<b>Representations</b>	--	--	3.3	--

**Table 2: Domains of the characteristics of the levels of cognitive demand in Smith and Stein (1998)**

Table 2 shows the assignation of the characteristics of the levels to the domains. It also shows that two domains are considered only in the definitions of a level, and that 3.4 includes references to two domains, while several characteristics of the level *doing mathematics* refer to a same domain.

Next step to improve the usability of the original definition of the Cognitive Demand model was to complete the definitions of the levels, by including characteristics referring to the missed domains, taking care that each new characteristic is consistent with the corresponding characteristics of the other levels. Table 3 shows the new characteristics, to be added to those in Table 1 to make a more

complete description of the levels of cognitive demand.

---

*Procedures without connections*

2.6 (representations). One or more representations may be used (arithmetical, geometrical, visual diagrams, manipulatives, etc.). When several representations are used, students use them independently, i.e., without establishing connections neither between them nor with the underlying concepts and ideas.

---

*Procedures with connections*

3.5 (explanations). Require explanations that focus on the underlying relationships by using specific examples.

---

**Table 3: Characteristics added to the levels of *procedures without* and *with connections***

Having completed the definitions of the levels by merging Table 1 and Table 3, we were ready to refine the characteristics that induced wrong or multiple identifications of the cognitive demand in some problems, like the problem analysed above (number of diagonals of polygons).

### Refining the characteristics of each level

A necessary feature of any set of disjoint categories is that their definitions have to make it clear the border between adjacent categories. As we showed above, this is not the case for the levels of cognitive demand. To refine the definitions of the levels, we made a systematic comparison of the characteristics in the same domain and decided to do some changes in their wording to make them more explicit and to clearly raise the particularities of each level.

The key difference between the levels of *procedures without connections* and *procedures with connections* is that, in the lower level, students do not need to be aware of the mathematical relationships implicit in the problem to solve it correctly but, in the higher level, students need to use consciously such relationships to solve correctly the problem. Table 4 shows the result of the comparison between those levels, where we have italicised the new characteristics (see Table 3) and the characteristics in Smith and Stein (1998) that we re-worded. Characteristic 3.4 was split because it included parts corresponding to two domains. The new wording of the characteristics of the levels has highlighted this key difference and now the border between those levels is clear.

If we repeat now the analysis of the problem in Figure 1, question 1a fits new characteristics 2.1, 2.3 and 2.4, because it focus students' attention to draw the diagonals from a vertex of each polygon and count them, so it can be easily solved without being aware of the relationship between the number of sides and diagonals from a vertex.

Domains	Levels of cognitive demand	
	Procedures without connections	Procedures with connections
<b>Procedure of solution</b>	2.1. Are algorithmic. <i>The procedure to be used</i> either is specifically called for or is evident <i>from the context</i> . <i>It is a simple procedure that students can follow without the need to connect to underlying concepts and ideas.</i>	3.2. <i>Are algorithmic</i> . They suggest explicitly or implicitly pathways to follow, that are general procedures <i>that students can follow only if they have established a close connection to underlying concepts and ideas.</i>

<b>Objective</b>	2.4. <i>Focus students' attention on producing correct answers. Students can solve them correctly without the need to understand underlying concepts and ideas.</i>	3.1. <i>Focus students' attention on the use of procedures for the purpose of developing deeper levels of understanding of underlying concepts and ideas.</i>
<b>Cognitive effort</b>	2.2. <i>Require limited cognitive effort for successful completion. Little ambiguity exists about what needs to be done and how to do it.</i>	3.4a. <i>Require some degree of cognitive effort. Although general procedures may be followed, they cannot be followed mindlessly.</i>
<b>Implicit contents</b>	2.3. <i>There may be implicit connection between the algorithms used and underlying concepts or ideas. However, students do not need to be aware of it to solve the problem correctly.</i>	3.4b. <i>Students need to engage with concepts and ideas that underlie the procedures to complete the problem successfully and that develop understanding.</i>
<b>Explanations</b>	2.5. <i>Require explanations that focus solely on describing the procedure that was used.</i>	3.5. <i>Require explanations that focus on the underlying relationships by using specific examples.</i>
<b>Representations</b>	2.6. <i>One or more representations may be used (arithmetical, geometrical, visual diagrams, manipulatives, etc.). When several representations are used, students use them independently, i.e., without establishing connections neither between them nor with the underlying concepts and ideas.</i>	3.3. <i>Usually are represented in multiple ways, (arithmetical, geometrical, visual diagrams, manipulatives, etc.). To solve correctly the problem, students have to establish connections between different representations by using underlying concepts and ideas, which help them develop meaning.</i>

**Table 4: Comparison between the characteristics of problems in two levels of cognitive demand**

Question 1a also fits new characteristics 2.2 (since there is no ambiguity about how to solve it) and 2.6 (students will use geometrical and arithmetical representations but without needing to connect them), but it does not fit characteristic 2.5, since this question does not ask for an explanation (so, this analysis is also useful to uncover flaws in the statements of problems). On the other hand, question 1a does not fit new characteristics 3.1, 3.2, 3.3, 3.4a, 3.4b and 3.5. So, now it is clear that question 1a requires a cognitive demand in the level of algorithms without connections, which agrees with our experimental analysis of real students' answers.

### Particularizing the new cognitive demand model to specific topics

As mentioned above, the Cognitive Demand model was generated after analysing problems that, in most cases, were related to school arithmetic or algebra. When we tried to use it to analyze problems in other areas of mathematics (plane geometry, geometric pattern problems and visualization), we found that the wording of quite characteristics of the levels were too generic and they did not help us to give meaning to the levels specific to those contexts. This forced us to re-word those characteristics of the levels to mention specific features of a given topic. We present here the particularization we have made to the context of geometric pattern problems.

Geometric pattern problems have proved to be a very fruitful way to introduce basic algebra to students (Amit & Neria, 2008; Rivera, 2013). A typical geometric pattern problem presents (Figure 2) a graphical representation of the first terms of a sequence of whole numbers, and asks students to calculate the value of certain terms of the sequence, to verbalize a general procedure to calculate the value of any given term, and to write an algebraic expression to calculate the value of any term.

You can see below a shape made with one dot, another shape made with three dots, and so on.

1. How many dots has the shape in the 4th position?
2. How many dots has the shape in the 6th position?
3. How many dots has the shape in the 20th position? How do you know it?
4. Is there some rule that could allow us calculate the number of dots of any given shape, for instance the one in the 100th position? Justify your answer.
5. Is there some rule that could allow us calculate the number of dots of the shape in the  $n$ th position? Justify your answer.

**Figure 2: A typical statement of a geometric pattern problem**

We are interested in analysing the relationships among the geometric patterns and the cognitive demand required by different kinds of students' answers. When we first used the definitions of the levels of cognitive demand (Tables 1 and 4) to classify answers to geometric pattern problems, we found that some characteristics were meaningless in this context, so we made a complete particularization of the characteristics of the levels to describe the answers to this specific type of problems.

Table 5 presents, as an example, the characteristics of the level of *procedures without connections* for the context of geometric pattern problems. It may be noted that most characteristics include reference to peculiar and unique aspects of those problems.

#### *Procedures without connections* (question 2)

Procedure of solution	• Are algorithmic. The procedure consists in drawing a few terms by following the pattern of the terms in the statement, and counting the items. It can be followed without the need to connect to the arithmetic structure of the sequence.
Objective	• Focus students' attention on producing a correct answer, the number of items in an immediate or near term, but not on developing understanding of the structure of the sequence.
Cognitive effort	• Solving it correctly requires a limited cognitive effort. Little ambiguity exists about what has to be done and how to do it, because the statement clearly shows how to continue the sequence.
Implicit contents	• There is implicit connection between the underlying structure of the sequence and the procedure used. However, students do not need to be aware of it and they may answer the question by drawing terms and counting their items.
Explanations	• Require explanations that focus only on describing the procedure used. It is not necessary to identify the relationship between the answer and the term.
Representations	• A geometric representation is used to get the number of items and an arithmetic

---

tic one to write the result. Students use the representations without establishing connections neither between them nor with the structure of the sequence.

---

**Table 5: Particularization of the Cognitive Demand model to the geometric pattern problems**

This description of the levels of cognitive demand has proved to be very useful to analyze this kind of problems and students' answers to them.

## Conclusions

We have presented a case of modification of a theoretical model to adapt it to the specific requirements of the analysis we had to do of our data. The Cognitive Demand model was a pertinent theoretical framework for our research project, with the potential to ground a deep analysis of our data, although the practice showed that the initial definition of this model, as formulated by its authors, did not fit well the requirements of our analysis. We have shown some difficulties that arose when we tried to apply the initial model. The way to overcome these difficulties was to analyze the theoretical model, to identify and understand the origin of and the reason for the difficulties, and to make adequate changes in the definition of the levels of cognitive demand to make it more accurate and useful. Finally, we had also to particularize the new definition of the levels to the specific context of geometric pattern problems. This general way of proceed may be applied, perhaps after an adequate adaptation, to modify other theoretical models not fitting adequately researchers' needs.

### **Rationale**

The study of mathematics teacher education and professional development has been a central focus of research during the last decades. Various research activities have focused on this topic. Within TWG 18, we focus on mathematics teacher education (pre-service and in-service), professional development and teachers' professional growth, teachers' professional development practices, collaboration and communities of practice, models and programmes of professional development (contents, methods and impacts) and the professional development of teacher educators and academic researchers. TWG 18 offers a communicative, collegial and critical forum for the discussion of these and other related issues, which allows diverse perspectives and theoretical approaches and which contributes to the development of our knowledge and understanding as researchers, educators and practitioners.

### **Participants**

52 papers were originally submitted to TWG18. 22 of them were re-directed to other TWGs. Thus, 30 papers underwent a peer review process in TWG18: during this process, all papers were revised by authors, according to reviewers' remarks. 29 papers were accepted as paper presentations, one was re-submitted for a poster presentation. One of the accepted papers was withdrawn. Finally, 28 papers were presented during the TWG sessions.

Two posters were originally submitted and underwent a peer review process in TWG18: both authors revised their posters, according to the reviewers' remarks; both posters were accepted. Together with the re-submitted poster (see above), finally, 3 posters were presented during the conference poster session.

### **Organisation**

TWG sessions comprised both plenary and sub-group working phases. During the plenary phases, two (or three) papers were presented for a maximum of five minutes each, in which the authors provided their paper's central message(s) and challenging questions for discussion. These plenaries were followed by parallel sub-groups, which were each managed by one of the presenting authors.

Participants were free to choose and join one sub-group, where they discussed the paper for 20-30 minutes. Afterwards, the TWG's participants met in plenary to hear reports of each sub-groups' central topics and to summarise emerging issues.

## Topics

The presentations were categorised into four main topics:

- Noticing Students' Work
- Teacher Instructional Practice
- Impact of Professional Development
- Pre-Service Teachers.

## Open questions and emerging issues

This section provides several questions and issues, which emerged during the sessions of TWG18:

Noticing Students' Work:

- **Open questions:**
  - How do we guide pre-service student teachers to notice particular things such as children's learning?
  - How do the different global country contexts and the constraints of each system locally, make a difference when you apply a learning trajectory?
  - Is there a connection between different teachers' views, what they see and their beliefs, based on noticing?
- **Emerging issues:**
  - Use of the language of the teacher educators in talking about errors e.g., concept image.
  - Different points of views about errors in different teacher education programmes and how we use/ understand errors in our teacher education programmes. Also differences in practices of 'noticing'.
  - Importance of context of the countries and coming to understand these to understand the organisation of the different teacher education programmes.

Teacher Instructional Practice:

- **Open questions:**
  - How to motivate teachers to document more of their work?
  - How do we change teachers feeling judged when getting feedback?
  - How do we understand the different notions of inquiry? What are the effective strategies to implement this approach in mathematics lessons?
  - How do we get to the mathematics? What mathematical knowledge do teachers need for inquiry approaches in mathematics lessons?
  - When we do our research, we use different tools such as philosophical perspectives and analytical frameworks. Is it the different tools that lead to different results? Is it the analytical framework that produces the results? What do we learn as teacher educators? Is that dependent on the frameworks used? Does working with multiple perspectives help us?

- **Emerging issues:**
  - Ethical and practical issues of using children to make interventions in the professional development of teachers e.g. use of video.
  - There might need to be different kinds of innovation dependent on the teachers.
  - Publishing negative cases as well as positive ones.

#### Impact of Professional Development:

- **Open questions:**
  - How could we ask questions to measure impact (e.g. changing of beliefs)? Are there other ways to what we do now?
  - What impact do ‘we’ want to sustain? Static image of change or dynamic change of teachers?
  - In discussing professional development, how do you track development/ learning, through the discourse, through anecdotes and, or?
- **Emerging issues:**
  - Comparing behaviour of teachers in lessons and in PD raises lots of ideas to consider, such as the perceived gap between what teachers do in classrooms and how they articulate their practice in PD.
  - The challenge is how to sustain the impact of professional development beyond its delivery.
  - There are differences in language and discourses between teachers, teacher educators and politicians. There is the need to define what is a good argument in the different contexts.
  - Describing frameworks when they are not familiar.

#### Pre-Service Teachers:

- **Open questions:**
  - Of the language use, such as theory, used in professional discussions at the university, what do pre-service teachers learn? Are they just naming names rather than gaining a deeper understanding of pedagogical concepts?
  - Can we measure the process of pre-service teachers’ development and conclude something from it? Do we want to measure these kinds of dimensions?
  - What does it take for one to become explorative both in learning and in teaching?
- **Emerging issues:**
  - Using videos and not having access to videos in the language of the teachers e.g. any non-English language. Resource implication for creating a local bank of videos.
  - The relationship between the mathematics that a teacher has to teach and the mathematics learned by pre-service teachers in education courses offered by the teacher educator focused on conceptual development.

- Finding ways to disrupt previous experiences of teaching and learning mathematics that pre-service teachers bring with them.

Moreover, some further general questions and issues concerning mathematics teacher education and professional development were discussed during the TWG sessions:

- **Open questions:**
  - Can we observe the development of teachers in their pupils' learning?
  - Does research in mathematics teacher education support the work in schools? Are we critical about our own practices?
  - How do we recruit participants for professional teacher development? How do we promote PD effectively? Use of social media?
- **Emerging issues:**
  - Complexity of appropriation of frameworks, the language across cultures does not always transfer.
  - Writing scientific and professional journal papers with teachers that address teachers' communities.
  - There is work to be done to create dynamical relationships between theories.
  - In researching with teachers, we attend to different things, such as the teacher might be focusing on the learning of the children and the teacher educator the development of the teacher, and we need to find ways to understand each other.

# Upper secondary teachers' *stages of concern* related to curricular innovations before and after a professional development course on teaching probability and statistics including the use of digital tools

Rolf Biehler and Ralf Nieszporek

Paderborn University, Germany; [biehler@math.upb.de](mailto:biehler@math.upb.de), [ralf.nieszporek@math.upb.de](mailto:ralf.nieszporek@math.upb.de)

*In 2013 the German Centre for Mathematics Teachers Education (DZLM) developed a professional development course called “stochastics compact”. This course was held three times during the period from 2013 to 2015 and reached more than 270 teachers. One of their goals was to increase the upper secondary teachers’ competence of teaching probability and statistics in combination with the use of graphic calculators (GC). A part of the research was to examine the stages of concern (SoC) linked to the implementation. Questionnaires were used as a survey method. In this paper, we present two selected and preliminary findings. At first we point out the development of SoC from 2013 to 2015. After that we will present the changes of SoC while participating in the course of 2015.*

*Keywords: Professional development, stages of concern, probability and statistic, graphic calculator.*

## Context of the professional development course

Our research is related to a four-day long (spread over several months) professional development course on teaching probability and statistics at upper secondary schools (grade 10-12) in the German federal state of North Rhine-Westphalia (NRW) from 2013 to 2015. About 270 teachers participated in this course. Due to new national standards (KMK, 2012) and subsequent new state curricula in NRW, probability and statistics became an obligatory part of the curriculum and the final examination (Abitur). Moreover, the use of graphic calculators became obligatory in the classroom and in the examinations. This was a challenge for many teachers and caused a high need for professional development. The German Center for Mathematics Teacher Education (DZLM) recognized this need and gathered a team of experienced school teachers and researchers to originate a professional development course called “stochastics compact” (Biehler, 2016). The design of this course was based on results from stochastics education (Biehler, Ben-Zvi, Bakker, & Makar, 2013; Burrill & Biehler, 2011; Oesterhaus & Biehler, 2014), their interpretation of the standards and the design principles of the DZLM (Barzel & Selter, 2015). The first implementation was done in 2013 and was followed by the second in 2014 and a third one in 2015. Accompanying research addressed the change of competences and beliefs of the participating teachers as well as teachers’ feedback to the courses they attended. Moreover we were interested in the teachers’ stages of concern related to the innovation. The main purpose of this article is to present results of the stages of concern questionnaire (SoC), which may be a relevant instrument for doing research on professional development courses and on teachers’ attitudes to innovations.

## Theoretical framework and related research on the Stages of Concern

The research of interests and concerns of teachers described in this article is based on the Concern-Based Adoption Model (CBAM). This model was developed by the Research and Development

Center for Teacher Education at the University of Texas in the early 1970s (Hall, Wallace, & Dosset, 1973). This model is partly based on Fuller's work on concerns of teachers (Fuller, 1969). One of the three diagnostic dimensions of CBAM is the Stages of Concern Model.<sup>1</sup> It is a framework which helps to understand the personal aspects of adopting an innovation and the connected change progress. The researchers of the University of Texas identified seven stages (see Table 1) which a person runs through while implementing an innovation. There are several techniques to monitor the SoC such as one-legged interviews, open-end concerns statements or the SoC questionnaires. For several reasons the most rigorous method for measuring SoC is the questionnaire (Hall & Hord, 2006). The team around Hall developed a SoC specific questionnaire with 35 questions, 5 per stage (Hall, George, & Rutherford, 1977). As Hall points out, changing anything besides the word "innovation"<sup>2</sup> will risk the reliability and validity of the items (see Schaafsma and Athanasou (1994) as a negative example).

Stages of Concern		Label	Typical items
Self	0	Unconcerned	I am more concerned about another innovation.
	I	Informational	I would like to know how this innovation is better than what we have now.
	II	Personal	I would like to know the effect of the innovation on my professional status.
Task	III	Management	I am concerned about time spent working with non-academic problems related to this innovation.
Impact	IV	Consequence	I am concerned about how the innovation affects students.
	V	Collaboration	I would like to develop working relationships with both our faculty and outside faculty using this innovation.
	VI	Refocusing	I now know of some other approaches that might work better.

**Table 1: Typical items of the different Stages of Concern, based on George et al. (2008)**

The course "stochastics compact" took place in Germany, so there was a need for a German translation of the English SoC Questionnaire. We used the translation that was used by Pant, Vock, Pöhlmann, and Köller (2008a)<sup>3</sup>. There are three international studies and three German studies which we compared our data to and whose results we will shortly summarize.

One of the first studies of SoC was executed by Hall et al. (1977). Hall's team identified several profiles and their characteristic graphical shape. These profiles were the basis for other SoC

<sup>1</sup> The development process of the SoC-Model is in greater detail described in George, Hall, Stiegelbauer, and Litke (2008).

<sup>2</sup> The innovation can be replaced by the name of the innovation or other phrases which respondents are more familiar with.

<sup>3</sup> We are grateful to Doreen Prasse for providing a copy of the German version of the questionnaire.

research like Liu and Huang (2005), who examined American teachers and their problems related to the integration of technology. They found out that the greatest concerns depend on the teachers' experience. Inexperienced teachers tend to have personal and informational concerns, while experienced teachers were mainly concerned about the consequences for their students, and renewing<sup>4</sup> educators placed their focus on collaboration and refocusing concerns. A second finding was that the strongest concerns were in the early stages of personal, informational and refocusing concerns. The three SoC profiles that were re-identified by Liu and Huang were first constructed by Hall et al. (1977). A second survey regarding concerns of 659 American pre K-12 teachers about the use of technology like computers in school was conducted by Casey and Rakes (2002). Peaks in the SoC profiles were found in informational, personal and collaboration concerns. The interpretation was that school teachers are still uncomfortable and in an initial stage of understanding the benefits of technology in school. Pant, Vock, Pöhlmann, and Köller (2008b) came to the conclusion that most German elementary and middle school teachers of their study have high self and impact concerns regarding the recently implemented national standards, thus they show a typical M-shaped profile (see Figure 1) of a *cooperator*. This profile was also found by other researchers like Bitan-Friedlander, Dreyfus, and Milgrom (2004) or Pöhlmann, Pant, Frenzel, Roppelt, and Köller (2014). Bitan-Friedlander et al. were able to identify five types of primary school science teachers which were confronted with the implementation of an innovation. Another result was that most of the participants were able to “adopt”<sup>5</sup> the innovation and developed a personal perception. Pöhlmann et al. (2014) chose a control group design to measure the efficiency of a new developed intervention to help teachers who are dealing with the new German national standards for the first time. The SoC Questionnaire shows that control and test groups were on a comparable level at the beginning and the participants show a high level of self-concerns. Impact concerns were secondary in both groups. After a year of training an increase in impact concerns as opposed to self-concerns was observed. This can be interpreted as consequences for teachers, for pupils, and for their mutual cooperation, which resulted in different foci. The control group also showed a different SoC profile, similar to one of an earlier test. There were no peaks recognizable, which might be due to a feeling of exaggerated demands.

## Research question

We will address the following research questions in this paper:

1. How does the SoC differ when a PD course is backed up by an official obligatory innovation and not only by an innovation suggested by the PD course designers?
2. How are the SoC towards probability and statistics (including the use of the GC) change distributed before and after a professional development course on the topic?
3. Does a professional development course change the stages of concerns of the participants?

---

<sup>4</sup> Liu and Huang defined renewing teachers as persons who understand the innovation and are adopting or thinking about different kinds of use of the innovation based on their experience.

<sup>5</sup> For primary school teachers the meaning of adoption needed to be redefined, because they did not challenge the theoretical knowledge or ground or mentioned a personal opinion about the implementation of the innovation.

Those questions are just one facet of a wider research project. We used our access to the participants not only to determine their SoC levels but also to identify other important aspects which we plan to associate with the SoC-profiles in our future research.

From a methodological point of view we were interested how well the SoC scales can be used to identify important characteristics and sub-groups of teachers, which are important to take into account, when designing and evaluating PD courses.

## **Design of the intervention**

There was a fundamental difference between the 2013 course and the 2014 and 2015 course. The 2013 course was run before the new curricula became obligatory and the GC was prescribed. The 2013 focused in day 3 and 4 on an approach to the teaching of hypothesis testing that was innovative for most German teachers, focusing on p-value hypothesis testing as a start, using authentic examples from real statistical studies instead of artificial problems, and discussing possible misinterpretations of hypothesis testing that are well known from studies in school and in statistical practice. We called our approach Best@Kontext (Oesterhaus & Biehler, 2014). The 2014 and 2015 courses (after the new state curricula) build on this approach but included more systematically the use of GC for interactive visualizations, simulations and calculations not only on day 3 and 4, where hypothesis testing remained the focus. Day 1 and day 2 was completely revised and restructured using simulation and the GC technology.

The SoC in 2013 was related to day 3 and 4 of our course and “our own” innovation Best@Kontext, the SoC in 2014/2015 was related to the whole course and to the state innovation “Teaching Probability and statistics with graphic calculators”. We communicated to the teachers that our course is compatible with the new state innovations, but that our specific foci are based on research in probability and statistics education related to student difficulties, valuable teaching approaches but also on normative aspects concerning the fundamental ideas in probability and statistics that should structure the course.

## **Data collection and data analysis**

In our study we collected 38 questionnaires in 2013 (post test), 55 in 2014 (post test) and 74 in 2015 (pre and post test) which were accepted for evaluation. The others had incomplete SoC Questionnaires or were not traceable in the pre and post test design of 2015.

We used the manual of Hall et al. (1977) as a guideline for the program SPSS 23 for analyzing our data. Therefore our statistical analysis is comparable to the above mentioned studies. For the determination of SoC subgroups, we used a cluster analysis of the individual subscale means. The ward method was chosen with the squared Euclidean distance as measure in every step of our analysis to divide the participants as recommended by Bortz and Schuster (2010). The clusters were created with the data of all four measurements so that we are able to analyze shifts in the distribution of participants into the identified clusters

## **Results**

The reliability of the SoC subscales (see Table 2) can be compared to other studies like Pant et al. (2008b) or George et al. (2008).

Subscale	0	I	II	III	IV	V	VI
	Unconcerned	Informational	Personal	Management	Consequence	Collaboration	Refocusing
Cronbach's $\alpha$	0.717	0.560	0.729	0.727	0.782	0.836	0,765

**Table 2: Cronbach's  $\alpha$  of the seven SoC subscales in our sample**

To answer research question 1, we constructed average SoC-profiles for the three years (including pre- and post test in 2015). Figure 1 shows that the subscale means of the 2013 questionnaire are considerably different to all other years. This observation is supported by *t*-test for every combination of subscales except for stage III of 2014 ( $p=.057$ ) and 2015's post test stage 0 ( $p=.176$ ). The graph shape of 2013 belongs to an *interested nonuser* (George et al., 2008).

The differences of stages I, II and IV in 2014 compared to the pre test 2015 and stage 0 of the post test 2015 are above the significance threshold of  $p=.05$ . In the comparison between the pre and post test of 2015 stages 0 and IV are the only stages without a significant difference ( $p>0.35$ ). Therefore it is unsurprising that those three measurements' graph shapes only deviate slightly and can be interpreted as *cooperators* (Bitan-Friedlander et al., 2004). Attendants of those three years have got a split attention focus in self (peak at stage I informational) and impact concerns (peak at stage IV collaboration) regarding the implementation of statistics and the GC at school and show an M-shaped profile.

This very clear difference can be related to different kind of innovations (related to our project in 2013 – state based innovations in 2014/2015). We have to be aware that below the average there is a lot of variability in the individual SoCs. We will discuss this below.

**Figure 1: Subscale means divided by measurement**

With regard to research question 2 and 3 we do not see a substantial difference between 2014 and 2015 (although one might have expected this because the teachers had been aware of the state innovations for one more year. On the level of the average profile we see a systematic difference, which however is not statistically significant.

Related to research questions 2 and 3 we did a cluster analysis to identify different types of participants and how often they occur in the various points of measurement. We decided to put all data ( $n = 167$ ) together for identifying clusters. This is useful, when the distribution into the clusters is to be compared for the different measurement points. At first six clusters were identified by our

cluster method and upon closer inspection of these groups, two times we found two clusters that were identical in their graph shape and were shifted by one scale point. So we decided to combine those two similar clusters into a bigger group. Finally, we worked with four clusters, which had been identified in a very similar way before in other studies (George et al., 2008; Pant et al., 2008b). These clusters can be labeled as *unconcerned innovation user* (n=4), *typical nonusers* (n=29), *information seeking cooperator* (n=59) and *self-orientated cooperator* (n=93) after their characteristic graph shapes (see Figure 2).

**Figure 2: Subscale means profile by cluster**

**Figure 3: Distribution of persons of one measurement into clusters in percent.**

It is noteworthy that all four people belonging to the *unconcerned innovation user* cluster were found in 2013, see Figure 3. Also the majority of the *typical nonuser* group attended the course in 2013. As mentioned before, the 2013 year differed from the other years. This impression continues for the distribution of persons into clusters. The differences to the others measurements are below the significance threshold ( $p < 0.001$ ). Participants in 2014 and 2015 are often assigned to one of the two *cooperator* clusters. The 2014 distribution shows an insignificant difference ( $p = 0.444$ ) to both tests from 2015. The pre and post test from 2015 show a slight deviation of the cluster distribution ( $p = 0.057$ ). In 2015 there is a migration of 14 persons into different clusters. 71.42% of those ( $n = 10$ ) shift from the *information seeking cooperator* cluster to the higher *self-orientated cooperator*

cluster. Another person switched from *typical nonuser* to *information seeking cooperator*. Only three swapped to a “lower” cluster.

## Discussion and remarks

According to the study we can distinguish two main groups in the 2014 and 2015 course, the *information seeking cooperator* and the *self-orientated cooperator*. One of the “effects” of the course is the shift from the first to the second. We have to study in more detail in which respect these two groups differ and what factors influence to which cluster teachers belong. The design of the course can take this into account by addressing specific course elements to the two different groups. As mentioned before, our further goal is to combine the SoC profiles with other parts of our study. Doing so will allow us to validate our results, gain new insights and recognize a correlation between to aspects. In 2016/2017 we are implementing a fourth course. We also intend to expand our study by adding questions to the level of use (Hall, Loucks, Rutherford, & Newlove, 1975), interviewing participants and conducting another surveys six months after the course’s end in order to measure the long term effects.

## Acknowledgements

We are grateful to Janina Oesterhaus (Janina Niemann since 2014) for starting the research on SoC in 2013 and 2014 and for doing preliminary analyses of the 2013 SoC data. We are also grateful to Ruben Loest for supporting the SoC data collection in 2015.

# Characteristics of pre-service primary teachers' noticing of students' thinking related to fraction concept sub-constructs

Àngela Buform<sup>1</sup>, Ceneida Fernández<sup>1</sup>, Salvador Llinares<sup>1</sup> and Gloria Sánchez-Matamoros<sup>2</sup>

<sup>1</sup>Universidad de Alicante, España; [angela.buform@ua.es](mailto:angela.buform@ua.es); [ceneida.fernandez@ua.es](mailto:ceneida.fernandez@ua.es); [sllinares@ua.es](mailto:sllinares@ua.es)

<sup>2</sup>Universidad de Sevilla, España; [gsanchezmatamoros@us.es](mailto:gsanchezmatamoros@us.es)

*The aim of this research is to characterise how pre-service primary teachers notice students' reasoning related to the fraction concept sub-constructs: part-whole, measure, quotient, ratio, operator and reasoning up and down. 82 pre-service teachers analysed primary school students' answers to five fraction problems. Each student's answer shows different characteristics of students' reasoning in each sub-construct of the fraction concept. Five profiles of pre-service primary teachers have been identified according to how they used the mathematical elements to recognise students' reasoning.*

*Keywords: Fraction, students' reasoning, noticing.*

## Introduction and theoretical background

The study reported here is part of a larger study focused on how pre-service primary school teachers notice characteristics of students' proportional reasoning (Buform, & Fernández, 2014). Several studies have indicated that the development of primary school students' fraction concept is important in order to develop relational thinking and proportional reasoning (Empson, & Levi, 2011; Lamon, 2007; Naik, & Subramaniam, 2008). However, the fraction concept is complex since it consists of multiple sub-constructs: part-whole, measure, quotient, ratio and operator (Behr, Harel, Post, & Lesh, 1992). In this paper, we are going to focus on how pre-service primary teachers notice students' reasoning related to the fraction concept sub-constructs. We also include the sub-construct *reasoning up and down* since it is an important component to develop proportional reasoning (Lamon, 2007; Pitta-Pantazi & Christou, 2011).

## The skill of noticing students' mathematical reasoning

Recent research has shown that being able to identify relevant aspects of teaching and learning situations and interpret them to take instructional decisions (Mason, 2002) is an important teaching skill (professional noticing). Focusing on the skill of noticing students' mathematical thinking, Jacobs, Lamb and Philipp (2010) characterise this teaching competence as three interrelated skills: (1) attending to students' strategies that implies identifying important mathematical details in students' strategies; (2) interpreting students' mathematical reasoning taking into account the mathematical details previously identified; and (3) deciding how to respond on the basis of students' reasoning.

Studies, in this line of research, have indicated that identifying the relevant mathematical elements of the problem plays an important role to recognise characteristics of students' mathematical reasoning and also to take instructional decisions (Bartell, Webel, Bowen, & Dyson, 2013; Callejo, & Zapatera, 2016; Sánchez-Matamoros, Fernández, & Llinares, 2015). In the last years, researchers

have focused on different mathematical domains such as the derivative concept (Sánchez-Matamoros et al., 2015), classification of quadrilaterals (Llinares, Fernández, & Sánchez-Matamoros, 2016), algebra (Magiera, van den Kieboom, & Moyer, 2013) and ratio and proportion (Son, 2013) showing that the development of the noticing skill is not easy for pre-service teachers during teacher education programs.

Our study is embedded in this line of research and focuses on analysing how pre-service teachers interpret students' reasoning related to the fraction concept and how they use their interpretation of students' reasoning to propose new activities to help students progress in their reasoning.

### **Sub-constructs of the fraction concept**

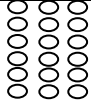

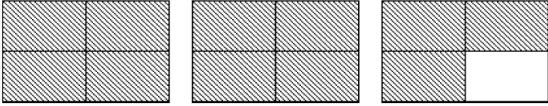

In our study, we consider the following sub-constructs of the fraction concept:

- Part-whole: it is defined as a situation in which a continuous quantity or a set of discrete objects is partitioned into parts of equal size (Lamon, 2005).
- Measure: it can be considered as a number which expresses the quantitative character of fractions, its size; or the measure assigned to some interval (Behr, Lesh, Post, & Silver, 1983; Pitta-Pantazi & Christou, 2011).
- Quotient: it can be seen as a result of a division situation (Pitta-Pantazi & Christou, 2011) and interprets a rational number as an indicated quotient (it is exemplified by sharing contexts).
- Operator: it is seen as a function applied to a number, an object or a set (Behr et al., 1992).
- Reasoning up and down: it is a particular case of the part-whole sub-construct where the unit in a task is implicitly defined (Lamon, 2005) and students need to reason up from a rational number to the unit and then back down from the unit to another rational number.

### **Participants and the task**

The participants in this study were 82 pre-service primary teachers (PTs) during their third year in an initial teacher education program at the University of Alicante (Spain). In previous years, pre-service teachers had attended a subject focused on numerical sense (first year) and a subject focused on geometrical sense (second year). In the third year, they were attending a subject related to the teaching and learning of mathematics in primary school. One of the units of this subject was about teaching and learning of the fraction concept and proportional reasoning. The aim of this unit is focusing pre-service teachers' attention on how primary school students learn the fraction concept including features of students' understanding of the different sub-constructs. Data were collected after this unit.

Pre-service teachers solved a professional task focused on interpreting three primary school students' answers to five primary school problems related to the five sub-constructs of the fraction concept (part-whole, measure, quotient, operator, and reasoning up and down) (Table 1).

Problems	Characteristics
<p>1. How many spots are in <math>\frac{2}{3}</math> of the set? Explain your answer.</p> 	<p><u>Part-whole</u>. Partitioning the set in 3 equal groups and selecting 2.</p>
<p>2. Indicate which number is X in the following number line. Explain your answer.</p> 	<p><u>Measure</u>. Identifying a unit fraction (for instance <math>\frac{1}{10}</math>) and iterating it to find X.</p>
<p>3. Four people are going to share three identical pepperoni pizzas. How much pizza will each person get?</p>	<p><u>Quotient</u>. Result of a division situation in which it is required the division of 3 pizzas between 4 people.</p>
<p>4. The teacher asked Nicolas to make some photocopies. Nicholas made a mistake and pressed the button that reduce the size of each copy by <math>\frac{3}{4}</math>. By how much should Nicholas increase each of the reduced copies to reproduce the original size?</p>	<p><u>Inverse operator</u>. Inverse function has to be applied: <math>\frac{3}{4} \cdot x = 1</math>.</p>
<p>5. The shaded portion of this picture represents <math>3 + \frac{2}{3}</math>. How much do the 4 small rectangles represent?</p> 	<p><u>Reasoning up and down</u>. Reasoning that implies identifying the unit “3 small rectangles” and then, representing a fraction.</p>

**Table 1: Problems related to the five sub-constructs of the fraction concept considered in the task**

Each student's answer shows different characteristics of students' reasoning in each sub-construct of the fraction concept. In Figure 1, the three primary school students' answers to the part-whole problem presented to pre-service teachers are given. To interpret students' answers, pre-service teachers answered the following four questions (Table 2).

Questions	Aim
a) What mathematical concepts must a primary school student know to solve this problem? Explain your answer.	Identifying the learning objective of the primary school problem
b) What are the characteristics of students' mathematical reasoning involved in each student's answer? Explain your answer.	Recognising characteristics of students' mathematical reasoning
c) How would you change the problem to help students progress in their mathematical reasoning if they have had difficulties solving the problem? Explain your answer.	Responding on the basis of students' mathematical reasoning, supporting (question c) or extending (question d).
d) How would you change the problem to help students progress in their mathematical reasoning if they have not had difficulties solving the problem? Explain your answer.	

**Table 2: Questions of the task**

Answer the following question using this picture:

How many spots are in  $\frac{2}{3}$  of the set? Explain your answer.

**Answer 1:**

- Dividimos el todo en tres grupos de 6 canicas cada uno.  
 - De esos tres grupos cogemos 2.  
 - La suma de los puntos de estos dos grupos es 12. (6 puntos  $\times$  2 = 12 puntos)

- We divide the whole in three groups of 6 spots each one.  
 - We have three groups and we choose 2.  
 - The addition of spots of the two groups is 12  
 (6 spots  $\times$  2 = 12 spots)

**Answer 2:**

$\frac{2}{3}$  of 18 spots are 12

$\frac{2}{3}$  de 18 =  $\frac{18 \times 2}{3} = 12$   
 $\frac{2}{3}$  de 18 puntos son 12

**Answer 3:**

dos grupos de 3 bolas

Two groups of 3 spots

Figure 1: Primary students' answers to the part-whole problem

## Analysis

Data of this study are pre-service teachers' answers to the first two questions (a and b) of the professional task (Table 2). Therefore, we focus on how pre-service teachers interpret students' reasoning related to the fraction concept in this paper. The answers to each question were analysed individually by three researchers and agreements and disagreements were discussed. We observed how pre-service teachers identified the mathematical elements involved in each problem and how they used them to recognise characteristics of students' mathematical reasoning.

From this analysis, we have identified six different profiles of pre-service teachers considering how they used the mathematical elements of the problem to recognise students' reasoning (Table 3).

## Results

Results show that 41 out of 82 pre-service teachers had difficulties in recognizing characteristics of students' reasoning (Profiles 0 and 1). However, 19 out of these 41 pre-service teachers identified the mathematical elements involved in each problem. This data suggests that recognising the important mathematical elements of the problem is not enough to recognise characteristics of students' reasoning.

How pre-service teachers identified and used the mathematical elements of the problem to recognise students' reasoning	Number of PT's
Profile 0: They do not identify the mathematical elements and do not recognise characteristics of students' reasoning in any task	22
Profile 1: They identify the mathematical elements related to all sub-constructs of fraction concept but do not recognise characteristics of students' reasoning in any task	19
Profile 2: They identify the mathematical elements and recognise characteristics of students' reasoning related to part-whole, measure, quotient, and operator	8
Profile 3a: They identify the mathematical elements related to all sub-constructs of fraction concept and recognise characteristics of students' reasoning related to part-whole, measure, quotient, operator and reasoning up and down (but not related to the inverse operator)	25
Profile 3b: They identify the mathematical elements related to all sub-constructs of fraction concept and recognise characteristics of students' reasoning related to part-whole, measure, quotient, operator and inverse operator (but not related to reasoning up and down)	5
Profile 4: They identify the mathematical elements related to all sub-constructs of fraction concept and recognise characteristics of students' reasoning related to all sub-constructs of the fraction concept	3

**Table 3: Profiles of pre-service teachers identified**

Pre-service teachers of Profile 0 did not identify the mathematical elements and used general expressions such as “*fractions and operations with fractions*”. Pre-service teachers of Profile 1 were more specific, identifying the mathematical elements implied in all the problems. For example, pre-service teachers of Profile 1 indicated: “*In problem 1, the mathematical element involved is part-whole. In problem 2, the idea of measure or number line. In problem 3, quotient. In problem 4, the idea of operator. In problem 5, part-whole and unit*”. However, pre-service teachers in these both profiles did not recognise characteristics of students' reasoning. These pre-service teachers provided general comments based on the correctness of the answer: “*answer 1 is correct; answer 2 is correct; answer 3 is not correct, the student doesn't understand the concept*”; gave a description of the student answer “*the student 1 divides in 3 groups and choices 2 groups, student 2 makes a multiplication and then a division, and student 3 doesn't understand the problem*”; or interpreted incorrectly students' answers “*the three students solved the problem correctly but using different strategies*”.

Pre-service teachers of profiles 2, 3a, and 3b identified the mathematical elements involved in each problem and recognised evidence of students' reasoning in some sub-constructs. Particularly, pre-service teachers of Profile 2 recognised characteristics of students' reasoning related to the sub-constructs part-whole, measure, quotient and operator. For instance, the next excerpt is a pre-service teacher's answer to the part-whole problem (problem 1): “*Answer 1: the student shows the understanding of the part-whole concept because identifies the whole and re-group the spots in equal groups (dividing the whole in equal parts). Answer 2: the student identifies the total of spots (whole) and selects  $\frac{2}{3}$ . He interprets the fraction as an operator. Answer 3: He doesn't identify the whole and doesn't re-group in equal groups*”; to the measure problem (problem 2): “*Answer 1: he*

*solves the problem correctly because he identifies the unit fraction ( $1/5$ ) in the number line. Answer 2: he solves the problem iterating  $2/5$  and then uses the idea of operator to obtain  $1/2$  of the interval. Answer 3: he doesn't identify the unit fraction and doesn't take into account what means  $2/5$  in the number line"; and to the quotient problem (problem 3): "In answers 1 and 2, the student understands the fraction as a quotient because he divides the pizzas in equal parts. Answer 3: he doesn't understand the meaning of quotient because he divides the pizzas in different parts".*

Pre-service teachers of Profile 3a identified the mathematical elements and recognised characteristics of students' reasoning related to the sub-constructs part-whole, measure, quotient, operator and reasoning up and down (but not related to the inverse operator). The difference with pre-service teachers of Profile 2 is that pre-service teachers of Profile 3a recognised characteristics of students' reasoning related to the reasoning up and down sub-construct: "*In answer 1, the student doesn't identify the unit and the unit fraction. In answer 2, the student identifies the unit but doesn't identify the fraction that represents 4 small rectangles. In answer 3, the student identifies the unit and identifies correctly which fraction represents 4 small rectangles*"; and pre-service teachers of Profile 3b recognised characteristics of students' reasoning related to the inverse operator instead of the reasoning up and down sub-construct "*A1: he uses an additive wrong strategy. A2: he doesn't know how to make the reduction and the enlargement. A3: he knows how to obtain the original paper multiplying by the inverse fraction of  $3/4$* ".

Finally, only 3 pre-service teachers (Profile 4) identified the mathematical elements and recognised characteristics of students' reasoning in all the sub-constructs of the fraction concept.

The different sub-constructs of the fraction concept were used by pre-service teachers to recognise characteristics of students' reasoning in different ways. The way in which pre-service teachers used the sub-constructs operator (and its inverse) and the reasoning up-and-down promoted the emergence of different pre-service teachers' profiles.

## Conclusions

The five pre-service teachers' profiles show characteristics of the way in which pre-service teachers notice students' fractional reasoning. The difference between profile 0 and profile 1 is that pre-service teachers start to identify the mathematical elements of the problems but continue giving general comments based on the correctness of answers. The difference between profile 1 and 2 is that pre-service teachers of profile 2 are able to recognise characteristics of students' reasoning related to part-whole, measure, quotient, and operator sub-constructs. However, these pre-service teachers were not able to recognise characteristic of students' reasoning in problems where the unit was implicit (inverse operator and reasoning up and down). The difference between profile 2 and profile 4 is the fact that pre-service teachers of profile 4 recognise characteristics of students' reasoning in all the sub-constructs. However, there are two possible profiles between the profile 2 and profile 4 characterised by: recognising characteristics of students' reasoning related to the inverse operator (but not related to the reasoning up and down, Profile 3a), and recognising characteristics related to the reasoning up and down sub-construct (but not related to the inverse operator, Profile 3b).

These results provide information about different pre-service teachers' stages in the development of the skill of interpreting students' mathematical reasoning related to some sub-constructs of the

fraction concept. This information provides data to conjecture a pre-service primary teacher's hypothetical learning trajectory of noticing students' mathematical reasoning related to those sub-constructs (Figure 2). This hypothetical learning trajectory could inform us about the pre-service teachers' learning process of the skill of interpreting students' mathematical reasoning in the particular mathematical domain of the fraction concept.

**Figure 2: A pre-service primary teacher's hypothetical learning trajectory of noticing students' mathematical reasoning related to the fraction concept**

*The purpose of this paper is to analyse mathematics teacher knowledge incorporated during one cycle of lesson study. Analysis is undertaken utilising an extended framework which combines both the theoretical frameworks of Mathematical Knowledge for Teaching (Ball et al., 2008) and Levels of Teacher Activity (Margolinas et al., 2005). The proposed framework is situated as a tool to detail and analyse the use of mathematics teacher knowledge in planning, conducting, and reflecting on research lessons in a lesson study cycle in a primary-school case study in Switzerland.*

## Lesson Study and models of knowledge for teaching

Lesson study is a collaborative model of professional development which supports teacher learning (Huang & Shimizu (Eds.), 2016). Originating in Japan, this model has grown in international popularity over the past two decades, particularly in the field of mathematics education, and much research has detailed evidence of mathematics teacher learning through lesson study (e.g. Lewis et al., 2009; Murata et al., 2012; Ni Shuilleabhain, 2016).

Lesson study provides teachers with opportunity to contextualize representations of their classroom activities, while also making their implicit knowledge and practices explicit through their conversations within the group (Fujii, 2016). Each lesson study cycle consists of a number of steps where teachers begin by studying the curriculum and deciding on a research theme, planning a research lesson according to that theme, conducting and observing the live research lesson, and reflecting on student learning within the lesson (see Fig. 1) (Lewis 2016; Lewis et al., 2009)

With increased international educational research on lesson study, there have been calls to deepen the knowledge base of the development of teacher knowledge within this model in order to provide a solid theoretical foundation for its use in teacher education (Clivaz, 2015; Miyakawa & Winsløw, 2009). In this paper, we hope to contribute to the literature on professional development for mathematics teachers by analysing the mathematical knowledge utilized by teachers in their participation in lesson study, utilizing our proposed theoretical framework.

The two authors of this paper, in their analysis of teacher knowledge and learning in lesson study, seek to deliberately build on previous existing frameworks of teacher knowledge: Mathematical Knowledge for Teaching (Ball et al., 2008) and the Levels of Teacher Activity (Margolinas et al., 2005). Through analysis utilizing a combination of these frameworks (Prediger et al., 2008), we will detail features of the mathematical knowledge for teaching utilized by teachers in their participation in lesson study and will also track the movement of this knowledge.

## **MKT/ levels in LS: Towards a coordinated model**

In this paper, we propose a framework which was developed based on data generated in two case study sites - with eight participating primary (grade 3-4) teachers in Switzerland and five lower secondary (middle school, grade 7) teachers in the Republic of Ireland. Analysis began by utilizing the Mathematical Knowledge for Teaching framework (Ball et al. 2008) to investigate the contributions by teachers in a lesson study cycle. However, we found that this model did not fully incorporate all the elements of teacher knowledge included in the lesson study cycle, particularly in capturing the educational values and conceptions of teaching and delineating between the layers of planning sequenced content of instruction, while also attending to students' thinking during the lesson. At this point in the analysis, Margolinas et al.'s (2005) Levels of Teacher Activity was identified as a framework which could encapsulate these elements of teachers' knowledge. Building on qualitative data generated through audio/video recordings of teacher conversations during lesson study meetings, teacher notes from lesson study meetings, researcher field notes, and selected samples of student work from research lessons, we present an extended model of the categorization of knowledge required for the teaching of mathematics. Our first example of analysis presented is from the Swiss case study and future work will present further analysis from the Irish case study data. In analysing and comparing these sets of local data, we attempt to demonstrate a more global sense of this proposed framework of mathematics teacher knowledge in lesson study.

### **Mathematical Knowledge for Teaching**

In their ground-breaking work in 2008, Ball, Thames and Phelps addressed the concepts of content and pedagogical content knowledge in their model of Mathematical Knowledge for Teaching (MKT - see upper part of Figure 1). In this paper, they identified domains of Subject Matter Knowledge (SMK) and Pedagogical Content Knowledge (PCK) used in teaching, which further defined the knowledge and skills required of mathematics teachers in relation to student learning and to mathematics content.

Research on these different categories of MKT has demonstrated direct links between teacher knowledge and high-level teaching practices (Clivaz, 2014; Hill, Ball, & Schilling, 2008) and with subsequent student learning outcomes (Hill, 2010).

Incorporating this model of MKT with teacher learning in lesson study, research has shown that Knowledge of Content and Students and Knowledge of Content and Teaching (features of PCK as defined by Ball et al. (2008)) are important elements of teacher knowledge utilized in lesson study cycles (Leavy, 2015; Ni Shuilleabhain, 2015b; Tepylo & Moss, 2011). However, considering the multitude of teacher knowledge and practices incorporated within each lesson study cycle in planning, conducting, and reflecting on a mathematics lesson, this model may not capture all the decisions, actions, practices, and skills required of mathematics teachers participating in lesson study.

### **Levels of teacher activity and MKT**

To describe teacher activity, both in and outside of the classroom, Margolinas developed a model of the mathematics teacher's milieu based on Brousseau (1997). This model was designed to take into account the complexity of teachers' actions and to capture the broad range of activities contained in teaching and learning (Margolinas et al., 2005, p. 207).

+3	<i>Values and conceptions about learning and teaching</i>
+2	<i>The global didactic project</i>
+1	<i>The local didactic project</i>
0	<i>Didactic action</i>
-1	<i>Observation of pupils' activity</i>

**Table 1: Levels of a teacher's activity (Margolinas et al., 2005, p. 207)**

At every level of environment (or milieu) the teacher must consider all that is occurring at the current level as well as those levels that are directly above and below. These multidimensional tensions relate to a non-linear and non-hierarchical interpretation of teacher's work (Margolinas et al., 2005, p. 208). In addition to commonplace professional opportunities where teachers speak about their beliefs and experiences on general educational concepts or about teaching and learning mathematics (level +3), about teaching and learning of a particular mathematical subject (level +2), or about the lesson they are preparing (level +1), during the phases of planning and reflection in LS teachers also have opportunity to discuss their classroom activities (level 0) or observations of student activity from a lesson (level -1).

This activity model was used by Clivaz (2014) and aligned with the MKT model in order to capture the movement of didactical situations, beyond the possible static characterisation which may be interpreted in the MKT model (Ball et al., 2008, p. 403). The combination of these frameworks allowed teacher knowledge to not only be analysed in terms of mathematical knowledge for teaching, but also mathematical knowledge in teaching (Rowland & Ruthven, 2011). Similarly, Ni Shuilleabhain (2015a) used the MKT model to analyse teacher learning in lesson study, but combined this with the idea of the 'student lens' (as suggested by Fernandez, Cannon, & Chokshi, 2003, p. 180), in proposing an additional layer of the model put forward by Ball et al. (2008). This concept of a 'student lens' incorporated the PCK a teacher utilises in seeing mathematics "through the eyes of their students" (Fernandez et al., 2003, p. 179).

When aligned with Margolinas et al.'s (2005) model, this layer of teacher knowledge relates partly to the -1 'Observation of pupils' activity' which can be anticipated and interpreted, but extends this observation to thinking of the mathematical content from the students' perspective. In our proposed framework, we therefore see this view of the mathematics through the eyes of the student as a layer below the observation of a students' work and include a new level of -2 level relevant to teacher knowledge titled the "student lens" (see Figure 1).

### **Proposed theoretical framework**

Explicitly combining these two approaches to analyse the knowledge utilized by mathematics teachers during lesson study, the authors here present a new theoretical framework (see Figure 1). This framework attempts to capture the knowledge required of mathematics teachers, in the broad and complex range of teaching and learning activities, and represents teacher knowledge and activities incorporated during each phase of a lesson study cycle (see Lewis & Hurd, 2006, p. 4).

**Figure 1: MKT and levels of teacher activity at lesson study phases**

We first utilize the model to categorize the knowledge (MKT and levels of activity) appearing during the lesson study cycle. The knowledge about a particular mathematical topic will then be tracked over each phase of lesson study and the relations between the occurrence of this knowledge examined. At this stage, ‘knowledge’ is considered as collective (e.g. Ni Shuilleabhain, 2016).

## Analysis

In this paper, data generated through video recordings of the Swiss case study are analysed utilising the proposed framework. Eight primary generalist teachers, new to lesson study, and two facilitators (one specialist in teaching and learning and the other a specialist in mathematics didactic (first author of this paper)) participated in the research which occurred over two academic years. Four cycles of lesson study were undertaken in this time, with a meeting held on average every two weeks during the school year (Clivaz, 2016). Each of these 37 meetings (about 90’ each) were videotaped and transcribed and form the base of the analysis utilizing the framework outlined above (Figure 1) and incorporating defined features of KCS and KCT as utilized in lesson study (Ni Shuilleabhain, 2015b).

We present analysis of the first lesson study cycle where teachers chose to focus on the topic of integers and place value. The main reason for choosing this subject was the difficulty students had with whole numbers. In the first session, teachers discussed a particular difficulty their students had with counting through to new groups in base 10:

Océane: The counting through to the next ten.

Caroline: But each time they have to count through to (tens, hundreds, ...)

Stéphane (facilitator): What’s happening with counting through to the next ten?

Caroline: It’s... that we have no more to write here! We have to use the digits which already exist. So, we count through to come back to one... In fact... Yes, it is the abacus, in fact, we need to move by one each time we arrive at a nine at the end. We need to move by one.

Océane: We exchange one packet of ten.

In this passage, during the *study curriculum* phase, teachers are at level of the *global didactic project* (+3) and this unpacking of mathematical knowledge is a Specialised Content Knowledge (SCK) i.e. the mathematical knowledge needed to perform the recurrent tasks of teaching mathematics to students (Ball et al., 2008, p. 399). At this stage, the place aspect of number system was predominant in teachers' discourse and, when the value aspect appeared, it was linked with the value. To further address this knowledge, the facilitators suggested working on students' actual mistakes. Teachers and facilitators proposed mistakes like:

$$5 \text{ hundreds} + 12 \text{ tens} + 3 \text{ units} = 515$$

This work prompted teachers to do the task as if they themselves were students. At some moments during the activity teachers even spoke like students - placing them at the level of *student lens* (-2). This allowed the teachers to go deeper into potential difficulties for students and by further studying curriculum materials (referred to as *kyozai kenkyu* by Takahashi & McDougal, 2016), teachers had opportunity to clarify this aspect for the research lesson. This passage is situated at the same phase, level and type of MKT as the previous excerpt above.

Anne (facilitator): [...] It's a particular type of exchange since it's in the place value system. So, we can distinguish the two dimensions: the dimension of the place and the dimension of the decimal value which is revealed in the exchanges.

Stéphane: In fact, I prefer to talk about grouping/ungrouping instead of exchanging.

Océane: Oh, I see!

Following these two excerpts, we will briefly summarize the work undertaken by these teachers planning the second research lesson and focus on this phase for analysis. The group chose a task in the form of a board game involving the exchange of "1 hundred", "1 ten" and "1 unit" cards. Following a planning exploration of the task, this research lesson was taught by one of the group and, during the post lesson discussion, teachers agreed that the task should be modified to allow students practice the exchange of values and relate these to aspects of the number system. This revised lesson was taught by another member of the group to a different group of students.

At the beginning of the game a student, Julie, arrived on the square "give 35". She had three cards of "1 unit", three cards of "1 ten" and four cards of "1 hundred". In order to get three cards of "1 ten" and two cards of "1 unit", Julie wanted to exchange two "1 hundred" cards. The teacher, Edith, wanted to explain to Julie that two "1 hundred" cards were worth more than these three cards of "1 ten" and two cards of "1 unit".

Edith: So, two hundreds - that's how many?

Julie: Two hundred.

Edith: That's two hundreds. If you tell me: "I want three tens and two units." Three tens, how many is that?

Julie: Thirty.

Edith: You told me three tens makes thirty. And what about two units?

Julie: Two.

Edith: If you put the thirty and the two together? How many is that?

Julie: Thirty-two.

Edith: So you swap two-hundred for thirty-two! You're very generous!

In this passage situated during the *conduct lesson* phase, at level 0 (*didactic action*), the teacher converted all cards into numbers to compare them, instead of doing direct exchanges. Julie followed the teacher without expressing her own way of reasoning (which can be observed in another passage and demonstrates a 'direct exchange' way of thinking). In this case, we categorize the MKT in two ways. First as a KCS, where Edith did not notice or interpret Julie's mathematical thinking or strategies. Second as a SCK, related to the unpacking of mathematical knowledge, as detailed in the following excerpt.

During her dialogue with the class, Edith had to explain that one hundred is the same as ten tens. Here, again, her argument is to convert to units - which requires students to already understand place value. This argument can be summarized as follows:

$$\begin{aligned} 1 \text{ hundred} &= 100 \text{ units} \\ \text{and } 10 \text{ tens} &= 100 \text{ units} \\ \text{therefore, } 1 \text{ hundred} &= 10 \text{ tens} \end{aligned}$$

In the final lesson plan, the group of teachers reflected on this strategy and argued against it:

"Often exchanges are not really carried out and we go through the number. For example, when asked to exchange 12 hundreds into tens, many students (and adults) will go through the number 1200, namely 1200 units, to say that that 1200 is 120 tens, without being able to make a direct exchange from hundred to tens. Teachers also often explain this exchange in this way. In this case, we are in a type of vicious circle, since it means that it is necessary to have understood number system to understand the grouping/ungrouping in the place value system."

This episode appears in our data in the research lesson (*conduct and observe lesson* phase, level 0), in the notes of the observing teachers (*conduct and observe lesson* phase, level 0), in the post lesson discussion (*reflect on lesson* phase, level 0) and, in the above extract, in the lesson plan (*reflect on lesson* phase, level +2) where observations and analysis of the group were generalized and decontextualized from the particular lesson to the level of a global didactic project. In each case the knowledge represents a typical SCK.

The final example of this knowledge was found at the end of the *reflect on the lesson* phase. After discussing the lesson and the mathematical difficulty of directly converting hundreds into tens, Valentine (a teacher with over 30 years of teaching experience) realized she had observed a similar difficulty her own students in this topic, outside of the lesson study group. As a result of their collaborative reflection conversations, she began to realize that her students' errors were likely due to her use of only one strategy in teaching this topic:

Valentine: But, I've got a question. For example, in nine-hundred-sixty-three - how many tens are there? Ninety-six. But my students, they learned a trick - they write the number 963 and just go to the tens digit and write what is left: 96. I'm convinced they just use this trick. I probably didn't know how to explain that to them! Myself... I always convert in money! You will have nine hundred and sixty three one-franc coins. If you need to only have ten-francs notes... then you will have ninety-six ten-francs notes.

Although this observation was not directly related to observations during the research lesson, we still categorize it as level -1 since Valentine put herself in the position of observing her students converting 963 into tens. This conversation incorporates teacher KCS in interpreting students' responses and is situated at level -1 (*observation of pupils' activity*).

Utilising our proposed framework and building on our analysis of teachers' collective conversations, we can detail the types and levels of knowledge incorporated by mathematic teachers in their participation of lesson study. Utilising this framework provides us with opportunity to track the knowledge included in the planning and reflection of mathematics research lesson over various phases of lesson study.

## Conclusion

This paper proposes an extended theoretical framework of mathematics teacher learning in lesson study combining the existing frameworks of Mathematical Knowledge for Teaching (Ball et al., 2008) with Levels of Teacher Activity (Margolinas et al., 2005). In this paper the proposed framework is situated as a tool used to detail and analyse the use and movement of mathematics teacher knowledge in planning, conducting, and reflecting on research lessons. Based on case study data generated through mathematics teachers' participation in lesson study, we have analysed teachers' qualitative conversations and considered the potential evolution of mathematics teacher knowledge over a cycle of lesson study. Analysis to date has demonstrated that in planning and reflecting on research lessons, teacher knowledge of various forms (e.g. SCK and KCS (Ball et al., 2008)) and across varying levels of activity (Margolinas et al., 2005) are incorporated in these separate phases of lesson study.

We hope this model will contribute to the literature on professional development of mathematics teachers and may serve to underpin further evidence of teacher learning in lesson study.

*This paper aims to potentiate the teaching of mathematics through hands-on experimental activities at the primary school level and by promoting teachers' professional development, using innovative practices. A Teacher Design Research cycle involving a group of primary school teachers during one school year was performed. This cycle consists in teacher training sessions, including an introduction to science and mathematics content, hands-on workshops for teachers and also classroom interventions in order to promote experimental activities and observe teachers in action. A particular case study of teacher Luísa will be presented. It was found that she gained motivation and self-confidence to innovate her practices, showing enhanced ability to perform experimental activities with her students.*

*Keywords: Teacher professional development, training practices, hands-on, teacher knowledge, primary school.*

## Introduction

This paper aims to potentiate the teaching of mathematics, through hands-on student-centered experimental activities at the primary school level and by promoting teachers' professional development using innovative practices.

Several studies show the importance of teaching mathematics and science through experimental activities in the early years of schooling to motivate the younger generations to scientific and technological areas, considered crucial for economic development and scientific literacy (Coll, Dahsah, & Faikhamta, 2010; Hallstrom, Hulten & Lovheim, 2014; Osborne, 2009; Perera, 2014).

Treacy and O'Donoghue (2014) also refer to scarce research about the integration of mathematics and science in classroom contexts as well as the lack of a widely-adopted teaching model. These authors advocate that "hands-on, practical, student-centered tasks should form a central element when designing an effective model for the integration of mathematics and science" (p. 1).

This study is part of a first round of a Teacher Design Research programme involving a group of primary school teachers in a cluster of schools of a region of central Portugal, held during the 2015/2016 school year. This experiment was carried out in the framework of a pedagogic intervention project that aims at introducing new methodologies to promote the learning of mathematics and science through hands-on experimentation and using the "inquiry" method.

To achieve this purpose, a lifelong training course was designed, with the collaboration of university researchers and a formation center, to include mathematics and science hands-on workshops, in order to help teachers develop their teaching skills and update their knowledge on these topics.

In this study, a particular case of a teacher, who used one of the proposed science experimental activities, to explore mathematical concepts and student-centered tasks, using the inquiry-based and problem-solving approach, will be presented.

## Literature review

The great lack of professionals in the STEM (Science, Technology, Engineering and Mathematics) areas must be countered with an intervention at the level of the early years of schooling, being crucial to provide quality scientific practices (DeJarnette, 2012; Eshach & Fried, 2005; Johnston, 2005). The incorporation of hands-on experimental activities into the classroom, with scientifically well-prepared adults, lead to significant improvements in performance and produce positive attitudes towards science and learning (Mody, 2015; Myers Spencer & Huss, 2013).

The inquiry approach calls on the natural curiosity of children and develop their creativity and critical questioning at an age when they have the urge to discover the world around them (Alake-Tuenter et al., 2012; Krogh & Morehouse, 2014; Rocard et al., 2007).

Teachers are the cornerstone of any renewal of science education and being part of a network motivates them, contributes to improve the quality of teaching and promotes the sustainability of their professional development (Abell & Lederman, 2007; Rocard et al., 2007; Zehetmeier & Krainer, 2011). Martins (2006) claims to be a priority to strengthen investment in scientific research in the field of science education in the early years of schooling and continuing teacher training. Murphy, Varley and Veale (2012) recommend a professional development for teachers that will allow them to enhance their conceptual and pedagogic knowledge on the inquiry-based approach. Ball (2003) says that an intervention to combat failure in math's performance will only be effective if it is focused on teaching methods: "No curriculum teaches itself and standards do not operate independently of professionals' use of them" (Ball, 2003, p. 1).

Ball, Thames and Phelps (2008) investigated competences that are required to teach and developed an empirical approach to determine the content knowledge needed for teaching (figure 1).

**Figure 1: Mathematical knowledge needed for effective instruction (Ball, Thames, & Phelps, 2008)**

Ball (2003) concludes that to improve children's mathematical learning, it is crucial to provide learning opportunities to teachers such as tailored courses, workshops and well-designed and taught materials. Afonso, Neves and Morais (2005) recommend that teachers should be given the opportunity to explore and experiment the contents to be developed in class in a reflective, collaborative environment where they feel supported. Also, Kuzle and Biehler (2015) sustain the

importance of “stimulate cooperation among the participants, and between the participants and the professional developer” (p. 2849).

## **Methodology**

### **Teacher Design Research**

Teacher Design Research (TDR) (Kelly, Lesh, & Baek, 2014) aims to promote the development of teachers as adaptive experts, using inquiry. This approach involves a collaborative work with research teams and teachers participating in the process, with the main objective to promote their professional development, leading them to innovate their practices and improve the whole teaching and learning process. The TDR premise is that the involvement of teachers in long-term (e.g. one year) design research periods can promote in-depth content learning and improve their ability to adapt to classroom environment and rethink their teaching beliefs and practices.

### **The pilot experiment: First cycle of the TDR**

A pilot experiment with primary school teachers has been conducted in the academic year 2015/2016. This experiment included continuous training sessions where proposals of new content and experimental mathematics and science hands-on activities, to be used in the classroom, have been put forward. The teachers had the opportunity to explore the content and manipulate the materials to be able to apply them later with their students. In addition, the instructors also visited the trainees' own classroom to carry out experimental activities to exemplify them, and observe the teachers in action with their students. The teachers have also been encouraged to develop their autonomy by creating and implementing their own experimental activities.

Focus Group (FG) (Williams & Katz, 2001) was one of the working methodologies used throughout the training sessions to support the teachers and improve their practices. The last session was mainly focused on FG to promote reflection on the practices developed and make proposals for the following cycles of TDR. “Innovations need to be owned by the person implementing them on a personal level and transformed into their own practice in order to have practical effect” (Zehetmeier, Andreitz, Erlacher, & Rauch, 2015, p. 168).

This paper describes the case study of teacher Luísa (fictitious name) who participated in the study, proposed and carried out math-based activities using the inquiry method.

### **Participants**

The participants in the pilot project comprised 14 teachers of 5 primary schools. These teachers participated in a first round of design research beginning in September 2015 and ending in July 2016. In this paper, we will study teacher Luísa who is 56 years old, has 37 years of service and is in charge of a third-year grade class with 25 students aged 8 and 9 years.

### **Data collection**

Data collection consisted in observations (first author of the paper was a participant observer), semi-structured interviews, written records, and video (Cohen, Lawrence, & Keith, 2007). The action took place in two main moments: workshops with the teachers (to learn and practice what they are expected to implement) and at their classrooms (to support and observe them in action). At the end

of the training action, the participant teachers presented a written report, with a critical account on the pilot experiment and their proposals of innovative practices.

## Data analysis and discussion

Teacher Luísa participated in the first TDR round. For about nine months, she attended the continuing training programme that consisted of seven workshops with, 3 to 4-hours duration, which introduced content, hands-on activities and methods of implementation in the classroom.

The first experimental activities carried out on the workshops was about electricity (<http://www.academiacap.ipt.pt/pt/atividades/ciencia/fisica/77/>). Before the intervention, Luísa completed a questionnaire that characterized her and her class. On the questionnaire, she refers that "the experimental aspect was not addressed in my graduation course" and "in the complementary training program (BA-equivalent degree) I attended it was dealt with only too briefly". Although she has attended several training sessions throughout her career, none of them was about electricity.

In the course of the training programme, Luísa was very participatory showing a great interest in the tasks performed. However, on several occasions she stated that: "I'm not comfortable to teach some of the content because I don't have full mastery of concepts and techniques and don't know how to apply them". She also admitted that: "I'm not able to handle some of the materials used in the experimental activities". As early as in the first sessions she posed a series of questions such as: "What if the students ask me a question about this theme and I don't know the answer?" or "And what if an experiment does not yield the expected results?"

In addition to concerns about specialized content knowledge, the teacher also reveals concerns about pedagogical content knowledge. These insecurities have led us to rethink the approach to content and experimental activities, because we realized that it was very important to adapt training to the knowledge and the needs of the teacher, to make her feel secure and motivated to implement the tasks. We also realized that she gives great importance to specialized content knowledge and that she hardly will perform experiments that involve concepts she does not fully understand.

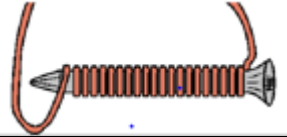

Given the great commitment of teacher Luísa to learn and her pedagogical concerns, she has been selected to receive the trainers in her own classroom to carry out experimental activities with her students, to exemplify the experiments, support the teacher and observe her in action.

During the intervention in the classroom, we have observed that teacher Luísa had a posture of inquiry, making questions to her students to guide them through the tasks, leading them to investigate, in order to find answers to the questions. It was interesting to observe Luísa making a reflection with her students, questioning them about the classroom hands-on activities, what they had learned, and what they would like to explore in the next experiments. Observations and interviews revealed she has a good knowledge of her students and knows how to introduce and adequate the content to each of them, according to their individual needs (KCS and KCT).

Two more sessions with teacher Luísa's students have been held which included tasks not covered by the training course with the other teachers. She again felt insecure and reported that she wouldn't be able to implement it without the support of the instructors. This shows the importance of the training workshops with the teachers before going to their classroom.

It has been suggested to her that she should propose activities involving mathematical content. Due to the difficulty shown by the teacher to achieve this objective, the researchers proposed a worksheet in which, based on experimental records like weigh, fruit diameter, potential difference measurements, it was possible to address the topic “organization and processing of data” that is part of the primary school syllabus. With this proposal, the teacher created some tasks (figures 2, 3 and 4). Figure 2 shows the method used by the teacher to propose mathematical problems, based on the classroom experiment performed by the team of instructors. In writing "electromagnet" she is showing that she knows the content acquired in training but she chooses to present mainly math specific content: problems involving operations, specially multiplication.

When you used the nail in the electromagnet it was wrapped in copper wire. I unwrapped one and measured the wire. It measured 40 cm.		
1. How many meters of wire were needed for the whole class?	2. One meter of wire costs 5 euros. How much was spent to wrap all the nails?	

**Figure 2: Math exercises suggested and implemented by teacher Luísa inspired by the activity performed in the classroom by the instructors**

Based on the same experiment Luísa was invited to suggest tasks for data handling and processing, but she decided to collect data with her students (Figure 3) for further processing (Figure 4).

OCTOBER 2015			APRIL 2016		
NAME	WEIGHT	HEIGHT	NAME	WEIGHT	HEIGHT
Adriana	30,7 Kg	129 cm	Adriana	32,2Kg	133 cm
André	31 Kg	139 cm	André	31,9 Kg	142 cm
António	36,4 Kg	139 cm	António	38,4 Kg	142 cm

**Figure 3: Recording of heights and weights of the students in teacher Luísa's class**

I grew _____kg In <b>October</b> , the <b>tallest</b> in my class was _____ In <b>May</b> , the <b>heaviest</b> in my class was _____ Which student <b>grew the most</b> ? _____ Which student <b>gained more weight</b> between <b>October</b> and <b>May</b> ? _____ <b>Build a chart</b> with the <b>weights</b> of the students in the class ( <b>October-May</b> )	I gained _____kg
--	------------------

**Figure 4: Math activity suggested and implemented by teacher Luísa**

This attitude shows some autonomy on the part of the teacher to propose activities that are not provided for, in the school books. It also shows ability to adapt content to the specific needs of students. On the other hand, this could mean some resistance in using an experiment that was not familiar, preferring to use a context where she felt more comfortable, i.e. collecting data from the students. A possible explanation can be drawn from her report, where she shows lack of SCK:

However, and given the nature of the subject matter addressed and the tools used, I do not feel comfortable to implement, in a natural/individual and consolidated process, many of the tasks proposed. (Teacher Luísa final report)

It also appears that she realized the importance of finding new ways of teaching math as she says in her report that math is part of day-to-day life: “The math activities performed in the class gained a new meaning as it was applied to practical real-life situations of individual students to complete the tasks proposed” (Teacher Luísa final report).

Luísa gained SCK and KCT, showing ability to do research, particularly on the internet, collecting information that she uses to make new approaches on teaching:

(...) finding new ways of teaching math so that people understand that we think mathematically all the time and solve problems at several moments during the day (...) Math is thus part of our life and can be learned in a dynamic, challenging and funny way. (Teacher Luísa final report)

Finally, the teacher recognizes the impact of the project on her students:

The class revealed very motivated when completing the tasks proposed by the instructors. The students adopted a cooperative, experimental attitude in which failure was regarded as a part of the scientific process. (Teacher Luísa final report)

In fact, student’s comments such as “this is the best experience of my life” “this is awesome”, “you should come more often”, among others, had impact on teacher Luísa motivation, contributing to make her recognize the importance of implementing hand-on experiments.

## **Final considerations**

Visits to the classroom to support the teacher during the implementation of the experimental activities revealed very useful to improve teacher knowledge and confidence. Also, the enthusiasm, involvement and participation of the students in the classroom activities (mentioned in the teacher's final report) served to raise her awareness to the importance/relevance of these approaches. Such motivation has been observed in teacher Luísa who gained confidence to innovate her practices after receiving training and guidance. This teacher developed and implemented hands-on experimental activities with her students in classroom context, exploring their curiosity (using inquiry) and proposing problems requiring the use of math.

Although she created mathematics hands-on experiments, there still was, on the part of the teacher, some lack of confidence to innovate without the support of instructors. Like her, almost all teachers who participated in the continuous professional course suggested, during the final FG, that some of the experimental activities should be carried out by the instructors in their classrooms. All teachers were reluctant to propose innovative activities promoting by resorting to the inquiry method. It was noted that strong encouragement and responses on the part of the instructors were required to make the teachers change habitual teaching practices. However, throughout the sessions increased trust of teachers on their instructors and a better response to the tasks proposed has been observed.

It follows therefore that it is necessary to invest more in training and monitoring of teachers to further engage them in these approaches and improve their confidence and autonomy. Special mention should be made to the importance of getting the teachers to work out the activities before implementing them. Finally, it is concluded that this is a process that takes some time to be implemented and further work is needed to achieve the desired results.

*As part of a larger research project, we asked third-year PSTs to reflect on what they had learned about being mathematics teachers of the teacher education programme. The reflections were intended as presentations for first-year PSTs. In this article, we analyse the films by the third-year PSTs to understand the messages more experienced PSTs choose to communicate to novices. Concepts from Gert Biesta are the framework for the content analysis, and we find a complex picture of how qualification, socialization and subjectification interact in the narratives.*

**Keywords:** Preservice teacher education, mathematics education, mentors.

### Introduction

This article presents partial results from a research project examining pre-service teachers' (PSTs) developing identities as mathematics teachers, and, in particular, their experiences of mathematics in school placement. Previously published results from the project report how first-year PSTs value what they learn from mentors in practice more than the 'theoretical' input of the university based courses, not seeing the theoretical knowledge as transferable into teaching practices (Bjerke, Eriksen, Rodal, Smestad, & Solomon, 2013). In one intervention addressing the challenge, third-year PSTs presented to the first-year PSTs films describing experiences of becoming mathematics teachers in the course of the first three years of the programme. In this article, we analyze the third-year PSTs' presentations to understand how they view their own emerging professional identities.

Our research question is: What domains of their educational experiences do PSTs highlight in their presentations of their first three years in mathematics teacher education?

### Research background and theoretical underpinnings

While learning to teach is about acquiring professional knowledge and skills, it is also about developing a teacher identity (Haniford, 2010). Adding to the identity work of experienced teachers, PSTs have the responsibility of successfully positioning themselves in relation to their teacher education programmes and cooperating teachers (Haniford, 2010). Identity formation is driven by the individual's goal state of what he/she wants to become (Smeby, 2007). Biesta (2012) discusses these processes under the headings of qualification, socialisation and subjectification, and we choose his concepts as the starting point of our analyses of PSTs' narratives.

For Biesta (2012), all education (including teacher education) is a question of judgement, because educators' decisions about the purpose of what they do occur within domains that may be in synergy with each other, but may also be in conflict. He notes three such domains, which interact and overlap: the domains of qualification, socialisation and subjectification. Qualification is about knowledge, skills and dispositions; socialisation and subjectification can be seen as opposites: while

socialisation applies to the induction of novices into existing practices, subjectification denotes how education contributes to a process of individuation, of becoming an independent subject. Educational judgements are underpinned by an understanding of the interdependencies between the three domains. In teacher education, the situation is more complex still: the purpose should not just be PSTs own qualification, socialisation and subjectification, but also to enable PSTs to become ‘educationally wise’, aspiring towards virtuosity in making educational judgements themselves. Such judgements are situated: they are made during the practice of teaching, and cannot be set out in advance, or in general - they are rooted in concrete situations and relate to the need to handle tensions and see possible synergies. To become ‘educationally wise’, one needs experience, together with opportunities to see more experienced others in action, and to discuss those actions in terms of the virtuosity of judgement which underpins them.

## Method

The 32 PSTs in this study were enrolled in a four-year programme for primary school teachers (grades 1-7, ages 6-13) in Norway. They had chosen to continue with mathematics beyond the compulsory course spanning the two first years in teacher education, and were asked to look back on their mathematics education course and four school placements and to prepare group presentations describing their development as mathematics teachers in grades 1-7. They were asked to reflect on what they know now which would have been good to know in their first year; how they plan their mathematics teaching now compared to in their first year; what they have learned along the way; and what are the pitfalls and experiences to bear in mind for future mathematics teachers.

Six presentations were made - all short films (F1-F6) incorporating line drawings and sometimes photographs, with voice-over commentary and music. Five of the six films were organised as developmental stories from their novice anticipation and preparation of their first placement, to their reflective stance as third-year PSTs. The remaining film focused on four pitfalls for novice PSTs.

To analyse the data, we operationalised Biesta’s (2012) concepts in terms of: descriptions of their knowledge, skills and dispositions; processes and accounts of making educational judgements and justification of judgement; and accounts of being and becoming a mathematics teacher, as exemplified below:

**Qualification:** References to knowledge, skills and dispositions, processes and practices from the teaching profession.

**Socialisation:** References to learning and to expectations in the school context.

**Subjectification:** References to inner feelings, identity and becoming a teacher and to perception of self (as a teacher).

The presentations were transcribed and analysed in several steps. First, they were coded according to Biesta’s terms *qualification*, *socialisation* and *subjectification*, synergies and conflicts between these domains, and professional judgement. Then disagreements among the researchers were resolved, and all presentations were re-read and coded by another member of the group. A decision was made to organise the analysis in two parts - one around PSTs’ novice anticipation, and one around their reflective stance in third year. Finally, we re-read each presentation to make sure that important longitudinal messages were not lost in our attempt to organise the analysis in two parts.

## Looking back at early experiences in school placement - Emergency sirens

### Qualification

In the films, there are a few examples of what PSTs learned in the first year, for instance pieces of ‘theory’, such as the importance of using multiple representations, giving feedback, and using the “didaktisk relasjonsmodell” (F1) (a hexagon connecting elements relevant for lesson planning: topic, learning objectives, the pupils in that class, etc.). The first-year PSTs are, however, uncertain about how to put the knowledge into practice. The uncertainty about effective use of manipulatives is most usual (F1, F4, F5), but other dilemmas are also identified:

I also thought about all the theory I learned at university: Piaget’s theory of stages of development, Bruner’s representation theory and theory of scaffolding, Vygotsky’s focus on cooperation, Bandura and his theories on motivation and self-efficacy. How should I use these theories to plan a lesson on fractions? [...] Which pupils should work together: the ones that are on the same level in terms of subject knowledge, or should the strong ones help the weak? (F1)

Several of the films show students meeting concepts as an overwhelming mass of words (Figure 1). At the same time, there are many statements about elements of qualification the PSTs perceive as lacking, both in terms of knowledge (“Do I know enough about this topic?” (F5)) and of processes:

Just think if I have to explain several ways of doing something, to support conceptual understanding! It won’t work. It just won’t work. Manipulatives, manipulatives. (F5)

It’s only natural to carry on from where we left off [in the textbook]. It’s not like I have other suggestions on what to do from here onwards. (F2)

Figure 1: Knowledge in overwhelming amounts in the first year (F1, F4, F5)

### Socialisation

The mentor is, naturally, the main role model for students in their first year of teacher education, and the mentor features in most of the (few) examples we find of socialisation when describing the first year. The PSTs are uncertain about what the mentor expects of them, other than using the “didaktisk relasjonsmodell” (mentioned above) which is common in Norway:

As first-year students we used it [the didaktisk relasjonsmodell] slavishly (F6)

...I have to carry on from here [in the textbook], that must be what [the mentor] expects (F2)

The mentor can be viewed as an evaluator:

Shit! This took the entire hour. The mentor glares at me. It didn’t go as planned. (F3)

However, the anxiety of seeing the mentor write “like there was no tomorrow” is followed by “I had so many questions” - suggesting that the mentor is regarded as a person to ask for advice, as well.

### **Subjectification**

A basis for subjectification is the development of a certain degree of self-confidence. In the description of the first year, we see little self-confidence - uncertainty and fear dominates:

What if I don't succeed? (F5)

I went from being one of the best in mathematics to being perplexed when the pupils asked me questions about the subject. (F1)

### **Conflicts and synergies between domains**

The three domains of education overlap. These non-empty intersections are implicitly present in the films. There are clear examples that a perceived lack of qualification (being overwhelmed by new concepts and by making sense of these in practice) leads to a lack of self-confidence - “I felt unsure and very, very small” (F1) - which we regard as part of subjectification. This can also work the other way: lack of confidence leads to lack in qualification:

In the first school placement, I struggled a lot with getting the class to settle down. Later on I came to think it was because I did not feel like a confident and clear classroom manager. (F1)

There can also be a conflict between qualification and subjectification, in the sense that learning more makes you aware of your shortcomings:

The more I learnt, the more I discovered what I didn't know. [...] Based on Piaget's theory I knew most of the pupils were at the concrete-operational stage. But which of Bruner's representations should I use? [...] Or should I use the strange Cuisenaire rods that I still haven't really gotten to grips with? (F1)

Drowned in the curriculum he feels puzzled. What is most important? (F4)

Inside the domain of qualifications there are interactions between elements. In one case, the confidence in mathematics is shaken by the practice of teaching:

I went from being one of the best in mathematics to being perplexed when pupils asked me questions. (F1)

At the same time, during the first year the process of lesson planning is weighed down by the awareness that there are many considerations to be taken. This is visible in form of the time that goes into writing a lesson plan (shown with clocks in the films), and the number of books that fill the desk in the process (Figure 2).

There can be a tension between socialisation and subjectification in meeting the mentor: in one example, the role model (supposed to provide socialisation) is so impressive that the PST's self-confidence suffers:

The meeting with the mentor was scary. I saw him as a Superman who really knew his work. He was confident, clear and, not the least, had strong subject knowledge. (F1)

**Figure 2: Lesson planning during first-year school placements (F1, F4, F6)**

In another example, a PST's attempt at making a choice outside of the textbook is struck down by the mentor:

Hmmm....I think maybe we should stick to the textbook. (F3)

With an emerging sense of agency, the PST questions the mentor's view and asks herself: "Should we always stick to the textbook?" (F3).

To conclude, there are synergies between (a lack of) qualification and (a lack of) subjectification, but also a conflict between qualification and subjectification, as well as between socialization and subjectification.

### **Practicing educational judgement**

Judgement is difficult. A lack of self-confidence leads to a very detailed plan with little room for judgement on-the-fly.

As a first-year PST the plan for the lesson was a long script. We had written down word for word what to say during the lesson. We were dependent on this script and could not improvise along the way. We even planned how to explain simple mathematical things that we actually knew well. This is also about lack of experience and confidence as a teacher. (F6)

At the same time, a lack of qualification translates into constraints on opportunities for judgement in the process of lesson planning:

It's natural to continue from where we left off, it's not like I have other suggestions. (F2)

### **Looking at their recent experiences in school placement - Birdsong**

#### **Qualification**

Changes from first to third year are visible in all aspects of qualification, from subject knowledge and knowledge of students and teaching, to the practices of teaching. In terms of knowledge, some films refer to knowing more mathematics, but, in terms of mathematics pedagogy, the films stress that the understanding is deeper, the knowledge can be operationalised to a greater extent.

The process of lesson planning during the first year involved long hours dedicated to the task (F1, F4, F6), and resulted in long scripts produced for each lesson (F4, F6). The films highlight, in comparison, how much quicker lesson planning goes (F1, F6), and how much shorter the scripts become (F1, F4) by third year, but the films give different suggestions on how to take advantage of the reduced burden, from watching TV and playing with the dog (F6) to investing time and energy on the 'frills' of differentiation and using a variety of teaching methods (F1).

Teaching practices out of reach during the first year are now on the agenda (F1): motivating pupils, providing them with opportunities to feel both confident and challenged, seeing the individuals as well as the class as a whole, giving more room to children's contributions, and encouraging enquiry.

### **Socialisation**

The main presence that embodies the socialisation component is the teacher mentor, although some PSTs also mention peers and other colleagues playing a role. At this stage the mentor has transitioned from a feared judge to a colleague (F1), in some cases a role model (F2, F4), although disagreements between the views of PSTs and their mentor may occur, for example regarding the role of textbooks (F3). However, adopting established practices of the teaching community, such as body language (F1) or ways of saying or doing things in the classroom, seems to be perceived by PSTs as a sign of having become teacher-like:

I've even put together extra handouts [for those who might need another type of challenge]. (F2)

### **Subjectification**

Through the journey from first to third year, the PSTs have grown into teachers who are aware that teaching is not just about what you know, it is about making choices about complex situations. As there are no deterministic answers to these dilemmas, neither objectively speaking nor in terms of what is the established way of the teaching community, these choices come down to the individual, they are drawing on the domain of subjectification: "We're more aware that there should be a reason behind our choices" (F4), "I understand my own thoughts" (F5). In their third year, we hear the PSTs stress the importance of trusting their own choices (F1, F2, F4), and being yourself (F2).

Planning lessons is now an altogether more positive experience, described with attributes such as joy, and belief in oneself. Importantly, some of the PSTs realize that becoming a teacher is a continuous process, and experimenting is a part of it:

Don't be afraid to try out new things. (F2)

A lesson plan can never be too good. It's like a piece of silverware that you take out and polish from time to time. (F4)

### **Conflicts and synergies between domains**

As PSTs become more comfortable as teachers (subjectification), some find reassurance in their theoretical knowledge (qualification) as well as their awareness of what is acceptable among teachers (socialisation):

Not everything has to be perfect [...]. The theory I used to think about while planning lessons in my first year is now under my skin. (F1)

The routines of teachers (socialisation) also contribute to being more successful in the practices of teaching, such as lesson planning (qualification): "You don't have to reinvent the wheel (F1)". There is an aspect of growing confidence (subjectification) when the PSTs reuse lesson plans they have had positive experiences with (F1).

Unlike in their first year, lesson planning in the third year takes less time (F1, F6) and the scripts for the lesson are shorter (F1, F4) or even disappear altogether ("We've thrown out the script", F6). The

change is attributed in general to an increase in confidence (subjectification) but in some cases also to an aggregated influence of all three domains:

... more confident in myself and the mathematics, I know more about the pupils' level in mathematics, I have become a clear leader, I dare to make mistakes, I am better at dealing with things as they happen. (F1)

In another film, the three domains come together in synergy to express the PSTs' development:

By contrast with first year, when we used the the syllabus for the course a lot, we now have more knowledge of the subject and of pedagogy. We've become better at making use of our own knowledge, we cooperate more closely with colleagues. (F6)

The way these sentences are linked, makes it possible to interpret it as meaning that better qualification leads to better self-confidence (subjectification) which again leads to better cooperation with others (socialization).

### **Practicing educational judgement**

Increased self-confidence by the third year is not synonymous with knowing just what to do:

How can I connect algorithms and conceptual understanding? I need to be able to show them different strategies, to be sure as many as possible understand. How many strategies for division are there? Maybe they come with some I haven't thought of? Maybe some misconceptions will surface during the lesson? How can I then, in the best possible way, deal with this? (F4)

The difference from the first year is being able to deal with dilemmas, to practice professional judgement, guided by what they see as the goals of teaching:

There's still a lot to think about, but I understand my own thoughts now, I know where I'm heading (F5)

In the third year practicing educational judgement features as a defining factor of the PST-mentor relationship at this stage: the detailed scripts for lesson plans that were in the first year in part written for the sake of the mentor (and in part to boost one's confidence, to feel prepared) are now shorter. A mentor's voice sets expectations:

Just show me that you are aware of the choices you make, and that you can argue for them (F2)

During the third year, educational judgement is visible in reflections on one's own teaching:

I've become better at assessing myself, and I can more readily explain what went well and what could have been done better in class (F1)

Teaching analysis draws on and at the same time feeds into the domain of qualification and perhaps also socialization. This way of assessing oneself - and the knowledge that you do it well - can be regarded as an engine for development also after graduation, it feeds into subjectification.

### **Concluding remarks**

The titles of two subsections of the analysis reflect the soundtrack of a film where the experiences of first- and third-year school placements are introduced with emergency sirens and birdsong respectively. In terms of Biesta's (2012) framework, the overall picture the presentations paint is

that, looking back on their first-year school placement, PSTs remember a combination of a lack of qualifications, unclear expectations from mentors and low self-confidence. The fear many PSTs report on, seems rooted in their low self-confidence and the unclear expectations. Although first-year PSTs are allowed to try different approaches and to fail, the same combination of a lack of repertoire, uncertainty of the mentor's role and lack of self-confidence holds them back. By the third year their qualifications have increased, their role as PSTs is clearer and their self-confidence has grown. Because of this, they also find themselves practicing educational judgement more often.

Such narratives, perhaps in combination with logs from early placements, could be part of educational experiences, supporting PSTs' identity work. First-years might also benefit from watching the films, as not all challenges discussed can be dealt with by the teacher educators. While teacher education can and should make explicit what is expected of PSTs in their school placement, it cannot rush becoming educationally wise. However, we hypothesise that creating spaces where first- and third-year PSTs can discuss their experiences would contribute to the domain of socialisation and subjectification for both groups. Analyzing the students' contributions in terms of Biesta's concepts reveal the complex relationships between qualification, socialization and subjectification in teacher education. The three domains are interdependent, with conflicts and synergies which influences PSTs overall experience. More insight into these conflicts and synergies may contribute to better understanding of PSTs' experiences of their school placements.

# Core practices and mathematical tasks of teaching in teacher education: What can be learned from a challenging case?

Janne Fauskanger and Reidar Mosvold

*In order to successfully carry out ambitious mathematics teaching, awareness about the underlying mathematical tasks of teaching involved is necessary. This paper presents the case of Martin, who started mathematics teacher education because he likes mathematics and feels that he knows the subject. We observe him in a period of field practice where he is supervised by an experienced mathematics mentor teacher. While planning, conducting and reflecting on a lesson on multiplication of fractions, neither Martin nor his mentor teacher focus on core tasks of teaching mathematics. We use this case as a starting point for discussing challenges and possibilities of increasing the emphasis on core practices and the embedded mathematical tasks of teaching mathematics in teacher education.*

*Keywords: Core practices, mathematical tasks of teaching, teacher education.*

## Introduction and theoretical background

Mathematics teaching is complex, and different attempts have been made to decompose it. Some have tried to identify the most critical practices involved in the work of teaching mathematics, and they describe them as “core practices” (e.g., McDonald, Kazemi, & Kavanagh, 2013) or “high-leverage practices” (Ball & Forzani, 2009; Forzani, 2014). These practices are fundamental for supporting students’ learning. Others emphasize the mathematical tasks of teaching that are embedded in the professional work of teaching mathematics (e.g., Ball, Thames, & Phelps, 2008; Hoover, Mosvold, & Fauskanger, 2014). In this paper, we focus on skills necessary to carry out the work of teaching mathematics by emphasizing mathematical tasks of teaching that are embedded in core teaching practices in teacher education. High-leverage practices and the underlying mathematical tasks of teaching “are essential for skillful beginning teachers to understand, take responsibility for, and be prepared to carry out in order to enact their core instructional responsibilities” (Ball & Forzani, 2009, p. 504). It is thus important to develop these practices during teacher education (TeachingWorks, 2015). The mathematical tasks included in these practices are instructional tasks that are mathematical and not pedagogical. When referring to “mathematical tasks of teaching”, we follow the conceptualization by Ball et al. (2008).

Researchers have made various attempts to categorize core practices (Forzani, 2014). In the TeachingWorks project (2015), a register of high-leverage practices is presented to serve as the basis for a core curriculum for the professional training of teachers. For instance, the first two of the nineteen high-leverage practices are: 1) “leading a group discussion”, and 2) “explaining and modeling content, practices, and strategies.” Both of these practices contain some mathematical tasks of teaching. For instance, the second practice obviously involves the task of “presenting mathematical ideas.” It may also involve “finding an example to make a specific mathematical point” (Ball et al., 2008, p. 400), a mathematical task of teaching that has proven to be difficult for pre-service teachers (Zodik & Zaslavsky, 2008). This practice may also involve the tasks of “recognizing what is involved

in using a particular representation” and “linking representations to underlying ideas and to other representations” (Ball et al., 2008, p. 400). Other mathematical tasks of teaching—some are embedded in more than one high-leverage practice—include using language carefully, highlighting core mathematical ideas while sidelining potentially distracting ones, and make their own thinking visible while modeling and demonstrating. The third high-leverage practice presented by TeachingWorks (2015) is “eliciting and interpreting individual students’ thinking.” This practice may involve asking and responding to questions, or presenting the students with exercises that provoke or allow them to share their mathematical thinking in order to evaluate student understanding, guide instructional decisions, and surface ideas that will benefit other students. When engaging in these practices, the teacher is faced with several mathematical tasks of teaching. For instance, teachers are challenged to ask “productive mathematical questions” and to evaluate “the plausibility of students’ claims” (Ball et al., 2008, p. 400). The mathematical tasks of teaching included in various core practices may vary depending on the context.

In Norway, the new national guidelines for primary and lower secondary teacher education use “core practices” as a term of reference (Ministry of Education and Research, 2016). Our study aims at discussing challenges and possibilities of implementing core practices and identifying underlying mathematical tasks of teaching mathematics in mathematics teacher education.

### **The Norwegian teacher education context**

Norwegian teacher education is politically controlled (Hammerness, 2013), and national curriculum guidelines direct the focus and content of all teacher education programs. There are differentiated teacher education programs for primary (years 1–7) and lower secondary (years 5–10) levels; both are four-year bachelor programs. In the primary teacher education program, a mathematics course of 30 ECTS is compulsory for all pre-service teachers, whereas the lower secondary teacher education program requires 60 ECTS in mathematics for pre-service mathematics teachers.

Field practice is a compulsory part of teacher education, but studies indicate that pre-service teachers’ opportunities to learn in this context are not sufficiently utilized (Hammerness, 2013). Pre-service teachers are required to complete 100 days of field practice at partner schools. The aim is that field practice should focus on the subject that pre-service teachers study on campus the current year. In field practice, pre-service teachers normally work in groups that are supervised by an experienced mentor teacher. Prospective mentor teachers are required to take a training course of 15 ECTS, and they are employed by the universities as teacher educators. From 2017, the Norwegian teacher education will be a five-year master program, and the field practice component will be extended to a minimum of 115 days spread across five years (Ministry of Education and Research, 2016).

### **Methods**

In order to discuss challenges and possibilities of implementing high-leverage practices (e.g., TeachingWorks, 2015) and identify underlying mathematical tasks of teaching (e.g., Ball et al., 2008), we consider an empirical case from a cross-disciplinary project in Norwegian teacher education entitled Teachers as Students (TasS). The TasS project has a focus on pre-service teachers’ learning in field practice.

Data collection includes video recordings of group interviews held with each group of pre-service teachers before and after their period of field practice. Based on analyses of these interviews, Martin

(pseudonym) stood out as a special case. He was one of only two pre-service teachers in the project who selected mathematics because they liked it and were good at it. A recent literature review suggests that being good at mathematics is important for pre-service teachers, for instance in perceiving and interpreting students' work (Stahnke, Schueler, & Roesken-Winter, 2016). In this case we only know that Martin sees himself as good, and this was a criterion for selecting him as a case. We observed Martin in a period of field practice in his fourth semester. In the previous semester, he had completed the 60 study points (ECTS) in mathematics/mathematics education that is required to teach mathematics in grades 5–10. Even though Martin enjoyed mathematics, his teaching practices cannot be seen as ambitious teaching practices (Lampert et al., 2010) fundamental for supporting students' learning (e.g., McDonald et al., 2013). In the following, we first show some glimpses from a lesson where Martin teaches multiplication of fractions in grade 7, followed by his discussions with the mentor teacher in the post-lesson mentoring session. The selected episode was typical for Martin's lessons in his three weeks of field practice. The lesson lasted for 38 minutes (we only focus on the whole class teaching in the selected episode), whereas the mentoring session lasted for 13 minutes.

### The case of Martin

After a brief repetition from the previous lesson, Martin introduces multiplication of fractions as the focus of this lesson. He writes  $\frac{1}{3}$  of  $\frac{3}{4} = \frac{1}{3} \times \frac{3}{4}$  on the blackboard and emphasizes that we say “one third of three quarters” when we write an expression like this. “What this means,” he continues, “is that we first have a fraction of one third and split it into three by using two horizontal lines.” He draws a quadrilateral on the blackboard, partitions it and shades the top third part. He draws another quadrilateral, partitions it vertically into fourths and shades three of these (see Figure 1). He then draws a third quadrilateral and says, “If we now want to take a third of this, we partition it into three [draws two horizontal lines in the figure]. How much is one third now?”

**Figure 1. Martin's illustration of  $\frac{1}{3} \times \frac{3}{4}$**

When the students struggle to respond, Martin points at one of the parts in the figure. “It is one of these. And then we only have a third of what is shaded—look at this one! Did you understand that?” Some students say no, whereas others shake their heads. Martin tries again: “What we can also do, is to say that we put the two fractions on top of each other.” He points at the first figure, pretends to move it over to the second figure and draws two horizontal lines in the middle figure. “What we focus on,” he continues, “is that which has been shaded twice.” When noticing that the students still do not seem to understand, he writes the expression. “It is as simple as taking this one [pointing at the first numerator] times this one [pointing at the second numerator], and then we take the first denominator times the second denominator.” While saying this, he writes it out on the blackboard. “Do you see

that  $\frac{3}{12}$  is the answer?” When the students are still hesitant, he quickly wipes everything out. “Let’s take one more example,” he continues.

In the next example, Martin writes  $\frac{1}{2}$  of  $\frac{1}{3}$  on the blackboard and draws two figures that he partitions and shades—this time by using colored crayons. The figures are of different sizes. “How much of this is both red and blue?” he asks. A girl presents  $\frac{4}{6}$  as an answer, whereupon Martin repeats, “That is both blue AND red?” When a boy provides the answer,  $\frac{1}{6}$ , Martin confirms. “We have one part that is both blue and red, meaning both fractions. There are six parts altogether, and then we get one sixth,” he continues. Martin tries to point the students’ attention to the procedural approach. “If I want to solve this expression [pointing at  $\frac{1}{2} \times \frac{1}{3}$  on the blackboard], the operation, how do I do it?” A boy mumbles that you are supposed to multiply, and Martin continues, “We are going to multiply denominator by denominator [pointing at the numerators (!) in the expression], and numerator by numerator [pointing at the denominators (!)].” He writes it out on the blackboard, seemingly ignorant about the fact that he has just mixed numerators with denominators. “Do you think you can make it if you try the tasks for yourselves now?” He then turns to the blackboard again and emphasizes how important it is to remember that although we write  $\frac{1}{2} \times \frac{1}{3}$ , we say one half of one third. “Important to remember,” he says. “If we don’t remember this, it will be very, very hard to solve the word problems!” Then he writes down  $\frac{3}{7} \times \frac{10}{2}$  as another example. “How many of you know how to solve this one?” he asks. “The very operation,” he continues, “forget about the figures!” After this introduction (14 minutes into the lesson) the students start working on similar tasks from their textbooks. When realizing that many students still have problems, Martin presents another example on the blackboard (after 18 minutes). Towards the end of the lesson, when summing up, he tells the students that he forgot to mention that the quadrilaterals (in Figure 1) are supposed to be equal in size.

Martin introduces the post-lesson mentoring session by saying that he can see what went wrong. When asked to elaborate, he points out that he should have used different colors from the beginning, and that he should have presented more examples before letting the students work individually on tasks. He continues to say that in his figures (e.g., Figure 1) he should have “mentioned that they [the quadrilaterals] were equally big”. The mentor teacher supports this by saying: “When you don’t show on the blackboard that they are equal, you cannot expect the students to understand it.” In the next part of the mentoring session, they discuss what different students managed to do during the part of the lesson that involved individual work on textbook tasks. This part of the lesson is not the focus of attention in this paper. Towards the end of the mentoring session, the mentor teacher ends the discussion about the figures used to illustrate fraction multiplication by saying, “I think they [the quadrilaterals] would have worked out very well, as you are pointing out, if you had used colors. And if you had thought about making them equal in size, it would have worked out very well.” Martin agrees, and adds that it is important to be careful about how you draw such figures.

## Learning from the case of Martin

The case of Martin illustrates the core practice of “explaining and modeling content, practices, and strategies” (TeachingWorks, 2015). A simplified response to the presented episodes and vignettes could be that Martin does not carry out the core practice of explaining and modeling content, practices, and strategies well, and he needs more practice. Based on research indicating that pre-

service teachers do not necessarily learn from their field practice (Hammerness, 2013), we believe there is more to it than this. Although Martin and his mentor teacher discuss his explanations and modeling of the content, they do not appear to get to the heart of the issue. Ball and Forzani (2009) suggest that certain mathematical tasks of teaching are embedded in these core practices (e.g., Ball et al., 2008; Hoover et al., 2014). In our discussion of challenges and possibilities of implementing core practices, we identify four challenges and discuss the possibilities for highlighting some of the embedded mathematical tasks of teaching.

First, and most importantly, Martin is faced with the mathematical task of “recognizing what is involved in using a particular representation” (Ball et al., 2008, p. 400). In his attempt to use the area model to represent multiplication of fractions, Martin draws three quadrilaterals (Figure 1). The area model for multiplication of fractions requires use of one rectangle only as unit. Martin does, however, say that the third rectangle illustrates the two others “on top of each other”, and he points at the first rectangle and pretends to drag it over the second rectangle. Still, this use of the model appears to confuse the students, and it would have been natural to focus on this mathematical task of teaching in a post-lesson mentoring session. In the given example one can draw three horizontal lines to show four equally large horizontal strips and then divide an area of three of these in three columns by drawing two vertical lines. Then there is still some work to do in order to understand that numerators can be multiplied as well as denominators. Martin tries to help the students develop this understanding by drawing two horizontal lines in the middle figure to illustrate how the four parts have now been divided into three and saying: “what we focus on, is that which has been shaded twice.”

In the post-lesson mentoring session, Martin starts by stating that he can see what went wrong. He points out that he should have used different colors (instead of double shading) and that he should have presented more examples. He continues to say that he should have “mentioned that they [the rectangles] were equally big.” The mentor teacher expresses his agreement. The area model requires use of one rectangle only as unit, but this is not discussed. “Recognizing what is involved in using a particular representation” (Ball et al., 2008, p. 400) is a mathematical task of teaching which might be fruitful in order to facilitate student teachers’ learning to carry out the core practice of explaining and modeling content in teacher education. This mathematical task of teaching is, however, not discussed in the post-lesson mentoring session.

Second, and related to the first, Martin consistently reads the product as “ $\frac{1}{3}$  of  $\frac{3}{4}$ ” indicating another model for multiplication of fractions than the area model: the multiplicative comparison model. In this model, one of the fractions is an operator, one is represented as a portion of the area of one rectangle, and the result is represented as another portion of the area of the same rectangle. In this case the rectangles might well be drawn separately, but Martin’s comment that the two first rectangles in Figure 1 should be placed on “top of each other” to make the third indicates that he does not have this model in mind. This is also not discussed in the post-lesson mentoring session.

Third, and related to the mathematical task of selecting appropriate examples “to make a specific mathematical point” (Ball et al., 2008, p. 400), Martin could have selected more appropriate examples when presenting the students with the area model for multiplication of fractions. In using this area model, it is necessary to not only use simple fractions as one-third and three-fourth. One can clarify much better that numerators can be multiplied as well as denominators with say three-fifth of four-

seventh. This illustrates an embedded mathematical task of teaching related to finding examples to make specific a certain mathematical point. In the post-lesson mentoring session, only the number of examples is discussed. For instance, they discuss that Martin should have presented more examples. Selection of examples, which has proven to be difficult for pre-service teachers (Zodik & Zaslavsky, 2008), is not discussed. One way to meet this challenge of randomly generated examples, when careful choices should be made, is to exemplify and discuss carefully selected examples in mathematics teacher education

Fourth, Martin is faced with the mathematical task of using correct mathematical language when presenting the mathematical idea of multiplication of fractions. On a couple of occasions, we observe that he mixes numerator with denominator. This might be regarded as a minor mistake of speaking mathematics, and we do not believe it is the most critical issue in the case of Martin. Correct use of mathematical language and notation is still important, however, and we suggest that this is a mathematical task of teaching that the mentor teacher could have discussed with Martin.

Martin is using a model for representing multiplication of fractions (Figure 1), but the students struggle to understand it. The high-leverage practice of eliciting and interpreting students' thinking (TeachingWorks, 2015) focuses on teachers' practice related to posing questions or tasks that provoke or allow students to share their mathematical thinking in order to evaluate student understanding and guide instructional decisions. To do this effectively, a teacher needs to draw out a student's thinking through carefully selected questions and tasks and to consider and check alternative interpretations of the student's ideas and methods. Although Martin knows the mathematical content himself, he struggles to understand the problems faced by the students. This illustrates the importance of pre-service teachers' mathematical knowledge in order to perceive and interpret students' work (Stahnke et al., 2016). In his communication with the students, Martin does not invite the students to engage in mathematical discussions and reasoning. Instead, the students are invited to give short and confirmative responses only. During the 14-minute whole-class introduction, as well as in the brief wrapping up of the lesson, the students were mostly invited to answer yes or no questions. Two examples of such questions are: "Did you understand that?" and "Do you think you can make it if you try the tasks for yourselves now?" Some questions are asked when the answer is already visible through the example presented on the board, like: "How much is one third now?" and "How much of this is both red and blue?" These questions invite students to answer by single words. Only once were the students invited to answer a how-question, and this question was related to how to carry out a routine procedure. Based on our analyses of how Martin invites the students to participate, we conclude that they are not invited to speak or reason mathematically. This kind of communication does not allow Martin to elicit students' thinking. We thus suggest that the core practice of eliciting and interpreting students' thinking is important to develop in teacher education.

## Conclusion

Learning to successfully carry out high-leverage practices in mathematics teaching requires awareness about the underlying mathematical tasks of teaching involved (Ball et al., 2008), and mathematics teaching is a professional practice that requires training (Hoover et al., 2014). In this paper, we have used illustrative data from field practice in Norwegian mathematics teacher education as a starting point for our discussion. From this challenging case, we observe that neither the pre-service mathematics teacher (Martin) nor his mentor teacher appear to be conscious about the

mathematical tasks of teaching that are embedded in the high-leverage practices that have been analyzed and discussed in this paper—all of which are involved in the planning, conducting and reflecting on a lesson on multiplication of fractions.

What challenges and possibilities of implementing core practices and identifying underlying mathematical tasks of teaching mathematics in mathematics teacher education can be identified by analyzing Martin's lesson? In this lesson, the pre-service teacher was challenged to carry out the practice of "Explaining and modeling content, practices, and strategies" (TeachingWorks, 2015). Previous research indicates that strong teacher knowledge supports teachers in using representations to attach meaning to mathematical procedures (e.g., Charalambous, 2010). Although he has completed all of his coursework in mathematics, Martin does not appear to be prepared to carry out this core practice. Martin is also challenged to elicit students' thinking (TeachingWorks, 2015), but he does not seem prepared to carry out this core practice of teaching mathematics either, at least not in an ambitious way (Lampert et al., 2010). From these illustrative data, it appears that there is a lack of awareness about the underlying mathematical tasks of teaching, and the post-lesson mentoring session includes little discussion of these underlying mathematical tasks of teaching.

At least four lessons can be learned from the case of Martin. First, the task of recognizing what is involved in using a particular representation challenges teacher education to include detailed discussions of the area model for representing multiplication of fractions, highlighting the importance of using only one rectangle and how this model relates to numerators are multiplied as well as denominators. Second, selecting appropriate examples using carefully chosen numbers is important in order to clarify that numerators can be multiplied as well as denominators, and therefore important to discuss in teacher education. Third, Martin could have selected better examples when presenting the students with the area model for multiplication of fractions. Fourth, and finally, the case of Martin illustrates the mathematical task of presenting mathematical ideas using correct mathematical language. These mathematical tasks of teaching all seem related to the high-leverage practice of explaining and modeling content (TeachingWorks, 2015).

Mathematics teacher education needs to focus more on preparing prospective teachers to carry out high-leverage practices. Discussions of the embedded mathematical tasks of teaching are then necessary. The vignettes and episodes discussed in this paper indicate that the "unnatural" and complicated work of teaching needs to be explicitly taught in teacher education. One way of approaching this is to practice carrying out the mathematical tasks of teaching on campus as well as in field practice. The national guidelines for current primary and lower secondary teacher education that are now being developed focus on core or high-leverage practices (Ministry of Education and Research, 2016). More research and development efforts are needed to ensure a high-leverage implementation of these ideas in teacher education.

*The aim of this study is to describe changes in the way that prospective secondary school teachers notice students' mathematical thinking related to the limit concept in a learning environment designed ad hoc. The learning environment progressively nests the skills of attending to, interpreting and deciding as three interrelated skills of professional noticing. Results show characteristics of how prospective teachers gained expertise in the three skills since four out of five groups of prospective teachers interpreted students' mathematical reasoning attending to the mathematical elements of the dynamic conception of limit. The links between attending to and interpreting helped prospective teachers justify the teaching activities proposed to support the progression of students' mathematical reasoning: from a mathematical point of view or considering mathematical cognitive processes involved.*

*Keywords: Noticing, prospective teachers' learning, learning environment.*

## Introduction and theoretical background

Research has shown that noticing is an important component of teaching expertise (Mason, 2002). Teachers need to attend to students' mathematical reasoning and make sense of it in order to teach in ways that build on students' thinking (Choy, 2016; Sherin, Jacobs, & Philipp, 2011). Noticing has been conceptualised from different perspectives. One of them consists of two main processes: attending to particular teaching events and making sense of these events (Sherin et al., 2011). Jacobs, Lamb, and Philipp (2010) particularise the notion of noticing to children's mathematical thinking, conceptualising this notion as a set of three interrelated skills: attending to children's strategies, interpreting children's mathematical thinking, and deciding how to respond on the basis of children's mathematical thinking.

Previous research has focused on pre-service teachers' ability to interpret students' mathematical thinking (Bartell, Webel, Bowen, & Dyson, 2013; Callejo, & Zapatera, 2016; Fernández, Llinares, & Valls, 2012; Llinares, Fernández, & Sánchez-Matamoros, 2016; Magiera, van den Kieboom, & Moyer, 2013; Sánchez-Matamoros, Fernández, & Llinares, 2015) showing that the identification of the mathematical elements involved in the problem (mathematical content knowledge) plays a significant role in interpreting students' mathematical reasoning. Furthermore, previous research has shown that some contexts can help pre-service or prospective teachers develop the noticing skill: watching video clips (Coles, 2012; van Es, & Sherin, 2002), participating in online debates (Fernández et al., 2012) or participating in learning environments (interventions) designed considering specific mathematical topics. For example, Schack et al. (2013) in the area of early

numeracy; Magiera et al. (2013) in algebra; Callejo and Zapatera (2016) in pattern generalization; Llinares et al. (2016) in classification of quadrilaterals; Sánchez-Matamoros et al. (2015) in the derivative concept; and Son (2013) in the concepts of ratio and proportion. These previous studies underline that the skill of deciding how to respond on the basis of children's mathematical thinking is the most difficult one to develop in teacher education programs. As Choy (2013) pointed "*the specificity of what teachers notice while necessary, is not sufficient for improved practices*" (p. 187). In other words, teachers can be very specific about what they notice without having a teaching decision in mind. So, the relation between how prospective teachers develop the skills of interpreting students' mathematical thinking and deciding how to respond on the basis of students' mathematical thinking deserves further research.

On the other hand, the concept of limit of a function is a difficult notion for high school students (16-18 years old) and is a key concept in the Spanish curriculum (Contreras, & García, 2011). Cottrill and colleagues (1996) indicated that the difficulty of students' understanding of the limit concept could be the result of a limited understanding of the dynamic conception. A way of overcoming this difficulty is by coordinating the processes of approaching in the domain and in the range in different modes of representation. Knowing these characteristics of students' understanding could provide prospective teachers with information to interpret students' mathematical thinking and to make instructional decisions based on students' reasoning.

Therefore, our study analyses changes in the way that prospective teachers notice students' mathematical thinking (attending to, interpreting and deciding) in relation to the limit concept when they participate in a learning environment designed ad hoc. The learning environment designed progressively nests the skills of attending to, interpreting and deciding and its relations. We hypothesise that the structure of the learning environment help prospective teachers to decide how to respond taking into account their previous interpretations of students' mathematical thinking.

## Method

### Participants and the learning environment

The participants were 25 prospective secondary school teachers (mathematics, physics and engineering) who were enrolled in an initial secondary mathematics teacher training program. One of the subjects of this program is focused on developing the skill of noticing students' mathematical thinking in different mathematical topics and on planning the instruction attending to students' mathematical thinking. One of the mathematical topics considered was the limit concept.

The learning environment consisted of 5 sessions of two hours each and was designed taking into account the nested nature of the skills of attending to, interpreting and deciding (Jacobs et al., 2010). Prospective teachers were divided into five groups of 5 persons to perform the tasks of the learning environment. Firstly, prospective teachers solved three problems related to the limit concept selected from high school textbooks (Figure 1) in order to unpack the important mathematical elements of the limit concept (session 1). Then, prospective teachers had to anticipate hypothetical students' answers to these problems reflecting different characteristics of conceptual development (session 2). That is, they had to anticipate what students are likely to do. Prospective teachers had a document with the definition of the dynamic conception of limit and its mathematical elements (Pons, 2014): (i) approaches from the right and from the left (in the domain and in the range), and

(ii) coordination of the processes of approaching in the domain and in the range considering different modes of representation (graphical, algebraic and numerical).

**Problem 1**  
Consider the function:

$$f(x) = \begin{cases} 2x + 1 & \text{si } x \leq 1 \\ 4 & \text{si } 1 < x \leq 2 \\ x^2 & \text{si } x > 2 \end{cases}$$

Calculate the limit of  $f(x)$  when  
a)  $x$  approaches 1  
b)  $x$  approaches 2

**Problem 2**  
Consider the next tables:

$x_1$	0,8	0,9	0,99	...	1,2	1,1	1,01
$f(x_1)$	1,64	1,81	1,9201	...	2,44	2,21	2,0201

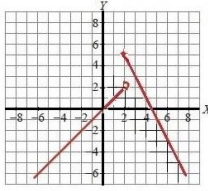

$x_2$	0	0,9	0,99	...	1,1	1,01	1,001
$g(x_2)$	0	-0,99	-0,9999	...	2,3	2,03	2,003

a) What is the value to which  
1.  $x_1$  and  $x_2$  are approaching from the right and from the left?  
2. The images of  $f(x_1)$  are approaching from the right and from the left?  
3. The images of  $g(x_2)$  are approaching from the right and from the left?

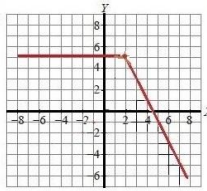

b) What is the value to which  
1. The images of  $f(x_1)$  are approaching in relation to the value that  $x_1$  approaches?  
2. The images of  $g(x_2)$  are approaching in relation to the value that  $x_2$  approaches?

**Problem 3**  
Relate the following graphs with the statements a, b and c. Justify your answer

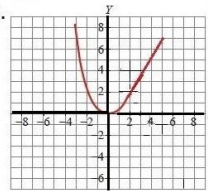

1.

2.

3.

a) The limit of the function in  $x = 2$  is 2  
b) The limit of the function in  $x = 2$  is 5  
c) There is not limit of the function in  $x = 2$

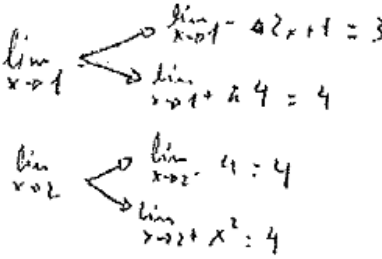

**Figure 1: The three problems related to the limit concept**

The aim of the tasks of identifying the mathematical elements in the resolution of the problems and anticipating hypothetical students' answers was to help prospective teachers focus their attention on the relationship between the specific mathematical content and students' mathematical thinking. We conjecture that focusing on this relationship is needed to develop the skill of noticing in a first step. Next, prospective teachers analysed a set of four high school students' answers (Pablo, Rebecca, Luigi and Jorge) to the same problems. Prospective teachers had to attend to students' strategies, interpret students' mathematical thinking and propose new activities (or modify them) to help students progress in their conceptual reasoning (according to their previous interpretations of students' mathematical thinking) (session 3 and 4). The high school students' answers, provided to prospective teachers, reflected different levels of high school students' reasoning of the limit concept (Table 1; Pons, 2014). We also provided prospective teachers with theoretical information that summarise the characteristics of high school students' reasoning of the limit concept from previous research to solve the task (Cornu, 1991; Cottrill et al., 1996; Swinyard, & Larsen, 2012). In figure 2, the answers of Pablo to the three problems are given.

Prospective teachers had to answer the next three questions: (i) which mathematical elements has the student used in each problem? Indicate if he/she has had difficulties with them; (ii) identify some characteristics of how the student understands the limit of a function. Explain your answer using the mathematical elements identified before; (iii) considering the student reasoning, propose an activity that helps the student progress in their conceptual reasoning of the limit concept. Therefore, the objective of sessions 3 and 4 was that prospective teachers focus their attention on the relation between identifying-interpreting and between interpreting-deciding. We conjecture that these relationships are necessary to develop the skill of noticing. Finally, in the session 5, prospective teachers had to answer a similar task individually.

High school students	Level	Levels of students' reasoning about the dynamical conception of the limit concept
Pablo and Luigi	High	Pablo and Luigi coordinate the processes of approaching in the domain and in the range in the three modes of representation
Rebecca	Low	Rebecca coordinates the processes of approaching in the domain and in the range in the graphical mode of representation when limits coincide
Jorge	Intermediate	Jorge coordinates the processes of approaching in the domain and in the range in the algebraic and graphical mode of representation (when limits coincide in this last mode of representation)

**Table 1: Characteristics of high school students' answers**

<u>Answer to Problem 1</u>	<u>Answer to Problem 2</u>	<u>Answer to Problem 3</u>
	<p>a1) <math>x_1</math> is approaching to 1 from the left and from the right and <math>x_2</math> is approaching to 1 from the left and from the right</p> <p>a2) The images of <math>f(x_1)</math> are approaching to 2 from the left and from the right</p> <p>a3) The images of <math>g(x_2)</math> are approaching to 2 from the right and is approaching to -1 from the left</p> <p>b1) when <math>x_1</math> is approaching to 1, images of <math>f(x_1)</math> tend to 2</p> <p>b2) when <math>x_2</math> is approaching to 1, the images of <math>g(x_2)</math> tend to -1 from the left and tend to 2 from the right.</p>	<p>a) Graph 3 because the limit of the function in <math>x=2</math> from the right and from the left is 2.</p> <p>b) Graph 2 because the limit of the function in <math>x=2</math> from the left and from the right is 5.</p> <p>c) Graph 1 because the limit of the function in <math>x=2</math> is not the same from the right and from the left.</p>

**Figure 2: Pablo's answers to the three problems**

### Data and analysis

Data of this study are prospective teachers' answers to the tasks of session 2 (anticipation) and sessions 3 and 4 (interpretation). Through an inductive analysis (Strauss & Corbin, 1994), we generated similarities and differences about how prospective teachers conceived high school students' reasoning of the limit concept and the type of activities they provided to help students progress in their conceptual reasoning. To carry out this analysis, five researchers analysed individually prospective teachers' answers to the anticipation and interpretation tasks and then, the agreements and disagreements were discussed to reach a consensus on these issues.

This analysis let us identify two ways of how prospective teachers conceived high school students' reasoning: as dichotomous (right or wrong) and as a progression (identifying different levels of students' reasoning). The type of activities that prospective teachers provided were categorised in three categories: general decisions, decision based on curricula contents and decisions based on cognitive processes. Examples of these categories are presented in the results section.

Finally, we compared categories obtained in the anticipation task with the categories obtained in the interpretation task to identify changes in the way of how prospective teachers conceived high school students' reasoning and proposed activities to help students progress in their conceptual reasoning.

## Results

Our results show that prospective teachers changed the way that they conceived students' reasoning from a dichotomous to a progression way and this shift influenced the type of activities that they proposed to help students progress in their conceptual reasoning.

### Changes in the way that prospective teachers conceived students' reasoning: From a dichotomous to a progression

In the anticipation task, three out of five groups conceived students' reasoning as dichotomous (right or wrong). For example, the group of prospective teachers G2 anticipated that a high school student with high level of reasoning of the limit concept (Maria) would coordinate in all modes of representation. For example, this group of prospective teachers anticipated the next answer for the algebraic representation:

Handwritten mathematical work on grid paper. At the top, a piecewise function is defined:  $f(x) = \begin{cases} 2x+1 & \text{if } x \leq 1 \\ 4 & \text{if } 1 < x \leq 2 \\ x^2 & \text{if } x > 2 \end{cases}$ . Below this, two parts are shown: a) 'x tiende a 1' (x tends to 1), where the limit is calculated from both sides:  $\lim_{x \rightarrow 1^-} f(x) = \lim_{x \rightarrow 1^-} (2x+1) = 3$  and  $\lim_{x \rightarrow 1^+} f(x) = \lim_{x \rightarrow 1^+} 4 = 4$ . Since the left and right limits are not equal, it is concluded 'No existe el límite' (The limit does not exist). b) 'x tiende a 2' (x tends to 2), where the limit is calculated from both sides:  $\lim_{x \rightarrow 2^-} f(x) = 4$  and  $\lim_{x \rightarrow 2^+} f(x) = 4$ . Since both limits are equal to 4, it is concluded 'existe el límite' (The limit exists).

*Maria understands the limit concept. The idea of approximation in the domain corresponds to the fact that she properly selects the branch of the function and uses the notion of approximation in the range adequately. It is demonstrated when she replaces on the limit the approach of the independent variable. This student also coordinates the approximations to establish the value of the limit according to the branch.*

Furthermore, these prospective teachers (G2) anticipated that a high school student with a not suitable level of reasoning of the limit concept (Pedro) would not coordinate in any mode of representation pointing out: “Pedro only approximates (from the left or from the right) when the function is defined”.

Then (in the interpretation task), four out of five groups of prospective teachers were able to interpret students' mathematical reasoning. They linked students' reasoning with the mathematical elements of the dynamic conception of limit: the approaches from the right and from the left (in the domain and in the range), and the coordination of the approaches in the domain and in the range considering different modes of representation (graphical, algebraic and numerical). For instance, the group of prospective teachers (G2) interpreted the student's answer of problem 1 (Figure 2) as:

The resolution of the student is correct (Pablo). We can notice that the student has identified the kind of function (piecewise function) since he (the student) has approximated in the range (he has calculated the approximation to  $x=1$  from the left and from the right and the approximation to  $x=2$  from the left and from the right) and in the domain (taking the correct definition of function in each interval). Furthermore, he has coordinated the processes of approaching in the domain and in the range since he has written, for example, that when  $x$  tends to 1 from the left, the image of the function tends to 3 (using the function  $2x+1$ ).

This group gave similar comments for the student's answers to the other two problems linking students' reasoning with the important mathematical elements in the other two modes of representations (problems 2 and 3). Afterwards, they wrote a summary about this student level of reasoning:

This student understands the limit concept since he approaches from the right and from the left (in the domain and in the range), and coordinates the processes of approaching in the domain and in the range in the three modes of representation (graphical, algebraic and numerical). This student would be in the high level of reasoning.

These prospective teachers were able to identify different levels of students' reasoning. Therefore, they conceived students' reasoning as gradual.

### **Changes in the type of activities they proposed to help students progress in their conceptual reasoning**

Prospective teachers who conceived students' reasoning as dichotomous did not propose specific activities to help students progress in their reasoning. These prospective teachers gave general comments about teaching as instructional actions. For instance, the group of prospective teachers G2 proposed to Maria (in the anticipation task) the representation of the graph of the function of problem 1. This decision was not based on the conceptual progression of the student.

When prospective teachers interpreted students' mathematical thinking identifying different levels of students' reasoning (linking students' mathematical reasoning with the important mathematical elements), they were able to provide specific activities to help students progress in their conceptual reasoning. For the students who only coordinate the approaches in the domain and in the range in one mode of representation, they proposed new activities to integrate these mathematical elements gradually in the different modes of representation. The proposed activities required a coordination of approaches in the domain and in the range in the different modes of representation. For the students who coordinate the approximations in the domain and in the range in all modes of representation (such as the student of Figure 2), they also provided activities to help students progress in their reasoning.

We have identified two ways in which they justified their new activities: some justifications were based on the mathematical elements and others on the cognitive processes involved. In the first case, prospective teachers focused their attention on introducing a new mathematic content. In the following example, they introduced a new type of discontinuity – an avoidable discontinuity. The justification of this type of activities was based on the use of new mathematical elements (in this case, introducing other type of functions).

The activity: We would modify the function of problem 1 and we would use:

$$f(x) = \begin{cases} 2x & \text{si } x > 2 \\ 5 & \text{si } x = 2 \\ 2x & \text{si } x < 2 \end{cases}$$

Our justification: The student (Figure 2) seems to understand the limit concept in the three modes of representation, so we would provide him a more difficult function with an avoidable discontinuity.

In the second case, prospective teachers focused their attention on the cognitive processes involved to understand the limit concept. In the next example, prospective teachers focused on the reversal as a cognitive mechanism that leads students to a new reasoning level. That is to say, prospective teachers justified the proposed activity by the need of generating learning opportunities to develop the reverse mechanism that allows the construction of cognitive objects.

The activity: Represent a graph of a function which limit in  $x=-1$  is 4 and that there is not limit in  $x=1$ .

Our justification: with this activity students need to do the inverse process that is, they need to use all the important mathematical elements to build that function.

## Discussion and conclusions

Results show that after the participation in a learning environment that progressively nests the three interrelated skills of professional noticing (attending to, interpreting and deciding), prospective secondary school teachers gained expertise in noticing. Four out of five groups of prospective teachers were able to interpret students' mathematical thinking linking students' reasoning with the important mathematical elements of the dynamic conception of limit. These findings support the claim that some characteristics of the learning environment such as considering the nested nature of the skills help prospective teachers develop the skill of noticing (Sánchez-Matamoros et al, 2015; Schack et al., 2013).

Furthermore, prospective teachers were able to provide specific activities to help students progress in their conceptual reasoning. Therefore, the characteristics of the learning environment in which prospective teachers were engaged in the analysis of mathematical elements of limit problems, in the analysis of students' reasoning and in proposing new activities to support students' conceptual development enable them to gain more accurate understanding of the relation between the mathematical content and students' mathematical thinking. This new understanding provides prospective teachers with the needed knowledge to give their teaching decisions based on the progression of students' reasoning: from a mathematical point of view or considering the cognitive processes involved.

*The program Math.Researchers (“Mathe.Forscher”) funded by the German foundation “Stiftung Rechnen” has the goal to implement discovery, inquiry- and project-based learning in mathematic school lessons. The students are meant to explore and discover mathematics in their every-day-life with the help of their teachers. The teachers are well educated in supporting their students by in-service education organized by the program. In addition to finding out if the in-service education is well established and if any correlation between the students’ or the teachers’ view on mathematics and the positive identification with the program is detectable, an evaluation was planned. The goal is to investigate if while taking part in the program Math.Researchers teachers’ beliefs concerning mathematics are influenced and if an effect on the students’ view on mathematics is detectable.*

*Keywords: In-service education; secondary school mathematics; discovery, inquiry- and project-based learning; beliefs.*

## Theoretical framework

The program Math.Researchers (“Mathe.Forscher”) funded in 2010 by the German foundation “Stiftung Rechnen” has the goal to implement discovery, inquiry- and project-based learning in mathematic school lessons. One motivation is that inquiry-based learning may increase the students’ mathematical achievement (Hattie, 2015). Bruner considers the benefit of learning through discoveries that one makes for oneself in the 60’s (Bruner, 1961). His discussed main benefits are similar to Winter’s arguments consisting the thesis that active discoveries by students themselves are the more effective way of especially learning mathematics (Winter, 1989, p. 1–3). The students are meant to explore and discover mathematics in their every-day-life with the help of their teachers. The program Math.Researchers supports the teachers in several sessions, with training, booklets and material for best-practice-activities. In addition a team of scientific assistants and process assistants support the program members. One example for a Math.Researcher activity is “Mathematics at the Zoo” (Ludwig, Lutz-Westphal, 2016). The pupils have to leave their classroom and visit the zoo to develop their own research questions there. The teacher supports the students’ ideas with mathematical knowhow. Back at school they work on their research questions and present their results. A reflection on the presented solutions completes this Math.Researcher activity. Although the teachers were supported in the terms of the program they were insecure whether their lessons were Math.Researchers-lessons. To improve transparency in this respect five special normative program-dimensions were developed by experts of the program in 2014 that can be used as a kind of checklist.

## Math.Researcher-dimensions

Derived from the program goals, the following five Math.Researcher-dimensions were determined in 2014: using the Math.Researcher-principles (MRP), opening the classroom (OC), working with researchers’ questions (RQ), acting as a learning guide (LG), and visualizing mathematics (VM).

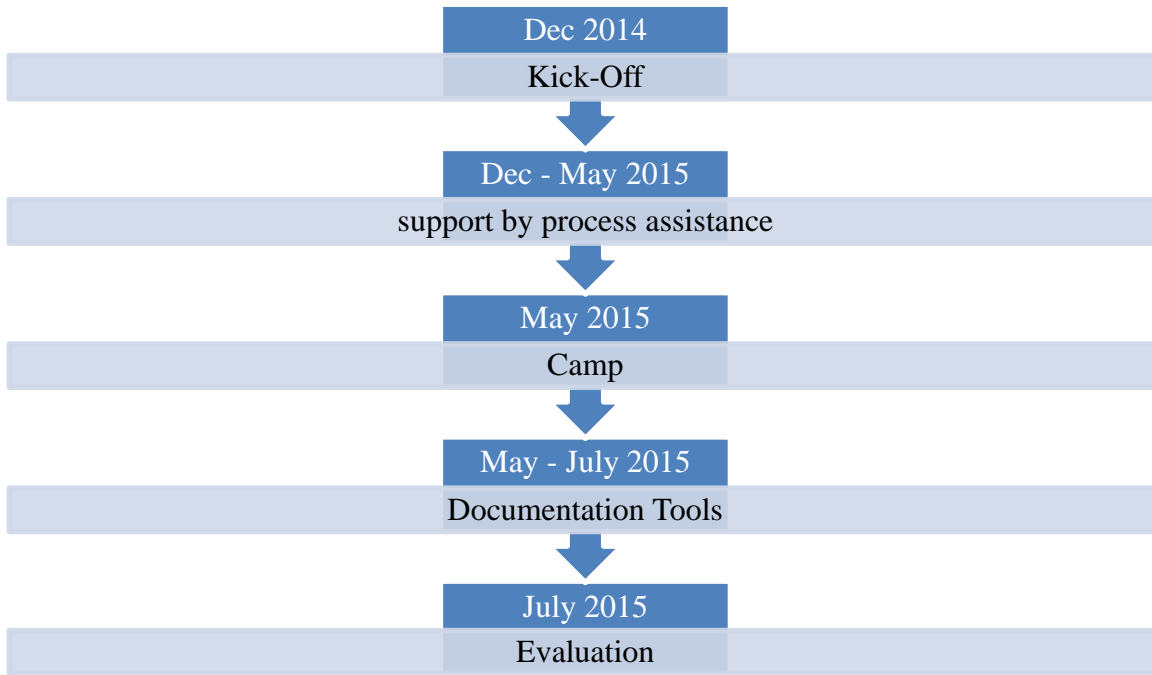

Each dimension consists of three main elements (Table 1). The more elements considered, the more Math.Researcher-like is the planned unit. The table can be used as a checklist so that the teachers are able to find out whether their planned lessons are conforming to the program. An ideal Math.Researcher-activity contains a minimum one element of each dimension.

Dimension	Main Elements		
Using the Math. Researcher Principles (MRP)	Inquiry-based learning	discovery learning	project-based learning
Opening the Classroom (OC)	interdisciplinary instruction	inviting experts	outdoor lessons
Working with Researcher's Questions (RQ)	including the students living environment	exercising asking questions with the students	allowing multiple approaches
Acting as a Learning Guide (LG)	enable active students role	constructive handling with students ideas	working out milestones together
Visualizing and presenting Mathematics (VM)	documentation of mathematics	using mathematical language	talking about ideas

**Table 1: The five dimensions and its main elements**

Considering the above-mentioned Math.Researcher activity's example "Mathematics at the Zoo" elements of all dimensions can be found here. The activity is project-based (MRP) and includes outdoor lessons at the zoo (OC). The pupils develop their own mathematical questions in an environment they usually do not connect to an educational context (RQ). The teacher enables student activities and supports them in mathematizing their ideas (LG). The phase of presentation and reflection at the end of this project represents the fifth dimension (VM).

To establish the dimensions a special PD course was conducted (figure 1). At a kick-off-meeting in December 2014 with all participating teachers the dimensions were introduced. The following months the teachers were meant to implement the dimensions in their teaching to get more familiar with them. So called process-assistance visited the teachers at school, watched the lessons, gave feedback. At the Math.Researchers' camp in May 2015 concrete activities were planned. 17 teachers met with program's scientific and process assistance to develop units focusing the dimensions. These units were conducted in May, June and July 2015. Every unit should be documented by a uniform document tool provided on the internet platform. The assistants analyzed these documentations and gave individual feedback.

**Figure 1: Timeline of treatments**

While carrying out the Math.Researcher program with a special focus on the dimensions it was not sure whether and how the terms and ideas of the program were implemented in mathematical school lessons after May 2015. The dimensions can be seen as a kind of program characteristics. So a natural research question came up: Did the development and application of these dimensions succeed sustainable? That means on the one side that they are helpful for the teachers to plan their Math.Researcher lessons, and on the other side that the included main elements are recognizable by the students in the way the teachers planned it. Furthermore, we wanted to know if there is any effect on the view on mathematics of the teachers and also the students. By taking part in the program the students are meant to explore and discover mathematics in their every-day-life. Does this goal reach the students, or is the main opinion after they have taken part in the program that mathematics is still a school topic where you have to learn formulas and not necessary for every-day-life?

Presenting the design principles of in-service education by the German Centre for Mathematics Teacher Education (DZLM) Barzel and Selter (2015) reviewed the current state of research on in-service education with a special focus on mathematics. The effectiveness of in-service education is possible on different levels: Among other things there can be an impact on the acceptance of the training, an impact on the professional competencies and an impact on the classroom teaching (Barzel & Selter, 2015, p. 266). To improve transparency in the respect which impact can be found with the Math.Researcher-program an evaluation was planned with a focus on the following research questions:

- Are the dimensions well established, do the teachers identify with them and integrate belonging elements in their classroom teaching? **(1)**
- Which view on mathematics has been built up by the participants identifying with the Math.Researcher program? **(2)**

Therefore the dimensions were related to the mathematical beliefs. The mathematical world view of teachers (Törner, 1997) can be described by a belief system including four main aspects: the aspect of formalism (F), the schematic aspect (S), aspect of process (P) and the aspect of application (A). The aspect of formalism and the schematic aspect can be interpreted as a static view on mathematics education: mathematics as a system. The dynamic process character allows understanding facts, recognizing connections and building knowledge: mathematics is an activity. This belief system is also part of the competencies framework for in-service education of the DZLM (Barzel & Selter, 2015, p. 263).

### **The pilot study**

A pilot study was conducted from May to July 2015 in the region Rhein-Neckar to find out whether the dimensions are well established and if any correlation between the students' or the teachers' view on mathematics and the positive identification with the dimensions are detectable. The program started in this region in 2012 in ten secondary schools. All respondents – students and teachers – of the pilot study have taken part in at least one Math.Researcher-activity within the last two years and especially in the PD course focusing the dimensions listed above.

### **Methods**

The questionnaire contained belief-questions (taken from surveys by Grigutsch/Raatz/Törner, 1998), questions belonging to the program and its dimensions and some general questions (mostly developed by ourselves and taken from an earlier Math.Researcher evaluation in the region Nord conducted by the TU Berlin, Lubke et al., 2011). The teachers (n=20) answered an online-questionnaire containing 139 questions. The students (n=168) answered a paper print-version with 79 questions. The items were scaled with 1="totally don't agree" to 5="totally agree". The higher the scale of questions belonging to the dimensions the higher is the identification with the program. All questions were formulated to be understandable for students not familiar with the dimensions. For example the students were asked whether they liked talking about their own mathematical ideas, which can be related to the dimension visualizing and presenting mathematics (VM). Or if they sometimes do outdoor mathematics, which is related to the dimension opening the classroom (OC). Compared to that the teachers were asked whether their students' have to present own results at the end of a project (VM). Or if they sometimes do outdoor mathematics with their students (OC). The items were related to the dimensions by an experts' rating.

Additionally, some teachers (n=14, 8 congruent with the respondents of the questionnaire) and some of the students (n=31, all of them also filled a questionnaire) were interviewed. The interviews only contained questions about the program. For example both groups were asked to characterize Math.Researcher lessons by identifying features or describing which special Math.Researcher-activity they did.

### **Results**

The analysis of the data (factor analysis and experts' rating) showed that the identification of the separate Math.Researcher dimensions was not possible. So in the following results the dimensions are considered in total, the belief aspects are separate. The five resulting factors formalism (F), scheme (S), process (P), application (A) and Math.Researcher-Dimension (Dim) can be seen as reliable (Cronbachs Alpha ,728 to ,800, Table 2).

	<b>F</b>	<b>S</b>	<b>P</b>	<b>A</b>	<b>Dim</b>
<b>Number of Items</b>	11	8	10	7	25
<b>Cronbachs <math>\alpha</math></b>	,728	,764	,798	,800	,769

**Table 2: Number of items and Cronbachs Alpha of each main factor**

Figure 2 shows the means of the four belief-aspects and the mean of the Math.Researcher-dimensions of all teachers in total. Comparing them, application (A), process (P) and the Math.Researcher-Dimensions (Dim) are rated similarly positive.

**Figure 2: Means of the teachers' belief aspects and the M.R-dimensions in total (1= do not agree at all, 5= totally agree)**

The exact scales can be seen in Table 2. The aspect of formalism (F) is rated not as positive as these, but considerably better than the scheme aspect (S). Scheme (S) is rated worse. (P) and (Dim) show a significant correlation of  $r = .59$  so 35 % of the processes variance can be explained by the dimensions. The other beliefs cannot be explained significantly by the dimensions. Comparing the standard deviations of the beliefs and the dimensions in total shows that the teachers have rated the single items reasonably homogeneously (Table 2). The scheme aspect rated average worse is perceived the most ambivalent.

<b>n=20</b>	<b>F</b>	<b>S</b>	<b>P</b>	<b>A</b>	<b>M.R-Dim</b>
<b>M</b>	3,51	2,26	4,35	4,34	4,22
<b>SD</b>	0,44	0,56	0,42	0,51	0,35

**Table 3: Mean and standard deviation of the teachers' belief aspects and the M.R-dimensions in total (1= do not agree at all, 5= totally agree)**

Comparing the teachers' results with the students' a decline in the values of the scheme aspect is not recognizable (Figure 3). The five means do not differ that noticeably. Comparing the standard deviations (Table 4) shows that the students' answers differ a lot. The process aspect has the highest standard deviation of nearly 1.

**Figure 3: Means of the students' belief aspects and the M.R-dimensions in total (1= do not agree at all, 5= totally agree)**

The process aspect has the highest standard deviation of nearly 1. The students' values are much more ambivalent than the values of the teacher's evaluation.

n=164	F	S	P	A	M.R-Dim
<b>M</b>	3,55	3,39	2,91	3,02	3,01
<b>SD</b>	0,69	0,68	0,91	0,85	0,47

**Table 4: Mean and standard deviation of the students' belief aspects and the M.R-dimensions in total (1= do not agree at all, 5= totally agree)**

The students were also asked whether they would recommend the Math.Researcher program. It is noticeable that the students who would recommend the program to friends and other students (values of 4 and 5) show a significantly higher identification with the Math.Researcher dimensions. The correlation of students' (P) and (Dim) is low but highly significant ( $r = .43$ ).

In order to answer the question whether the dimensions are well established (1) the dimensions have also been considered separately. The analysis revealed that the dimension "working with researchers questions" (RQ) could not be identified separately. Items of this dimension (RQ) were assigned to the dimension "using the Math.Researcher principles" (MRP) or the dimension "acting as a learning guide" (LG). That's why in the following (RQ) is not included.

N=20	MRP	OC	LG	VM	RQ
<b>M</b>	4,26	3,56	3,99	4.43	-
<b>SD</b>	0,43	0,43	0,33	0,41	-

**Table 5: Mean and standard deviation of the teachers' M.R dimensions separated (1= do not agree at all, 5= totally agree)**

The dimensions "using the Math.Researcher principles" (MRP) and "visualizing mathematics" (VM) were high and homogeneously rated (Table 5). The identification with the dimension "opening the classroom" (OC) is the lowest. This assumption gets strengthened by the students' data. In interviews they were asked to characterize Math.Researcher lessons by conspicuous features. Compared to the teachers who are familiar with the dimensions, the students have not been educated in the Math.Researcher dimensions. Features belonging to the dimension (OC) with its main elements

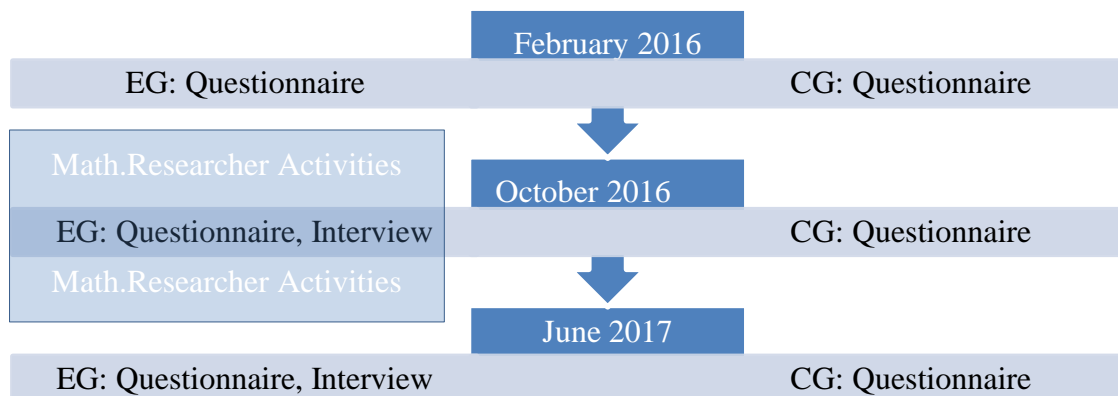

“interdisciplinary instruction”, “inviting experts” and “outdoor lessons” were only rated by 10 % of the interviewed students. Features belonging to the dimensions (MRP), (LG) or (VM) were more often mentioned noteworthy.

## Discussion

In summarizing these results we can say that the dimensions are well established (1). During the interviews the teachers often answered that the Math.Researcher program became more structured and concrete since the dimensions were introduced. They reported that the dimensions made them more certain about their planned lessons.

We can also say that a dynamic view on mathematics is more predominant if the participants identify with the Math.Researcher program (2).

However, the pilot study gives no data about a sustainable impact of the Math.Researcher program. So the researched questions of the evaluation of the pilot study were reused and extended into a main study. The main study still wants to investigate whether the dimensions are well established (1) and which view on mathematics is connected to the participants’ identification with the Math.Researcher program (2). Additionally, the main study wants to find out whether taking part in the program influences the students’ or the teachers’ view on mathematics (3). This third question is similar to previous research questions, for example of Cooper and Touitou (Cooper, Touitou, 2013). They wanted to find out, which beliefs can be found and how these identified beliefs change during a one-year PD course.

**Figure 4: Three survey periods**

The program-region Heilbronn-Franken joined in the Math.Researchers program in December 2015 and started activities in February and March 2016. Three survey periods from 02/2016 to 06/2017 are planned: one before, one during and one after taking part in the program (figure 4). The experimental group (EG) fills in a questionnaire in all of the three periods. In addition, teachers and students of the experimental group get interviewed in the second and third survey period. The control group (CG) gets the same questionnaire as the experimental group in all the three survey periods, but the control group will not be interviewed. If the control group and the experimental group show the same results at all of the three times of measurement, it is not possible to attribute any influence on the view on mathematics to the Math.Researcher program.

The questionnaires of the pilot study were shortened with the help of factor analysis and expert ratings. Items that were rated clearly by the experts, items with loadings exceeding ,39 and some

items of special interest stayed in the questionnaires. For example, the students' questionnaire had 79 content-related questions in the pilot study. Their questionnaire in the main study only has 29 content-related questions.

The next step is the second survey period in October 2016. First comparisons to the results of the first survey period and further details of the pilot study will be presented at CERME 10 in Dublin.

# Factors influencing the developing effectiveness of early career teachers' mathematics teaching – initial findings

Alison Godfrey

University of Leicester, United Kingdom; [ag384@le.ac.uk](mailto:ag384@le.ac.uk)

*Early career primary school teachers in the UK enter a varied and complex situation in terms of professional development opportunities and support for their ongoing career progression as teachers of mathematics. Literature suggests that the professional development a teacher receives impacts on both their subject knowledge for teaching and their beliefs and attitudes to the subject. This multiple case study looks to fill gaps in the research undertaken in this area through detailed analysis of the personal perspectives of the participants over a two year period. This paper reports on the initial findings of a comparative analysis of the trajectory of two teachers to date. These teachers were in seemingly similar contexts for their first year of teaching, yet had very different experiences and held very different perspectives on their development.*

**Keywords:** Teacher characteristics, professional development, elementary school mathematics.

## Introduction

Students start a primary teacher education course in England with a range of qualifications in mathematics, a range of experiences in school mathematics and a range of attitudes and beliefs about the subject. During the course student teachers develop their subject and pedagogical knowledge and gain experience in mathematics teaching. They then enter a complex and changeable situation in schools in terms of provision for their ongoing development (Advisory Committee on Mathematics Education, 2013). Using a multiple case study approach, the aim of this study is to gain a deeper understanding of how the effectiveness of early career primary school teachers' mathematics teaching develops and what impacts on this, with a particular focus on each teacher's own perspective.

## Theoretical background

The notion of effectiveness as applied to mathematics teaching is complex and ideas vary about what this looks like and even what its impact should be (Cai, 2007). Although generally agreed that teaching can only be considered effective if there is an impact on those being taught, i.e. effective teaching leads to effective learning and gains in understanding (Bryan, Wang, Perry, Wong, & Cai, 2007), the notion of 'understanding' is complex. Skemp (1976) made a clear distinction between instrumental understanding, simply knowing rules and procedures at a shallow level, and relational understanding which enables pupils to build conceptual schemas. Most mathematics educators agree that this second type of understanding is the most desirable and teachers internationally agree that an indicator of mathematical understanding is that pupils can use this understanding to problem solve flexibly in a range of situations (Byran et al., 2007). The significance of understanding the connected nature of mathematics is very apparent (e.g. Askew, Brown, Rhodes, Johnson, & Wiliam, 1997) and is consistent with the notion of relational understanding. The concept of effective learning in mathematics being based on this type of understanding within the context of appropriate intellectual challenge is endorsed by current policy makers and teacher inspection systems in the UK (Department for Education (DfE), 2013; Ofsted, 2012) and is the definition used in this study.

The literature suggests that teachers' effectiveness is impacted by their subject knowledge and by affective dispositions including beliefs, attitudes, motivations and emotions. Definition of these constructs are debated in the literature and indeed there are a range of ideas as to how they overlap and directions of influence (Lewis 2016). In agreement with Hannula (2011) I consider beliefs are both cognitively and affectively situated. As a starting point for discussions of attitude and emotion, I am adopting the three dimensional model of attitude from Di Martio and Zan (2010): emotional disposition towards mathematics, vision of mathematics (relational/instrumental) and perceived competence in mathematics.

Many studies, e.g. Ernest (1989) and Askew et al. (1997), have looked at teachers' beliefs about the nature of mathematics and the impact these beliefs have on their teaching. Ernest (1989), for example, argues the most effective teachers see mathematics as a dynamic, creative, problem solving subject and adopt a 'Facilitator' teaching approach.

Teachers' attitudes to the subject, including their emotional disposition, also impact on effectiveness. Particularly in primary teaching, teachers and student teachers find themselves teaching subjects that they have not necessarily enjoyed or been particularly successful at learning themselves. Many feel insecure with their subject knowledge in mathematics and recount their experience of mathematics at school as a subject that caused difficulties and even "real emotional turbulence" (Brown, 2005 p. 21). For many teachers therefore, mathematics is linked with negative emotions, particularly anxiety, and this can impact on their wider attitudes to it. It seems that teachers even protect pupils from mathematics and, in seeking to simplify it, emphasise the step by step procedures that are likely to lead pupils into developing instrumental understanding and potentially negative attitudes (Hodgen & Askew, 2007), reducing their effectiveness.

A further influence on the effectiveness of teaching of mathematics is subject knowledge. Indeed, evidence suggests that the impact of beliefs and attitudes and subject knowledge are interdependent (Askew et al., 1997). Most recent research on teachers' subject knowledge for mathematics uses Shulman's (1986; 1987) seminal papers as a starting point. Others have applied his ideas to mathematics teaching, debated which aspects are most essential and relevant, and sought to measure or evaluate them. Ball, Thames & Phelps (2008) argue that there is knowledge that is specific to teachers of mathematics and that might have an identifiable impact on the effectiveness of their teaching; Specialised Content Knowledge. This includes, for example, the understanding needed to be able to explain procedures, to analyse errors and strategies, and to consider appropriate examples. Baumert et al. (2010) conclude that pedagogical content knowledge (PCK) makes the greatest contribution to pupil progress, but weaknesses in mathematical content knowledge are not offset by greater PCK. Askew et al. (1997) found that it was not the formal qualifications or the amount of subject knowledge that the teachers had which was significant in the effectiveness of their teaching, but rather the connectedness of their subject knowledge "in terms of the depth and multi-faceted nature" of the meanings and uses of concepts in mathematics (p. 69). Other authors highlight the importance of pupil voice and the ability of the teacher to choreograph classroom discourse as key characteristics of effective teaching in mathematics (e.g. Schoenfeld, 2013), and Barwell's (2013) discursive psychology perspective emphasises that knowledge is contextual and can be changed or reconstructed accordingly. There is much critiquing of Shulman's and Ball's ideas but there seems

to be general agreement that the subject knowledge needed for effective teaching goes further than just having a strong conceptual knowledge of the subject being taught.

There is considerable evidence that a teacher's depth of reflection and their beliefs and attitudes towards mathematics are a crucial influence over their trajectory of development (Di Martino & Zan, 2010; Turner, 2008). Hodgen and Askew (2007) and Schoenfeld (2013) suggest that the development of some teachers is hindered by their linking of mathematics with emotion and that, for some teachers, professional development activities and goals should be much more about changes in their beliefs and attitudes than about improving their subject knowledge.

Teachers' work is within a social context, (Levine, 2010), and this can have a significant impact on the nature of a teacher's professional development. The community within the school might have a range of different foci and agendas and there seems to be a wide variation in practice between schools. The very structured collaborative approach to teacher development in China seems high effective although dependent on the considerable time given to teachers to discuss, prepare and analyse their work (Paine & Ma, 1993). In contrast Ball, Ben-Peretz & Cohen (2014) consider that in the US most teachers work in isolation and the potential benefits of sharing good practice are lost. In England, although the need for quality on-going professional development opportunities for primary teachers is recognised and highlighted by Ofsted (2012), the current context is of variable provision in formal professional development (ACME, 2013).

In summary, the literature suggests that a teacher's trajectory as a teacher of mathematics is influenced by the interaction of their beliefs and attitudes, their subject knowledge and the professional development they receive, through both formal education opportunities and personal reflection, and these factors therefore influence the effectiveness of their teaching and the effectiveness of their pupils' learning. My study sits within this theoretical framework and seeks to extend the existing literature particularly though highlighting teachers' own perspectives on this process.

## **Methodology**

A multiple case study approach is being employed to follow the trajectories of a small sample of teachers as they progress into their first two years as a qualified teacher. Four participants were chosen for the pilot study, two with mathematics qualifications beyond the minimum required for primary school teachers in England. An initial interview at the end of their one year postgraduate teaching course focused on their relationship with, and attitude to, mathematics and their progress in teaching the subject as a student teacher. To facilitate discussion, Lewis's (2016) idea of a graphic display was adopted; participants were asked to draw and explain their relationship with mathematics over time. This gave insights into participants' attitudes to mathematics and their perspectives as learners of the subject as well as in their student teacher role. Participants were able to reflect on how their relationship with the subject influenced their current teaching approaches. Twice yearly interviews, including further graphing at the end of each year, and discussion of documentation related to their progress as early career teachers, such as formal observation feedback, provide evidence of their ongoing development as teachers of mathematics. Interview questions have been designed to probe about the participants' beliefs, attitudes and subject knowledge for teaching mathematics, what they perceive to be the characteristics of effective teachers of mathematics and their perspectives on their development as teachers of the subject. Within each interview they also describe two particular

lessons: their chosen ‘best’ and ‘most challenging’ lessons since the previous interview, providing insights into what they consider to be effective and ineffective teaching and their subject knowledge. In addition, they keep records of their professional development in teaching mathematics.

To begin to analyse the data, a mind map has been drawn of each data collection point for each participant. The mind map contains evidence of the participants’ changing context and development as a teacher of mathematics, including both factual and non-factual information, and also the participant’s interpretation and my interpretation of this evidence. The mind maps allow for a thematic approach, enabling identification of concepts and themes such as ‘awareness of self as a mathematician’ and ‘priorities in teaching mathematics’. In regard to their relationship with mathematics and their development as teachers of the subject, the participants have stories to tell and thus narrative analysis techniques are being used to support analysis of these stories. Whilst these techniques have enabled useful analysis of the early findings, the next stage is to further research and develop these analysis methods so that data can be analysed increasingly effectively and efficiently.

## Results and discussion

In this paper the focus is on the early findings of a comparative analysis of the trajectory in the first year of the study of two of the teachers, Gina and Rama (pseudonyms), who in their first year as qualified teachers were in seemingly similar contexts: they both taught children aged 5-6 years in schools with a two class entry, working alongside more experienced colleagues and teaching mathematics to their own, mixed attainment, classes. Rama has a stronger mathematics background and also chose to study a mathematics specialism as part of the teaching course, but both students achieved the highest teaching course grade in all areas of the Teachers’ Standards (DfE, 2011). In their interviews, both were able to identify many ways in which they had evolved as teachers of mathematics to date, but they answered questions in ways that revealed very different perspectives on their development. In addition, their professional development records indicated that they received very different opportunities and approaches to their professional development. This raises questions about why these are so different and the extent to which this is school dependent or dependent on the approach and philosophy of the teachers themselves.

Descriptions of each participant’s relationship with mathematics and how this had evolved over time revealed interesting and complex relationships (Figure 1) and it was clear that past experiences impacted their current thinking. Whilst the graphs drawn are not directly comparable as the interpretation of the vertical scale was left open, the trajectories illustrated and discussion of these provide some scope for comparison. The two peaks in Gina’s relationship with mathematics indicate two different perceived aspects of success in mathematics. Firstly she recalls being successful in the subject in Year 9 (aged 13-14) when she felt she responded well to the high expectations her teachers had of her. The second period of success, during the teaching course, was due to her own development of the conceptual understanding that the literature suggests is essential for learners to gain for long term, secure understanding of mathematics. This enabled her to reflect on her previous period of ‘success’ which she then realised was based on superficial learning:

Gina: I could do the methods, but I didn’t understand them.

**Figure 1: Gina and Rama's relationship with mathematics, drawn at end of teaching course**

Gina's personal experience seems to have given her a particular focus in her own teaching of mathematics, particularly how strategies she is aiming to use in her teaching could prevent the children taking the path of superficial learning that she had followed. Discussing how she developed her teaching in her first few months as a qualified teacher, for example, she identified the use of representations as significant and something that she perceived as missing in her own learning:

Gina: And the pictorial things, definitely. I don't think I've ever done that as a maths learner myself and I think maybe if I had it would have been much more easy.

Rama's mathematical background also seems to have impacted on her priorities in teaching mathematics. Although she finished her studies with a degree where she used mathematics, she finished primary school not enjoying the subject and lacking in confidence. She seems to have been a shy and hesitant learner, fearful of getting the wrong answer in a subject she saw as right or wrong. At secondary school she was initially placed in lower sets but talked with great enthusiasm about her Year 11 class (aged 15/16), a top set, where the environment of the classroom was such that she felt she could make mistakes without fear. She described too a change at this point from memorising how to do certain methods to taking ownership of her learning and finding her own ways of solving problems. Priorities identified by Rama in her teaching include the importance of children enjoying mathematics alongside gaining conceptual understanding, both aspects that for her were missing until the later stages of her schooling.

It seems that Gina and Rama entered two very different teaching communities with different agendas which also impacted on the nature of their professional development (Levine, 2010), and graphs drawn at the end of their first year of teaching revealed very different perspectives on their year (see Figure 2). Rama's saw her journey as a teacher of mathematics as a smooth upward trend, with occasional dips when she taught poorer lessons. Whilst having few formal professional development opportunities, she indicated that she is confident in her own subject knowledge and in independently planning and teaching the subject. Gina described a much more structured and intensive programme with regards to the support she received. However, her graph illustrates her perspective that she has had a sometimes difficult year and narrative analysis revealed, interestingly, that the intense involvement of her school in her professional development seems to have led to a crisis in her confidence and a turbulent second half of her first year of teaching.

**Figure 2: Gina and Rama’s relationship with mathematics during their first year of teaching**

This analysis highlights the emotional impact on Gina of the series of intervention events that followed on from a formal observation of her teaching that she labelled several times as a ‘disaster’, and then her subsequent recovery. In her story particular emphasis is evident of the impact on both the perceived competence and emotional disposition aspects of her attitude (Di Martino and Zan, 2010), with a consequent impact on her confidence in her ability to teach mathematics:

Gina: It seemed no matter what I was doing to change, I was still getting negative feedback and it was disheartening. There was a big period of time when I literally dreaded every single lesson, because you just think “What could happen? I don’t know what I’m doing”

The records of professional development kept by Gina and Rama over the year confirm that Rama’s in school support has been much more informal and she places a high priority on targets she generally sets for herself, seeking to improve the quality of her teaching through a reflective approach (Turner, 2008). In contrast to Gina’s record of events, her record is a series of targets. Contrasts in their priorities in planning and teaching of mathematics, and indications of their subject knowledge have been evident through different ideas about the characteristics of effective teachers and descriptions of their best and most challenging lessons. It seems that both teachers are seeking to teach with a relational approach, with Rama at this stage in a stronger position regarding subject knowledge. It is interesting that end of year assessment information indicates that children in both Rama and Gina’s classes progressed well in their mathematical understanding over the year; this seems to have contributed to Gina finishing the year in a more confident frame of mind.

## Conclusion

The findings of these case studies to date confirm my analysis of the literature in that there are two related and interwoven, but distinct, categories of factors that might influence an early career teacher’s trajectory in relation to the effectiveness of their mathematics teaching - those that are related to the teacher themselves, in terms of beliefs, attitudes and subject knowledge and those that are related to their teaching context. Gina’s experience during her first year of teaching provides a particularly interesting example of professional development that impacts in complex ways on beliefs and attitudes to the subject. Although it is too early to draw more than very tentative conclusions, it is interesting to ponder to what extent Gina and Rama’s trajectories would have been different had they been in one another’s school, and this leads to potential implications for initial teacher education.

These case studies align with current professional documentation (ACME, 2013) to suggest that there is a lack of uniformity in teachers’ professional development experiences despite there being systems in place in the UK promoting uniformity. The existence of these issues has implications for the

preparation of student teachers in Initial Teacher Education (ITE) and suggest that ITE providers could seek to more explicitly discuss differences and similarities in primary school approaches to teacher development and further strengthen their policies of students gaining experience in a range of contrasting placements, within which they can not only participate in whole school professional development events, but also talk with teachers about their development experiences.

# A theoretical framework for analyzing training situations in mathematics teacher education

Claire Guille-Biel Winder<sup>1</sup> and Frédérick Tempier<sup>2</sup>

<sup>1</sup>COPIRELEM, CAFEP-ESPE de Nice Université de Nice, France; [claire.winder@unice.fr](mailto:claire.winder@unice.fr)

<sup>2</sup>COPIRELEM, LDAR Université de Cergy-Pontoise, France; [frederick.tempier@u-cergy.fr](mailto:frederick.tempier@u-cergy.fr)

*The thoughts on the primary schoolteacher training have led to the production of many resources for primary schoolteachers. Faces of the abundance of such documents, teacher educators need some tools to identify the knowledge potentially at stake in training situations and to allow them to implement such situations according to their own objectives and context. We present a five-level analysis framework that characterizes the training tasks, taking account of the activities induced by the task, according to the expected posture of the prospective teacher, to the type of the knowledge at stake and to possible degrees of decontextualization. We illustrate this analysis framework by presenting an example of a training scenario based on the principle of role-play.*

*Keywords: Teacher education, professional development, primary education, knowledge for teaching, analysis framework.*

## Introduction

The research about primary schoolteacher education in mathematics and professional development has led to the production of many resources for educators. In France, the COPIRELEM<sup>1</sup> group produced many of them. These resources provide “training situations” based on various training strategies (Houdement & Kuzniak, 1996), and are generally accompanied with information about their implementation (phases, steps, instructions, elements of institutionalisation) with regard to the stakes of the training. But their quality does not guarantee an accurate appropriation by teacher educators. Our questioning is: how is it possible to help teacher educators to exploit any “training situations” in a relevant way, according to their objectives?

The research literature usually provides studies about knowledge for teaching, teacher conceptions, and their evolution (Shulman, 1986; Houdement & Kuzniak, 1996; Ball, Thames, & Phelps, 2008). Other studies present one training situation, and generally focus on its effect on the prospective teachers. For example Horoks and Grugeon (2015) “analyse the contents and methods of an initiation course in research in mathematics education, and [...] how it can influence the beginner teachers’ practises” (p.2811). To our knowledge, no study focuses on the characteristics of training situations nor provides specific framework in order to analyse any training situation. This led us to develop an analysis framework for training situations. The paper presents this COPIRELEM’s work in progress.

---

<sup>1</sup> The COPIRELEM is a commission dedicated to the education to the primary school. It is stemming from the network of IREM (French institute of research on mathematical education).

## Presentation of the analysis framework

We define a *training situation* as a situation that involves prospective teachers (students, pre-service or in-service teachers) and educators within an institution of teacher education. It is composed of a set of tasks that could be conducted by a teacher educator. We take into account all the tasks proposed by the teacher educator. From a training situation, the educator may elaborate a training scenario that is to say a set of chronologically organized tasks chosen among all the tasks that constitute the training situation. We voluntarily distinguish situations from “scenarios” because we intend to underline the dynamic aspect of the scenario.

In response to each task of a training situation, prospective teachers develop an *activity* that corresponds to “what [they engage] in during the completion of the task” (Rogalski, 2013, p.4). We distinguish five different types of activity: “mathematical activity” (doing maths during the completion of a mathematical task), “mathematical analysis activity” (analysing the maths at stake in a mathematical task), “didactical and/or pedagogical activity” (highlighting didactical and/or pedagogical choices related to the mathematical task), “didactical and/or pedagogical analysis activity” (analysing didactical and/or pedagogical choices related to the mathematical task), “problematisation activity” (identifying and investigating professional issues by mobilizing mathematical, didactical and pedagogical concepts). For each type of activity we take into account three dimensions (Fig. 1): the type of knowledge at stake; the degree of decontextualization of this knowledge; the posture of the prospective teachers expected by the teacher educator. These dimensions are specified in the next sections.

**Figure 1: Three dimensions for characterizing a type of activity**

### Three types of knowledge

We rely on the three types of knowledge for teaching mathematics identified by Houdement and Kuzniak (1996): mathematical knowledge, pedagogical knowledge and didactical knowledge. “Mathematical knowledge corresponds to mathematics that a teacher needs to know in order to prepare, regulate and evaluate his lesson and his students” (Houdement, 2013, p.12). It “includes and specifies the content knowledge” identified by Shulman (1986). It roughly can be related to Subject Matter Knowledge (Ball and *al.*, 2008), and the specific didactical nature of mathematical knowledge can be identified to the Specialized Content Knowledge (SCK). According to (Houdement, 2013), didactical knowledge is linked to the mathematical content and fed by research in the field of mathematics didactics. It corresponds to analysis of teaching and learning phenomenon and to propositions of engineering. Therefore it can be associated with at least two categories (Ball and *al.*, 2008): Knowledge of Content and Students (KCS) and Knowledge of Content and Teaching (KCT).

Pedagogical knowledge<sup>2</sup> is characterised as “knowledge of experience” (Portugais, 1995). It is related to teaching and learning conceptions and to the organisation and management of the class. It is less dependent of the mathematical content than other types of knowledge. It is important to take this knowledge into account because schoolteachers deal with various school subjects.

### Three degrees of decontextualization

Brousseau (1997) and Douady (1985) identify three degrees of decontextualization of a mathematical knowledge: implicitly mobilized, explicitly mobilized in context or decontextualized (to become available in other contexts). We extend this notion to didactical and pedagogical knowledge. A mathematical knowledge is (*implicitly*) *mobilized in context* (in act) if it is used as tool (Douady, 1985) in a mathematical task. This task can be carried out: what is asked is effectively achieved (manipulation, elaboration and writing a solution for example). But the task can only be evoked: it is mentally achieved. A mathematical knowledge is *explicit in context* if its use (as tool) is identified and formulated. At least, a mathematical knowledge is *decontextualized* if it is identified as an object of learning: a status of object is given (by the educator) to the concept used previously as tool, usually during an institutionalisation phase<sup>3</sup> (Brousseau, 1997). The didactical/pedagogical knowledge is *mobilized in context* when the didactical/pedagogical choices are made for the considered mathematical task. It is *explicit in context* during the analysis about the consequences of these choices. At least, it is *decontextualized* when the underlying didactical/pedagogical concepts are highlighted.

### Four postures of the prospective teachers

In conjunction with the teacher trainer’s relationship to the prospective teachers identified by Sayac (2008), we define four specific postures of prospective teachers, which are expected by the educator during a training situation<sup>4</sup>. Prospective teachers are in a posture of *student* relatively to the mathematical knowledge when they have to perform mathematical activity or when they are concerned with the mathematical knowledge of this activity. They are in a *student/teacher* posture when they investigate mathematical tasks for students or students’ works, or when they analyse the conditions of implementation of a task in the classroom. They are in a *teacher* posture when entering in a broader questioning on classroom practices and issues of mathematical learning. Finally, they are in a *practitioner/researcher* posture when they problematize a professional issue related to mathematical learning or teaching.

### Five study levels

In order to analyse a training situation, we define five study levels. To each level corresponds a type of activity, that induces (implicitly or explicitly) a posture of the prospective teacher (expected by

---

<sup>2</sup> According to (Houdement, 2013), Ball’s, Phelps’ and Thames’ typology doesn’t seem to take into account this type of knowledge.

<sup>3</sup> In institutionalisation phase (Brousseau 1997), the teacher gives a cultural (mathematical) status to some knowledge emerging from students’ actions during the situation.

<sup>4</sup> We notice that prospective teachers are not always aware of these postures.

the educator), and that involves different types of knowledge in a certain degree of decontextualization (see Fig. 2).

<i>Study levels</i>	<i>Type of activity</i>	<i>Posture of prospective teachers</i>	<i>Type of knowledge</i>	
			<i>Mathe- matical</i>	<i>Didac- Pedago- tical gical</i>
<b>Level 4</b>	Problematisation activity, related to professional issues classroom practices, learning issues and/or didactical analysis tools)	<i>Practitioner/ researcher</i>	Decontextualized	Decontextualized
<b>Level 3</b>	Didactical and/or pedagogical analysis activity, related to the activity of level 2	<i>Teacher</i>		
<b>Level 2</b>	Didactical and/or pedagogical activity, related to the activity of level 0	<i>Student/teacher</i>		Explicit in context
<b>Level 1</b>	Mathematical analysis activity, related to the activity of level 0	<i>Student/teacher Student</i>	Mobilized implicitly or explicitly in context	Mobilized implicitly in context
<b>Level 0</b>	Mathematical activity (action performed effectively or mentally)	<i>Student</i>		

**Figure 2: Characteristics of the five study levels**

**Level 0.** A task may induce a mathematical activity. This activity can be performed or evoked (mentally performed). The mathematical knowledge is mobilized (implicitly or explicitly) in context. The prospective teachers are in a posture of student (relatively to the mathematical knowledge).

**Level 1.** A task may induce a mathematical analysis activity related to the activity of level 0 when it highlights decontextualized mathematical knowledge and the prospective teachers are in a posture of (learning mathematics) student. In this task, the didactical and/or pedagogical knowledge can be implicitly mobilized in context and then initiates the change toward a student/teacher posture of prospective teachers.

**Level 2.** A task may induce a didactical and/or pedagogical activity related to the activity of level 0 when it corresponds to the analysis of implementation conditions - actual or anticipated only of the mathematical task. The didactical and pedagogical knowledge is explicit in context. The prospective teachers are in a student/teacher posture.

**Level 3.** A task may induce a didactical and/or pedagogical analysis activity related to the activity of level 2 when it is for example a questioning on classroom practice (specific learning tasks, professional actions...) or on issues of mathematical learning for one or several contents (curriculum, progressions...), or even a highlighting of didactical analysis concepts (didactic situation phases, types of tasks...). This analysis leads to the decontextualization of didactical and/or pedagogical knowledge. The prospective teachers are in a posture of teacher.

**Level 4.** A task may induce a problematisation activity when it corresponds to the problematisation of professional issues related to classroom practices, learning issues and/or didactical analysis tools.

The prospective teachers are in a posture of practitioner/researcher, especially when it comes to developing an analysis methodology of this issue and to infer results.

Each study level is based on the study of the activity of previous levels and involves some mathematical, didactical and/or pedagogical knowledge. The change from study level  $n$  to study level  $n + 1$  is linked either to a change of the prospective teachers' posture or to a change of degree of decontextualization for at least one type of knowledge (from implicitly mobilized in context to explicit in context, from explicit in context to decontextualized). But the different activities induced by a training situation don't usually appear in a chronological order (from level 0 to level 4). For examples, see the analysis of various training situations developed in French context by the COPIRELEM group (Guille-Biel Winder, Petitfour, Masselot & Girmens, 2015; Bueno-Ravel and al., 2017). We think that the analysis could be extended to situations based on different training strategies. That is why we present here the analysis of a training scenario based on the principle of role-play developed in an international context (Lajoie and Pallascio, 2001; Lajoie and Maheux, 2013; Lajoie, accepted).

## **An example of use of the analysis framework**

### **Definition of role-play**

As Lajoie and Pallascio (2001) state "role-play involves staging a problematic situation with characters taking roles". It is used over many years in mathematics education course in UQAM (University of Québec in Montréal) and is organized as follows:

First, the 'theme' on which students will need to role-play is introduced (introduction time). Second, students then have about 30 minutes to prepare in small groups (preparation time). Third comes the play itself (play time), where students chosen by the educator come in front of the classroom and improvise a teacher-student(s) interaction (sometimes, like in the case reported here, involving the whole class). Finally, we have a whole classroom discussion on the play (discussion time). (Lajoie, accepted)

We designed a role-play on the teaching of proportions based on a problem from a textbook. We use the analysis framework to illustrate an example of analysis aimed at highlight the potential of this situation.

### **An example of role-play**

The role-play presented below is intended for pre-service schoolteacher education. We describe the different phases.

*Introduction time.* The educator distributes to prospective teachers an excerpt from a fifth grade (10-11 year old pupils) handbook presenting a problem of proportions (Fig. 3), and various productions of pupils. The teaching issue announced by the educator is the following: to manage a class discussion about the pupils' strategies and about their ideas and solutions, in order to share them in the class community and to determine their validity and efficiency.

*Preparation time.* The prospective teachers have to prepare the discussion class about the pupils' strategies.

*Play time.* At the end of the preparation time, the educator chooses prospective teachers to play the game: some of them play pupils, one of them plays the teacher, while the others are watching the discussion class and taking notes.

*Discussion time.* The debate intends to highlight and to analyse the choices of the « teacher » during the play game: what worked well during the implementation of the discussion class? What was difficult? What seemed to be important? What alternative implementations could be realized?

*Institutionalisation time*<sup>5</sup>. The educator institutionalizes the knowledge at stake: he generalizes some elements about how to manage a discussion class or about proportion problems solving.

**Research**

**Some chocolate for everybody**

Here is the part of chocolate taken by each child:

Figurine

Millie

Logix

Decimus

1. How much weights the part :  
a. of Figurine?      b. of Millie?
2. How much weights the part :  
a. of Logix?        b. of Decimus?
3. How much weights the remaining part  
of chocolate ?

**Figure 3: A proportion problem**

### Analysis of this role-play

The initiating task is a professional situation and corresponds to a level 2 activity: the prospective teachers are initially in a student/teacher posture. But they will need « to go down » to a student posture and « to go up » to a teacher posture during the phases of the scenario. The preparation time of the discussion class leads the activity of the prospective teachers “to go back and forth” to the study levels 0, 1 and 2. The problem solving corresponds to a level 0 activity and the mathematical analysis of the problem solving to a level 1 activity. Moreover there are various strategies to solve this proportion problem. Preparing the discussion class of the pupils’ strategies (level 2 activity) hence needs to analyse and rank them (from the least to the most elaborate). This analysis corresponds to a level 2 activity. The prospective teachers don’t have the same activity during the playtime. The study level is different according to the role to play: mostly levels 0 and 1 for the students’ roles and level 2 for the teacher’s role. The discussion time corresponds to a level 2 activity when the prospective teachers analyse how the discussion class has been managed. But it can also correspond to lower levels activities, when they discuss about pupils’ strategies, difficulties, mistakes and their exploitation during the discussion class. Various institutionalisations can be considered, according to the knowledge that was developed at different study levels. The institutionalized elements will be more or less developed according to the teacher educator’s objectives and progression, the prospective teachers’ knowledge, etc. Here are some propositions organized in ascending order of study levels. The teacher educator can institutionalize some

<sup>5</sup> We add this new time to the four ones proposed by Lajoie and Pallascio (2001).

Proceedings of CERME10

2881

mathematical knowledge at stake (level 1) and related to the proportionality field: various methods to solve a proportion problem, mathematical justifications and mathematical theories they are relied on. He can situate the proportion problems in the more general category of multiplicative problems, or he can explicit some didactical variables usually at stake in proportion problems (level 3). He also can identify some difficulties or mistakes revealed by the pupils' productions as « usual » and highlight mistaken conceptions: identification of quantities, choice of an adapted strategy, persistence of an « additive model », etc. At least, in regard of the announced objective of the role-play, the teacher educator also can institutionalize some didactical knowledge, relatively to the organization of a discussion class (level 3): formulation and validation in mathematics; teacher's tasks before, during and after the discussion class...

## Conclusion

The example of role-play situation shows how the analysis framework can be a tool for an *a priori* analysis. Moreover this example shows that the organization of the study levels is not a chronological but a hierarchical one: the initiating task can induce an activity of level 0, 1, 2, 3 or 4. But the transition to lower levels activity is often necessary. The conceptual maps of the knowledge for teaching developed by Houdement and Kuzniak (1996) or by Ball and *al.* (2008) have a descriptive, predictive and prescriptive dimension (Ball & *al.*, 2008, p.405). But beyond their interest, (Houdement, 2013, p. 21) stressed the importance of the knowledge reconfiguration in connection with the mathematical content. The analysis framework reports how, during a training situation, the types of knowledge for mathematics' teaching are dynamically hinged to one another in connection with the mathematical content. The analysis framework allows teacher educators to identify the potentialities of a full range of training situations. We intend to extend its use to study other types of training situations (for example e-learning situations). By clarifying the stakes of the various phases of the implementation, the analysis framework reveals various possible strategies for the teacher educator. Thereafter it could be a useful tool for elaborating different training scenarios. Hence, the teacher educator should be able to implement situations in a specific context according to his objectives and constraints (time and period of training, place in a progression which take into account the mathematical, didactical and pedagogical knowledge ever studied...). Besides it is possible to consider a sequence of successive scenarios. The analysis framework could also highlight various possible "training paths", which should reveal the educator's training strategy at a more global scale. A perspective is now to study how teacher educators appropriate this framework and how it supports their teaching practises.

# Changes in beliefs of teachers on a PD course after reflecting on students' learning results

Hahn, Thomas and Eichler, Andreas

University Kassel, Germany; [thahn@mathematik.uni-kassel.de](mailto:thahn@mathematik.uni-kassel.de), [eichler@mathematik.uni-kassel.de](mailto:eichler@mathematik.uni-kassel.de)

*In this paper, we discuss results of a qualitative part of a research project aiming to investigate the impact of a professional development course with a specific focus on reflecting of students' learning results on teachers' beliefs towards teaching and learning of mathematics. We refer briefly to some aspects of teachers' professional development. Afterwards, we discuss teachers' beliefs as the main theoretical construct for our research. Data for this paper about teachers' beliefs were collected by semi-structured interviews with three teachers after the professional development course. Results show that teachers report in interviews changes referring to teaching and learning of mathematics from a transmission-oriented view to a more constructivist-oriented view.*

**Keywords:** Beliefs, belief change, professional development, reflecting students' learning results.

## Introduction

There is a consensus that university studies and internships are not enough to prepare future teachers for all challenges in their professional career (Mayr & Neuweg, 2009). For this reason, professional development (PD) is understood as being a key factor for innovating and reforming mathematics teaching in school (Garet et al., 2001). However, every change seems to be dependent on specific characteristics of PD: Desimone (2009) summed up five key features of high quality teacher PD. She described that PD will be effective, if a PD course is content-focused, enables active learning, is coherent, has a critical duration and if teachers take part in a PD course collectively. In addition, Franke et al. (1998) reported that reflecting students' learning results makes teachers' learning sustainable. Reflecting students' learning results means, that teachers collect in distance phases of a PD course students' results when working in a specific learning environment or working on a specific task developed in the PD course. Afterwards these students' learning results were the basis of the next face-to-face meeting in the PD course.

Although research identified several features of PD, in most cases the effectiveness is not clear (Yoon et al., 2007). In addition, it is not clear how they influence teachers' learning. For example, Franke et al. (1998) could show that a mix of several characteristics including reflecting students' learning results is effective for teachers' learning, but they did not focus on reflecting students' learning results as a single variable. In a qualitative design, for example also Strahan (2003) found that teachers reflecting on students' learning results increased students' achievement on elementary school level. In addition, Schorr (2000) showed that students' achievement increases when teachers completed a PD including the analysis of students' problem solving processes. Like a conclusion, Little et al. (2003) state that reflecting students' learning results has the potential to bring students more explicitly into deliberations of teachers. However, more research is needed to understand how teachers learn from reflecting students' learning results and whether it impacts on teachers' professional competence including particularly teachers' beliefs.

To investigate the efficiency of reflecting students' learning results in PD courses on the teachers' knowledge, beliefs or motivation, the study as a whole considers two PD courses with a quasi-

experimental setting. Content, teacher trainer and learning time were mostly the same in both courses. However, we integrated reflecting students' learning results in the first PD course, but not in the second. In this paper we will not refer to quantitative results of our research that we reported elsewhere (e. g. Hahn, & Eichler, 2016). We further do not refer to differences between the effects of the two PD groups, but we emphasize results of a qualitative interview study including three teachers of the PD course with reflecting students' learning results. In these interviews, we primarily refer to the teachers' beliefs concerning the teaching and learning of mathematics.

## **Beliefs about teaching and learning of mathematics**

Beliefs can be defined as “psychologically held understandings, premises, or propositions about the world that are thought to be true. [...] Beliefs might be thought of as lenses that affect one's view of some aspect of the world or as dispositions toward action.” (Philipp, 2007, p. 259).

For our research a crucial question is whether beliefs could be viewed to be stable or changeable. Partly, researchers use stability as a part of their definition of beliefs (Fives & Buehl, 2012; Liljedahl, Oesterle, & Bernèche, 2012). In contradiction to that, there are studies which demonstrate belief change by a special intervention. For example, Decker, Kunter, and Voss (2015) reported changes referring to teaching and learning of preservice teachers and teacher trainees. Liljedahl et al. (2012) analyzed related literature and conclude that there is a different meaning of stability in research studies. As a result, they propose to avoid stability in the definition of beliefs. For them, belief change is a natural process that requires a sufficient extent of time. For this reason, in this research study beliefs are described as changeable.

A further crucial question concerns the definition of the belief object that should be changed by PD. Beliefs can refer to a special subdomain of mathematics (Eichler & Erens, 2015), to mathematics itself, teaching and learning of mathematics or an overachieving orientation that is independent from a subdomain (Staub & Stern, 2002). Beliefs referring to teaching and learning of mathematics can be divided into two paradigms: the transmission-oriented and the constructivist-oriented view of learning (Fives, Lacatena, and Gerard, 2015). Transmission-oriented beliefs of teaching imply that knowledge is directly transmitted from teacher to the learners and learners absorb all information. In this case, learners are passive recipients. For this reason, teachers' role is to prepare all information for students to enable an effective storing and an optimal recall. In contradiction, the constructivist-oriented view of learning reflects the active role of learners as constructors of their own knowledge structures. In this case, students learn new information based on their existing knowledge and beliefs to enable an integration of information in their mental networks (Decker et al., 2015; Staub & Stern, 2002). For this reason, teachers take a role as constructor of learning environments that enable students to learn self-directed. Voss, Kleickmann, Kunter, and Hachfeld (2013) proposed evidence that these two dimensions are not the endpoints of a continuum. Instead of this, the authors proposed to understand these two dimensions as two distinct, negative correlated dimensions. These dimensions can be assessed on different scales. For this reason, it is possible that teachers have a high extent of both views on teaching and learning of mathematics.

Based on the definition of beliefs and the two main aspects of beliefs for our research, we primarily focus on the following research question:

Which influence show the PD course with reflecting on students' learning results on teachers' beliefs referring to teaching and learning of mathematics out of teachers' perspective?

## Methods

We regard three groups of teachers in our study as a whole. Two groups of teachers were enrolled in a PD course that focused on problem solving and modelling in secondary school. An ongoing task for both PD courses was to develop tasks that meet different criteria of problem solving and modelling. The first group further was asked to give these tasks to their students and to collect the results of students' work that we call results of students' learning. These results of students' learning were the basis of the next face-to-face phase of the PD course. Teachers of second group were asked to improve problem solving tasks and a third group of teachers did not get any intervention.

We conducted pre- and posttests to measure the efficiency of the mentioned specific aspect of teachers' PD, i.e. reflecting students' learning results. Further we conducted interviews with the teachers. In this paper we regard three teachers of the first group who took part in the interview session voluntarily. The interviews took place about one month after the last meeting of the PD course. In semi-structured interviews the teachers were asked to report about their changes towards beliefs of teaching and learning of mathematics. All teachers are teachers of upper secondary schools and at the age of 40 to 50 and were women. These teachers could be representative for the whole group, because it consists of 21 teachers at the mentioned age. In addition, seventeen of these teachers were women.

We analyzed the interviews with a coding method including deductive and inductive codes (Mayring, 2015). The deductive codes were based on existing research referring to teaching and learning of mathematics considering the transmission-oriented and the constructivist-oriented beliefs. According to both types of beliefs, we created codes for teachers' answers. In this context, we distinguish between teachers' beliefs before and after the professional development course. The distinction is based on hints in teachers' statements which enables us to match beliefs to the appropriate point in time. In addition, we analyzed the role of "reflecting students' learning results" for teachers' learning during the PD course.

## Results

The results section is structured into three parts. At first, we want to show how teachers' statements are coded according to beliefs about teaching and learning of mathematics. Second, we sum up beliefs of the three teachers. And third, the effects of "reflecting students' learning results" are considered.

In the interviews teachers were asked to report about their beliefs before and after taking part in the professional development course. In particular, they should consider changes in their statements. For example, Mrs. B states:

Mrs. B: [...] it has changed that the tasks are different. Students should argue more and I do not have to work off stacks of tasks. I can work off all facets more determined and I do not have to say that I must work off a model and then practice, practice, practice  
....

Mrs. B reported about changes in her beliefs about teaching and learning mathematics. We interpreted her statement as follows: At the end of her statement, she mentioned that she now does not have to introduce a mathematical model followed by many exercises in the lessons. Furthermore, she reported

on working off stacks of tasks before the PD course. Both parts of the statement are coded as transmission-oriented beliefs, because she emphasized practicing as repetition of information or procedures which is represented in stacks of tasks. In addition, the mentioned parts of the statement were coded as beliefs at the beginning of PD course, since she reported about changes during the PD (see table 1). In the first part of her statement, she considered a change in tasks and argumentation in her classroom. She also mentioned that she can work off the mathematical ideas more determined. These parts of the statement were coded as constructivist-oriented beliefs, because Mrs. B reported a student centered teaching style where students are asked to argue about mathematical concepts and to talk about mathematical problems with each other (see student-oriented perspective in teaching in table 2). In addition, these parts of the statement were coded as beliefs after taking part in the PD course, because in the whole statement Mrs. B reported about changes. In conclusion, the statement of Mrs. B shows a belief change from a transmission-oriented view to a constructivist-oriented view of teaching.

The three teachers showed similarities in reporting aspects of a transmission orientation and a constructivists orientation. A code that seemed to be crucial for all three teachers, but was not included in the quotation of Mrs. B, was expressed by Mrs. C:

Mrs. C:           Students should do more and I have to restrain myself a little bit more.

We interpret the statement as following: Mrs. C also reported changes in her beliefs. The whole statement was coded as constructivist-oriented belief, because she wanted the students to be more active in her classroom when they are learning mathematics. In addition, Mrs. C reports on restraining herself in lessons. This is in line with the constructivist view, because on this perspective, teachers are creators of learning environments and students shall learn self-directed. For this reason, it is necessary that teachers shall restrain themselves in lessons. This statement was coded as beliefs after taking part in PD course, since “more” indicates that she had other beliefs at the beginning of PD. In particular, the beliefs at the beginning compared to those reported in the statement included that Mrs. C was more in the center of the lesson and students were more passive which are in line with transmission-oriented beliefs.

The results of the analysis of the three teachers’ beliefs showed that they were transmission-oriented before they took part in the PD course. However, they seem to change their beliefs towards a constructivist-orientation during the PD course. The teachers also reported existing constructivist-beliefs they had at the beginning of PD course, but they stated changes towards more constructivist beliefs while they reduced the strength of transmission-oriented beliefs. Table 1 shows the results of coding for beliefs before teachers take part in the PD course:

	Mrs. A	Mrs. B	Mrs. C
repetition of information (practicing)	X	X	X
frontal teaching	X	X	X
exact instruction	X	X	
teacher is in center of lesson	X	X	X

**Table 1: Predominant beliefs before taking part in PD course (mentioned by teachers)**

Teachers reported in the interviews that they changed their beliefs referring to teaching and learning from a teacher-centered perspective to a more constructivist-oriented teaching perspective. The following table shows statements of teachers referring to beliefs of teaching and learning of mathematics after taking part in the PD course.

	Mrs. A	Mrs. B	Mrs. C
active role of students	X	X	X
knowledge construction	X		
teacher withdrawing in lessons	X	X	X
students' discussions are important	X		X
students should analyze own mistakes	X		X
tasks with a meaningful context within real life			X
cooperative learning (group work, ...)	X		X
student-oriented perspective in teaching		X	
pool of teaching methods		X	X

**Table 2: Predominant beliefs after taking part in PD course (mentioned by teachers)**

Both tables show different beliefs of teachers before and after the PD. These tables do not imply that all teachers had only teacher-centered beliefs at the beginning of the PD. They reported also that they had constructivist beliefs. For example, the statement of Mrs. C shows that she has more constructivist beliefs about teaching. This does not imply that she has not had constructivist-oriented beliefs at the beginning of the PD course. In her statement, Mrs. C only reported about more constructivist-oriented beliefs after taking part in PD. In addition, all the coded statements show that they also have transmission-oriented beliefs after PD course, but they report to think of teaching with more student-centered beliefs. Note, both tables only show predominant beliefs of teachers before and after PD. For this reason, peripheral beliefs about teaching and learning of mathematics are left out.

The results about beliefs show changes. For this reason, we want to know how reflection of students' learning results impact on teachers learning. In this context, Mrs. A and Mrs. C state:

Mrs. A: [...] I have learnt a lot about my students and I have also learnt a lot about myself and for this reason I have tested some things.

Mrs. C: I think it was good. The students' learning results show how other teachers proceed in teaching, which approach they use and how they describe. Within this action, you could take new ideas that I found in students' solutions. [...].

The statements of the three teachers show that "reflecting students learning results" were used to reflect the own practice of teaching. In this context, these teachers learnt about characteristics of their students and about themselves as teachers. As a consequence, Mrs. A tested some ideas contained in the PD course. In addition, the three teachers recognized other teaching styles when they reflected on students' learning results. For this reason, they also reflected about the practice of other teachers and their teaching approaches. In particular, they also reflected about their own practice compared to the

one of others to get new ideas (Mrs. C). These statements are typical for all three teachers. According to this, the reflection of teaching style could be understood as one factor that result in changes of beliefs about teaching and learning.

## Discussion

The data from the interviews indicate that the three teachers changed their beliefs from a more transmission orientation to a more constructivist orientation of teaching and learning of mathematics. This is shown by statements of teachers after taking part in the PD course. The phrases in both tables consider the aspects of both beliefs about teaching and beliefs about learning. Based on the analysis in the results section, statements of table 1 refer to transmission-oriented beliefs and statements of table 2 to constructivist-oriented beliefs (e.g. Fives et al., 2015). In fact, teachers focused on constructivist-oriented beliefs, but they still expressed some transmission-oriented beliefs. This is in line with research findings of Voss et al. (2013), who supposed that both types of beliefs can co-exist. The statement of Mrs. C supports this assumption. Although she expressed transmission-oriented beliefs before the PD, she said that students should be more active, which indicates that she has had constructivist-oriented beliefs at the beginning of the PD.

Belief changes in teacher education are also shown in the study of Franke et al. (1998) for teachers on primary level who examined a student-centered framework in their PD. In this context, our results are similar to those of Franke et al. on secondary level, because we also used reflecting students' learning results to emphasize student-centered teaching. Furthermore, the teachers reported that they used students' solution to reflect their own teaching and to get to know information of other teachers' approaches and also about their students. This is in line with the results of Little et al. (2003), because teachers consider the ideas of their students in their deliberations more strongly after taking part in the PD course. In addition, belief change caused by reflection is reported by Decker et al. (2015) in the way that there is a relationship between the extent of reflection and teachers' belief change. For this reason, it is possible that all teachers of this study changed beliefs because they reflect intensively about their own practice. Skott (2015) stated that substantial new experiences are necessary to change beliefs. Concerning our research, we hypothesize that the intensive reflection of the own classroom practice includes the mentioned new experiences.

There are some limitations of this research. At first the interviews took place after the whole PD course. For this reason, teacher reports about the practice before the PD course can be influenced by the experiences of the PD. For a more precise research approach it would have been necessary to interview the teachers at the beginning of the PD. Considering the external circumstances in this research project, it was not possible to interview teachers, because they took part in PD voluntarily and the first meetings last about the whole day. In addition, these qualitative data provide no proof for "reflecting students learning results" as a feature of effective PD, but there are hints that beliefs can change and teacher reflect their own practice during this part of PD. Furthermore, the teachers of the second group were not interviewed. For this reason, it is not possible to indicate whether the teachers of the second group also changed their beliefs. In addition, we do not know whether second group teachers reflect on their own practice as deep as teachers of the first group.

## Future research

This part of the whole research project considers qualitative data of the first PD course. Future research should use also quantitative data (measured by items of Staub & Stern (2002)) to support the results of teachers' belief change during PD. This could also show whether reflecting students learning results is one element that is connected with teachers' belief change empirically. In addition, it is necessary to link the qualitative data analyzed in this paper and the quantitative data which will we analyzed in the future. Combination of both resources can show the positive impact of reflecting students' learning results on teachers' knowledge, beliefs and motivation.

## Shifting frames - A teacher's change towards explorative instruction

Einat Heyd-Metzuyanin

Technion, Israel Institute of Technology, Israel; [einat.metz@google.com](mailto:einat.metz@google.com)

*The case of one middle school teacher's change in practice is examined through the lens of "shifting frames" from ritual to explorative instruction. These frames are collection of coherent mathematical as well as subjectifying (people-related) meta-rules. The teacher, who participated in a year-long PD program, started out in a ritual frame and gradually shifted to a more explorative frame. The shift was not uniform, and could be seen first in the subjectifying meta-rules, and only later (and very partially) in mathematical meta-rules of exploring objects. In addition, newly learned practices were partially distorted through the old ritual frame.*

*Keywords: Mathematics instruction, professional development, frames, explorative practice.*

Classrooms where students engage in explorative mathematical learning produce more robust, conceptual learning, and more positive mathematical identities (Schoenfeld, 2014). Despite these findings, teaching in the US and worldwide still provides mostly opportunities for ritual participation, where learning is made up of reciting procedures and facts (McCloskey, 2014; Resnick, 2015). Efforts at changing mathematical instruction, have shown ritual instruction is difficult to change (e.g. Santagata, Kersting, Givvin, & Stigler, 2011). However, the complex processes of change that do occur in teachers' practice, in the context of certain professional development (PD) programs, have largely remained obscure, perhaps because of the lack of theoretical frameworks for examining such complex processes. In this study, I offer the concept of "frames" for tracking subtle changes in one teacher's practice over a period of a school year.

### Theoretical background

I take as a starting point Sfard's (2008) view, that the gist of mathematical activity, both in the classroom and over history, is the construction and exploration of "mathematical objects." These discursive objects, like numbers, triangles, and functions are not existing objects in the physical world, yet the "metaphor of object" is used by any skilled mathematician to talk about them as though they were indeed such physical objects. Mathematical objects can have many realizations, or physical symbolic representations. A function, for instance, can be represented as a graph, a table, an algebraic expression or a verbal statement. In the process of learning, according to Sfard, students come to see all these realizations as signifying one object. Once they do that, they start talking about it as an object existing of itself, a process termed "objectification."

Within this view, Sfard and Lavie (2005) theorize the process of mathematical learning as moving from a ritual, peripheral phase, where activity is first and foremost aimed at pleasing the experts of the discourse (e.g. the teacher), to an explorative phase where new mathematical narratives are produced by oneself for the sake of the activity itself. In contrast to explorative participation, the focus of ritual participation is activity itself, not the mathematical narrative produced by it. Ritual participation is often characterized by *syntactic mediation*, where instead of using mathematical signs as signifiers of objects, these signs are manipulated according to prescribed (often memorized) rules.

Ritual and explorative participation are governed by certain meta-rules or “patterns in the activity of the discursants” (Sfard, 2008, p. 201). These rules can be divided into mathematical meta-rules, which dictate how mathematical narratives are to be derived from each other (for example, by proof or by computation) and *subjectifying* meta-rules which govern the actions of people (e.g. asking questions, giving directions, talking with each other). To capture the fact that meta-rules have a certain structure and coherence, Heyd-Metzuyanim, Munter & Greeno (in review) suggested the term “frames”, borrowed from socio-linguistic and socio-cognitive research to describe “a set of expectations an individual has about the situation in which she finds herself that affect what she notices and how she thinks to act” (Hammer, Elby, Scherr, & Redish, 2005, p. 9). Accordingly, they defined “frames” in mathematical classrooms as a set of meta-rules, both mathematical and social, which includes appropriate questions, answers, justifications and other discursive actions in a situation of solving a mathematical problem or performing a mathematical task. Whereas frames of explorations would be sets of meta-rules that cohere around the goal of producing mathematical narratives based on logical justifications, ritual frames would be more aligned with goals such as performing a procedure accurately according to a prescribed set of steps, and adhering to external authority.

## Method

The case of Mr. M is taken from a larger study, where we followed 7 teachers and 5 teacher leaders throughout 8 months of professional development (PD) during 2014 – 2015. The PD was led by Margaret Smith and Victoria Bill from the University of Pittsburgh. It centered on Smith & Stein’s (2011) “5 Practices for Orchestrating Productive Mathematics Discussions” and on Accountable Talk™ (see [http://ifl.pitt.edu/index.php/educator\\_resources/accountable\\_talk](http://ifl.pitt.edu/index.php/educator_resources/accountable_talk)). Teachers were supported via four full-day PD sessions and in-school individual coaching sessions.

Mr. M was chosen for closer inspection because he showed a steady growth in the “implementation” score of the Instructional Quality Assessment tool (Boston, 2012), used in the larger study (Heyd-Metzuyanim, Smith, Bill, & Resnick, 2016) to score lessons for cognitive demand. Mr. M’s lesson 1 scored a 1, lesson 2: 2, lesson 3 & 4: 3 (where 4 is highest). Though his lessons never achieved the highest level of cognitive demand, in the last two lessons cognitive demand was partially preserved.

Data collection included four cycles (September, December, February and May), each containing: 1. Pre-lesson and post-lesson interviews with the teacher; 2. Lesson recording and students’ worksheets. Frames of mathematical instruction were searched in four data categories:

(1) The potential of the task to engage students with different realizations of mathematical objects and with mathematical meta-rules of justification and generalizations. (2) Teacher’s plans as collected from the pre-lesson interviews, as well as his post-lesson reflections. In these we looked for evidence of mathematical and subjectifying aspects of explorative frames. (3) Students’ work: evidence of engagement with different realizations of objects and with connecting between them. Evidence for justifications and explanations based on mathematical logic. (4) Whole-classroom discussions: evidence for ritual vs. explorative meta-rules. Is there only talk about routines for manipulating symbols detached from their meaning, or are the symbols also related to mathematical objects?

## Findings

During the first, introductory interview, Mr. M declared himself to be aligned with what may seem to be explorative instruction. Describing quality instruction, he said:

... where groups get together in giving a situation in which they come up with strategies on their own, as opposed to a teacher standing up in front of the room and just saying “okay, this is how you do this, this is how you do this, now just take this problem and solve it”. So ... I keep trying to look for my own stuff that I’m doing, so I would look to see that in other peoples.

Notably, in remarking that such instruction was “my own stuff that I’m doing”, Mr. M attested for practicing quality instruction. To this, he added:

one of my philosophies (is that) there’s never, ever, only one way to solve a problem, that there’s many different strategies and many different pathways you can take to find different problems ...

Mr. M also described his challenges in encouraging students to take on agency and not rely ritually on his guidance.

I would say a majority of the students I’ve worked with over the last 7, 8 years pretty much when they were on a challenging problem, their first shot is to ask me to give them help and guidance along the way. I used to do that more often, ..., so I tried to step back away from that for a moment, getting to know the kids a little bit better helps me understand those that are just being lazy and those that truly don’t know it.

Thus, in his introductory interviews, Mr. M seemed to be well aligned with “reform” mathematical pedagogy, especially with regard to letting students struggle and encouraging them to look for “different strategies” for solving problems.

### Lesson 1

Despite these declarations, the first lesson revealed Mr. M’s actual practices were not well aligned with the explorative frame. For the main task of the lesson, Mr. M chose the task seen in Figure 1:

**Figure 1 - Pythagorean Task given in lesson no. 1**

The task was part of a module that introduced irrational numbers through the Pythagorean Theorem. The EngageNY<sup>1</sup> teacher guide encourages explicitly to present the task only after students had become familiar with this Theorem. The task was taken verbatim from the module, which assumed this previous experience, thus including the “use what you know” phrase. However, Mr. M. was well aware of the fact that his students were probably not familiar with the Pythagorean Theorem. In the pre-conference of the lesson he said:

<sup>1</sup> See <https://www.engageny.org/resource/grade-8-mathematics-module-7>

The first challenge that I'm expecting is that we've not introduced Pythagorean Theorem at all last year. .... Um, I'd like to hear where their conversation goes and what they're focusing on –... when they're trying to find an opposite base, ... given the  $a^2+b^2=c^2$  idea, do they put the numbers in the right place – do they remember the square numbers, do they remember to take the square roots of numbers to get themselves back to what the – the single variable would be? ... So I'm looking to see – what kind of challenges working with square roots and squares creates.

Though Mr. M was anticipating “challenges” in working with the problem (aligned with the PD encouraging letting students struggle), the way he talked about students coping with these challenges was through “remembering”. Thus, meta-rules belonging to the explorative frame (student agency) were distorted through the ritual frame into meta-rules of fact-retrieval, and memorizing procedures.

During the lesson, the launch of the task proceeded as follows:

90. T Okay, so when we take a look at this (*pointing to a right triangle on the board, the sides of which are labeled 'a', 'b,' and 'c'*) I'm going to give you a little bit of a formula. And it may help you today in doing some of your work (*writes  $a^2+b^2=c^2$  on the board*) ... Who can read this out loud for me, please?
- 91.-95. *Three students are prompted to read the formula "in different ways". One reads "a two plus b two equals c two". The second "a to the second power, b to the second power, and b to the second power", the third "a squared plus b squared equals c squared"*
96. T You see, all three of those ways that they said say the exact same thing. ... So when we're looking at this, can you now start to see that knowing two of the three sides will allow me to figure out the third side? ... I'm gonna have you work in groups today to see if you can't use ...any knowledge that you have plus anything that you've seen today. Alright?

The subjectifying meta-rules enacted in this excerpt bore resemblance to explorative frames. Students were asked to provide “different ways” of saying the “exact same thing”, and were directed to “figure out” and “work in groups” to “use any information” they have to solve the problem. Yet the mathematical meta-rules, that is, the ways to derive one mathematical narrative from another, were obscure at best.  $a^2+b^2=c^2$  was written on the board, detached from the right triangle, with no indication of  $a^2$ ,  $b^2$ , and  $c^2$  signifying the geometrical squares adjacent to the triangles sides. By that, Mr. M was treating the  $a^2+b^2=c^2$  Pythagorean Theorem syntactically, as a series of signifiers, detached from their meaning as signifying geometrical objects.

Not surprisingly, since students had no access to the meaning of the Pythagorean Theorem mediated by geometrical objects, they struggled over where to place the a, b, and c labels given by the formula, on the newly presented triangle. After some leading questions from Mr. M. students concluded they should label the base of the triangle as ‘C’ or ‘C<sup>2</sup>’. They subtracted  $9^2-7^2=32$ , but then were unsure as to what to do with that result. Some students thought it should simply be divided between the two halves of the base, labeling the whole base as ‘32’ and halves of it with ‘16’. Others simply labeled the whole base as ‘16’ or went another step and labeled the halves with ‘8’. Only 3 or 4 students, out of 24, figured out that the 32 should be square-rooted and multiplied by 2. However, even they did not label the triangle’s base with the resulting number 11.4 (or estimated 12). The mathematical meta-rules governing the classroom activity were thus primarily ritual. They could be summarized as “apply a set of symbols, somehow related to a right-triangle, to a new triangle”.

It was not that Mr. M was intending students to apply the ‘a’, ‘b’, and ‘c’ symbols randomly. He did have a certain type of reasoning he was looking for. After having asked a student to come to the board and present her solution, and while the student was labeling the triangle sides, he said:

289. T            Yeah, please notice - ... if we looked at that formula -  $A^2 + B^2 = C^2$ , and then I asked this question of some of you: Does it make a difference where  $C$  is? ... (*Student answers  $C$  has to be bigger than  $A$  and  $B$* )
291. T            So if it's bigger than all the other ones, then the question becomes where does the  $C$  have to go - which side?
292. Student    On the longest side.
293. T            The longest side. Now the one misconception I saw that I didn't expect was that some of you thought that this (the base) was the longest side, the whole way across. Just be careful about that, you're focusing on just one of those two triangles, okay?

The meta-rules of the activity, as gleaned from Mr. M's words were thus “figure out where the  $C$  is according to it being bigger than  $a + b$ . Then figure out the longest side and label it as  $C$ ”. However, this was detached from the physical meaning of the Pythagorean Theorem. In relation to the confusion or “misconception” the students had, regarding where to place the  $C$ , Mr. M did not have much advice besides “be careful about that” [293]. There was no other indication why they should be focusing on one of the right triangles, and not the whole triangle.

In the post conference, Mr. M seemed reasonably content with the results of the activity. He explained that since students were unfamiliar with the Pythagorean Theorem, he expected them to struggle, but that that wasn't the focus of the lesson. Rather the focus was discussing imperfect squares, to which they got at the end of the discussion, when one student said 32 should be rooted and Mr. M led students to estimate the root between 5 and 6. Yet having detached the geometric, physical realization of the Pythagorean Theorem from its algebraic formula, the rationale behind the existence of imperfect squares had no way of being foregrounded. The fact that Mr. M was not concerned with students struggling considerably with something that was not “the focus of the lesson”, indicates that through his frame, the whole process of working in groups and discussing solutions was not a central measure for achieving the mathematical goal of the lesson. Rather, it was a sort of a “side effect”, performed for the sake of the lesson recording or for students to practice working in groups.

I now move to a similar examination of the last lesson. A description of the two middle lessons is out of the scope of this paper. However, evidence for movement from a ritual frame to a more explorative frame were starting to show during the 3rd lesson, where Mr M received, together with the rest of the teachers of the PD, a high-level task selected by the PD leaders and directed explicitly on the different solution paths that should be sought in the lesson. Lesson no. 4 seems to have reaped the benefits of this process, though as we shall see, the shift between frames was still very fragile.

#### Lesson 4

The first indicator that Mr. M's practice was starting to align with an explorative frame could be seen in his choice of a task. This task involved modeling of real-life processes with a quadratic equation. Following is the task as presented on the worksheet (taken from [EngageNY, Algebra 1](#)):

The baseball team pitcher was asked to participate in a demonstration for his math class. He took a baseball to the edge of the roof of the school building and threw it up into the air at a slight angle

so that the ball eventually fell all the way to the ground. The class determined that the motion of the ball from the time it was thrown could be modeled closely by the function:  $h(t) = -16t^2 + 64t + 80$ , where  $h(t)$  represents the height of the ball in feet after  $t$  seconds.

Students were then asked to find the behavior of the function (maximum, minimum, vertex), to graph it and to indicate how many minutes passed until the ball fell to the ground and what was the meaning of  $h(0)$ . The task thus had ample potential for using different realizations for a mathematical object – namely the quadratic formula.

The next indication for Mr. M's movement between frames was his talk about expectations for students' work during the pre-lesson interview. This is how he presented the choice for the task:

I've been working on questions ... like "how do you know that that's where your graph crosses the X axis?" So more than just– what is that value, how do you know what it is. How did you figure it out. Um, why does your graph continue past zero? In the context of the problem, what does that mean? ... And try to gain some understanding of their understanding.

Instead of "remembering", Mr. M now talked about students' "understanding". He was also working hard on preparing questions that would assess students' understanding, a skill specifically taught in the PD sessions.

Examination of students' worksheets showed that most students performed the calculations involved in the problem correctly. 4 out of the 27 students wrote that  $h(0)$  indicated the height in which the ball was thrown was 80 feet, and 3 more related  $h(0)$  to the initial stage, before the ball was thrown in the air. Other students, however, either left this question blank, or stated that  $h(0)$  means "the ball is on the ground" indicating incongruence between the physical situation and the graphical realization. Thus, in contrast to the first lesson, there was evidence that a small part of the classroom was able to flexibly move between different realizations of the quadratic function.

During the whole classroom discussion, students' explanation on the board were mostly concentrated on the calculations involved in the problem. Mr. M encouraged this by calling on students to present "different ways to solve the problem" which referred to factoring by dividing the expression by 16 or by 8. He also referred to finding the value of  $h(0)$  by substituting  $t=0$  or by just "looking" at the last term in the equation, as two different ways to find  $h(0)$ . Yet these two "ways" were, in fact, both tending to the algebraic realization and could be considered as "different" only when looking at the function's expression syntactically. There was no mentioning in the whole classroom discussion of the graphical realization of the function or the physical "real life" story modeled by it. It was thus still mostly characterized by meta-rules of carrying out prescribed procedures using syntactic mediation, rather than meta-rules of exploring mathematical objects. However, some slight changes could be observed. One of the students who talked in the whole classroom discussion did, even if very briefly, mention the physical "real life" situation that the function was modelling. He talked about the ball ("the ball hasn't been thrown yet") and hinted at the height of the roof in "throw the ball at 80". Also, there was brief mentioning of the physical realization when Mr. M elicited from one student that the maximum was at "2 minutes".

In terms of social meta-rules, there were many more prompts for students to "restate" what other students have done. Mr. M made every effort to use this talk move, taught in the PD, albeit somewhat inflexibly, whenever a student made a mathematical statement he deemed as important.

## Discussion

In this paper, I have used the concept of “framing” to examine subtle changes in one teacher’s practice over a period of one school year, through which the teacher was receiving support both through PD sessions and through in-school coaching. These changes, including the different aspects of frames, are summarized in table 1.

**Table 1 - Social and Mathematical aspects of frames in two lessons**

	Social (subjectifying) meta-rules	Mathematical meta-rules
Lesson 1	<b>Beginnings of explorative social meta-rules</b> through teacher’s declarations (students expected to persevere, work together). In practice, most of the talking is done by the teacher.	<b>Ritual:</b> Meta-rules only have to do with recalling facts and procedures from memory. Mathematical signifiers are detached from the object they are representing. Students’ work indicates syntactic mediation with no connection to geometrical realizations.
Lesson 4	<b>Explorative social meta-rules are more dominant.</b> Students are asked to restate each other’s ideas. Two students explain their thinking to the whole class. Evidence that some student listen to each other.	<b>Beginnings of explorative mathematical meta-rules:</b> Teacher seeks students “understanding”, not just rule following. A small portion of students’ work indicates connections between multiple realizations of the quadratic function. Still ritual meta-rules in teacher’s discourse still dominate instruction.

As can be seen from Table 1, the shift from ritual to explorative frames in Mr. M’s case was not uniform. The shift occurred first in the social meta-rules and only later in mathematical meta-rules. Also, both shifts seemed to occur first at the level of declarations and only later in practice. Thus, talk about social meta-rules aligned with explorative participation was evident already in the first interview, but enacted mostly in the last lesson. Talk about expectations for explorative mathematical meta-rules was evident in the last lesson pre-conference interviews, and only very slightly evident in the enactment of the lesson. This finding corroborates earlier findings showing that teachers are quicker to adopt declarations about explorative instruction than they are to enact it (Cohen, 2001) as well as our previous findings regarding social meta-rules of teachers trying to enact “dialogic” or “reform” instruction being more aligned with explorative instruction than mathematical meta-rules (Heyd-Metzuyanim et al., in review). Most importantly, the findings reveal that teachers’ learning of new practices is not a matter of acquiring new practices on a “tabula rasa” of non-existing former practices. Rather, at first, new practices are seen through the old frame. As such, they gain unpredictable “twists”, such as perceiving different syntactic procedures as “different solutions” sought after, or encouraging students to restate unimportant mathematical ideas.

# Situation-specific diagnostic competence of mathematics teachers – a qualitative supplementary study of the TEDS-follow-up project

Jessica Hoth<sup>1</sup>,

<sup>1</sup>University of Vechta, Germany; [jessica.hoth@uni-vechta.de](mailto:jessica.hoth@uni-vechta.de)

*Abstract: One main facet of teachers' professional competences is diagnostic competence. While diagnostic competence of teachers becomes relevant in several situations within teaching and learning, this paper focuses on situation-specific diagnostic competence required by teachers within class. In a qualitative supplementary study of the TEDS-Follow-Up project, this situation-specific diagnostic competence is analysed using the video instrument of the TEDS-Follow-Up study. 131 primary level mathematics teachers participated in the primary study of this project and examined specific learning situations in the video instrument. These instances were analysed using qualitative text analysis (Mayring 2015). Results indicate that teachers notice very different aspects in those teaching situations. Two different diagnostic types can be differentiated: content-related and judging diagnostic type versus student-related and action-oriented diagnostic type.*

*Keywords: Professional competences of mathematics teachers, diagnostic competence, mathematics teachers' knowledge, situation-specific skills of mathematics teachers, video study.*

## Introduction

Teachers are faced with many challenges in the context of teaching and learning. In order to plan and to conduct teaching sequences that enable students to achieve their best possible learning results, teachers need several characteristics such as professional knowledge and situation-specific skills. According to Weinert et al. (1990, p.172), diagnostic knowledge is one of the “four areas of knowledge [...] as constituting the cognitive components of teacher expertise” in addition to classroom management subject matter knowledge and instructional competence. With this perspective, this article focuses on the diagnostic competence of primary school mathematics teachers, more precisely on their diagnostic competence that becomes relevant during class – the so-called situation-specific diagnostic competence.

## Theoretical background

Theoretical background of the study is the discussion on mathematics teachers' professional competences, which will be described specifically focusing on their diagnostic competence.

## Professional competences of teachers

According to Weinert (2001), competence involves two main facets: a cognitive facet as well as an affect-motivational facet. The cognitive facet is often differentiated following Shulman (1986, 1987) into (Mathematics) Content Knowledge (MCK), (Mathematics) Pedagogical Content Knowledge (MPCK) and General Pedagogical Knowledge (GPK). Several empirical studies that deal with

Figure 1: Modeling competence as a continuum (Blömeke et al. 2015, p. 7)

teachers' professional competences use this conceptualization of competence (see for example Mathematics Teaching in the 21<sup>st</sup> Century (MT21); Blömeke et al. 2008, Teacher Education and Development Study in Mathematics (TEDS-M); Blömeke et al. 2014 and Cognitive Activation in the classroom (COACTIV) Kunter et al. 2011). In addition to teachers' knowledge, these studies assess affective-motivational aspects such as epistemological beliefs,

motivational aspects and those about the teaching profession (cf. Blömeke et al. 2008, Blömeke et al. 2014, Baumert and Kunter 2011). Thus, cognition and affect-motivation are hypothesized to build the basis of competent performance in classroom situations.

More situated approaches to assess teachers' professional competences are based on models of competence that also include more situated facets such as teachers' perception, interpretation and decision-making that become especially relevant during classroom interaction. According to Blömeke et al. (2015), competence is a continuum from personal traits such as cognition and affect-motivation that underlie and affect situation-specific skills which again determine the actual performance or behaviour in specific situations. Here, the perception, interpretation and decision-making in concrete situations "mediate between disposition and performance" (ibid., p. 7). A content-based specification of this broader concept of competence is the diagnostic competence (Abs 2007).

## Diagnostic competence

Diagnosis and diagnostic tests are usually associated with medicine. Doctors need to diagnose illnesses on the basis of symptoms. However, teachers need diagnosis in their profession as well. They may use diagnostic (clinical or standardized) tests to detect learning disabilities (Ketterlin-Geller and Yovanoff 2009) but they also need to diagnose students' achievements and learning processes during class without using standardized educational or psychological tests. Both described instances require teachers' diagnostic competence. However, we describe the process of diagnosing in the course of teaching and learning as teachers' situation-specific diagnostic competence as opposed to the facet of diagnostic competence that becomes relevant in adequately choosing, using and evaluating diagnostic tests (see Hoth et al. 2016).

For this situation-specific diagnostic competence, teachers' situation-specific skills become relevant as proposed by Blömeke et al. (2015) in their model of competence (see figure 1). On the basis of this theoretical background, the study presented in this paper focuses on the following research questions:

1. How do the perception, interpretation and decision-making of primary mathematics teachers differ?
2. Can different diagnostic types be reconstructed?
3. How do these diagnostic types relate to their professional knowledge regarding the three knowledge facets mathematics content knowledge (MCK), mathematics pedagogical content knowledge (MPCK), general pedagogical content knowledge (GPK)?

To address those research questions, the methodological approach that was used to analyze the data, will be described.

## Methodological approach

The study presented in this paper is a qualitative supplementary study of the TEDS-Follow-Up project (Follow-Up to the international Teacher Education and Development Study in Mathematics, TEDS-M). For the specific purpose of analysing teachers' situation-specific diagnostic competence, the focus of the supplementary study lay on the video instrument of the TEDS-FU study. TEDS-FU, its conceptualisation and design will be described in the following, prior to the outline of the methodological approach that was realised in this specific supplementary study.

### The TEDS-FU study

The TEDS-FU study is the German Follow-Up-study of the international comparative study about mathematics teacher education TEDS-M. A subsample of primary and secondary school mathematics teachers who participated in TEDS-M was reassessed after four years of work experience. A total of 300 mathematics teachers participated in the primary school study, including 131 primary school teachers who are at the focus of this paper. Therefore, the TEDS-FU study analyses the teachers' development in their first years of work experience.

The study is based on an understanding of competence as a continuum (Blömeke et al. 2015, figure 1) and closely refers to research in the field of teachers' expertise (cf. Li & Kaiser 2011) and the concept of 'Teacher Noticing' (cf. Sherin, et al. 2011). In order to assess more situated facets of teachers' professional competences, three situated facets are distinguished in TEDS-FU in addition to knowledge-based facets of teachers' professional competencies (MCK, MPCK, GPK):

“(a) *Perceiving* particular events in an instructional setting, (b) *Interpreting* the perceived activities in the classroom (c) *Decision making*, either as anticipating a response to students' activities or as proposing alternative instructional strategies” (Kaiser et al. 2015, p. 373).

Therefore, different test instruments are used in the study. An online-survey assessed different contextual components such as beliefs, working conditions and school characteristics, a newly developed video analysis instrument assessed teachers' situation-specific skills and a shortened version of the TEDS-M proficiency test was used to assess teachers' MCK, MPCK and GPK. In addition, a time-limited test was included where teachers had to identify typical student errors (see Pankow et al. 2016).

With the aim to analyse teachers' situation-specific diagnostic competence, all tasks were focused from the TEDS-FU primary school study that required situation-based diagnostic competence. This was ensured by the video analysis test instrument as well as in some verbally described situations of the reduced proficiency test. The video test consisted of three short video clips of a primary school

mathematics classroom and corresponding questions concerning didactical and pedagogical aspects of the teaching sequence. A total of 19 questions were selected for the analyses, 14 questions from the video analysis test and five questions concerning verbally described situations in the MPCK proficiency test. Teachers' answers to the selected questions were analysed using qualitative text analysis (Mayring 2015; Kuckartz 2014). All answers of all teachers to all 19 selected questions were analysed using reducing and structural procedures (Mayring 2015).

To exemplify the coding process, one example item will be introduced as well as teachers' responses to the item and the result of their analysis. The example item refers to the video analysis instrument, more specific, it refers to the video 'real world problem' that shows a third grade mathematics classroom in Germany dealing with a real world mathematics problem that is shown in figure 2. In the video, three students' working groups are shown who discuss their working results. The students use very different approaches, one student produces a symbolic result while another student solves the task using a visual drawing of the situation. Referring to this scene, the teachers were asked to characterise the two solution approaches contrastingly. Teachers' responses to this task were coded

**Figure 2: Real world mathematics problem that is discussed in the video vignette**

Anna and Felix want to go to the movies. They take the bus together. Felix pays the bus tickets for both of them. One ticket costs 2€. Anna pays both cinema tickets. One ticket costs 7€. At the end of the day, the children want to share the costs equitably. How can they do that?

using reducing processes of qualitative context analysis, capturing the content of the teachers' answers. In this regard, the following teacher's answer was categorised as 'contrasting the students' form of representation':

**Teacher 1:** *"Lea does mental arithmetic and uses a symbolic approach. She does not have to use an iconic or enactive solution while Kim needs an iconic approach. She should try an enactive approach to see that Lea's approach is correct as well."*

This coding approach categorized each of the teachers' answers with regard to their content. In another coding process using structuring procedures, the teachers' answers were coded with regard to judgments. A teacher's response that contained a judgment of the two students' solutions is the following:

**Teacher 2:** *"Lea's approach is more practical and more advanced than Kim's approach because she already subtracted the amount that the girl has to give to the boy."*

Finally, in another structuring coding procedure, all teachers' responses to the selected questions were coded with regard to proposed alternatives or continuations. A teacher's response that proposes a possible continuation of the presented situation is the following:

**Teacher 3:** *"Lea does mental arithmetic and uses a symbolic approach. She does not have to use a visual or acting solution while Kim needs a visual approach. She should try an acting approach to see that Lea's approach is correct as well."*

These coding processes resulted in a category system that built the basis for type-building text analysis (Kuckartz 2014). Here, three dimensions emerged which further constructed a feature space to generate diagnostic types: the perspective that teachers' chose on the teaching sequences, their tendency to judge and their tendency to propose alternatives and continuations. In order to reconstruct ideal diagnostic types, connections between these three dimensions were analysed and idealised. Finally, these diagnostic types were interrelated using contingency analyses in a Mixed-Method-Design (Kelle & Buchholtz 2015) with the teachers' knowledge scores that resulted from the reduced

	Didactical perspective	Didactical AND mathematical perspective	Mathematical perspective
Average MCK	519	567	597
Average MPCK	536	552	543
Average GPK	647	640	683

**Table 1: Contingency analysis between teachers' professional knowledge and their perspective**

teachers' situation-specific skills and their professional knowledge. Table 1 shows this contingency analysis between the perspective chosen and the professional knowledge for the example item. However, since the perspectives were coded in every selected question, these connections were also analyzed independent of specific teaching sequences.

## Results

Resulting from the reducing and structuring procedures, teachers' responses differed with regard to several aspects. On the one hand, teachers chose different perspectives on the classroom incidents. While some teacher focused on the content, other teachers focused on the students, their understanding, motivation, behaviour etc. On the other hand, it became obvious that teachers had varying tendencies (a) to judge the classroom events which they observed and analyzed and (b) to anticipate teaching alternatives or continuations.

Relating the three dimensions that resulted from the coding processes—(1) the perspective chosen (2) the tendency to judge (3) the tendency to anticipate teaching alternatives or continuations and—showed that teachers who often chose a content-related mathematical perspective in classroom situations also often judged these incidents. In addition, the more often teachers chose a student-related perspective, the more teaching alternatives and continuations were anticipated. These connections between the three dimensions formed the basis for building diagnostic types. In this regard, the following two ideal diagnostic types could be identified:

**“Content-related and judging:** This diagnostic type is characterized by a content-related perspective in the phases of perceiving and interpreting relevant incidents. These noticed criteria are subsequently used to judge the relevant incidents. The phase of decision-making is also characterized by a content-related focus. Here, the teaching continuation is conducted by the subject's (here mathematical) content.

**Student-related and action-oriented:** This diagnostic type is characterized by a student-related perspective in the phases of perceiving and interpreting relevant incidents. This means that the students, their learning processes, understanding, motivation and behaviour are the noticing focus. If classroom situations show deficits with regard to students' understanding and learning, this phase is automatically followed by a phase of deciding on alternatives that improve the given situation or possibilities to optimally continue the situations. The phase of decision making is primarily characterized by considering teaching methods and the instructional organization." (Hoth et al. 2016, p.50)

Connecting to these results concerning different diagnostic types, a Mixed-Methods Design was realised that interrelated the different perspectives chosen with the teachers' knowledge that was assessed by the proficiency test in the TEDS-FU study. In this regard, connecting the perspectives chosen by the teachers to their professional knowledge showed the following results:

- Teachers who often choose a mathematical perspective on teaching situations have average or above average mathematics content knowledge while their mathematics pedagogical content knowledge is below average.
- The more often teachers choose a didactical perspective on teaching situations, the higher is their mathematics pedagogical content knowledge.
- The general pedagogical knowledge of teachers who often choose a pedagogical perspective exceeds their content specific knowledge.
- Teachers who often judge teaching instances have high mathematics content knowledge.
- Teachers who often propose teaching alternatives and continuations possess high mathematics and mathematics pedagogical content knowledge while teachers who seldom do this have below average general pedagogical knowledge.

With regard to specific teaching instances, the results indicate that teachers with comparatively high content-related knowledge (MCK and MPCK) plan their teaching with regard to the content while teachers with comparatively high general pedagogical knowledge focus to a greater extent on pedagogical facets while planning their teaching. Furthermore, other connections indicate that teachers with only little content knowledge more often miss aspects in teaching and learning that are relevant for the students' learning processes but focus on behavioural aspects if they are very striking. Teachers who focus on aspects of understanding and learning despite of the striking student behaviour have above-average mathematics content knowledge.

## Summary and discussion

In this paper, mathematics teachers' situation-specific diagnostic competence is analysed. This is the diagnostic competence that teachers require during class. For this purpose, the answers of 131 mathematics teachers are analysed who took part in the TEDS-Follow-Up study. In this video-based study, the teachers are asked to answer questions referring to video scenes of mathematics classroom. Analyses showed that teachers focus on very different aspects in the same teaching scene and two diagnostic types were differentiated: the content-related and judging type on the one hand and the student-related and action-oriented type on the other hand. In addition, contingency analyses showed that there are connections between the teachers' professional knowledge and their focus on and analysis of teaching sequences.

The results enrich the already existing findings in the field of teacher noticing (cf. Sherin et al. 2011). The proposed connection between teachers' noticing and their knowledge is verified empirically. As a consequence, teachers' practice is essentially influenced by their professional knowledge which in turn emphasizes the importance of mathematics teacher education. However, following questions arise about further connections between teachers' identification, their beliefs and the perspectives that were distinguished in this paper. In addition, developing and implementing teacher education courses to foster teachers' situation-specific diagnostic competence may give further insight into the development of this specific facet of teachers' diagnostic competence.

*The changes concerning the final state examination, determined by the novelty of Slovak university law, stimulated us to make serious changes in the examination model of Didactics of Mathematics at our university. Moreover, we have observed significant gaps in pedagogical content knowledge (PCK) of our secondary pre-service teachers during the last years. These two stimuli led us to an improvement of the course of Didactics of Mathematics. In this paper, we present our new approach which was mainly focused on the assessment of the lesson plans presented by the pre-service teachers. The assessment was based on the rubrics which were developed through the course. After the application of the new approach, we have observed growth in PCK. We have partially confirmed reliability of the rubrics as well.*

*Keywords: Secondary pre-service teacher, pedagogical content knowledge, lesson plan, rubrics for PCK assessment.*

## Introduction

Before we introduce our new approach to secondary pre-service mathematics teacher PCK development, we bring a short description of the system of pre-service teachers' preparation at our university. First, all the secondary pre-service teachers (PSTs) study two disciplines in various combinations, including combinations of natural and humanistic disciplines. Second, pedagogical, psychological and didactics studies are reduced to the minimum for the bachelor level. Therefore, we speak about the joint degree study of the particular two subjects (e.g. mathematics and physics) at the bachelor level. Most of the pedagogy is concentrated at the master level of university studies, where we talk about the teacher preparation program. Third, complex state exam from both disciplines and their didactics, Pedagogy and Psychology and the thesis defense are required for successful finish of the study. The aim of our university was to make state exams more efficient and foster mutual relationships of all parts of state exams. Moreover, we had found out serious gaps in the PCK of our PSTs, so the bigger pressure for its growth was necessary. Implementation of the PCK assessment into the state examination seemed to be a way, because "what you test is what you get," is the broadly accepted quote (attributed to Lauren Resnick). As we realized, when the assessment is changed, the instructions should be changed as well. Therefore, we have prepared a new model of state exams and apply inevitable changes at the classes of Didactics of Mathematics. To be sure that the new approach has the positive impact on the PSTs' learning, we posed following research questions: **(1)** Are the rubrics reliable tool to assess PSTs? **(2)** Was the pre-service teachers' PCK developed effectively? Which of its components were developed?

The novelty of the approach can be understood geographically - there are no serious studies on PCK development in Slovakia or even in neighbor countries (Depaepe, 2013). Moreover, we have not found any study which would consider utilization of general – not thematically specific – rubrics for

development of PCK of secondary PSTs. The new approach is described and discussed below; however, some theoretical underpinnings are necessary to be stated first.

## Theoretical background

Knowledge areas, in which should a good teacher of mathematics systematically grow and achieve a certain standard, are named for several decades. Shulman (1986) explained pedagogical content knowledge (PCK) which is beyond subject matter knowledge and

„includes an understanding of what makes the learning of specific topics easy or difficult. Teachers need knowledge of the strategies most likely to be fruitful in reorganizing the understanding of learners, because those learners are unlikely to appear before them as blank slates” (p. 9).

Furthermore, Shulman (1986) emphasized the importance of curricular knowledge, familiarity with the instructional materials and tools available for teaching distinct concepts at different levels. PCK in the domain of mathematics comprises mathematical knowledge a different kind to that used in everyday life and in other professions which need mathematics (Ball & Bass, 2000).

Hill et al. (2008) built on Shulman’s (1986) definitions of different types of knowledge and proposed the model with three types of content knowledge and three types of PCK:

### Subject matter (content) knowledge

(1) **Common Content Knowledge (CCK)** – knowledge which is used in the classroom in ways common with how it is used in other professions that also use mathematics. (2) **Specialized Content Knowledge (SCK)** – knowledge how to accurately represent mathematical ideas, provide mathematical explanations for common rules, procedures, understand unusual methods of solution. (3) **Knowledge at the mathematical horizon** – awareness of the large mathematical landscape in which the present experience and instruction is situated (Zazkis & Mamolo, 2011).

### Pedagogical content knowledge

(1) **Knowledge of Content and Students (KCS)** – knowledge how students in general learn a concept, what mistakes and misconceptions are common, it involves understanding of students’ thinking and what makes the learning of particular concepts easy or difficult. (2) **Knowledge of Content and Teaching (KCT)** – knowledge about how to develop students’ thinking and how to deal with student errors effectively, “knowledge of teaching moves” (p. 378). (3) **Knowledge of Curriculum (KC)** – knowledge about the content of curriculum and knowledge how to utilize the content of curriculum to present.

In our approach we suggest an authentic assessment in order to make bigger pressure for the growth of each component of PCK and to move forward PST beliefs about mathematics. There are four features of authentic assessment (Darling-Hammond, Aness & Falk, 1995): (1) “they are designed to be truly representative of performance in the field” (p. 11); (2) “the criteria used in the assessment seek to evaluate “essentials” of performance against well-articulated performance standards.” (p.12); (3) “self-assessment plays an important role in authentic tasks” (p.12), (4) “the students are often expected to present their work publicly and orally.” (p.12).

## The course design

Ten PSTs attended mandatory class in Didactics of Mathematics led by the second author and assisted by the first author. Total time of every week meeting was two hours and 15 minutes, the course lasted for 10 weeks, 5 of them were designed as follows:

(1) All PSTs picked randomly one of the topics which were prescribed by the second author. They were asked to create a lesson plan due to a particular date. The lesson plan had to be focused on the mastering a new curriculum. The template they were asked to fill as the front page of the preparation contained following items: topic, grade, goals, necessary entry knowledge, didactics problem and misconceptions, tools, methods and forms. Only the front page was fixed, the rest of the preparation was in the hands of the PSTs. (2) The PST who was up to present his/her preparation the next week, sent his/her lesson plan in one week advance to the whole group. Everybody was expected to raise some questions. (3) The PST had 30 minutes for the presentation of the lesson plan. Next 20 minutes were reserved for discussion. The PST explained the main line of the new curriculum mastering, underlined the important connections between the information from the front page and the tasks and subsequently, in the discussion, clarified inconsistencies pointed out by the teachers or the PSTs. (4) Everybody who was actually present at the class was asked to assess the presentation and provide the feedback and score for the PST who presented the preparation. To minimize subjectivism of the assessment, following rubrics (Table 1) were created and used for the scoring. The PSTs were instructed how to use it, examples for the particular levels were supplied.

## Rubrics for lesson plan assessment

The base for the initial rubric version was the observations which were conducted by the second author in the previous academic year. The PSTs were asked to fulfil the similar assignment. Nevertheless, the scoring was not conceptualized; everybody was expected to assess presenting PST an appropriate number of points. Such assessment did not produce pressure for specific part of PCK growth. That was the reason why we, for the next academic year, developed five rubrics that we believe to enhance PCK of PSTs during the preparation of the lesson.

(1) Rubric **Learning Objectives** is defined as the ability to formulate and clarify essential objectives of the unit and to link them with the rest of the preparation. Learning objectives result from curriculum. The rubric is connected with KC. We assess whether PST applies this curriculum content to appropriate learning activities for students. (2) Rubric **Motivation** shows PSTs' potential to present mathematical ideas in an attractive way, to provide reasons and mathematical explanations for the topic. It is linked with SCK. (3) Third rubric – **Correctness** - pertains to mathematical correctness of the lesson plan. It is associated with CCK and SCK. (4) Rubric **Didactic Means (Tools)** includes chosen didactic method, tasks and materials. Using this rubric we assess PST knowledge about how to build on students' thinking and how to address students' errors effectively. The aim is to identify the level of KCT. (5) Last Rubric we called **Didactic Problems** and it contains assessment of the level of PST knowledge of how students think about the topic, how students typically learn a concept from the topic, what mistakes and misconceptions are common. Rubric is designed to determine the level of KCS.

Level	Learning objectives	Motivation	Thematic Working Group 18 Correctness	Didactic Means	Didactic problem and misconceptions
0	A PST cannot explain the objectives of the unit, or the explanation is only formal (there are only weak connection between the objectives and the preparation and/or the objectives are not appropriate for the students age group).	There is no explicit motivation within the lesson plan, or the stated motivation is very formal (neither students' activity nor questions cannot be expected).	The unit curriculum is introduced incorrectly (mathematics terms definitions, mathematics statements or tasks assignments are not formulated correctly or comprehensively or they are not appropriate for the students age group,) and/or the learning trajectory is not respected at all.	Chosen didactic means clearly support instructive approach to mathematics education, there is no prompt for students' activity and/or the tasks are chosen superficially.	A PST does not realize didactic problem and misconceptions connected to the unit topic or he/she realizes only marginal or general problems and misconceptions.
1	A PST explains the objectives of the unit partially, and/or he/she does not propose certain of the important goals, and/or certain objectives are not appropriate for the students' age group.	The motivation stated in the lesson plan probably would be interesting only for a few students, and/or there are no tight relations between the motivation and the objectives.	Language inaccuracies in oral or written communication are observable and/or the learning trajectory is respected only partially.	Chosen didactic means lead to rather instructive approach, there is small prompt for students' activity. The structure of the teaching unit is not well thought out and/or some important cognitive phase is missing and/or selection of the tasks is only partly thought out.	A PST can name the didactics problem and misconceptions connected to the unit topic and he/she resolve them within the preparation just partially.
2	A PST formulates and clarifies essential objectives of the unit, links them with the rest of the preparation and the objectives are appropriate for the students' age group.	The motivation stated in the preparation probably engages most of the students and it is linked with the objectives. If possible, the motivation suggests connection of mathematics and everyday life.	The unit curriculum is introduced correctly (mathematics terms definitions, mathematics statements and tasks assignments are formulated correctly and comprehensively and they are appropriate for the students age group,) and the learning trajectory is respected.	Chosen didactic means leads to a creative environment where activity of students dominates and the proposed teaching unit has a coherent structure, no important cognitive phase is missing. Task selection is thought out.	A PST can name the key didactics problem and misconceptions connected to the unit topic and he/she resolve them within the preparation.

**Table 1: Rubrics for PCK assessment**

In the rubric Correctness, the term learning trajectory is not conceptualized, it is used in simplified meaning concerning the important entry knowledge before the new one is going to be taught and learnt.

The presented lesson plans were not the first ones created by the PST. They had prepared and taught 18 lessons during their practice teaching before the course started. Additionally, they developed 15 lessons plans for the state examination, which was scheduled 5 months after the course finished. Some of PSTs worked on these lesson plans in groups. All these lessons plans were taken in account to track the PCK development.

Each of the rubrics also provides three general development levels: Beginning, Developing, and Advancing (see table 1). In order to explain more precisely authors' approach to assessment, we present two examples for the rubric Motivation from level 0 and level 1.

Level 0 - Example for "the stated motivation is very formal (neither students' activity nor questions cannot be expected)": Lesson plan for the Topic: How to multiply decimal by decimal numbers

PST: For the motivation, I chose the following task: A farmer stored fuel for the tractor in canisters of 0.5 hl. He has a) 10, b) 5, c) 2, d) 1, e) 0.5 canisters full of fuel. How much fuel does he have for the tractor (write result in hl)?

T (teacher – the author): Explain the reasons why you consider this task as motivating one.

PST: I think, in fact, this is not very motivating task. Maybe students could solve the last case of the task and found out how to multiply decimal by decimal number.

Level 1 - Example for "there are no tight relations between the motivation and the objectives": Lesson plan for the Topic: Definition of the concept Limit of a sequence

PST: Motivation task: In the hotel we have an infinite number of single rooms. Rooms are sequentially numbered by natural numbers. The hotel is fully booked. To the hotel, however, added three other tourists who would like to stay. Is it possible to accommodate them?

T: What is the connection between this task and the definition of the concept Limit of a sequence?

PST: The task is about infinity and when we count limit of a sequence we work with infinity.

## **Preliminary results and discussion**

We try to answer the research questions mentioned in the Introduction.

(1) The concept of inter-rater reliability was used to find the answer to the first research question. The Table 2 depicts numbers of consistent and inconsistent decisions for each particular rubric.

Only the authors' assessment was taken in account because the PSTs' assessment was obviously loaded by the social norms and the relationships within the group. Some inconsistencies between the authors were caused by the usage of the rule, that for one deficiency only one point should be get off and the authors included the same mistake in the different rubrics. As we can see, the rubrics worked well and after precise preparation of their user, they can be considered as reliable tool. The certain vagueness of the developing levels formulations does not seem to be a problem when comes to its identification within the actual presentation.

The rubric	Match	One level differences	Two level differences
Learning objectives	9	1	0
Motivation	9	1	0
Correctness	9	1	0
Didactics Means	7	3	0
Didactics Problem	8	2	0

**Table 2: Inter rater reliability**

(2) At the beginning, PSTs filled the front page formally (see The course design). Most of the PSTs had no idea about how the front page tailors to remaining part of lesson plan. As the course continued, we could see how PSTs were moving forward in the development of their PCK. We explain it using examples from 3 rubrics (Learning objectives, Didactic Means, Didactics Problem).

(2a) Development of PCK within the group of PSTs - Learning objectives

At the beginning of the course, PSTs did not formulate any learning objectives or formally mention some objectives of prepared lesson but were not able to explain how to achieve it. Also, some of PSTs did not meet the learning objectives they have formulated.

Example from the lesson plan for the topic: The Binomial Theorem

PST: The student is able to formulate the binomial theorem and to write the binomial theorem by using the summation operator.

T: Formulate the binomial theorem and write it by using the summation operator.

PST: *(Started to write on the blackboard, but did not remember correct formulation, then started to look for the correct formulation in the hard copy of the lesson plan.)*

T: The student should be able to formulate the theorem and the teacher is not?

At the end of the course, PSTs started to formulate learning objectives in connection with chosen tasks and their solutions and they also explain more precisely what they expect.

Learning goals for the topic: Increasing and decreasing function

The student is able to identify whether the function is increasing or decreasing from the graph, from the table. The student is able to draw graph of increasing and decreasing function. The student is able to define increasing and decreasing function. The student is able to prove from the formula whether the function is increasing, decreasing or neither one nor the other.

Additionally, in the prepared lesson plan we can found tasks as means to meet the formulated objectives.

(2b) Development of PCK within the group of PSTs - Didactic Means

In the first stage, PSTs chose the tasks superficially, e.g. the PST prepared lesson plan for the Topic: Law of sines and he explain the task selection as follows:

PST: (*Presents some task where students have to calculate side or angle of triangle using law of sines.*)

T: Explain us, why did you choose exactly these tasks.

PST: I found them in the textbook.

T: Did you solve them?

PST: Only the last one because it looked hard.

T: Do you think these tasks will help your students to understand deeply methods of solution using Law of sines?

PST: Maybe some types of tasks are missing. (He started to draw on the blackboard.)

At the last stage the PST who prepared for the topic Definition of the concept Limit of a sequence explained precisely the reasons for each selected task.

T: Why did you solve the absolute-value inequality:  $|x - 4| \leq 2$  at the beginning of the lesson?

PST: I chose this task because I wanted to recall the geometric properties of absolute-value which students meet in the definition of the limit.

T: You suggest dividing students into 6 groups and each group will work with different sequence. Explain your reason.

PST: Two groups will get increasing sequence, two groups decreasing and two groups oscillating sequence. I chose these sequences in order to prevent the following misconception: Only decreasing sequence has limit. Oscillating sequence cannot have a limit.

During the presentation of the lesson plans on the state exams the most of students showed that they are better able to intertwine all the items from the front page of the lesson plan with the tasks and their solutions, activities, mathematical explanations. Students were also able to explain better their reasons for selecting the particular tasks and activities for the lesson.

#### (2c) Development of PCK within the group of PSTs - Didactics Problem

Firstly, most of PSTs did not see any didactic problem and misconception with the most of the topics, some PSTs wrote the most common misconceptions, such as problem with negative sign during working with algebraic expression, or they formulated didactic problem very generally such as students have problems while working with fractions. Later, when PSTs were trying to identify didactics problems and misconceptions, they started to utilize experience from their life (this task/concept/method was a problem for my sibling, friend, me) and also from their teaching practice. The next example illustrates formulation of the misconception based on PST experience.

PST: Students think that the following scalar products  $(1,1) \cdot (3,2)$  &  $(2,2) \cdot (3,2)$  are equal. To prevent this misconception I formulated the following task: Find out if following scalar products have the same value:

A.  $\vec{u} = (1,1); \vec{v} = (3,2); \varphi = 60^\circ$

B.  $\vec{u} = (2,2); \vec{v} = (3,2); \varphi = 60^\circ$

Although the task is incorrect it shows PST's effort not only to formulate the misconception but also to look for the way how to prevent it.

Our experience indicates that the authentic assessment focused on PSTs' lesson plans and objectivized by five rubrics, tied with the content knowledge and three types of PCK, can help PSTs to develop their PCK. Presented examples demonstrate development of KCS (identification of didactic problems and misconceptions), KCT (precise selection of tasks) and KC (formulation of learning objectives).

# Measuring beliefs concerning the double discontinuity in secondary teacher education

Viktor Isaev<sup>1</sup> and Andreas Eichler<sup>2</sup>

<sup>1</sup>University of Kassel, Germany; [isaev@mathematik.uni-kassel.de](mailto:isaev@mathematik.uni-kassel.de)

<sup>2</sup>University of Kassel, Germany; [eichler@mathematik.uni-kassel.de](mailto:eichler@mathematik.uni-kassel.de)

*In this paper, we discuss a research project to measure prospective mathematics teachers' beliefs towards their perceived disagreements between mathematics at university level and school mathematics that is known as double discontinuity. Firstly, we introduce the double discontinuity problem. Secondly, we refer to the construct of beliefs as the main part of our theoretical framework. Afterwards, we outline our method including a brief discussion on our approach of bridging the double discontinuity problem with so-called teacher-oriented tasks that are appropriate to illustrate connections between university mathematics and school mathematics. Furthermore, our results of pilot studies aiming to measure prospective teachers' beliefs are provided.*

*Keywords: Beliefs, double discontinuity, prospective teachers, teacher education.*

## Introduction

Over 100 years ago, Felix Klein coined in the preface of his textbook “Elementary Mathematics from a Higher Standpoint” the term of a “double discontinuity” (Klein, 1908, p. 1). This notion embodies the challenges of transitions in the mathematical socialization of mathematics teachers. The first discontinuity, i.e. the transition from secondary to tertiary education, became a main topic in research on university mathematics education during the last decades (e.g. Gueudet, 2008; Thomas et al., 2015). A challenge that accompanies the second discontinuity is the transformation of academic mathematics gained at university into educational forms of school mathematics (Prediger, 2013; Winsløw & Grønbaek, 2014). As a consequence of both discontinuities, teachers may lose sight of academic mathematics after university studies and, thus, teach on the basis of experiences from their own schooldays (Bauer & Partheil, 2009; Hefendehl-Hebeker, 2013).

Although mathematics instruction in schools as well as teacher education in universities changed considerably since Klein's claim, the phenomenon of a double discontinuity still seems to exist and prospective teachers nowadays frequently believe that the topics of university mathematics do not meet the demands of their later profession in school (cf. Ableitinger, Kramer, & Prediger, 2013; Hefendehl-Hebeker, 2013). The prospective teachers' perception of the mentioned relationships between school mathematics and university mathematics could be regarded as part of teachers' beliefs (Eichler & Isaev, 2016). Considering this background, we primarily rely on teachers' beliefs as the main construct of our theoretical framework in the next paragraph. Subsequently, we outline the method for our research project with a specific focus on pilot studies. Finally, we use the results of these pilot studies to explain the development of our instrument aiming to measure prospective teachers' beliefs concerning the double discontinuity.

## Theoretical framework

### Prospective teachers' beliefs

On the construct of beliefs we refer to the definition of Philipp (2007, p. 259), who defines beliefs as “psychologically held understandings, premises, or propositions” affecting an individual’s view of the world or a special part of it, such as filters for receiving information. Beliefs can be considered as a component of teachers’ mathematics related affect (Hannula, 2012), which itself can be defined as “a disposition or tendency or an emotion or feeling attached to an idea or object” (Philipp, 2007, p. 259). Thus, in our research we regard prospective teachers’ beliefs as their propositions concerning the relationships between school mathematics and university mathematics. Following Calderhead (1996), teachers’ beliefs are understood not only to impact on teachers’ professional knowledge but also to potentially have an effect on teachers’ classroom practices (cf. also Skott, 2009). Therefore, it seems essential to tackle the issue early and to investigate, how beliefs concerning the double discontinuity develop in secondary teacher education.

In related literature, beliefs are partially seen and sometimes even defined as relatively stable dispositions. In contrast, several studies provided a change of beliefs due to interventions, especially concerning prospective teachers (e. g. Decker, Kunter, & Voss, 2015). In this paper, we aim to provide an instrument in order to investigate, whether and how prospective mathematics teachers change their beliefs concerning the double discontinuity phenomenon based on our intervention project. From this background, we address beliefs being changeable and consider change as “a natural part of the development of beliefs and the reaction of beliefs in the face of experiences” (Liljedahl, Oesterle, & Bernèche, 2012, p. 35).

### Related Research

Although numerous projects and institutions across the world aimed to overcome the perceived gap between school mathematics and university mathematics in recent years, not much research has been done on the perception of prospective teachers’ concerning the double discontinuity problem. Winsløw and Grønbæk (2014) distinguished three dimensions of Klein’s double discontinuity, which are not independent but important to separate: the institutional context (i.e. school vs. university), the difference in the subject’s role within the institution (i.e. student at university or school vs. teacher of mathematics), and the difference in mathematical contents (i.e. elementary vs. advanced). In our research, we primarily refer to the content aiming to figure out possibilities of “building bridges” (Winsløw & Grønbæk, 2014, p. 64) and to investigate the effect of bridging activities on the prospective teachers’ beliefs referring to the double discontinuity.

Becher and Biehler (2016) used narratives in order to ask prospective secondary teachers in their third year of university studies about what benefits they see in learning university mathematics for their future career as a school teacher and which aspects are articulated by the prospective teachers in their evaluation of benefits of university mathematics. The results revealed a wide range of prospective teacher’s beliefs on benefits of learning university mathematics with regard to school mathematics. Most of the statements can be matched with one of four levels of mathematical content knowledge based on Krauss et al. (2013), i.e. “A deep understanding of the content of the secondary school mathematics curriculum (e.g., ‘elementary mathematics from a higher standpoint,’ as taught at university)” (Krauss et al., 2013, p. 155). Taking these studies into account, we developed a

questionnaire for measuring prospective mathematics teachers' beliefs towards their perceived disagreements between mathematics at university level and school mathematics.

## Method

### The institutional frame

Referring to this theoretical framework, the main target of our project is to investigate changes in prospective teachers' perception of a double discontinuity that could be explained by our approach of building bridges. Prospective secondary mathematics teachers in Germany are usually enrolled in the same mathematics courses as mathematics majors (e.g. analysis), particularly in the first semesters. A big challenge for all students in the initial phase of the studies is the task to complete a range of exercises every week as homework (Ableitinger & Herrmann, 2013). These tasks can be solved on the basis of the plenary lectures (by usual four hours per week) and are reviewed in additional small courses (by two hours per week) which are organized by student assistants. Our aim is to develop and establish the desired bridges in these introductory mathematics courses for prospective secondary teachers. Our focus is here to enrich the set of tasks for homework with so-called "teacher-oriented tasks" that are appropriate to illustrate connections between university mathematics and school mathematics to prospective secondary teachers.

### Teacher-oriented tasks

We conceptualize specific tasks which potentially demonstrate bridges between school mathematics and university mathematics to a model of domains of teacher knowledge according to Ball, Thames, and Phelps (2008). More precise, we differentiate our teacher-oriented tasks referring to the subdomains of specialized content knowledge (SCK), knowledge of content and students (KCS), knowledge of content and teaching (KCT) as well as curriculum knowledge. One example that represents specialized content knowledge (SCK) within the notion of mathematical tasks for teaching is provided below. In this exercise, "Evaluating the plausibility of students' claims" and "Giving or evaluating mathematical explanations" (Ball et al., 2008, p. 400) are requirements which can be used well to describe the setting.

In the subsequent task from a mathematics contest for students ("Känguru der Mathematik 2009") the participants were asked to solve which of the following figures is the greatest one.

$$(A) \sqrt{2} - \sqrt{1} \quad (B) \sqrt{3} - \sqrt{2} \quad (C) \sqrt{4} - \sqrt{3} \quad (D) \sqrt{5} - \sqrt{4} \quad (E) \sqrt{6} - \sqrt{5}$$

A student in grade 12 chose answer (E) and stated:

" $\sqrt{6} - \sqrt{5}$  is the greatest figure, because roots are monotone. So, the greater is  $x$ , the greater is  $f(x)$ . Thus, their difference is the greatest, as well (by going more to the right)."

1. Analyze the student's answer. Where do you see problems with the argumentation?
2. Provide an own student-oriented answer to this topic.
3. Show in general:  $\lim_{n \rightarrow \infty} \sqrt{n} - \sqrt{n-1} = 0$

**Figure 1: Task "roots" for prospective secondary mathematics teachers**

## The design

In order to gain empirical evidence for the efficiency of our method, prospective teachers in the relevant mathematics courses are assigned at random to a treatment group and a control group. While the control group is taught traditionally, the treatment group gets an extra teacher-oriented task for homework every week that focuses on bridging mathematics at university level and school mathematics. Our main research question is whether and how prospective teachers change their beliefs about the double discontinuity phenomenon based on our intervention in the introductory mathematics courses. In this paper we only refer to pilot studies where prospective teachers got homework including an extra teacher-oriented task on a trial basis. The main aim of these pilot studies was to develop an instrument for measuring teachers' perception of a double discontinuity.

During the winter semester 2015/16, two basic mathematics courses at the University of Kassel were selected in which the mentioned teacher-oriented tasks bridging mathematics and mathematics education was administrated: "principles of mathematics" and "analysis". Prospective mathematics teachers attend these courses usually in the first or in the third semester of their university studies. Three prospective teachers from the third semester were interviewed at the end of the semester. The data was analyzed by qualitative content analysis. We also developed a questionnaire with 16 items for measuring prospective teachers' beliefs concerning their perceived disagreements between mathematics at university level and school mathematics. The questionnaire was piloted in a mathematics course for prospective secondary teachers ( $N = 60$ ) and is outlined in the following paragraph.

## Discussion of results

The analyses of the interviews revealed that all prospective teachers took the contents dimension into account when reflecting their university studies. For example, the first prospective teacher (PT\_1), believes, that in university mathematics, there are too little relations to school with regard to the content.

PT\_1: "There are not many connections - direct contents connections, so - as well as in the other lectures. And also in analysis I notice, that it - that the university stuff of the mathematics lecture - almost simply goes beyond school and it is more or less by chance, if there are contents, which fall together with school mathematics - I have the feeling."

Further, two of the prospective teachers also mentioned another aspect of the double discontinuity problem, i.e. their beliefs concerning the relevance of learning university mathematics with regard to school mathematics, such as can be found in the proposition of PT\_2.

PT\_2: „If I finished school, I would have the same status, which I want to teach the students. And if now deeper questions arise, I would not be able then to answer them, for instance, because I myself have never had this and then - such a teacher one also did not want formerly, who could only tell, what he has just done.“

Indeed, Klein (1908) addresses both aspects in the double discontinuity phenomenon since on the one hand the problems at university may not suggest the things at school, and on the other hand, university studies may remain only a memory with no relevance upon teaching.

The collected data from the interviews also supported the development of our current questionnaire. Our first version (cf. Eichler & Isaev, 2016) contained 9 items using a 6-point Likert scale to assess students' beliefs about the double discontinuity problem. The questionnaire was piloted in a mathematics course for prospective secondary teachers ( $N = 60$ ) and seemed to provide good internal consistency (Cronbach's alpha 0.782). Interestingly, a higher reliability (Cronbach's alpha 0.831) was achieved when regarding only the prospective teachers in the course ( $N = 35$ ) and not all university students in the mathematics course. As a possible reason for this phenomenon, we identified two theoretical discernable domains in our questionnaire. On the one hand, we asked items which contained a personal statement including the words “I” or “me” like “I think that I require a deep understanding of mathematics in order to teach mathematics in school.” On the other hand, we provided a few statements such as “University mathematics has mostly little relation to school mathematics”, which were rather matter-of-fact. These items might have led to a different extent of identification within the different groups of university students. To provide useful information, we applied both dimensions in our current questionnaire containing 16 items.

Taking into account the four levels of mathematical content knowledge based on Krauss et al. (2013), we derived further items from the interviews such as “By the use of university mathematics, gaps are filled in the mathematical knowledge that is required in school”. We grouped all items into three subscales which we identified through our development process: “contents relationship”, “relevance for profession” and “higher standpoint”. In a further pilot study with prospective secondary teachers in higher semesters ( $N = 24$ ), we approved these subscales to be internal consistent<sup>1</sup> with a total reliability value of Cronbach's alpha .911. Moreover, we used our qualitative approach in order to validate our survey afterwards.

<b>Contents relationship – beliefs concerning the connections between university mathematics and school mathematics on the contents dimension (4 items; Cronbach's alpha .821):</b>	
4.	University mathematics offers many parallels to school mathematics with regard to contents.
9.	School mathematics and university mathematics are applied to each other in contents.
11.*	In university mathematics, there are too little relations in contents to school.
12.*	School mathematics and university mathematics are two different worlds with regard to contents.
<b>Relevance for profession – beliefs concerning the relevance of university mathematics for the later profession as a school teacher (6 items; Cronbach's alpha .814):</b>	

<sup>1</sup> 7 Personal items with Cronbach's alpha .845 and 12 non- personal items with Cronbach's alpha .858.

1.	University mathematics is very useful for the teaching profession.
3.*	I will hardly ever need university mathematics after studying.
5.	By the use of university mathematics, I am well prepared to the job profile of a mathematics teacher.
10.	Without university mathematics, I could hardly teach mathematics in school.
15.*	Learning mathematics at university is not so important for the teaching profession.
19.	The relevance of university mathematics for the teaching profession is <sup>2</sup>
<b>Higher standpoint – beliefs concerning the usefulness of university mathematics as a higher standpoint for elementary mathematics (6 items; Cronbach's alpha .818):</b>	
2.	University mathematics helps me to get deeper into school mathematics.
6.	By the use of university mathematics, gaps are filled in the mathematical knowledge that is required in school.
7.	By the use of university mathematics, I gain a deeper understanding of concepts in school.
8.	By the use of university mathematics, I understand relationships within school mathematics much better.
14.	Learning mathematics at university promotes me to be in thinking “one step ahead” of the students.
16.	As a mathematics teacher, an in-depth mathematical content knowledge is required.

**Table 1: questionnaire for measuring prospective teachers' beliefs concerning a double discontinuity**

The possible range of scores for each component is between 1 and 6. Higher scores correspond to more positive beliefs (by reversing the responses to the negatively formulated items indicated with an asterisk\*).

### Concluding remarks

The main topic of this paper was to discuss our approach of measuring prospective mathematics teachers' beliefs towards their perceived disagreements between mathematics at university level and school mathematics that is known as double discontinuity. In order to be able to investigate changes in prospective teachers' beliefs referring to the double discontinuity problem, we chose a mixed methods design and developed a questionnaire including 16 items that actually seems to measure these beliefs. Grounded on our preliminary results, the following steps of our research will be a comparison between two groups of prospective teachers - one group in a traditional course and one group in a course using the mentioned teacher-oriented tasks to prove if the type of the course has an effect of the prospective teachers' beliefs. Since a variety of other factors may be related to our outcomes, we also collect among others data to study interest (Schiefele, Krapp, Wild, & Winteler,

---

<sup>2</sup> Whereas in the previous items the prospective teachers may choose an option in a scale from “strongly disagree” to “strongly agree”, the last item refers to a scale from “very low” to “very high”.

1993) and study satisfaction (Dargel, 2005) in a pretest and a posttest as well as additional items referring to relevant demographic and academic background information.

# Using a fraction learning trajectory as a tool to develop pre-service primary teachers' noticing of students' fractional reasoning

Pere Ivars, Ceneida Fernández and Salvador Llinares

Universidad de Alicante, Spain

[pere.ivars@ua.es](mailto:pere.ivars@ua.es); [ceneida.fernandez@ua.es](mailto:ceneida.fernandez@ua.es); [sllinares@ua.es](mailto:sllinares@ua.es)

*Since noticing has been identified as a critical skill that teachers must develop, research on how pre-service teachers develop this skill in teacher education programs has emerged. In this study, we focus on how pre-service teachers notice students' fractional reasoning through a task designed taking into account a students' Learning Trajectory of fractional reasoning. Our results show that pre-service teachers' learning of the Learning Trajectory helped them to notice students' fractional reasoning in a structured way: identifying important mathematical elements of the problems and, establishing relationships between the mathematical elements and students' fractional reasoning levels of the Learning Trajectory to help students progress in their fractional reasoning.*

*Keywords: Noticing, fractional reasoning, learning trajectories.*

## Noticing and learning trajectories

Noticing has been shown as an important skill for teachers. This skill has been conceptualised from different perspectives (Jacobs, Lamb, & Philipp, 2010; Mason, 2002, 2011; Sherin, Jacobs, & Philipp, 2011) but all of them emphasise the importance of identifying the relevant aspects in teaching and learning situations and interpreting them to make teaching decisions. Mason stated that “noticing is a movement or shift of attention” (Mason, 2011, p. 45) and identified different ways in which people can attend (p.47):

*Holding wholes* is attending by gazing at something without particularly discerning details.

*Discerning details* is picking out bits, discriminating this from that, decomposing or subdividing and so distinguish and, hence, creating things.

*Recognizing relationships* is becoming aware of sameness and difference or other relationships among the discerned details in the situation.

*Perceiving properties* is becoming aware of particular relationships as instances of properties that could hold in other situations.

*Reasoning on the basis of agreed properties* is going beyond the assembling of things you think you know, intuit, or induce must be true in order to use previously justified properties as the basis for convincing yourself and others, leading to reasoning from definitions and axioms.

This perspective emphasises the importance of identifying the relevant aspects of the teaching-learning situations (discerning details) and interpreting them (recognising relationships) to support instructional decisions (perceiving properties).

On the other hand, research has shown that when pre-service teachers attend to students learning progressions in a particular mathematical domain, they are better able to make decisions about next

instructional steps (Wilson, Mojica, & Confrey, 2013). In this context, students' learning trajectories (Battista, 2012) can assist pre-service teachers in identifying learning goals for their students, in anticipating and interpreting students' mathematical reasoning and in responding with appropriate instruction (Sztajn, Confrey, Wilson, & Edgington, 2012). Our study is embedded in this line of research and analyse how pre-service teachers' learning of a fractional reasoning Learning Trajectory supports their development of noticing students' fractional reasoning. Our research question is: how do pre-service teachers interpret student' fractional reasoning and respond with instructional actions using a learning trajectory of fractional reasoning?

### **A learning trajectory of fractional reasoning**

A Learning Trajectory consists of three components: a learning goal, learning activities, and a hypothetical learning process (Battista, 2011). A Learning Trajectory includes descriptions of learning activities that are designed to support students in the transition through intermediate stages to a more sophisticated level of reasoning.

The learning goal of the fractional reasoning Learning Trajectory used in this study is derived from the Spanish Primary Education's curriculum: the meaning of fraction and its different representations and, the meaning of fractions operations. This learning goal highlights two key aspects: a) the transition from an intuitive meaning of splitting into equal parts to the idea of fraction as part-whole taking into account different representations, and b) the construction of the meaning of operations with fractions.

The student's learning process takes into account how the student reasoning about fractions develops over time (Battista, 2012; Steffe, 2004; Steffe, & Olive, 2009). We have considered six different levels of students' fractional reasoning (learning trajectory proficiency levels): **at level 1**, students have difficulties in recognising that the parts of the whole must be congruent; **at level 2**, students recognise that the parts could be different in form but congruent in relation to the whole. This allows them to identify and represent fractions in a continuous context but they have difficulties with discrete contexts. They also begin to use unit fractions as an iterative unit (i) to represent proper fractions (although they have difficulties with improper fractions) and (ii) to solve some fraction addition problems with the same denominator; **at level 3**, students identify and represent fractions in discrete contexts recognising that the groups must be equal. They also recognise that a part could be divided into other parts. When comparing fractions, they recognise that the size of a part decreases when the number of parts increases. They can use a part (not necessarily the unit fraction) as an iterative unit to represent proper ( $f < 1$ ) and improper ( $f > 1$ ) fractions. They can also reconstruct the whole using any fraction as an iterative unit (continuous and discrete contexts). In addition, they use intuitive graphical representations to add/ subtract fractions with different denominators; **at level 4**, students can solve simple arithmetic problems with the help of a guide or support. They can do equivalent fractions so that operations can be graphically represented. When they add or subtract fractions with different denominators, they understand that the parts must be congruent to join/separate although they need a guide that allows them to choose the unit correctly. When they multiply, they understand the fraction as an operator " $a/b$  of  $c/d$ " and when they divide, they develop two types of reasoning; (i) division as a measure and (ii) division as a partition; **at level 5**, students can operate and solve arithmetic problems symbolically, identifying patterns. They can graphically justify what they do but only in simple situations. At this level, they

are able to interpret the remainder of a division of fractions; **at level 6**, students can explain operations graphically. They do not need a guide to represent fraction operations.

## Method

### Participants and context

Participants were 31 pre-service primary school teachers (PT) enrolled in a degree to become primary school teachers. They were enrolled in a subject of 150 hours (60/90 attendance/nonattendance) related to teaching and learning of mathematics in primary school. In previous courses, these pre-service teachers had participated in a subject related to Numerical Sense and in a subject related to Geometrical Sense.

### Instrument: The task

The task consists of three pairs of primary school students answers, with different learning trajectory proficiency levels of fractional reasoning, to a problem that implies the identification of a fraction (adapted from Battista, 2012) (Figure 1). These answers reflect characteristics of the first three levels of the Learning Trajectory. The answers of Xavi and Victor show characteristics of the level 1 since they are not able to identify that the parts of a whole must be congruent. The answers of Joan and Tere reflect characteristics of the second level since they are able to identify that the parts of a whole must be congruent in continuous contexts but they still do not recognise that a part can be divided into other parts. This last characteristic is evidenced when they say that Figure E is not three quarters because it is divided into 24 equal parts and there are 18 shaded. Finally, the answers of Álvaro and Félix show that not only they are able to recognise that the whole must be divided into congruent parts but also they acknowledge that a part could be divided into other parts.

Pre-service teachers had to answer the next four questions. To answer them, we provided pre-service teachers with theoretical information about the mathematical elements of the fraction concept and about the Learning Trajectory of fractional reasoning used in this study.

**Q1-** Describe the problem taking into account the learning objective: what are the mathematical elements that the student needs to know to solve it?

**Q2-** Describe how each pair of students has solved the problem identifying how they have used the mathematical elements involved and the difficulties they have had with them.

**Q3-** What are the characteristics of students' reasoning (Learning Trajectory) that can be inferred from their responses? Explain your answer.

**Q4-** How could you respond to these students? Propose a learning objective and a new activity to help students progress in their fractional reasoning.

These questions and the theoretical information given (Learning Trajectory of fractional reasoning) focus pre-service teachers' attention on relevant aspects of students' answers (discerning details) identifying the relevant mathematical elements; on interpreting these answers (recognising relationships between the mathematical elements and students' reasoning) and on supporting instructional decisions (attending students' mathematical reasoning).

**1. Choose the figures below that show  $\frac{3}{4}$ . Explain your answers.**

**Xavi and Víctor's answers**

Víctor: Mmmm, well we think Figures A, B, C and D represent three-quarters.

Teacher: Xavi, do you agree with Víctor?

Xavi: Yes, A, B, C and D are divided in 4 parts, and 3 are shaded.

**Joan and Tere's answers**

Tere: We believe that Figures B and D are three quarters because they are divided into four equal parts and three are shaded. Figures A and C have 3 parts of 4 shaded, but the parts are not equal...

Teacher: And Figure E? What do you think about Figure E?

Joan: Figure E is not three quarters because it is divided into 24 equal parts and there are 18 shaded.

Tere: Sure, it is not three-quarters.

Teacher: And the F?

Both: It is not a fraction. In figure F, there are only 6 shaded squares.

**Félix and Álvaro's answers**

Félix: Well ... yes. We agree with Joan and Tere answers related to figures A, B, C, and D but we think differently about figure E...

Teacher: What do you think? Could you explain your answer?

Álvaro: Well ... mmm sure. If you look each line of Figure E, each line has 6 squares, and as there are 3 lines shaded of the 4 total lines then it is three quarters. In addition, Figure F also represents three quarters because if you group the squares in groups of 2, you get 4 groups of 2, and there are three groups shaded.

Álvaro and Félix answer to Figure F

**Figure 1: Task to support pre-service teachers' learning of a fractional reasoning Learning Trajectory to notice students' mathematical reasoning**

**Analysis**

Taking into account Mason's work and the Learning Trajectory of fractional reasoning, we analysed pre-service teachers' answers according to if they had (i) identified relevant elements of fractional reasoning in the student's answers (discerning details); (ii) interpreted the student's reasoning considering the characteristics of students' fractional reasoning from the Learning Trajectory (recognising relationships between the elements identified and the different levels of students' learning progress of fractional reasoning); (iii) made instructional decisions (reasoning about next steps providing different activities that promote students' progression in the Learning Trajectory).

To carry out the analysis, initially a subset of pre-service teachers' answers was analysed by three researchers independently considering the points mentioned above. Then, we put together our respective analyses and compared and discussed our discrepancies until reaching an agreement. Afterwards, new data samples were added to review our allocation.

## Results

From the analysis, we have identified three groups of pre-service primary school teachers according to the way that they used the Learning Trajectory to interpret students' fractional reasoning and make teaching decisions. These results show that 20 pre-service teachers were able to use the Learning Trajectory to interpret students' fractional reasoning, while the other pre-service teachers (group 1) had difficulties in using the Learning Trajectory to interpret students' answers. The characteristics of the different groups of pre-service teachers are:

- Group 1. Pre-service teachers who used some mathematical elements of the Learning Trajectory but in rhetoric way or without sense (11 PT).
- Group 2. Pre-service teachers who used the mathematical elements of the Learning Trajectory to recognise different levels of students' fractional reasoning, but they were not able to propose new activities considering the learning trajectory proficiency levels (11 PT)
- Group 3. Pre-service teachers who used the mathematical elements of the Learning Trajectory to recognise different levels of students' fractional reasoning, and proposed new activities to help students progress in their fractional reasoning taking into account the learning trajectory proficiency levels (9 PT)

### Group 1: Pre-service teachers who used some mathematical elements of the Learning Trajectory but in rhetoric way or without sense

Pre-service teachers of this group used the mathematical elements implied in the problem (the parts of the whole must be congruent and a part can be divided in other parts) in a rhetoric way when they described students' answers but they did not recognise characteristics of the different Learning Trajectory proficiency levels in students' answers. For instance, the pre-service teacher E27 answered question 3 of the task, pointing out (emphasis has been added underlying the mathematical elements):

Víctor and Xavi: They are at Level 1 of the Learning Trajectory because they do not know the concept of congruence and they do not know that a part could be divided in other parts

Joan and Tere: They are at Level 1 because they have difficulties in recognising that the part must be congruent and they do not recognise that a part could be divided in other parts.

Félix and Álvaro: They are at Level 1 because, related to congruence they know the same that Joan and Tere, although they recognise that a part could be divided in other parts in continuous and discrete contexts.

This pre-service teacher did not recognise differences between students' fractional reasoning saying that all pairs of students have difficulties with the mathematical element *the parts of the whole must be congruent* although he used the mathematical elements to describe students' answers.

**Group 2: Pre-service teachers who used the mathematical elements of the Learning Trajectory to recognise different levels of students' fractional reasoning, but they were not able to propose new activities considering the Learning Trajectory proficiency levels**

Pre-service teachers of this group used the mathematical elements of the Learning Trajectory that correspond with the problem (the parts of the whole must be congruent and a part can be divided in other parts) to recognise the different levels of students' fractional reasoning. However, these pre-service teachers did not justify a new activity taking into account the students' fractional reasoning. For instance, the pre-service teacher E09 answered to question 2 and 3 for each pair of students (emphasis has been added underlying the mathematical elements):

Víctor and Xavi have difficulties in recognising that the parts must be congruent as they identify as a  $\frac{3}{4}$  figures A and C whose parts are not equal. Another characteristic that we can identify is that they have difficulties in recognising that a part could be divided in other parts. They do not notice that figures E and F are divided in 4 parts, maybe they notice that E has 24 squares and F has 8 squares. Thus they do not realise that both are equivalents. So, these students are at Level 1.

Joan and Tere are able to identify and represent fractions in a continuous context recognising that the parts must be congruent as they recognise that, although figures A and C are divided in 4 parts and 3 are shaded they do not represent  $\frac{3}{4}$  because the parts are not congruent. They also identify that B and D are  $\frac{3}{4}$ . They are not able to recognise that a part could be divided in other parts/consider a group of parts as a part since they do not identify that even though E and F are divided in more parts, they represent  $\frac{3}{4}$ . So, these students are at Level 2.

Félix and Álvaro agree with Joan and Tere about figures A, B, C, and D, thus they recognise that the parts must be congruent. Furthermore they recognise that a part could be divided in other parts and they identify fractions in discrete contexts since for figure E they say that, although it is divided in 24 squares, it represents  $\frac{3}{4}$  because there are 4 lines with 6 squares each and 3 of those 4 are shaded (they recognise the equivalence  $18/24=3/4$ ). Besides of that, in figure F they group in pairs the eight squares of the whole to represent the  $\frac{3}{4}$ . So, these students are at Level 3.

Nevertheless, this pre-service teacher was not able to propose a specific activity considering the Learning Trajectory in order to help students progress in their conceptual reasoning. For instance, this pre-service teacher proposed for the first pair of students: *“With Víctor and Xavi we would work with the recognition that the parts must be congruent. To do that, we could propose the same task but with other figures and they (students) could represent  $4/6$ ”*.

The answers of this group of pre-service teachers indicated the difficulty of making instructional decisions considering the Learning Trajectory proficiency levels.

**Group 3: Pre-service teachers who used the mathematical elements of the Learning Trajectory to recognise different levels of students' fractional reasoning, and proposed new activities to help students progress in their fractional reasoning taking into account the learning trajectory proficiency levels**

Pre-service teachers of this group, after using the mathematical elements (the parts of the whole must be congruent and a part can be divided in other parts) to recognise different levels of students' fractional reasoning, proposed new activities focused on helping students progress in their fractional

reasoning according to the learning trajectory proficiency levels. For example the pre-service teacher E25 proposed the next objective and activity to help Victor and Xavi progress in their fractional reasoning:

Objective: In order to progress from Level 1 to Level 2, students have to recognise that the parts of a whole must be congruent (although they could be different in form).

Activity: Represent in the following figure (square)  $\frac{2}{4}$  in three different ways

This group of pre-service teachers used their knowledge of the Learning Trajectory to interpret students' fractional reasoning, and proposed new activities to help students develop their fractional reasoning.

## Discussion and conclusions

The aim of this research was to analyse how pre-service teachers' learning of a Learning Trajectory of fractional reasoning supports their development of noticing students' fractional reasoning. We focus on how pre-service teachers interpret student' fractional reasoning and respond with instructional actions using a learning trajectory of fractional reasoning.

Twenty out of thirty-one pre-service teachers who participated in the task were able to use the mathematical elements to interpret students' fractional reasoning considering the characteristics of the students learning progression of fractional reasoning and identifying different levels of students reasoning. This result indicates that the information about a Learning Trajectory of a particular mathematic topic can be used by pre-service teachers to begin to notice features of students' mathematical thinking in a particular domain and therefore, to develop the skill of noticing. The Learning Trajectory can be seen as a powerful tool that help pre-service teachers focus their attention on important mathematical aspects of the problem, on the students' mathematical reasoning and on making instructional decisions on the basis of students' mathematical reasoning. The other eleven pre-service teachers had difficulties in using the Learning Trajectory to interpret students' answers. This result is in line with other studies that have shown that interpreting students' mathematical reasoning is a challenging task for some pre-service teachers (Llinares, Fernández, & Sánchez-Matamoros, 2016; Sánchez-Matamoros, Fernández, & Llinares, 2015).

However, only nine out of these twenty pre-service teachers could use their interpretations of students' fractional reasoning to propose new activities according to the Learning Trajectory in order to help students progress in their fractional reasoning. Previous research has pointed out that the skill of making instructional decisions is the most difficult one to develop in teacher education programs (Callejo & Zapatera, 2016; Ivars & Fernández, 2016; Llinares, Fernández, & Sánchez-Matamoros, 2016; Sánchez-Matamoros, Fernández, & Llinares, 2015). Nevertheless, approximately one third of the participants, in our task, were able to design an activity to promote students' progressions of fractional reasoning according to the Learning Trajectory. Therefore, we think that the task of our study, designed according to a Learning Trajectory, seems to have a relevant paper in the development of the skill of providing activities that could help students progress in their learning. The Learning Trajectory could be seen as a referent or guide for pre-service teachers that could help them to link the mathematical domain (mathematical elements), the student's reasoning and the instruction that considers students' learning progressions.

# Collaborative research in in-service teacher professional development

Jónína Vala Kristinsdóttir

University of Iceland, School of Education, [joninav@hi.is](mailto:joninav@hi.is)

*Teachers in Iceland are faced with challenges to differentiate teaching as they implement a policy of inclusive education. This collaborative inquiry into teaching of mathematics aims at learning to understand how teachers develop their mathematics teaching through participating in a developmental research. Seven primary teachers worked at improving their mathematics teaching and researched their practice together with a teacher educator for three years. Narrative inquiry was used as an analytical tool to study the teachers' learning. In this paper the focus is on one of the teachers and her learning from participating in the project. The results indicate that she gained confidence in teaching mathematics in diverse classrooms while participating in workshops and that collaborative research can support teachers in developing their practice when meeting new challenges in their work.*

*Keywords: In-service teacher education, developmental research, collaborative inquiry.*

## Introduction

This paper reports on findings from a three-year qualitative collaborative inquiry into mathematics teaching and learning with the purpose of deepening our understanding of how teachers meet new challenges in their classrooms. The aim was to learn about the processes that emerge through collaborative inquiry between classroom teachers and a teacher educator. In this paper the focus is on one of the teachers', Pála, and her development in teaching mathematics while participating in the project. The research question that will be answered is:

In what way did Pála affect the learning developed within the project and how is her participation reflected in her mathematics teaching?

The study built on earlier research on teacher development in mathematics teaching in Iceland that revealed that teachers take a passive role in their mathematics teaching and lack experience in creating meaningful learning environments for all children (Guðjónsdóttir, & Kristinsdóttir, 2011; Savola, 2010). They have particularly focused on instrumental understanding as opposed to relational understanding (Skemp, 1976) and emphasised that their pupils learn to carry out the steps of the 'traditional' algorithm (Fosnot & Dolk, 2005). My fellow teacher educators and I have found that if teachers are given opportunities to collaboratively investigate 'with' mathematics and solve mathematical problems, they discover how the different experiences they bring into the community can contribute to their own understanding of the mathematics involved, as well as how individuals learn mathematics (Guðjónsdóttir & Kristinsdóttir, 2011; Gunnarsdóttir, Kristinsdóttir, & Pálsdóttir, 2013). In our work with pre- and in-service teachers, we found that they must be offered opportunities to experience learning that enhances inclusive education. Our results correspond with those of Bredcamp (2004) and Moore (2005), who emphasised that if teachers' work is expected to be aimed at diversity and mutual understanding, they require the opportunity to develop and enhance their knowledge about teaching and learning in an environment that reflects the very same aspects that they are expected to foster in their own classrooms.

## Teacher development in inclusive settings

Teaching children mathematics requires teachers to understand how their students learn mathematics and they need to be skilled both in mathematics and pedagogy as well as the knowledge that combines knowing about teaching and knowing about mathematics. In recent years the Nordic countries have emphasized mathematical competences of which eight specific mathematical competences were identified. These form two clusters; the ability to ask and answer questions in and with mathematics; and the ability to deal with mathematical language and tools (Niss & Højgård, 2011). Niss & Højgård also outlined a model for mathematics teacher competency where the ability to develop one's competency as a mathematics teacher as well as the competencies of working with students and others towards professional development were identified. It is important to note that development of teaching in classrooms is dependent both on the teachers' knowledge and their ability to learn together with others, both their students and colleagues.

Attention and awareness are important features of mathematics learning. Mason, (1998) holds that teaching is fundamentally about attention and teachers can enhance pupils' attention by attending to their own awareness. When someone else points something out to us our awareness changes slightly; we become more explicitly aware of some features, and less aware of others. Thus in collaborating with colleagues, teachers are afforded the ideal conditions in which work on their own awareness, which can provide conditions for their students to experience them too.

When gaining competence in teaching mathematics teachers build on their knowledge and experience and an essential factor in this process is the participation in learning communities. In order to be able to support learners in their classrooms in acquiring mathematics competence, teachers need to urge their pupils' to ask probing questions, take risks and learn from their mistakes.

In communities of learning the individual learner draws on knowledge in the community as well as on personal knowledge. Nevertheless the main emphasis has been on individualized learning in response to diversity in classrooms. Schools have thus adopted what Ainscow (1995) called integration by making only a limited number of arrangements for including all learners in classroom activities. Askew (2015) argued that learning communities are more inclusive than taking the individual as the starting point for planning learning experiences. In these communities teachers work with the collective construction of mathematical knowledge while still ultimately addressing the needs of the individuals within that community. This is the same position I took in working with teachers, attending to their diverse needs for improving their teaching and finding ways to work in inclusive ways with diverse groups of learners.

Through collaborative activity a community learns from the thinking, practices, and development of the individual. Important features of such communities are discussions about the mathematics attended to in the classroom. In the communities learners listen to each other's solutions and think about connections to their solutions while helping each other refine their methods and explanations. When learners participate in mathematical practices in whatever way they can diversity is no longer an obstacle to classroom talk. It is thus being enriched through the diversity of learners' contributions (Askew, 2015).

## Methodology and methods

The study is a collaborative inquiry into mathematics teaching and learning (Goos, 2004), and the aim is to build a co-learning partnership between teachers and a researcher in order to support classroom inquiry (Jaworski, 2006). The methodology of developmental research (Gravemeijer, 1994) and the ‘developmental research cycle’ (Goodchild, 2008) guided the cyclic process of the research.

In an attempt to make explicit the ‘practice’ in which teachers and researchers participate when collaborating, Jaworski (2003) suggested shifting from the notion of community of practice (Wenger, 1998) to that of ‘community of inquiry’, where teaching is seen as learning-to-develop-learning. In such a community, teachers and researchers both learn about teaching through inquiring into it. In this project the vision was that all the participants would learn about teaching mathematics in diverse classrooms.

For three years I worked with seven teachers at 90-minute workshops on monthly basis. They taught 10 to 12 years old pupils in two neighbouring schools, four were homeroom teachers and three were support teachers that joined them in mathematics classes. The focus of the workshops was on reflection on mathematics, and on mathematics teaching and learning. To help the teachers develop their own understanding of mathematics, we worked with problems that had the potential to promote mathematical activity and thinking as well as to stimulate collaboration where discussions and sharing thinking were meaningful. We also discussed new research on mathematics education and stories from the teachers’ classrooms, reflected on their pupils’ mathematics learning and considered how their mathematical thinking developed. To learn about the teachers’ visions for the project and the cultures in their mathematics classrooms I interviewed them and observed their classrooms at the outset of the project, after the first year, and one year after the last workshop. Data was collected of videotapes from workshops, audiotapes from interviews and notes from classroom observations.

Narrative inquiry was used as an analytical tool to study the teachers’ learning in participating in this project. It is a way of understanding and researching experience through collaboration between a researcher and participants and to research with practitioners their lived experience as a source of their knowledge and understanding (Clandinin, 2013). The stories the teachers told about their work, at the workshops and in interviews, are the basis of the narrative inquiry. The teachers read the drafts of their narratives and commented on them, and then on the final version.

## Findings

Pála had been a general classroom teacher over 30 years in grades 5-7 when she participated in the collaborative project. In her teacher education her focus was on language skills and she had attended many in-service courses about language teaching but only a few about mathematics teaching. As a classroom teacher she taught mathematics to 10-12 year old children.

### Emphasis on instrumental understanding

When I observed Pála’s classroom at the outset of the study her emphasis on carefully describing the steps of algorithms was dominant. She started the lesson by reviewing homework and then

discussed the content of the lesson. She described carefully to her pupils how to work through the problems in their textbook that she wanted them to solve.

Pála worked closely together with her colleague Dóra, at teaching pupils in their 5<sup>th</sup> grade classrooms. At our first workshop Dóra wanted to discuss the teaching of ‘traditional’ algorithms (Fosnot & Dolk, 2005). She had discussed the algorithm of long division with Pála and questioned her belief that is necessary for their pupils to learn the steps of the algorithm. Pála added:

What we have been reflecting on is, is it bad, does it spoil anything for them? Does it destroy their thinking process, does it stop anything?

Pála was eager to learn more about how to teach children to calculate. She had emphasised the memorising of facts and at her school children were regularly tested on multiplication facts. Dóra had also questioned this tradition and Pála was starting to review her beliefs about instrumental understanding (Skemp, 1976).

### **Reviewing her own way of calculating**

Pála was eager from the beginning to improve her own way of solving mathematical tasks. When we at our forth workshop discussed how many cans there were needed to build a ten storey tower of cans she said:

There would be 10 here [points to the bottom row of the 10 storey tower she drew]. Then I would count 9 and 1, 8 and 2, 7 and 3, 6 and 4. Then I have 10, 20, 30, 40, 50 and then add these 5 [points to her drawing for each step] and have got 55. I do this to be quick at counting.

Pála was reflecting on her own way of calculating when she said that she did this to be quick at calculating thus attending to her own awareness of learning (Mason, 1998).

As the project developed Pála brought in problems she had been solving with her pupils and wanted to discuss her understanding of the problems with us. At Workshop 15 she told us about her discussions with her pupils about how many handshakes there would be in their class if they all shook hands with each other. The children decided to try this and were quick to realise that they would only shake hands once with each person. They developed a rule that could be used to calculate the handshakes in their group of 15 pupils:  $14+13+12+ \dots +2+1$ . They then split into smaller groups to test if their rule could be applied to a group of any size. Pála had not thought about the solution of this problem before it was discussed in her class and therefore took an active part in the solution process. By comparing the total handshakes for different number of pupils, they then had developed a formula together. Pála was keen to discuss with us whether the formula  $n(n-1)/2$  could be applied to calculate the handshakes for a group of any size. Pála said:

I do not understand why this equation works, why this connection. I know it works, we have tried it for many cases. Can you help me to understand why it works? I would like to proceed to work with the children in this way.

By asking us to discuss her experience with us Pála was adding to her competence of learning together with colleagues and in discussing with her pupils she was developing her competence in learning with them. She was also supporting her pupils in developing their the ability to ask and answer questions in and with mathematics (Niss & Højgård, 2011).

I reminded Pála on her earlier addition of consecutive numbers in relation to the tower of cans. Pála said that she remembered it but she still could not understand why the formula she had developed with her pupils worked. We then discussed their formula and why it could be used to calculate the handshakes and in doing so we were inquiring into our own mathematics learning (Goos, 2004) and cultivating our learning community (Jaworski, 2003). I pointed out that she took an active part in the learning process in the classroom. Not only did she learn about the children's thinking but also about her own thinking about the problem. She had given them a problem that neither she nor they knew beforehand how to approach. Then they all started to investigate and look for patterns and developed a rule together. Through these discussions our co-learning partnership was cultivated as we focused on classroom inquiry (Jaworski, 2006).

### **Learning together with her pupils**

Pála was starting to learn together with her pupils by exploring with them in the classroom as opposed to the beginning of our collaboration when she had carefully explained to her pupils, how to solve problems. At our final workshop she shared with us her discussions with her pupils. They had worked with different kinds of word-problems in their textbook. They were required to write their solutions to the problems with algebraic expressions. She gave examples of the pupils' discussions about the problems and how they wrote the expressions. She had recorded these examples in her notebook and now wrote on the whiteboard to show us how the pupils calculated and how she interpreted their thinking about the problems.

We discussed two of the problems:

Klara is 4 years younger than her brother Kári. Their total age is 18 years. How old is Kári?

A large apple costs 11 ISK more than a small apple. The total price of a small apple and a large apple is 59 ISK. What is the price of a large apple?

Pála had solved the problems herself and her thinking was different from her pupils' but they all came to the same conclusions. She wanted to discuss this experience with us and hear my interpretation of the different ways they solved the problems. She was particularly keen to hear my opinion with regard to the way she had accepted her pupils' way of solving a problem instead of telling them to think about it in the same terms she did.

Jónína: Pála, you said that the children wrote  $x+x+4=18$  and you wrote  $x+x-4=18$ .

Pála: Yes. And for the apples they wrote  $x+x+11=59$  and I wrote  $x+x-11=59$ .

We discussed how the value of the unknown variable in Pála's equation was different from the value in the children's equation. Still in both cases they came to the same conclusion about the age of the siblings and the price of the apples. Pála said that all the children in her class were able to solve the word problems by first trying some numbers and then adjusting them until they found the right numbers. Many of them could write the equations and they then supported each other in doing so. Finally Pála concluded: "These were just my thoughts. I found it interesting to see how they understood and thought about this".

When Pála shared this story with us she was cultivating our learning community (Askew, 2015; Jaworski, 2006). But she had also attended to her pupils' way of learning and was now focusing on their way of expressing themselves instead of describing carefully to them the steps they needed to

take as she did to begin with thus making herself aware of her pupils diverse ways of learning (Mason, 1998).

### **Grouping pupils into ability groups**

In Pála's school it had been the custom for many years to group children into groups in mathematics classes based on the outcomes of an end of term test. When the project began Pála and Dóra had divided the 43 children in fifth grade into three groups in mathematics classes. A special education teacher taught the pupils who got the lowest grades, Dóra taught those who got the highest grades and Pála taught the middle group. With this arrangement they were responding to diversity by making only a limited number of arrangements for including all learners in classroom activities (Ainscow, 1995). To begin with Pála was concerned that the pupils in her group were not capable of solving problems without her leading them step by step. Gradually as she became more confident with exploring with mathematical problems herself she started to listen to them and allow herself to join them in their explorations with problems as discussed above.

When Pála shared her experiences of working with her pupils with us we discussed how her approach supported the children's learning like the case with the handshake problem. She told us that some of her pupils understood why the formula could be applied to solve this problem and others did not. They though all understood that they could calculate the total number of handshakes by adding  $(n-1) + \dots + 1$ . We then related to our former discussions of tasks that can be solved at many levels and are therefore suitable to work with in diverse classrooms. Pála was satisfied with this experience and found that she was beginning to trust that all her pupils were capable of more in-depth learning than she had realized before thus acknowledging that diversity is no longer an obstacle (Ainscow, 1995; Askew, 2015).

The final year the project was running Pála and her close colleague, Dóra, had decided not to group their pupils into ability groups any more. They had become confident in investigating in mathematics with their pupils and found that all the children in their classes were capable of learning together and gained from sharing experiences with each other.

### **Professional development and influence on our project**

Pála took an active part in using the tools for professional development that I offered the teachers in our learning community. She visited her colleague's classrooms and discussed with them what they learned from their visits and she recorded her lessons to learn from her communication with her pupils. She also shared her experience from her learning in the classroom with us and gradually started to lead what to focus on at our workshops. Not only did she share this experience with us she also brought in problems she had found elsewhere and asked us to solve them with her.

The project was only planned for one year to begin with. As we approached the end Pála expressed her wish to meet for a second year. She felt that she and the other teachers were just starting to develop their teaching and could not stop when they felt that they were gaining so much from our collaboration. The other teachers agreed with her and our project ran for three years as the teachers wished to extend it for the third year. With her willingness to share her thinking with us and take lead in what to focus on at the workshops Pála shaped the developmental process of the project and affected the 'developmental research cycle' (Goodchild, 2008).

## Conclusions

Based on the narratives of Pála's participation in the collaborative project I have concluded that she gained confidence in teaching mathematics in diverse classrooms and that collaborative research can support teachers in developing their practice when meeting new challenges in their work. The sketches from our collaboration are representative for the learning that emerged during our collaboration. In the communities of inquiry we managed to build at the workshops we supported each other in learning-to-develop-learning (Jaworski, 2003) by reflecting collectively on the stories the teachers told of their classroom experiences. From the stories Pála told us we learned how her pupils' competences in dealing with mathematical language and tools were developing as well as their ability to learn about their own learning in working with their pupils (Niss & Højgård, 2011).

By offering the teachers opportunities to experience learning that enhances inclusive education (Bredcamp, 2004; Moore, 2005), the teachers were empowered to develop their teaching as was reflected in Pála's learning.

During our three years of collaboration I, as a teacher educator and a researcher learned about teachers' capabilities to develop their own teaching if they are supported in reflecting on their learning of mathematics as well as their pupils' learning. In reflecting on their learning about mathematics teaching my understanding has deepened of the opportunities and challenges teachers meet when including all learners in meaningful mathematics learning.

# Integrating teachers institutional and informal mathematics education: The case of ‘Project ArAl’ group in Facebook

Nicolina A. Malara<sup>1</sup> and Giancarlo Navarra<sup>2</sup>

<sup>1</sup> Modena & Reggio Emilia University, FIM Department, Italy; [malara@unimore.it](mailto:malara@unimore.it)

<sup>2</sup> Modena & Reggio Emilia University, FIM Department, Italy; [giancarlonavarra@gmail.com](mailto:giancarlonavarra@gmail.com)

*After a sketch of our ArAl project devoted to teaching/learning early algebra, we introduce our ‘Progetto ArAl’ group in Facebook, conceived not only to share and discuss among teachers didactical experiences, theoretical questions and materials but, more in general, to educate in informal way teachers in early algebra. For its features it can be said a non standard group (NSG) in Fb. The main question we put ourselves is: may a NSG become a community of practice? To find an answer to this question we compared our group with a larger Italian group devoted to mathematics at primary school analyzing the interactions in the two groups launched by some common members. On the base of this comparison we delineate some hypotheses for the management of a NSG as a community of practice, where well known mentors and transparent theoretical guidelines allow the teachers consciously to approach the theory for the practice.*

*Keywords: Early algebra, community of practice, informal on line education, teachers’ professional development.*

## Introduction

The ArAl project belongs to the stream of studies devoted to the renewal of the teaching in the arithmetic-algebraic area in the perspective of early algebra. It is characterized by the intertwining among: a) the activation in the classes of innovative didactical paths on early algebra; b) educational processes of teachers based on the critical analysis of the mathematical discussions developed inside the didactical paths. It promotes a relational approach to arithmetic of linguistic and metacognitive type, to be realized through socio-constructive modalities. The classroom activities are based on the negotiation of a didactical contract for the solution of problems according to the principle: “first represent, then solve”. For room questions we cannot discuss deeply our theoretical frame (we refer to Cusi et al. 2011 and related references), here we simply recall some key aspects of it: (i) the plurality of representations of a given quantity, beyond the canonical decimal representation<sup>1</sup>; (ii) the identification and making explicit algebraic relationships and structures underpinning concepts and representations in arithmetic<sup>2</sup>; (iii) the initiation to the essential algebraic cycle: *representing*,

---

<sup>1</sup> For instance, the number twelve, has a canonical representation in base 10, i.e. 12, but expressions such as  $3 \times 4$ ,  $(2+2) \times 3$ ,  $36/3$ ,  $10+2$ ,  $3 \times 2^2$  are other ways to express the same quantity, we call them non-canonical representations of 12, each has its sense related to the process that characterizes it and offers pieces of information about the number. Being able to fluently shift among these forms allows pupils to easier recognize structural similarity among different numbers and to build the basis for understanding scriptures as  $a.b$ ,  $-4p$ ,  $x^2y$ ,  $k/3$ ).

<sup>2</sup> For instance to see the equal sign, in writings such as  $3+4=7$ , not only in its *procedural* sense of connection between an operation and a result, but in its *relational* sense, as an indicator of equivalence between *two different representations of the same number*).

*transforming, interpreting* (Bell 1996) through *the devolution to the students of: a) the formalization of verbal relationships* individuated during explorative numerical activities (process named by us *algebraic babbling*); (b) *the interpretation of simple algebraic sentences* both in themselves and with reference to a given context<sup>3</sup>; (v) the stress on natural language as didactical mediator in the slow construction of syntactic and semantic aspects of algebraic language<sup>4</sup>.

Our work with and for teachers has always been realized in a community of practice, or better of inquiry in Jaworski sense<sup>5</sup>, where the practice of the researchers and the one of the teachers meet, compare and develop in co-partnership and where, in addition to theory, methods and aims, values and expectations are shared (Cusi & Malara 2015). Because of the teaching in an early algebra perspective requires in the teachers, mainly the ones of primary school, a deep rebuilding of knowledge, beliefs, behaviours, and manners in the class, we have conceived specific modalities and apposite tools for teachers education. We simply recall here our *Multicommented Transcripts Methodology*, we have enacted to promote in teachers awareness of their own ways of being in the class and to guide them in managing mathematical discussions. Key tools of this methodology are the teacher's transcriptions of the classroom discussions enriched by written multiple comments (by tutors, maths educators and other teachers), *the MTs*. The joint reflections on each MT attain a shared development of the theoretical frame, of the classroom methodologies and of the teaching materials that shall create the basis for the teachers' professional evolution. The productions of MTs became in the time a distinctive character of the Project Aral membership.

## The ArAl Project Group in Facebook

Along the years many times we have been asked to make available ArAI materials to a greater number of teachers; for this in 2014 we opened the ‘ArAI Project’ group in Facebook. Fb is mainly used as a way to share experiences, practices and materials among teachers and other professionals (see for

<sup>3</sup> For instance, to recognize that the sentence  $85=4\times 21+1$  represents 85 through the quotient and the remainder of its division by 4 (or by 21), and in the same time - looking for the letter which stays at the  $85^{\circ}$  place in a sequence generated by the ABCD module – to recognize that the same sentence allows to understand what the letter is (the pupils have to interpret the term  $4\times 21$  as the part of the sequence done repeating 21 times the module and the remainder as the number of place of the letter in the successive module).

<sup>4</sup> For instance, two pupils express in natural language, and then translate in mathematical language, their different ways to calculate the number of pearls in the necklace ○○●●○○●●○○●●○○●●○○●●○○●●○○●●: the first pupil says “I counted white and black pearls and I added them” and translates:  $2 \times 6 + 3 \times 6$ ; the second says: “I saw that there are 6 groups, each group has 2 white and 3 black pearls and I multiplied 2 plus 3 by 6 and wrote  $(2+3) \times 6$ . The comparison of the two sentences allow the pupils to gain experience about the distributive property.

<sup>5</sup> We recall that a community of practice (CP) is constituted by a group of people who share a craft and/or a profession. The group can evolve because of the members' common interest in a particular domain or area, or it can be created specifically with the goal of gaining knowledge related to their field (Lave and Wenger, 1991). Jaworski (2003), referring to the joint work developed between maths educators and in service teachers about classroom teaching-learning processes, introduces the construct of Inquiry Community (IC) and underline that what distinguish a CI from a CP is that all the participants engage with inquiry as a tool to develop meta-knowing, a form of critical awareness that manifests itself in inquiry as a way of being.

example Bodell & Hook 2011, Manca & Ranieri 2014), but in the last years it has also been used in educational activities for teachers (Staudt et al. 2013, Van Bommel & Liljekvist 2016). In our case, the initial idea was to spread themes and principles of early algebra among teachers and to motivate and help them in approaching it in the class but also to observe new, spontaneous didactical experiences, arising under the stimuli offered by the ArAl institutional courses. We believe that the Fb group can be a way to integrate institutional and informal education offering the teachers new occasions to promote their professional development. We started inviting expert teachers collaborating since long time in our project to become supporters of the group and to share their experiences with the teachers, recently involved in ArAl courses promoted by the schools, who have been invited to become followers of the Fb group. The fundamental methodological choices in managing the group are: our daily on line presence and prompt reactions to the teachers posts; the stimuli offered by the expert teachers posts through videos or pictures of classroom activities; our periodical posts about: mathematics questions and related theoretical references; examples of innovative activities, equipped by MTs, papers, powerpoint presentations for deepening the discussed questions and stimulating free experiments among the followers. The posts in Fb are classified in: ‘like-agree’ interventions; ‘propositive-constructive interventions’, doubtful-skeptical interventions; moreover meaningful sets of interventions related to interesting mathematical teaching questions are collected and commented in files put in our website. Periodical analysis of the data allowed us to highlight the interplay between our interventions and the teachers’ ones, and to reflect on the teachers change. We discuss their evolution according to three temporal phases.

**First phase** (scholastic year 2014–15). In this first period, in front of a small group of teachers (in most part coordinators in the schools of the ArAl project activities), who were very active in posting documents related to their class activities as well as in commenting other posts, the other members were not so active, and their comments often were short and superficial. These teachers appeared *awed*: the most part of them had a feeble or null control over the early algebra topics and the strong difference among the competence of the expert teachers in the group and their knowledge in the arithmetic-algebra area did not encourage them to do more ‘important’ interventions. At the same time every day new members enrolled to the group. Some more expert teachers, members both in our group and in other groups for maths teaching, suggested us to visit them and in particular invited us to take part into the group ‘Mathematics at primary school’ (one of the most numerous and active Italian groups on maths teaching in the web, more than 5000 members), to offer our interventions whenever we seemed appropriate to do so. We call this last group a Standard Group (SG), in the sense that there are not pre-established leaders and that the exchange takes place freely through the sharing and negotiation of the individuals’ knowledge. The comparison with the SG and other groups dealing with teaching issues brings in evidence that ArAl Project group is different from them, mainly for two reasons: (a) it deals with a well defined subject area, early algebra, it is structured according to a clear theoretical perspective for facing it, and it proposes methodologies, problematic situations, tools fitting with this framework; (b) it is daily supported by us and it is animated by experts teachers who may act as mediators among the members. Therefore we call it a non-Standard Group (NSG).

**Second phase** (scholastic year 2015-16): In this period we had continued to enter, as previously, examples of didactical activities, MTs, papers, powerpoint presentations but, at the same time - on our initiative or invited by the teachers - we had become more active in intervening on posts both in SG and in NSG. By way of example of this change in our strategy we focus on an episode: a post

inserted by a teacher which received great attention (154 likers and 75 comments), started in the SG and developed, through reciprocal sharings, also in the NSG. The initial post contained a link to a note inserted in the Unit 12 of ArAl project and presented in the form of FAQ in [www.progettoaral.it](http://www.progettoaral.it) site. In this post it is developed a critical analysis of a typical Italian school practice, supported also by many textbooks, for introducing in primary school the decimal system of representation of the natural numbers: the indication of the units with the letter 'u', the tens with 'da', the hundreds with 'h' and so on (the so-called 'marks'); thus there follow improper equalities such as  $653=6h+5da+3u$ . Because of the impasse generated in the SG, a follower - a member of both groups - asked us for an intervention on this topic. In a comment of a theoretical and linguistic type Malara wrote:

“The symbols h, da, u represent words of Italian language. They are categorical terms that refer to orders of magnitude and they are used as ‘indicators of quantity’. They are useful for bringing the pupils to shift from the experience with the abacus - where an assigned quantity is split into opportune multiple of powers of 10, operating for successive groupings of 10 – to the representation of the result of this operation through a string of symbols, each between 0 and 9 (extremes included), from which the name of the given quantity was born. This means that, for example the string 6h, 5da, 3u synthetizes the verbal sentence ‘the quantity is constituted by six hundreds, 5 tens and 3 units’ which generates the name of the number 653. The translation into the arithmetical language of this verbal sentence requires the conversion of the term ‘hundreds’ in the arithmetic operator ‘ $\times 100$ ’, the term ‘tens’ in ‘ $\times 10$ ’ and the ‘units’ in ‘ $\times 1$ ’ and the conversion of the connector ‘and’ in the operation of addition ‘+’. So, the total verbal sentence is translated into ‘ $3 \times 100 + 5 \times 10 + 3 \times 1$ ’. The sentence  $653=6h+5da+3u$  is improper because it mixes the two languages, verbal and arithmetic, and confuses the metacognitive plan with the operational one”.

While the debate on this issue was developing in the GS, many teachers did not understand why in the ArAl project sentences as  $653=60+50+3$ ,  $653=6 \times 100 + 5 \times 10 + 3 \times 1$ ,  $653=6 \times 10^2 + 5 \times 10^1 + 3 \times 10^0$  were proposed as correct and not the one they used, and opposed resistance to accept the explanation that  $653=6h+5da+3u$  is to be discarded because it is not a correct representation in mathematical language. To facilitate this understanding, the improper mingling between verbal and arithmetic languages has been pointed out also using examples of verbal sentences with words in two languages; the discussion then focused on the correct and incorrect representations of a natural number, the concept of ‘equality’ and on the meanings of the symbol ‘=’.

**Third phase** (June 2016 to now) The analysis of the dynamics arisen and the kind of the comments posted in NSG and SG led us to the identification of some thematic questions who have given us valuable indications on a question that we did with increasing frequency: may a group with the characteristics of ArAl group become a *community of practice*? If the answer is yes, in which ways may this happen? How may a gradual constitution of a library of shared knowledge be put in place? This leads us to identify some answers to these questions concerning the prevailing attitudes of teachers who enroll in these groups. We discuss them articulating in the following points.

#### **Features of a SG and of a NSG**

Members of a SG feel all *equal*: they exchange information, questions, requests without demanding to receive in-depth and substantive answers; they hope to share with their peers working suggestions which are at the level of their knowledge and of their willingness to get involved. Individual growth stems from the strength of exchanges and the wealth of experiences put into circulation. Internal

leaders emerge, who often are recognizable more by the diligence than by the quality of interventions; they often are the most convincing not for their knowledge but because they expose themselves more than others, writing frequently comments. Members may find appealing ideas for new activities but their enthusiasm is not supported by an adequate knowledge; they express insecurity when discussing their colleagues' proposals of those embryos of new ideas. Everyone feels free to comment on impulse. On the contrary, a NSG as 'Progetto ArAl' gives the majority of subscribers some (cultural and psychological) constraints that limit them in exposing their contributions. The same dynamics occur in a working-group in which an expert is present. But then: if it is understandable, for the reasons explained, that a GS exceeds 5000 subscribers, how has to be interpreted the success of our NSG that in two years is approaching 1000 members? The answer could be given with a metaphor: the members *have the impression of living a moment of institutional training*. They know that in the NSG there are experts involved in the discussions, extemporary comments should be avoided and the participants are invited to put forth questions and to interact with others. At the same time they know that there are not 'free rounds' (as often happens in the SGs, where a rich variety of cues are offered but they often remain at a messy, unspecified, superficial level) and should deal with the theoretical aspects through an *individual study*. In fact, at the base of ArAl Project there is an organic vision that aims to propose a framework on early algebra, offering the participants opportunities to reflect on knowledge, beliefs, stereotypes. They accept a commitment which attracts them: to avoid free, trivial conversations or Pindaric flights.

### **How can personal experiences, beliefs, inclinations be influenced by interventions based on strong theoretical references?**

The interventions on SG highlight different objectives between mathematics educators and teachers: basically, specialists focus their interest on the discipline, the teachers on their pupils. These different perspectives can create misunderstandings or misinterpretations. Then, in the NSG, mediations between them are necessary, that is: on one side the founding principles of mathematical knowledge – in our case of early algebra - have to be respected, but on the other side, at the same time, it has to be offered to the teachers a certain 'serenity' about the fact that deepening and changes of perspectives in teaching do not affect learning, but on the contrary pave the way for subsequent extensions of mathematical concepts. There is a strongly felt concern that pupils do not understand or that a concept is too difficult or inappropriate (of course this concern is correct because teachers have the responsibility of the learning of their students, so they constantly consider the difficulty and feasibility of new proposals).

### **Limited capacity to distinguish between different types of knowledge**

The posts and comments put in evidence that most teachers, along the years, reach their convictions grounding them more on the accumulation of heterogeneous strategies, methods, tools than on their consistency. One of the consequences of this behavior is that teachers confront themselves superficially with the theoretical references. For example:

Elena: I think sometimes that famous 'didactic contract', of which we all partake the negative effects on pupils, has been moved up on teachers: "It is so, Tom said, Dick reiterated it"; someone makes it [i.e. the didactical contract] arguing and expressing his/her opinion (experience counts,

anyway!); someone else makes it 'getting on the chair'. But: be they teachers or pupils or propagandists or colleagues, always 'didactic contract' is.

To what is Elena referring when she writes "the negative effects on pupils"? Her so peremptory statement was not reconsidered in the later comments: what does this mean? It could indicate that it has not been understood, or that it has been read superficially, or that it is not shared, or that it is an unfamiliar concept and no colleague wants to explore it. This short episode shows indeed that there are interactions between members, but in general they go on without reaching a real conclusion; at most, members achieve a superficial agreement, or a generic praise, or they remain on their positions. It would have been important to ask Elena what she means with this term (originally it is a theoretical construct by Guy Brousseau). Probably such statements would not have been made in our NSG. This might be a limit for the group because many convictions would not be expressed for a kind of compliance towards the coordinators experts. A low understanding of the key aspects of mathematics education (at the primary-secondary school level) favours the choice of cues - references, materials, paths, methods - that fit with the convictions and the personality of the teachers more than with the organicity of the knowledge taught. In this way, those facilitators that favour the perspective of *making* are privileged. The weak capacity to connect effectively the suggestions of experts and mentors implies that one prefers a 'do-it-by yourself' shared with those who are felt as fellow-travellers: if an activity, a text, a method are exalted or defended by other members of the group, they may be adopted, or at least tested. Often, the length of an experiments is short because the activities are heterogeneous, have 'little oxygen' (the interest on them goes out early); almost immediately they are put aside without any reflection in general terms, mostly on the basis of local success achieved by pupils (or, more trivially, because they appear 'nice').

### **New characters emerging in NSG**

The dense interactions developed in the NSG together with the offered theoretical and practical supports brought some new attitudes and awarenesses in the members of NSG. The members begin to understand that a new approach to the arithmetic and algebra teaching lies on a different role of the teacher. As to this a decisive importance assumes what J. Mason has called *the art of noticing* the classroom micro-situations for being ready to adopt the opportune micro-decisions (Mason 2002), intertwined with the attention to the *languages* and to the continuous recourse to the *argumentation*. Thanks to our frequent interventions where we underline that: a) a math teacher has to control a *plurality* of languages and that also a formal language must be monitored at two levels, the *semantic* one about the meanings and the *syntactic* one about the structure of the sentences into play; b) the weak control over grammatical/syntactical aspects of a sentence in mathematical language leads to temporary and unstable jargons in which the meanings assigned to the symbols are dictated by an apparent common sense that reduces the difficulties, promotes an immediate but feeble understanding that leaves the problem unsolved; we observed in the activities posted by many members a bigger attentions forwards the translations questions between verbal and fromal languages and the increasing use of argumentations in their students. From a methodological point of view, thaks to our suggestions, when the teachers publish at the NSG the post of an activity, they begin to understand that it is not enough to insert some captivante images, but that it is necessary to equip them with a presentation that synthetically shows the activated competencies and that includes the most meaningful protocols, the path in which the activity is inserted, how it develops in the next steps, the

theoretical references (ArAl Units, items on the website, Powerpoint presentations, papers). **Our idea is to slowly bring them to approach the MTs methodology.** An important contribution in this sense is offered by an increasing number of members the NSG, who are not involved in ArAl experimentations but following the project in a convincing way (teachers educators, mentors, collaborators of publishing houses, members of other research groups). Thanks to this people the posted comments begin to be richer and meaningful; the authors express their ideas also asking for experts' suggestions aimed at promoting new and more adequate behaviours for teaching arithmetic/algebra in a *relational* perspective. So, posts and comments begin to produce virtuous relations which gradually enhance the system: the posts induce comments of increasing quality, which generate important feedbacks in the organization of the successive posts.

The recent mutations observed in the NSG members' posts delineates a new character of their participation which appears in tune with our aim to build a shared identity in the NSG and effective in offering contributions which can bring it to become *a community of di practice*. As to this, particularly meaningful appear the recent initiatives generated by the NSG discussions concerning the publication in the ArAl project website (<http://www.progettoaral.it/>) of two documents, respectively devoted to: (1) the most interesting classroom episodes presented by the NSG members, with the main related comments; (2); the early algebra papers written by members external to the project and inspired by our previous productions. Next to this we have to consider the request expressed on the web by several members of NSG to organize some ArAl meetings of one or few days to allow the participant know themselves *de visu* and to plan some common work. It seem us that these new tends in NSG may generate inside the group, mainly with the more sensitive and expert members, an embryo of a *community of inquiry*. In this frame institutional and informal ArAl educational initiatives are developing important merging points.

## Final considerations

A NSG as 'Progetto ArAl' may initially disorient new participants, but its own structure can be considered its force because many of them declare that they appreciate the possibility to join to a group where experts favor an organization of knowledge according to transparent and shared principles. On the base of the observations made, we formulate some key points related to early algebra for the management of the NSG so that it can become a significant community of practice in this field: (a) to help teachers understand not only merits and limitations of instruments and didactical strategies that they implement along the years, but above all the importance of their coherence and adherence to a set of theoretical principles, such as: the importance of languages and, consequently, of the translation between them; (b) to bring teachers to consider the perspective of the generalization since the first years of primary school, highlighting the structural analogy between representations of the various occurrences of a phenomenon and guiding their modeling; (c) to propose any time, during the discussion on the issues raised by the members, gradual general frameworks, accompanying them with clarifications, insights, extensions which give answers for doubts, perplexities, conflicts emerging from the discussion. The basic idea is that the theory should be gained through a gradual process of refinement of knowledge in a continuous exchange among the members of the group, adapting explanations and deepening to the difficulties or to the resistances and injecting now and then proposals of mini-workshops.

*We present a study about the development of interpretative skills in prospective teachers. In particular we discuss a kind of tasks designed by us for teacher education, containing the request of interpreting students' answers. The task in this study was built on an item concerning the sum of powers of 10 and was proposed to a group of prospective secondary teachers who were attending a Math Education course. The task was first faced individually by them and then discussed in group. We present the interpretations proposed by two prospective teachers before and after the collective discussion, in order to reflect on the differences in terms both of mathematical knowledge put in play and of attitudes exhibited.*

*Keywords: Teacher education, prospective secondary teachers, interpretation of students' answers, arithmetic and algebra.*

*Mistakes are the portals of discovery (James Joyce)*

## Introduction

In their daily practice, teachers are required to continuously interpret students' responses and productions. This not only assists them in evaluating their difficulties and achievements, but also allows to plan the next steps of the teaching activities. Therefore, this "interpretation activity" is one of the most crucial (and often most difficult) tasks teachers perform. Empirical evidence suggests that the true quality of a mathematics teacher stems largely from his/her ability to interpret students' productions, along with a flexible attitude to redesign the teaching approach based on them. However, the ability to make sound and accountable interpretations is rarely recognized as a crucial goal in teacher training. Moreover, in a previous research study (Ribeiro, Mellone, & Jakobsen, 2013), we observed that teachers do not naturally develop this ability as they gain work experience. So, presently, our research questions are the following. Is it possible for a teacher to acquire these interpretation skills or is it a matter of innate talent? In the first case, how can a prospective teacher develop this ability? Should we engage prospective teachers in mathematical discussions concerning the interpretation of students' reasoning?

Guided by our conviction that it is possible for a teacher to develop this ability, as a part of a joint research project, we explored a particular type of tasks we have conceptualized. In one part of these tasks, we asked the prospective teachers to interpret some students' responses to a problem and reflect on possible feedback they could provide to each student. This exercise had a twofold aim: to support prospective teachers in developing the skills required for interpreting and commenting on student work, and to investigate to what extent the particular mathematical knowledge and skills possessed by the (prospective) teachers support or hinder them in their interpretations and

“constructive” reactions. Our analysis shows that the abilities to interpret and to design an educational activity based on students’ productions are inhibited in prospective teachers with a poor mathematical knowledge, due to their limited understanding of the subject and lack of appreciation of various ways that problems can be solved (Ribeiro, Mellone, & Jakobsen, 2013). In particular, this is true for prospective primary teachers, many of whom have poor mathematical knowledge. However, we have also observed that prospective secondary mathematics teachers—who have studied more advanced mathematics during the three years of their Bachelor in Mathematics degree (Jakobsen, Mellone, Ribeiro, & Tortora, 2016)—also struggle with this kind of work. This led us to posit that the ability and knowledge to interpret student work depends not only on (prospective) teachers’ mathematical knowledge and its components, but also on their attitudes and beliefs toward mathematics and its teaching.

The tasks described herein are presently used in our Mathematics Education courses in three different modalities. First, we ask prospective teachers to individually solve the problem, before interpreting and reflecting on some selected students’ productions, and finally engaging in group discussions on the mathematical aspects involved in these students’ productions. Given that the prospective teachers (both primary and secondary) have difficulties in interpreting and in giving meaning to some students’ answers, it was necessary to first assess their ability to solve problems that these students are given. This was informative, as some prospective teachers struggle with providing constructive feedback to the students even when they do not encounter any difficulties in solving the given problems for themselves. The findings yielded by this first phase of our research were utilized in the subsequent mathematical discussions of students’ solutions and corresponding teachers’ interpretations. These group discussions were helpful to most prospective teachers, as they were able to gain new perspectives on students’ work and strategies that can be employed in teaching.

In this paper, we present the interpretations, given by a group of Italian prospective secondary teachers, of students’ responses concerning a problem where sums of powers of 10 are involved. (see Jakobsen et al. (2016) for details). Here, we present analysis of the interpretations teachers gave before and after the mathematical discussions, in order to document their progress, as most demonstrated more sophisticated attitudes and greater mathematical knowledge following group discussions.

## **Theoretical framework**

In order to characterize and study the features of teachers’ interpretations of students’ productions, in some of our previous work (see for example Ribeiro, Mellone, & Jakobsen, 2016), we have introduced the notion of *interpretative knowledge*, framed within the general Mathematical Knowledge for Teaching (MKT) framework (Ball, Thames, & Phelps, 2008). We define interpretative knowledge as the knowledge that allows teachers to give sense to pupils’ answers, in particular to “non-standard” ones, i.e., adequate answers that differ from those teachers would give or expect, or answers that contain errors. We posit that interpretative knowledge is closely related to the ability of teachers to support the development of pupils’ mathematical knowledge, starting from their own reasoning, even if students’ ideas are incomplete or non-standard. Some similar ideas are implied in the notion of *discipline of noticing* (Mason, 2002). In particular, our construct encompasses the idea of teachers working “on becoming more sensitive to notice opportunities in

the moment, to be methodical without being mechanical” (Mason, 2002, p. 61). The development of pupils’ mathematical knowledge starting from their own reasoning is, in our view, only possible if the teacher activates a real process of interpretation, shifting from a simple evaluative listening to a more careful hermeneutic listening (Davis, 1997).

In this sense, the notion of interpretative knowledge incorporates into the MKT framework the idea that errors and non-standard reasoning are considered as learning opportunities (Borasi, 1996). Moreover, the content of interpretative knowledge shapes teachers’ ability to make informed choices in contingency moments (as defined by Rowland, Huckstep, & Thwaites, 2005), in order to respond to and deal with non-planned situations. In that sense, we felt the need to incorporate the role of beliefs and attitudes pertinent to the use of mathematical knowledge (Carrillo, Climent, Contreras, & Muñoz-Catalán, 2013).

With the goal of better understanding (prospective) mathematics teachers’ act of interpretation, we characterized their interpretations of students’ productions and attitudes, using the following three categories: (i) Evaluative interpretation: a process through which the teacher determines congruence between pupils’ productions and the mathematical scheme of correct answers he/she has; (ii) Interpretation for the educational design: the manner in which the teacher designs educational steps based on the work produced by the students; (iii) Interpretation as research: teacher’s willingness and ability to revise his/her mathematical formalization in order to ensure that it is coherent with students’ productions (even when these seem in conflict with the traditional mathematics taught in school).

In Webster dictionary, “interpretation” is defined as “The act of interpreting, explanation of what is obscure”; however, it is also defined as “An artist's way of expressing his thought or embodying his conception of nature.” This last definition stresses the potential creative nature of the act of interpreting that is in our context perceived as the potential new mathematical knowledge that can be developed owing to the process of analyzing students’ productions.

## **Context and method**

For several years, we have been studying the nature of (prospective) teachers’ interpretative knowledge (e.g., Ribeiro et al., 2013; Jakobsen et al., 2016) by exploring the manner in which prospective teachers respond to specific interpretation tasks. In this design study the tasks are developed after the typical cycles of redesign of the design study method (Cobb et al., 2003). In their present form, essentially consist of three steps: (i) the teachers are initially required to solve a mathematical problem by themselves; (ii) they are given several students’ productions in response to the same problem, some containing errors and some mathematically valid but following less standard procedures, which they are asked to interpret; and (iii) teachers are prompted to provide what they deem would be appropriate feedback to these students based on their solutions. The teacher trainees are asked to address these requests individually and in paper format (they are usually given 90 minutes to complete all three steps). In the next phase of the study, the educator engages all prospective teacher participants in a collective mathematical discussion (which again typically lasts about 90 minutes). The framework of the mathematical discussion is based on that proposed by Bussi (1996), as the aim is to allow the group of prospective teachers create a polyphony of articulated voices on the mathematical object starting from the interpretation of a

student's production. Upon completion of the group discussion, the prospective teachers are asked to provide in writing a new individual interpretation of the students' productions, allowing the researchers to determine if any progress has been made.

The task utilized in the present study is depicted in Figure 1, and was adopted from the annual Italian national assessment (2010-2011) for grade 10 released by INVALSI (Istituto Nazionale per la VALutazione del Sistema educativo di Istruzione e di formazione). A group of 34 fourth-year master students of mathematics enrolled in a Mathematics Education course took part in this investigation. Since most of these students are going to become secondary school teachers, we consider them prospective secondary teachers.

In our previous study, we focused on the interpretation these prospective secondary teachers gave to their students' productions (Jakobsen et al., 2016). Our analysis revealed that they experienced problems in mobilizing their mathematical knowledge for interpreting students' work. Indeed, while they were able to "see" some of the mathematical aspects involved in the solutions to the problems their students proposed, they seemed unaware of many important aspects relevant to mathematics teaching and problem solving.

The expression  $10^{37} + 10^{38}$  is also equal to:

A.  $20^{75}$

B.  $10^{75}$

C.  $11 \cdot 10^{37}$

D.  $10^{37 \cdot 38}$

**Figure 1: Item given to students to solve**

In the next section, we will present two out of seven students' productions that were included in the task given to the study participants (for their selection, see Mellone, Romano, and Tortora (2013)). This will be followed by the interpretations of these students' productions, provided by two prospective teachers—to whom we refer as Rossella and Gennaro (pseudonyms)—before (BF) and after (AF) the mathematical discussion.

### **Interpretation of two students' productions**

The following brief analysis of the students' productions included in the task aims to elucidate our reasoning behind the decision to deem these two students' productions effective for exploring prospective secondary teachers' ability to interpret the work of others.

Emanuela (Figure 2a) obtained the correct result, despite making three errors in her work: the first and the last can be described as lack of use of parenthesis and the second can be seen as a wrong application of linearity. Ciro (Figure 2b) arrived at the right answer using the arithmetical algorithm of the arrangement of the decimal representation of the numbers in column. In his responses, we can also recognize his perception of the algebraic structure connected with more general ideas implicit in calculus. Indeed, Ciro's use of the ellipses reveals the potentiality of generalization of his

response to other two consecutive powers of ten, and not only to the particular case given (as one of the mathematics students that took part in our study noted during the collective mathematical discussion).

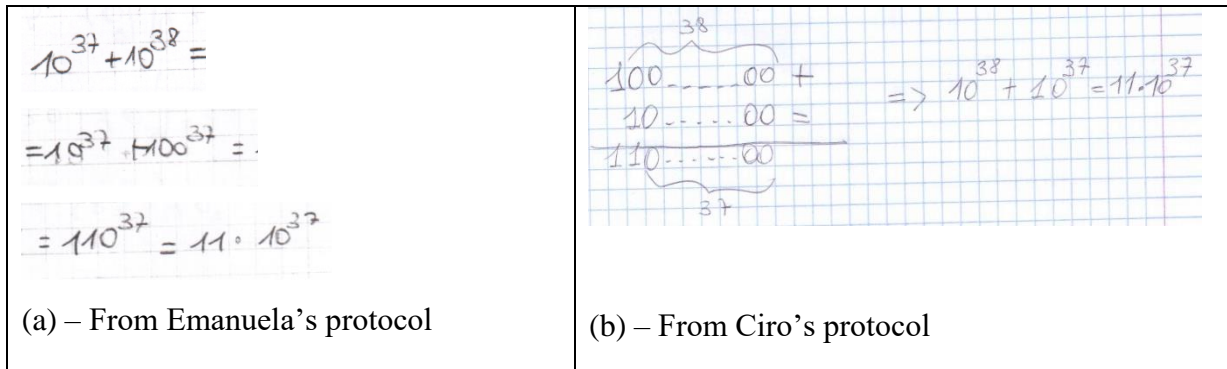

Figure 2: Two out of seven students' productions

## Prospective teachers' comments on students' productions before and after mathematical discussion

### Reflections on Emanuela's work

When individually interpreting Emanuela's response, prospective teachers seemed to experience difficulty in trying to understand the steps she used in arriving at the solution (see Jakobsen et al., 2016). Here, we focus on the interpretations given by a secondary prospective teacher —Rossella— before (BF) and after (AF) the discussion<sup>1</sup>:

The second prospective teacher, Rossella, shared the following:

Rossella (BF): There is no application of rules; it is pure invention. I don't know what I would say to the girl, but I would think that she had copied the solution and then tried to invent a justification.

Rossella (AF): Even if Emanuela's answer is correct, her arguments are far from being mathematically founded. Still, we can observe an interesting aspect in them, namely that if we repeat the steps with two powers having the base different from 10 and the exponents differing by one, we get the correct result. I followed this approach using different numbers, just to test this reasoning, which allowed me to assert that Emanuela's thought process appeared to work. More specifically, when you change the bases and use two consecutive numbers as exponents, or even not consecutive, her logic gives the correct result.

$$37^{25} + 37^{26} = 37^{25} + (1369)^{25} = 1406^{25} = (38 \cdot 37)^{25} = 38 \cdot 37^{25}$$

$$\frac{x}{c} - \frac{1}{10} \frac{0^3}{0} + \frac{x}{c} - \frac{1}{10} \frac{0^4}{0} = \frac{x}{c} - \frac{1}{10} \frac{0^3}{0} + \frac{x}{c} - \frac{1}{100} \frac{0^3}{0} = \frac{x}{c} - \frac{9}{100} \frac{0^3}{0} = \frac{x}{c} - \frac{9}{10} \frac{0}{0} - \frac{1}{10} \frac{0^3}{0}$$

$$2^{-3} + 2^{-2} = 2^{-3} + 4^{-3} = 6^{-3} = 3 \cdot 2^{-3}$$

$$x^n + x^{n+1} = x^n + (x^2)^n = (x+x^2)^n = ((x+1)x)^n = (x+1)x^n$$

<sup>1</sup> Of course, the students' words were translated from Italian into English. We tried our best to retain the exact expressions, including some errors, but some nuances are inevitably lost.

In other words, the above three errors, made in sequence, yield a correct result that does not depend on the particular numbers used. This observation has prompted our reflection on how mathematics is usually managed. We are used to judge, without hesitation, arguments such as those mentioned above as wrong and completely invented. However, after our discussions, we were of view that errors should be seriously considered and, if possible, exploited as a stepping stone toward the construction of new knowledge. This is exactly what I tried to do in order to bring out something new from Emanuela's reasoning. Indeed I also tried to build a new system of rules for powers according with her reasoning. Several attempts have convinced me that this is not possible. Thus, my conclusion is that no new knowledge about the rules of powers can be derived from Emanuela's suggestions. However, her errors can be an invaluable tool to stimulate discussions and to highlight the need for a true comprehension of the rules of powers, which are often hard to grasp for students.

Reflecting on Rossella's BF and AF words, we can observe a change in the attitude when interpreting student's work. The first interpretation is an evaluative one—there is no effort to understand the rationality of Emanuela's steps. This results in Rossella's bias towards a solution like that Emanuela offered (referring to an her possible unfair behavior), which can be due to fear of moving toward an educational path she cannot (immediately) control.

The interpretation given by Rossella after the discussion is markedly different. She not only made an effort to derive a generalization from the errors in Emanuela's production, but further concluded that the three steps Emanuela used in solving the problem will give the right answer with other bases and exponents. Rossella thus went beyond the simple observation that Emanuela's steps are not mathematically sound, as she investigated the possibility to build “a new system of rules for powers according with her reasoning.” For this reason, her second interpretation can be considered a form of interpretation as research.

### **Reflections about Ciro's work**

Gennaro (BF): Ciro reached the correct answer by a more practical method than those employed by his peers. In addition, the formalism seems original. He appears to have a strong expertise in the calculations with powers of 10, which highlights their significance and the importance of handling them correctly. Still, his method seems limited to powers of 10. It would be interesting to see how Ciro would proceed if presented with a different base. I think that Ciro's protocol could be used as an opportunity to explore differences between the properties of powers of 10 and those of other bases.

Gennaro (AF): Ciro's argument is of an arithmetic character. Nonetheless, it allows us to appreciate some deep algebraic insights. Moreover, although it seems confined to powers of 10, it can actually be generalized to any base, if one represents the number in the base of the power. Hence, from Ciro's production going further, it would be possible to study the tables of operations in different bases, or even the divisibility rules in bases other than 10.

In his first interpretation of Ciro's protocol, Gennaro appreciates the originality of his method, while noting that it is limited to powers with base 10. Based on this observation, Gennaro proposed possible questions and issues that could be explored with Ciro and the rest of the students in the classroom, starting from his production. For this reason, Gennaro's first interpretation is aimed at educational design.

As with Rossella, whose interpretations we analyzed previously, the comments Gennaro gave on Ciro's protocol after the discussion shifted in focus. First, there is a subtle distinction between arithmetic and algebra that could be investigated and debated endlessly. Moreover, Gennaro's comments reveal his awareness that Ciro's method can be applied to other bases (indeed,  $100\dots0$  always represents the  $n$ -th power of the base). This fact was observed during the collective discussion by another prospective teacher, and for Gennaro, this discovery was so important that it became part of his new written interpretation. In other words, Gennaro's knowledge and interpretation benefitted from the mathematical discussion on Ciro's production. He reconceived the systems of representing numbers in different bases, which motivated him to explore the true meaning of digits, as well as of strings of digits. For this reason, Gennaro's second interpretation is perceived as interpretation as research.

### **Conclusive remarks**

We started this paper by asking if mathematics teachers can develop the ability to interpret their students' productions in order to flexibly redraw the mathematical learning path, or if this should be considered as an innate talent. We are convinced that it is not only possible to develop this skill but is highly desirable. The observed difficulties these prospective teachers experienced when giving sense to student productions, along with the findings yielded by extant studies, indicate that the development of this ability requires a special attention in teacher education. These first results about our proposed method of working with prospective teachers appear to support its effectiveness. It stimulates prospective teachers' interpretive and critical skills and increases knowledge they must possess in order to teach effectively, taking into consideration the specificities of such knowledge. The value of our method stems from the nature of interpretive tasks involving student productions, as well as subsequent discussions among peers under the guidance of an expert on these interpretation tasks.

Our analysis of the interpretations given by two prospective teachers, before and after the collective discussion led by the educator, clearly demonstrates changes in terms of both their attitude and mathematical knowledge or awareness. We can hypothesize that the collective discussion mobilized mathematical knowledge that was previously present, but probably not put in play, and it also support the development of new mathematical knowledge, like for Gennaro. However, the improvements we witnessed were also due to the change in attitudes and beliefs supported by the discussion, and of course by the attitudes and beliefs incorporated in the educator's practice.

Still, our work leaves many questions to be answered in future research. It would be interesting to evaluate the sustainability of these changes, for example, by following the work of these prospective teachers in their future educational practices. Moreover, analysis of the mathematical discussion on interpretative task needs to be developed in order to clarify its features and dynamics.

# Investigating potential improvements of mathematics student teachers' instruction from Lesson Study

Reidar Mosvold<sup>1</sup>, Raymond Bjuland<sup>1</sup>, & Janne Fauskanger<sup>1</sup>

<sup>1</sup>University of Stavanger, Faculty of Arts and Education, Stavanger, Norway;  
[raymond.bjuland@uis.no](mailto:raymond.bjuland@uis.no)

*This paper reports from a project where Lesson Study (LS) was implemented in the field practice component in four subject areas of two teacher education programs at one Norwegian university. Previous analyses of data from interviews and mentoring sessions indicate that mathematics was a challenging case that makes it interesting to investigate further. In the present study, we analyze classroom observations with the Classroom Assessment Scoring System (CLASS) in order to investigate potential improvements from the intervention. The results indicate that there were no significant differences between the control group and the intervention group. Possible explanations for this are discussed and implications for future implementations of LS in field practice are suggested.*

*Keywords: Mathematics teacher education, field practice, Lesson Study.*

## Introduction

This paper has a focus on developing student teachers' ability to teach mathematics through LS. When Stigler and Hiebert (1999) published the results from their comparative study of mathematics teaching in Japan, Germany and the USA, they argued that there was a "teaching gap" among these countries. The teaching quality of the Japanese classrooms appeared significantly higher than in German and US classrooms, and Stigler and Hiebert suggested that a main explanation for this teaching gap could be found in the incremental developments of teaching through LS in Japan. In the aftermath of this study, LS continues to gain popularity as a practice-based approach to professional development outside of Japan. There is also growing interest among researchers to adapt and use LS in teacher education (e.g., Ricks, 2011).

In mathematics education research, numerous studies focus on how LS might increase mathematics student teachers' knowledge and understanding of the mathematical content. For instance, Cavey and Berenson (2005) argue that their adapted version of LS has a potential to increase student teachers' understanding of the mathematical content. Drawing upon the idea that knowledge for teaching must be learned in and from practice (Ball & Cohen, 1999), one might argue that LS has a potential to serve as a "professional development tool when faced with the challenge of providing high-quality learning experiences for student-teachers" (Murata & Pothen, 2011, p. 104).

From an ongoing review of literature on LS in mathematics teacher education, we notice that, while several studies attempt to measure the effects of LS on student teachers' knowledge and understanding, few studies report on effects of LS on the quality of instruction. Chassels and Melville (2009) suggest that LS "provides opportunities for teacher candidates to build professional learning communities, to deepen understanding of curriculum and pedagogy, and to develop habits of critical observation, analysis, and reflection" (p. 734). When investigating mathematics student teachers' development of lesson plans, Fernandez (2010) suggests that implementation of LS appears to influence their development of professional knowledge. Jansen and Spitzer (2009) focus on

mathematics student teachers' reflective thinking, and their study includes analyses of student teachers' own interpretations of their teaching. Although the issues raised in these studies are of importance, neither of them focus directly on effects of LS implementations on the quality of teaching. Leavy's (2010) study includes a focus on observing teaching, but the analyses emphasize student teachers' reflections and development of knowledge rather than their actual teaching. Ricks (2011) reports from an intervention study, but his focus is on mathematics student teachers' reflections rather than on their teaching. With this as a background, the aim of this paper is to investigate possible effects of LS implementation on the quality of student teachers' mathematics teaching. We consider the following research question: What potential influences can be observed from a LS intervention on the quality of classroom interactions in the field practice of mathematics student teachers? In order to approach this research question, we analyze classroom observations from a time-lagged design experiment where LS was implemented in the field practice of two Norwegian teacher education programs. Videos of classroom teaching are analyzed by using the Classroom Assessment Scoring System (CLASS).

### **The Classroom Assessment Scoring System**

CLASS scores are related to students' academic performance (Teachstone, 2012), and research indicates that substantial gains in measured student achievement is mediated by teacher-student interaction qualities (Allen, Pianta, Gregory, Mikami, & Lun, 2011; Teachstone, 2012). An important mediator for academic outcome is the extent to which the students' interactions with their teachers motivate them (Pianta & Allen, 2008). Based on this, student-teacher interactions in the classroom are the focus of attention when observing classrooms using the CLASS instrument. This instrument is designed to assess the fit between teacher-student interactions and students' developmental, intellectual, and social needs, i.e. elements of high-quality teaching that have been identified as central to student achievement (Allen et al., 2011). The CLASS instrument consists of three major domains that provide behavioral anchors for describing and assessing critical aspects of classroom interactions (Teachstone, 2012): 1) Emotional Support, 2) Classroom Organization, and 3) Instructional Support. Student Engagement is also included, due to the importance of observing student behavior in addition to behavioral anchors on the classroom and teacher level.

The first domain, Emotional Support, relates to students' social and emotional functioning in the classroom and is highlighted in the CLASS instrument because "relational supports and connections, autonomy and competence, and relevance are critical to school success" (Teachstone, 2012, p. 2). Second, Classroom Organization is included in the instrument based on research, highlighting the relationship(s) between aspects of organization and students' opportunities to learn. The foundation for the third domain, Instructional Support, is constituted by the following teaching strategies that enhance learning: "consistent, process-oriented feedback, focus on higher-order thinking skills, and presentation of new content within a broader, meaningful context" (Teachstone, 2012, p. 4).

These three domains can be further divided into twelve dimensions or CLASS indicators that are defined in the CLASS manual (see Tables 1, 2 and 3). In addition to these observable indicators of effective interactions, the CLASS manual includes behavioral markers that provide clear examples of how teacher-student interactions in the classroom can be observed and assessed. These descriptions are specified and examples of justifications are provided on the basis of concrete classroom videos, coded by CLASS experts.

## Method

This study is situated within the larger, cross-disciplinary project, Teachers as Students (TasS), which involved mathematics, science, physical education, English as a second language, as well as pedagogy. The TasS project (2012–2015), supported by the Norwegian Research Council (grant number 212276), investigated student teachers' learning during field practice, aiming at learning more about how student teachers develop the knowledge and skills required to promote student learning in schools. LS was used in a time-lagged design experiment (Hartas, 2010) in two Norwegian teacher education programs, both four-year integrated programs, one for grades 1–7 and one for grades 5–10. Subject matter and didactics (pedagogy) should thus be integrated in all subjects, and there should be a close relationship between what was taught on campus and in schools when student teachers had field practice (100 days within the four years). The mentor teachers have an important role and are considered teacher educators in field practice.

The student teachers were organized in groups of three or four during a three-week period of field practice both in the Business as Usual condition (BAU) and in the LS intervention (INT). The TasS study recruited student teachers during the spring term of their fourth semester (except the science groups in the BAU condition, who were in their sixth semester). The TasS project includes data with two groups of student teachers from the four subjects in both data collection periods (see Munthe, Bjuland & Helgevold, 2016 for an overview). In this paper, we mainly report from analyses of classroom recordings of lessons taught in mathematics from the BAU and INT condition, using the CLASS (Classroom Assessment Scoring System) observational instrument (Allen et al., 2011; Teachstone, 2012). We also draw upon findings from previous analyses in the discussion section based on conversations in mentoring sessions and pre- and post interviews (before and after the field practice in both conditions).

In the BAU condition, the mentor teachers were asked to conduct their mentoring sessions the way they normally did without any influence from the researchers in the project. In the LS condition (INT), it was crucial that mentor teachers were introduced to essential principles about LS since “they played the role as facilitator and knowledgeable other for the group of student-teachers who made up the Lesson Study group” (Munthe et al., 2016, p. 145). This required another approach. Three afternoon seminars were organized (from November 2012 to January 2013) for mentor teachers and the research group in order to discuss important characteristics within the LS cycle and to establish a shared understanding of implementing LS in student teachers' field practice. An important component of these afternoon sessions was to develop a “Handbook for Lesson Study”, which included a text about important principles in LS and a list of questions which could support both the mentor teachers and the student teachers through pre- and post-lesson mentoring sessions.

Three researchers (the authors of this paper) took part in the coding of videos from the four lessons in both conditions (INT and BAU). We divided the videos into 19-minutes sections. This resulted in 22 sections (12 BAU and 10 INT). After watching a video section, we started the scoring for each dimension individually, using the 7-point range that is described in the CLASS manual, Low (1, 2), Mid (3, 4, 5) and High (6, 7). We made our judgements based on the general scoring guideline. Our scores were then discussed before we started to observe a new video section. The results that are presented in the three tables below illustrate the scores given by the three researchers (see Tables 1, 2 and 3). Where two scores are given, our individual coding differed.

## Results

The CLASS domain of Student Engagement intended to capture “the degree to which all students in the class are focused and participating in the learning activity presented or facilitated by the teacher” (Teachstone, 2012, p. 109), was coded as Mid for both BAU and INT. This code means that either the students are listening to, or watching the student teacher, rather than actively engaging in classroom discussions and activities, that there is a mix of student engagement, or they are engaged part of the time and disengaged for the rest of the time. Across all the videos, there is a lack of off-task behavior and the students appear to be engaged.

### Emotional support

The domain of Emotional Support is divided into three dimensions (Table 1)<sup>1</sup>. Across the first two dimensions, the code Mid was given by all three coders. A Mid score on the first dimension, Positive climate, indicates that the student teacher and students sometimes provide positive comments and appear quite supportive and interested in one another. A Mid score on the second dimension, Teacher sensitivity, indicates that the student teacher sometimes monitors students for cues and generally attempts to help students who need assistance, but these attempts are not always effective in addressing student concerns. This code also indicates that some of the students sometimes seek support, respond to questions and share their ideas.

CLASS dimension	BAU	INT
Positive climate	MID	MID
Teacher sensitivity	MID	MID
Regard for adolescent perspectives	LOW/MID	LOW/MID

**Table 1. Results from CLASS analysis of Emotional Support.**

The third dimension, Regard for adolescent perspectives, was coded as Low/Mid, illustrating that individual coding differed among the coders. Low to Mid on this dimension indicates that the teaching is the teacher’s show. The students are rarely provided opportunities for autonomy and leadership.

As can be seen from Table 1, the LS intervention did not affect the coding for any of the dimensions included in this domain.

### Classroom organization

The domain of Classroom Organization is composed by three dimensions (Table 2). Behavior management encompasses the student teacher’s use of methods to maximize the learning time for the students. The code Mid indicates that there is some evidence that the student teachers encourage desirable behavior and prevent misbehavior. Productivity, the second dimension, does not relate to quality, but rather deals with the students’ opportunity to get involved and the extent to which the teacher makes sure that everyone has something to do. A Mid score on Productivity indicates that most of the time there are tasks for the students and some routines are clearly in place. However, transitions could be more efficient and the student teachers could be better prepared.

<sup>1</sup> The CLASS domains are written with capital letters in both words (e.g., Emotional Support), whereas the CLASS dimensions are written with one capital letter (e.g., Positive climate).

<b>CLASS dimension</b>	<b>BAU</b>	<b>INT</b>
Behavior management	MID	MID
Productivity	MID	MID
Negative climate	LOW	LOW

**Table 2. Results from CLASS analysis of Classroom Organization.**

The dimension Negative climate is scored in reverse. A low score indicates that the overall level of negativity among student teachers and students is low or absent. This code counts for more than the others in this domain, indicating that the classroom processes related to the organization and management of time, student behavior and attention in the classroom provide the students with opportunities to learn. As can be seen from Table 2, the LS intervention did not affect the coding for any of the dimensions included in this domain.

### **Instructional support**

The domain of Instructional Support is divided into five dimensions as shown in Table 3. The first dimension, Instructional learning formats, was coded Mid in both conditions, illustrating that learning objectives may be discussed, but they are not clearly communicated in order to support student attention which is an indicator for a high score.

It is only in the second dimension, Content understanding, that there are indications of a possible effect, from discrete pieces of depth of lesson content to sometimes finding meaningful discussions in order to help students comprehend the mathematical content. The three last dimensions, which emphasize higher-order thinking among the students with a purposeful use of a content-focused discussion in the classroom, are all coded Low or Low/Mid. The focus on mathematical content is not strong in the teacher-student classroom interactions. A Low score on Analysis and inquiry indicates teaching that does not let the students think, or that students are neither engaged in higher-order thinking, metacognition, nor have opportunities for novel application. The teaching is in a rote manner. A Low/Mid score on the dimension of Quality of feedback indicates that the feedback provided to the students neither expands or extends learning nor encourages student participation. A Low/Mid score on the dimension of Instructional dialogue indicates that the student teachers do not involve the students in content-based discussions in class.

<b>CLASS dimension</b>	<b>BAU</b>	<b>INT</b>
Instructional learning formats	MID	MID
Content understanding	LOW/MID	MID
Analysis and inquiry	LOW	LOW
Quality of feedback	LOW/MID	LOW/MID
Instructional dialogue	LOW/MID	LOW/MID

**Table 3. Results from CLASS analysis of Instructional Support.**

The results illustrate that our LS intervention had little effect on the quality of classroom interventions (Table 3). Across the videos, and in both BAU and INT, the classes are mostly dominated by student teachers' talk.

## Concluding discussion

Many studies suggest that LS has potential to contribute to mathematics student teachers' development, but few studies analyze potential effects of LS interventions in mathematics teacher education on the quality of classroom interactions. CLASS analysis of classroom videos from a control group and an intervention group indicates that our LS intervention did not increase the quality of classroom instruction. One might argue that the challenging results that arise from this study are problematic since one would hardly expect the results to show any variance based on one LS cycle only. However tempting it is to bypass the reporting of such challenging results, we do the opposite. The majority of research reports in mathematics teacher education appear to be success stories, but we suggest that it is also important to discuss results that were not as positive as desired. In the following, we highlight three issues that might have influenced the results of this study: 1) experience and time, 2) lack of focus on critical aspects of LS, and 3) personal factors.

First, we discuss the issues of experience and time. Stigler and Hiebert (1999, p. 109) describe LS as a “system that leads to gradual, incremental improvements in teaching over time.” Japanese improvements in teaching happen through systematic work over several decades, and it is unfair to expect significant improvements in teaching from groups of student teachers who have just been introduced to LS. Most implementations of LS in mathematics teacher education seem to involve participants with little or no previous experience with LS (e.g., Bjuland & Mosvold, 2015; Leavy, 2010). In addition, most of these studies are short-term studies that often report results from participants who have completed one LS cycle only (e.g., Bjuland & Mosvold, 2015; Chassels & Melville, 2009; Leavy, 2010). It is not realistic to expect significant long-term effects from studies like this.

Second, a possible explanation for the challenging results in this study might be that the participants failed to implement some important aspects of LS. Previous analyses of data from mentoring sessions and interviews support this. For instance, Bjuland and Mosvold (2015) identified four indicators of why the implementation was challenging in mathematics. First, the student teachers reported about a lack of emphasis on pedagogical content knowledge on campus before field practice, and they called for more focus on students' difficulties and teaching strategies. A second indicator was related to a lack of formulating a research question. In a LS cycle, the student teachers should collaboratively plan, conduct and evaluate a research lesson with a focus on students' learning, but they should also formulate a research question that focuses on their own learning. No signs of this were found in the mentor sessions in the mathematics groups (Bjuland & Mosvold, 2015). Third, there was little focus on student learning and structured observation – both of which are decisive in LS. The mentor teachers' questions did, however, focus more on planning, observation and student engagement in the LS intervention (Bjuland, Mosvold, & Fauskanger, 2015). A fourth indicator was that student teachers organized research lessons around individual work with textbook tasks – making observation of student learning difficult (Bjuland & Mosvold, 2015). These observations may explain why the LS intervention was not successful and why the quality of classroom interactions did not increase.

Third, other factors like the student teachers' background, motivation and support may have influenced the results of this study. From analyses of data from mentoring sessions as well as focus-group interviews, we learned that one group of student teachers in the intervention may have had a lack of motivation for participating in the study. In the other group of student teachers from the

intervention, the mentor teacher was absent for a period of time, and the resulting lack of support from the mentor teacher might have influenced the quality of classroom interactions. Similar factors were also observed in the BAU groups. For instance, one of those groups struggled to collaborate (Bjuland & Mosvold, 2014), and we cannot revoke the potential influence of such problems. Although many problems can be avoided or taken care of in a research project, there will always be a potential influence of human factors that cannot be controlled by the researcher.

Further long-term studies are called for in mathematics teacher education to investigate participants who have completed more than one LS cycle, emphasizing that teaching develops through incremental improvements over time (Stigler & Hiebert, 1999). We observe that many studies focus on potential effects of a LS intervention on student teachers' understanding of the mathematical content. More studies are called for to investigate effects of LS implementations on classroom instruction.

# Ritual towards explorative classroom participation of pre-service elementary school mathematics teachers

Talli Nachlieli and Yafim Katz

Levinsky College of Education, Israel; [talli.nachlieli@gmail.com](mailto:talli.nachlieli@gmail.com), [katzyafim@walla.co.il](mailto:katzyafim@walla.co.il)

*In this paper we follow preservice elementary school mathematics teachers learning processes in a course that was organized around problem solving and aimed at providing opportunities for students to participate exploratively. The goal of this study is to characterize pre-service teachers' participation on the "ritual-explorative" continuum, to understand better what opportunities for explorative participation are given and taken up by students. Findings show that the request to suggest various solution paths seems to help students focus on the explorative question of "where do I want to get at?" rather than at the ritual question of "how do I proceed?".*

*Keywords: Rituals, explorations, preservice mathematics teachers.*

## Introduction

This paper focuses on learning processes of pre-service elementary school mathematics teachers during a course whose goal was to promote students' mathematical thinking by engaging them in a discourse which is closer to that of mathematicians, and thus to provide our pre-service teachers opportunities to participate exploratively in doing mathematics. This resonates with Blanton (2002): "The development of a cadre of classroom mathematics teachers whose practices reflect current research on teaching mathematics rests in part on how pre-service teachers, as students, experience mathematics" (p. 117).

In a former study about opportunities for learning in a prospective mathematics teachers' classroom (Heyd-Metzuyanim, Tabach & Nachlieli, 2015), we found that despite what seemed to be an explorative environment, pre-service students still participated mostly ritually in a mathematics course. Since we believe that the opportunities to learn that preservice teachers provide their future students should be more explorative, it is obvious that they themselves should participate exploratively. We therefore designed a course that would provide opportunities for explorative participation. The course was taught in two separate groups by two instructors simultaneously. We are now starting to learn about what actually happened in those courses - could the participation of students be characterized as, at least sometimes, explorative? What characteristics of the course design and instruction seems to provide explorative learning opportunities? In the current study we focus only on one group of students, working on one type of tasks during two lessons, and follow learning processes in an attempt to characterize pre-service teachers' participation on the "ritual-explorative" continuum.

## Theoretical framework

In this study we adopt Sfard's socio-cultural approach to conceptualize and study learning – the communicational framework (Sfard, 2008), and refer to the on-going development and refinement of the discourse on rituals and explorations (Sfard & Lavie, 2005; Nachlieli & Tabach, 2012; Heyd-

Metzuyananim, Tabach & Nachlieli, 2015; Heyd-Metzuyananim & Graven, 2015; Sfard & Lavi, in process).

One of the main characteristics of a discourse is the routines participants perform. Routines are repetitive patterns that are repeated in similar situations. That is, when one views a situation as similar to one he had participated in, and performs the same action. This could be social – e.g. when entering your home and placing the keys at a particular place. It could also be a cognitive action – e.g., in a mathematics classroom, when a student refers to a certain problem as similar to one performed earlier, and adopts the same procedure to solve the problem. The participant is not always aware of this repetitiveness. That is, a routine is such in the eyes of the researcher. Sfard & Lavie (in process) define the term *explorations* as "routines whose success is evaluated by answering the single question of whether a new endorsed narrative has been produced". That is, the task of an exploration is to produce new "historical facts" or a new "truth" about mathematical objects. Exploration is hence an act of production. Performers of explorations focus on the question: "what it is that I want to get?".

Rituals are "routines performed for the sake of social rewards or in an attempt to avoid a punishment." (Sfard & Lavie, in process). Ritual performance is usually initiated by, and addressed at, somebody else. Usually, the performance is an imitation of someone else's former performance. The procedure is rigid and the performer of the ritual never tries to make independent decisions. Performers of rituals ask themselves: "how do I proceed?".

It is important to stress that the same procedure performed (even simply multiplying 26 by 31) could be an exploration or a ritual, depending solely on whether the participant is engaged in trying to produce a new narrative, or, simply socially engaging in class, doing what she is expected to do using given procedures.

Former studies suggest that while explorative participation is desired, rituals are inevitable. Especially in the process of objectification, of developing new mathematical objects (such as the development of numerical discourse by children (Sfard & Lavie, 2005; Sfard & Lavie, in process) or the development of the discourse on function of 7<sup>th</sup> grade students, (Nachlieli & Tabach, 2012).

In mathematics classrooms, students' participation is usually neither purely ritual nor explorative. Those could be seen as ends of some continuum that differ in the performer's ability to separate the procedure and the task. As long as the performer does not just strive to arrive at a particular outcome but also feels compelled to do this by performing a specific procedure, the routine cannot count as a pure exploration.

The goal of this study is to characterize pre-service teachers' participation on the "ritual-explorative" continuum so that we could understand better what opportunities for explorative participation are given and taken up by students.

## Method

### Data collection

The data for this paper are taken from a course about "promoting mathematical thinking", for prospective elementary school mathematics teachers studying at a college of education in Israel. The course was a one-semester course which was taught in 2014. It included 13 lessons, each lasting an hour and a half. During the first lesson, the project was described to the students and consent forms

were collected and hence the lesson was not videotaped. The remaining 12 of the 13 lessons were videotaped and transcribed. Lesson plans and all of the students' written work (exams and the planned unit) were collected. The language of the data was Hebrew. This data was analyzed in its original language and parts were translated to English by the authors. To learn about students' ritual and explorative participation, we focus on their studying a specific type of problems - serial tasks (calculating sums of sequences). This topic was discussed in lessons 2 and 3. Assuming that students' participation may change when shifting to a new subject, we chose to focus on one specific topic in its entirety. The data analyzed include all whole class discussions that took place during each of the lessons.

### **Participants**

The research participants include a group of 18 prospective elementary school mathematics teachers. The students are studying at their final academic year in a college of Education in Israel. The course instructor, the first author, has a B.Sc in mathematics and PhD in mathematics education. She had been teaching in this college for 15 years.

### **The course**

Over the past two decades, accumulating evidence has shown that classroom environments that support “explorative” participation, that is, that encourage students' authority (Herbel-Eisenmann, Choppin, & Wagner, 2012); engage students in tasks that are cognitively demanding and are open to different solutions and procedures (Boston & Smith, 2009); and foster a community of learners that listen to each other and build on each other's ideas (Resnick, Michaels, & O'Connor, 2010) promote conceptual understanding. The aim of the designed course was for students to deepen their mathematical thinking by working on high cognitive-demand problems (Smith & Stein, 2011), solving problems in various ways and making connections between the different solutions as well as between the mathematical ideas related to the problems and the solutions. During the lessons, students worked in small groups to solve the problems and were encouraged to come up with as many solutions as possible. Whole-class discussions about the different solutions followed. The instructors chose to provide students with as much time as needed to work on certain problems alone or in groups, focusing entire lessons on discussing different solution paths suggested by the students. The students had to take three exams during the course and were required to plan a 3-lesson unit about any topic for elementary school students, which aim was to promote their students' mathematics thinking. Two groups (of around 20 students each) were taught simultaneously – by each of the two authors. This study refers to Talli's group only.

### **Data analysis**

To identify whether students' participation is more ritual or more explorative, and to identify shifts in participation we followed all whole-class discussion around a specific type of tasks. The discussions were analyzed by addressing the questions in Table1.

		Ritual	Exploration
1.	What is the question the performer is trying to address?	How do I proceed?	What is it that I want to get?

2.	How does the performer evaluate its' success?	Performing a specific task-related procedure	A new narrative had been produced
3.	By whom is the routine initiated? To whom it is addressed?	Initiated by former performer of a similar task. Addressed at the teacher (or other superior).	oneself
4.	Flexibility	Applies a rigid routine. Seldom makes independent decisions	Could consider various routines. Makes independent decisions on the way.
5.	Separation between procedure and task	Not separated as the main task is to perform a (certain) procedure.	Separated
6.	Authority	The teacher	One's own

**Table 1: Rituals and explorations**

## Findings and discussion

To understand what opportunities for explorative participation were given and taken up by students, we present our findings about students' participation while working on a specific type of tasks (calculating sums of sequences). This learning took place during lessons 2 and 3.

The first problem that the students solved was calculating the number of Hanukkah candles one lights during the 8 days of the Holiday (2 candles on the first evening, 3 on the second, ... and 9 candles on the eighth night):  $2+3+4+5+6+7+8+9 = (2+9) + (3+8) + \dots = 4 \cdot 11 = 44$  (following Gauss's idea of pairing elements of the sequence: first element with the  $n^{\text{th}}$ , second element with the one in the  $(n-1)$  place, and so on. The sums of each of the pairs are equal.). Then, after quickly calculating the sum of integers between 1 and 99, the students were asked to calculate the following sum:  $1+3+5+7+\dots+997+999 =$  .

The following conversation took place:

- 1     Maya    I remember that there's something, a formula, I don't remember it now. To find the element in the middle.
- 2     Inst.     To find a formula for finding the middle element?
- 3     Maya    no, no, there is a formula
- 4     .....    [the class discusses a solution path suggested by a student]
- 42    Sonya    it could be factorial, right?
- 43    inst.     Factorial?
- 44    Sonya    yea, factorial, I remember something, I think this could be related.
- 45    inst.     [to the class] do you what factorial is? Remember what it is?

The first student's (Maya) saying referred to the existence of a formula that could, perhaps, be helpful in this situation. She also talked of remembering. That is, Maya's first reaction was to seek a formerly learned routine that could be helpful in this situation. Maya followed Gauss's idea to add pairs of

numbers. As the number of elements in this sequence is even (500 numbers), Maya's search for the "middle number" is surprising. It is possible that either Maya mistakenly thought that there actually is an odd number of elements in the sequence. A different interpretation is that as all the problems that the students have worked on in the course so far have been of an odd number of elements, Maya looked for the "middle element" as part of performing a given routine practiced earlier.

After Maya's remark, a whole-class discussion arose about the number of elements in the sequence, whether it was even or odd. After agreeing that there are 500 elements (half of the elements in the sequence 1, 2, 3, ..., 1000), the students used Gauss' idea and calculated:  $(1+999) \cdot 250 = 250,000$ . The instructor asked for a different solution when Sonya replied: "it could be factorial, right?" she then added: "I remember something, I think this could be related". That is, similar to Maya, Sonya seeks a formerly learned and used routine to be applied here. She does not remember the routine or what the idea behind "factorial" is, but something about this problem reminds her of this formerly learned idea. Considering Maya and Sonya's communication about the given problem, it has strong ritual characteristics:

		Ritual	Exploration
1.	What is the question the performer is trying to address?	How do I proceed? <i>There is evidence of the students' attempts to seek a ready-made formula that could help them proceed. In Maya's case, the formula is not needed as there is an even number of elements. In Sonya's case – the idea she thinks of (factorial) is not relevant. Sonya is not sure what it actually is, but she does find some connection between the procedure and the problem at hand.</i>	What is it that I want to get?
2.	How does the performer evaluate its' success?	Performing a specific task-related procedure <i>Although not yet performing the procedure, Maya &amp; Sonya seek a task-related procedure to follow. Both turn to memory (1, 3, 44).</i>	A new narrative had been produced
3.	By whom is the routine initiated? To whom it is addressed?	Initiated by former performer of a similar task. Addressed at the teacher (or other superior). <i>The routine was learned sometime in the past (not during this course). They do not try to develop a routine for the specific task by analyzing where it is they want to get at (1, 3, 44).</i>	oneself
4.	Flexibility	Applies a rigid routine. Seldom makes independent decisions <i>The students do not make any decisions at this moment. They turn to the instructor to remind them of the formula / concept that they thought was relevant (42).</i>	Could consider various routines. Makes independent decisions.
5.	Authority	The teacher (42)	One's own

**Table 2: Analysis of Maya & Sonya's participation**

During the rest of the lesson, the students worked in groups and came up with three ways to solve the problem. Later in the second lesson, the students suggested and discussed different solutions paths different series.

During the lesson the students learned: (1) that a problem could be solved by different solution paths; (2) that Gauss' idea could be helpful to solve sums of certain sequences; (3) to apply Gauss' idea, one needs to know the number of elements in the sequence. If the number is odd, then either the element in the middle should be identified or, the first or last element should be sided and later returned to the series. The students were encouraged to come up to the board to suggest solution paths, to make certain that they understand others' ways of solving the problem and ask questions when things were not understood.

At the beginning of the 3rd lesson students were asked to suggest ways to calculate:

$$1 + 2 - 3 - 4 + 5 + 6 - 7 - 8 + \dots + 2009 + 2010 - 2011 - 2012 + 2013$$

Solution paths suggested by two students (Nur and Sara):

- 1 Nur so, I put the 1 aside, and saw that (in) each two pairs, the first gives me minus 1 and the second pair gives me plus 1. So I have 2012 numbers here and then, if I divide this to pairs, I have 1006 pairs. So half of them give me 1, 503 altogether, and the other half gives me minus, so it's (-503) and it cancels and so I have 1 left.
- 2 Inst. Do you see what Nur did? Any questions?
- 3 Ziv no. it's perfectly clear
- 4 Nur now I found another one. After... I left the 1 aside here too, then I saw that if I take the 2 and the 2013, it gives me 2015. If I take then the minus 3 and the minus 2012 it will give me (-2015). So I have the sum of two negative numbers that give me (-2015) and the sum of two positive numbers give me (+2015). So it still cancels out and I have the 1 left.
- 5 inst. What do you all say? yes?
- 6 Sara I have another one. I saw here, my language is not that well, correct me, ok? like a sort of continuum, that every four, every three operations give (-4) each time, then its repeated.
- 7 Inst. Every three operations, you mean, the sum of four numbers?
- 8 Sara yes, the sum is (-4). So it's repeated till number 2012. So 2012 is divided by 4 and I get 503 times that it's repeated. ... then I multiplied 503 by (-4) cause every such part is, mm.... (-4). And this is the result so far [-2012]. Then I have plus 2013 and it's 1.

The analysis of Nur and Sara's suggested solution-paths is in Table3.

		Nur (2 solution paths)	Sara
1.	What is the question the performer is trying to address?	<i>What is it that I want to get?</i> The student is trying to solve the given problem and create a new solution path.	
2.	How does the performer evaluate its' success?	By creating narratives of two types – (1) the sum of the series (equals 1), and (2) new solution paths to	By creating narratives of two types – (1) the solution (the sum is 1). However, this

		solve the problem. In both, the first number of the sequence is left aside. In the 1st solution, adjacent numbers are paired. The sum of each pair is 1 or (-1) alternately. Therefore the solution is 1. In the 2nd solution, Gauss' principle is applied to create pairs of numbers whose sum is 2015 or (-2015) alternately. Therefore, the total sum is 1.	narrative is already known from previous answers. (2) a new solution path to solve the problem: the sum of every 4 adjacent elements is (-4). The sum of all quadruplets is $503 \cdot (-4) = (-2012)$ . The last element of the sequence (2012) is added. Therefore, the sum of the sequence is 1.
3.	By whom is the routine initiated? To whom it is addressed?	The routine used by the student to solve the problem (placing the first or last number aside and checking sums of sets of numbers), as well as Gauss's principle were used by the class in the previous lesson. However, this is not simple mimicking of previously performed routines by others, as those routines have not been used together for the same problem yet. Some adaptation needed to be done. Therefore, the routine is initiated by the student.	
4.	Flexibility	The student used previously performed procedures to create a new solution path to solve this problem. Considering the students' decision making – the student made all decisions for adapting previously used routines to this problem.	
5.	Separation between procedure and task	It is not clear whether for the student the procedure is a part-and-parcel of solving this problem or not.	
6.	Authority	One's own	

**Table 3: Analysis of Nur and Sara's participation**

It seems that Nur and Sara participated exploratively: they produced narratives that include new solution paths for the task and reaching a solution. They articulate their solution path in a way that makes clear that they have made independent decisions while adapting different formerly performed routines to solve the given problem.

## Discussion

In this study we tried to characterize students' learning while solving a specific type of tasks on the ritual towards exploration continuum. In the discussed course, in which students were constantly asked to work on problems on their own or in small groups, and suggest various solution paths to each problem, there is evidence of students shifting from more ritual to more explorative participation. It may seem obvious - the course was designed in a way that would invite students to engage exploratively. Yet, studies show that even when teachers design lessons that aim at certain opportunities to learn, this does not always happen. We found that when faced with a task that is of a new type (to the learner), the learner's immediate response is of a ritual type - to seek related procedures that would assist her in solving the task. The request to suggest various solution paths seems to help students focus on the question of "where do I want to get at?" and not remain focused on the question of "how do I proceed?". Also, once a student chooses a certain routine as a solution-path, it is sometimes followed blindly, ritually, thus getting farther away from the task at hand.

# Co-disciplinary mathematics and physics Research and Study Courses (RSC) within two groups of pre-service teacher education

María Rita Otero<sup>1</sup>, Viviana Carolina Llanos<sup>1</sup>, Marcelo Arlego<sup>1</sup>, María Paz Gazzola<sup>1</sup>

<sup>1</sup>Universidad Nacional del Centro de la Provincia de Buenos Aires (UNICEN), Consejo Nacional de Investigaciones Científicas y Técnicas (CONICET), Argentina; [rotero@exa.unicen.edu.ar](mailto:rotero@exa.unicen.edu.ar); [vcllanos@exa.unicen.edu.ar](mailto:vcllanos@exa.unicen.edu.ar), [marlego@exa.unicen.edu.ar](mailto:marlego@exa.unicen.edu.ar), [mpgazzola@exa.unicen.edu.ar](mailto:mpgazzola@exa.unicen.edu.ar)

*In this paper, we present results of an inquiry based teaching implementation carried out on a teacher training course in the University. The framework of the Anthropological Theory of Didactics (ATD) is adopted, and a co-disciplinary Research and Study Course (RSC) whose generative question requires studying physics and mathematics together is carried out by N=25 training teachers of Mathematics at University. Some conclusions concerning on the conditions, restrictions and relevance of introducing the RSC in teachers training courses at the university are performed.*

*Keywords: Inquiry based teaching, pre-service teachers training, modelization; research and study course.*

## Introduction

The Anthropological Theory of the Didactic (ATD) has proposed the Paradigm of Research and Questioning the World (Chevallard, 2012, 2013 a) advocating an epistemological and didactic revolution (Chevallard, 2012) of the teaching of mathematics and school disciplines, where knowledge should be taught by its usefulness or potential uses in life. The present work shows results obtained in two courses of pre-service mathematics teacher education (N=25) during a teaching inspired in the paradigm of questioning the world, by means of a Research and Study Course (RSC). To learn what an RSC is, and which kind of teaching is involved in, the trainee teachers (TT) must deeply experience a genuine RSC. Thus, a physics and mathematics co-disciplinary RSC is designed, implemented and analyzed with the students. Co-disciplinary means that in this case, physics does not only trigger the study of mathematics, but rather that both disciplines play a central role, being necessary to study both as well. The starting point of the RSC is the question Q<sub>0</sub>: Why did the Movediza stone in Tandil fall? Which, to be answered – in a provisional and unfinished way- needs study Physics and Mathematics jointly. The rationale of the paper is to describe the trainee teachers' activities and their difficulties when they must experience a genuine RSC and to face a strong question. Some reflections on the ecology and economy of this kind of didactic devices for the pre-service teachers training are performed.

## The research and study courses (RSC)

The ATD defines the RSC as devices that allow the study of mathematics by means of questions. The RSC establish that the starting points of mathematical knowledge are questions called generative questions, because its study should generate new questions called derivative. Teaching by means of RSC is complex and demands rootle changes in the roles of the teacher and students. The RSC are defined by the *developed Herbartian model* (Chevallard, 2013 b):

$$[S(X;Y;Q) \rightarrow \{R_1^\diamond, R_2^\diamond, R_3^\diamond, \dots, R_n^\diamond, Q_{n+1}, \dots, Q_{m+1}, \dots, O_m, O_{m+1}, \dots, O_p\}] \rightarrow R^\heartsuit$$

Where  $Q$  is a certain generative question;  $S$  is a didactical system around of the study of  $Q$ .  $S$  is formed by a group of people trying to answer the question ( $X$ ) and by people helping the study ( $Y$ ). In classrooms of mathematics,  $X$  represent the students and  $Y$  represent the teacher and other instruments helping in the search of answers to  $Q$ .  $S$  has to build a didactic medium  $M$  to study  $Q$ , whereas  $M$  is composed by different knowledge, expressed by  $R_i^\diamond$ ,  $Q_j$  and  $O_k$ . The  $R_i^\diamond$  are any existing answer or “socially accepted answer”, the  $Q_j$  are derivative questions of  $Q$ , and the  $O_k$  are any other knowledge that must be studied developing the answers. Finally,  $R^\heartsuit$  is some possible and partial response to  $Q$  given by  $S$ . In the a priori analysis stage, the specific and didactic knowledge which could be involved within an RSC is set up and the Praxeological Reference Model (PRM) is elaborated. The researchers analyze the potential set of questions which the study and the research into  $Q$  might encompass together with the knowledge, mathematics and physics in this case, necessary to answer those questions (Chevallard, 2013). The PRM underlies the whole of the teacher, student and researcher’s activity, being always likely and desirable to identify and clarify it, emphasizing the dynamic nature of the PRM.

## Methodology

This is a qualitative and exploratory research that aims to carry out inquiry based teaching as it is proposed by the ATD, in a mathematics teacher training course at the University. The RSC was implemented in a state university, in the city of Tandil, Argentina, in a discipline which is part of the didactic studies within the Mathematics Teaching Training Course, in which the researchers are also the teachers, where  $N=12$  and  $N=13$  students from the last year (4<sup>th</sup>), aged 21-33 took part in it. The students had studied the ATD in two Didactic courses; however, they had problems to understand what an RSC is, and how it works? To emphasize the inquiry dimension of the RSC, the lessons were carried out in the University Library, given the wide availability of books and internet-based searching, during 10 weeks (the half of the course extension), with a total of 7 weekly hours provided in two lessons. Six work groups were organized with approximately 4 members each. During the lessons students and teachers interacted permanently. In a RSC, the generative question  $Q_0$  has to be pointed out by the teacher, and this was made in the first lesson. Then, the students started their research in the library, by selecting some texts, documents etc. as possible  $R_i^\diamond$ . At the end of this class, each group presented and discussed with the teacher and the other groups their findings and possible ways to face  $Q_0$ . In the second class, many emergent questions  $Q_i$  were made explicit, and the teacher and students groups selected which questions  $Q_i$  and their related knowledge  $O_k$  were to be studied. This was the regular dynamic during the RSC. Recordings of each meeting were obtained and the students’ productions were digitalized and returned in the subsequent meeting. The data analysis was performed by using the categories provided by the *developed Herbartian model* (Chevallard, 2013) summarized before, and all derivative questions  $Q_i$ , all “socially accepted answers”  $R_i^\diamond$  found by the students, together with the  $O_k$  studied were described and analyzed.

## The Praxeological model of reference (PMR) and the RSC

The starting question  $Q_0$  is: Why did the Movediza Stone in Tandil fall down? This enormous basalt stone has remained the city’s landmark, providing it with a distinctive feature. Many local people

and national celebrities visited the place to watch closely the natural monument. It was a 248-ton rock, sitting on the top of a 300-meter-high hill (above sea level), which presented very small oscillations when disturbed in a non-arbitrary spot, as shown in Figure 1. Unexpectedly, on February 28, 1912, the stone fell down the cliff and fractured into three pieces, filling the town with dismay at the loss of their symbol. For over 100 years the event produced all kinds of conjecture, legends, and unlikely scientific explanations for the causes of the fall. Within the two groups where the RSC has been performed, there existed a certain curiosity and interest in finding a scientific answer to this question.

Once in contact with the available information, the question evolved into: What conjectures are about the causes the Movediza Stone fall, and which is the most likely from a scientific viewpoint? Considering that the fall can be explained by means of the Mechanical Resonance phenomenon, several questions  $Q_i$  arose which are linked to the physical and mathematical knowledge necessary to understand and answer  $Q_0$ .

Figure 1: Photography of the Movediza Stone (Photo Archivo General de la Nación Argentina, available in: <http://bibliocicop.blogspot.com.ar/2012/02/piedra-movediza-100-anos-de-su-caida.html>)

If we consider that the real system is an oscillating system, the study can be carried out within the Mechanic Oscillations topic, starting from the spring or pendulum models which are ideal at the beginning. In this case, frictionless systems are used, in which the only force in action is the restoring force depending in a linear way on the deviation respect to the equilibrium position, and which produces oscillating systems known as harmonic, whose motion is described by a second-order linear differential equation, called by the same name. In the case of the pendulum, the restoring force can be considered depending on the oscillating angle (for small angles).

Progressively, the system becomes more complex. If friction-produced damping is considered, it provides a new term to the differential equation connected to the first derivative of the position (speed). Finally, it is possible to study systems that apart from being damped, they are under the action of an external force, and therefore called driven systems. Whenever this given force is periodic and its frequency coincides with the natural (free of external forces) frequency of the oscillating system, a maximum in the oscillation amplitude is produced, generating the phenomenon known as mechanical resonance. By increasing the complexity of the model, it is possible to consider a suspended rotating body, instead of a specific mass. This leads to the study of the torque and the moment of inertia of an oscillating body. Here again, the linear system is for small amplitude oscillations and the damped and driven cases can be also considered, corresponding to the same mathematical model, but in which the parameters have a different physical interpretation.

However, as it refers to a suspended oscillating body, this is not a suitable physical model for the Movediza stone system. Since that the base of the Stone was not flat, it is necessary to consider more precise models of the real situation. This leads to the mechanics of supported (and not hanging) oscillating rigid solids. In this case, we consider a rocker-like model in which the movediza stone base is curved and it lies on a flat surface, where the oscillation is related to a roto-translation motion (Otero, Llanos, Gazzola, Arlego, 2016 a, b). The application of Newton Laws to the rocker model of the movediza stone leads to a differential equation of the type harmonic oscillator, where the parameters are now specific of the movediza system: mass, geometry, inertia moment, friction in the base, external torque, etc. It leads to the following *effective* Harmonic oscillator mathematical model of the movediza physical system:

$$\ddot{\varphi} + \gamma \dot{\varphi} + w_0^2 \varphi = (M_0 / I) \cos(wt) \quad (1)$$

The solution to equation (1) is  $\varphi(t) = \varphi_M \cos(wt - \psi)$ , being the amplitude  $\varphi_M$  and the phase  $\psi$

$$\varphi_M = \frac{M_0 / I}{\sqrt{(w_0^2 - w^2)^2 + w^2 \gamma^2}} \quad \psi = \text{tg}^{-1} \left( \frac{\gamma w}{w_0^2 - w^2} \right)$$

The maximum of  $\varphi_M$  is for  $w = \sqrt{w_0^2 - \gamma^2}$ . The parameters:  $M_0$  (external torque),  $I$  (inertia moment),  $w_0$  (natural oscillation system frequency) and  $\gamma$  (friction coefficient), must be estimated. Detailed data about the shape, dimensions and center of mass position of the movediza stone are available (Peralta, et al 2008) after a replica construction and its relocation in 2007 on the original place (although fixed to the surface and without possibility to oscillate). These data bring us the possibility to fix some parameters in our model, as e.g. mass, inertia moment, and the distance of 7.1 m, from which the external torque could be exerted efficiently by up to five people (per historical chronicles) to start the small oscillation. By using these values, it is possible to study the behavior of the  $\varphi_M(w)$  function for  $w_0$  in a range of frequencies between 0,7 Hz and 1 Hz, historically recognized as the natural oscillation frequencies in the movediza stone system and calculate for each case the maximum amplitude  $\varphi_M(w_m)$  that occurs for  $w_m = \sqrt{w_0^2 - \gamma^2}$ . The Stone would fall if  $\varphi_c \leq \varphi_M(w_m)$ , being  $\varphi_M(w_m) = M_0 / w_0 I \gamma$  the maximum value of the amplitude function, that is to say  $\varphi_c \leq (M_0 / w_0 I \gamma)$ . The value of  $\varphi_c$  can be determined by an elementary stability analysis, which according to the dimensions of the base of the stone and the center of mass position is estimated to be approximately of  $6^\circ$ . In the present model, we cannot estimate  $\gamma$ . If we adopt “ad doc” for this parameter, a magnitude order  $\gamma \geq 10^{-2}$ , we obtain in the various situations considered with different torques and the interval frequencies previously mentioned, that all the scenarios support the overcoming of the critical angle, i.e., predict the fall. Later, in search of a more appropriate approximation of the physics model for the damping that is clearly not due to air, we can consider the stone as a deformable solid, where the contact in the support is not a point, but a finite extension. Therefore, the normal force is distributed on such a surface, being larger in the motion direction and generating a rolling resistance, manifested through a torque contrary to the motion due to friction. The rolling resistance depends on the speed stone, giving a physical interpretation to the damping term. Therefore, the physics behind the damping is the same that

makes a tire wheel rolling horizontally on the road come to a stop, but in the case of the stone, the deformation is much smaller. Although the deformable rocker model has extra free parameters, tabulated values of rolling resistance coefficient for stone on stone, which are available in the specialized literature, allowed us to estimate and justify the damping values that we incorporate otherwise ad-hoc in the rigid rocket movediza model.

### **Some results obtained in the two implementations**

During the implementations, the students aim at answering how and why the stone fell down the cliff. At the beginning, the TTs searched in the elementary physics textbooks for an “already-made” mathematical and physical model, which allowed them to solve a differential equation in a specific way. In both implementations, several physical and mathematical questions arose; the main preoccupation of the TTs was to study the oscillations subject, because it was a new knowledge to them. The implementation was carried out in parallel with a Differential Equations course, and none of the groups seemed to have difficulties with the underlying mathematics. In both implementations, the TTs tried to find a physical model suitable for the situation and they decided on the physical pendulum model initially, whose mathematical model might be adequate to the problem, although physically inadequate. However, the path performed in the first implementation was different from the second. In the first case, the TTs did not question the physical model, and spent most of the time to the study of inertia moment concept and their calculation for regular solids, which would result in an appropriate model for the irregular shape of the stone. Several interesting questions were therefore generated, for which the answers were provided by the teacher and the students together. After, the students calculated by themselves the characteristic frequency of the system, making use of the moment of inertia previously obtained. Thus, only a parameter resulted undetermined: the damping. But in the end, the physical pendulum model became an obstacle, because the stone was a supported body, and not hanged. On the other hand, the damping they considered was due to air-friction, whereas in the case of the movediza stone the main source of friction is the contact with the support surface.

At this point, the external torque (there were different trials to analyze and estimate it) and the solution of the equation remained unstudied. Until this moment, the solution for the differential equation did not seem to present any obstacles to the students, who considered they were facing an initial value problem. Once they had obtained the parameters, which they considered fixed, the solution seemed simple. However, they had problems to arrive at a final solution, even though this can be found in the physics textbooks (without its deduction). For this reason, it was discarded and they decided to do the calculation on their own. This event complicated the quantification they aimed to obtain, as well as the physical interpretation. Some groups in this cohort removed the term of damping, to reduce degrees of freedom; thus, the stone would have been in perpetual motion. This did not create any contradiction to them. Other ones adopted a damping value due to air-friction, which also led to wrong results. In summary, instead of adopting and adapting the solution that was presented in physics books, the TTs in this cohort dismissed it and did not interpret the answer in the texts concerning the Stone. The decision of the teachers to delay their intervention was with the purpose to make students live the dynamics of progress and drawbacks typical of the research and study courses. In addition the TTs had problems to understand the utility and necessity

of mathematical models, due to an epistemological conception close to pure or formal mathematics. The TTs did not understand how to use the mathematical models, neither the role that the parameters could play, which were considered as fixed and universal. In consequence, they failed to establish different sets of parameters and did not generate the feasible families of functions and values, whose compatibility with the physical situation could have been analyzed. These difficulties were considered for the second implementation of RSC. In the second cohort (TT2), the teachers had already perceived that the fundamental problem seemed to be in the models and in the modelization. For this reason, it was decided to devote 8 sessions to the development of two intra-mathematical RSCs (Chappaz & Michon, 2003; Ruiz, Bosch, Gascón, 2007), that the TTs could experience by themselves, therefore emphasizing the role of the modelization and the use of devices as spreadsheets and plotters. Besides, in this case, the teachers intervened as soon as the students proposed the physical pendulum and spring models. One group studied the AMS for the simple pendulum, the spring, and the physical pendulum, another group studied the spring model in all its possibilities and the third one did not develop further than the AMS in simple pendulum and spring. The synthesis stage corresponding to that class allowed the production of a complete answer for the three models and its possibilities, from which the TTs and the teacher arrived at the conclusion that the same mathematical model represented (9) nine different physical systems (Figure 2). A large amount of time was devoted to pondering on the differences and similarities between the mathematical and physical models and their connection with the real system we aimed at modeling. Then, the answers to the equations presented in the books were checked out.

Figure 2: Protocol of the student E17. Implementation 2

In both cohorts, as a fixed route that is inevitably set by the books, the TTs came across the physical pendulum. However, in the second cohort some students presented strong objections to the possibility of using it in the case of the stone, not so much in relation to a body that is supported but as an “inverted” pendulum. This drew the discussion once more towards the real system and the standing point, so that the path went through the models which refer specifically to the system and that are not, usually in elementary books, like a rocker.

Firstly, the equilibrium was analyzed and the critical angle was calculated, and then, the model of the base of the movediza stone was sophisticated. For the study of the rigid solid physical model, the teacher proposed to the students a little text, as a new  $O_k$  that could be introduced into the didactic medium  $M$ . Finally, the students and the teacher calculated and estimated the parameters of the differential equation solution, and the classroom elaborated an answer that allows the explanation, by means of a model, of the plausibility of the fall.

## Conclusions

Despite of the difficulties, the TTs experienced a genuine RSC within its means. There is a visible initial reluctant attitude on the part of the TTs: Why physics should be studied if we are teachers of mathematics? Later, it was gradually understood that the idea was to experience a genuinely co-disciplinary RSC, to analyze it and comprehend the teaching model supporting an RSC.

Even though the TTs had studied the ATD and other didactic theories, they did it in a traditional way comparable to the traditional training they get. This is reflected in the difficulties they have to understand and to use both physics and mathematical models. It was not expected that the TTs developed the models by themselves, but it was expected that they used the mathematical answers presented in the physics textbooks in a pertinent and exoteric manner. This fact did not occur in the first group and improved in the second one from the didactic decision to make a previous incursion into mono-disciplinary RSC particularly suitable for evidencing the role of the functional modelization. In addition, this allowed teachers to discuss the relationship between the mathematical model and the physical model and the meaning and role of the parameters.

The TT's behavior is interpreted from the fact that although they have experienced four years of "hard" university studies, the utility of the science they aim at teaching had never been visible. The epistemological conception about the mathematics produced by the traditional paradigm is so ingrained, that it is complex to reverse it. This would be, in our view, the most relevant drawback to permit the TTS at least understand what an RSC is and how the modelization activity works? However, it is important to notice that the sporadic incursions in the modelization activity do not seem enough to allow the TTs develop such school practices. Although the predominant teaching is mainly traditional, the TTs will face increasing demands for a change to a mathematic teaching based on the research, questioning and modeling. It is unlikely that a teacher whose training has been answers-based teaching can teach by means of questions. Then the training of teachers has to change profoundly.

# Writing fictional mathematical dialogues as a training and professional advancement tool for pre-service and in-service math teachers

Tikva Ovadiya

Oranim Academic College of Education, Israel; [tikvao@actcom.net.il](mailto:tikvao@actcom.net.il)

*Pre-Service and In-Service Math Teachers are often surprised to find themselves at a loss for words in the mathematics classroom. This feeling is not limited to the first day of class or to beginning teachers. Even experienced teachers describe unexpected classroom situations in which they cannot find the proper words to respond or to explain or mediate ideas. The teaching routine is fraught with on time decisions teachers must make. The objective of the current study was to promote the development of spoken and written mathematical discourse among pre-service and in-service math teachers in the context of classroom scenarios they considered unexpected and complex. The training was directed toward developing argumentative mathematical discourse skills through writing, with emphasis on writing fictional dialogues. The research focuses on the characteristics of fictional mathematical dialogues written by pre-service and in-service math teachers and seeks to show that these dialogues can be used as a professional advancement tool.*

*Keywords: Writing fictional mathematical dialogues; professional advancement tool; pre-service and in-service math teachers.*

## Introduction

Teachers make decisions based upon knowledge, goals, beliefs and orientations. Accordingly, developing all of these factors can help promote decision making in the mathematics classroom.

For many years, I have been seeking creative ideas that will enable in-service and pre-service teachers to predict scenarios and unexpected situations in the mathematics classroom. Thus, they will be able to practice mathematical discourse before coming to class and to learn to provide argumentative responses that are quick, accessible and flexible. Teachers' responses in class and their responsibility in developing mathematical discussions and discourse have been the topics of much investigation (e.g., Schoenfeld, 2008-2011). The literature has placed less emphasis on examining training methods for developing discourse management for predicting unexpected classroom situations in advance, particularly training all that through writing.

Zazkis and Koichu (2015) describe a fictional dialogue on infinitude of primes between Euclid and Dirichlet and use this as a research method. The current study focuses on pre-service and in-service math teachers who write "fictional dialogues" as part of their training. The goal of this writing is to develop their ability to explain, respond and engage in argumentative mathematical discourse in a learning situation characterized by unexpected situations. The results of the current study indicate that the task of writing fictional dialogues has several advantages. One advantage relates to professional development and renewal. Veteran teachers tend to feel less challenged and less interested in preparing lessons in advance. Writing fictional dialogues challenges them to formulate unexpected mathematical situations for mathematical topics and ideas that for them are seemingly

simple and trivial. In writing fictional dialogues, they discovered both mathematical and didactic innovations. Another advantage applies to training. In writing the dialogues, beginning teachers learned to develop written mathematical discourse that explains the essence of mathematical terms. Further, they learned to use visual or other representations in context and practiced giving explanations to learners with a variety of learning styles.

## **Theoretical background**

Unexpected situations in the mathematics classroom differ from teacher to teacher due to differences in the extent and depth of their mathematical knowledge, their ability to identify such situations and their ability to make decisions in real time about the didactic concepts appropriate for each situation. Hence, I examined the research literature on major topics related to the current research. These include training pre-service and in-service math teachers by means of writing, the role of the teacher in discourse development and management in the mathematics classroom, mathematical argumentation as a teaching tool and interaction in the mathematics classroom (Malaspina, Mallart, Font, , & Flores, 2016). The conclusions of these studies led me to formulate ideas for a unique intervention "training" program with the potential to promote mathematical discourse in the classroom in general and argumentative mathematical discourse in unexpected situations in particular. In the following sections, I review the relevant literature in these fields and explain how these studies relate to the current research.

### **Professional development and learning through writing**

Teacher training usually incorporates writing through writing assignments about ideas learned in class or as reflection on learning (Korkko et al., 2016). Turning writing into a goal in and of itself is an innovation in the training of mathematics teachers. Therefore, in order to construct an intervention program that emphasizes writing, I surveyed and studied research that examines the advantages of writing in teaching math and of pedagogy based on writing in general.

In the study by Bostiga, Cantin, Fontana and Casa (2016), the students learned by writing diaries on mathematical argumentation. The research indicates that the process of writing develops students' in-depth thinking about mathematical concepts as well as underlining erroneous or other perceptions of concepts or phenomena. The writing process and the accompanying feedback prompted the students to write more precisely about mathematics, directed them to give arguments, explanations and reasoning in their writing and taught them to edit and rethink mathematical ideas. From this study among students, I decided to try to generalize the method for adults and to examine the results. Adults with a common professional interest often write together in a process that advances their shared understanding and learning in the field (Lowry et al., 2004).

Griffin and Beatty (2010) examined the attributes of shared writing among adults with a common professional interest. Their research pointed to several advantages, including professional and personal growth among the writers, a greater degree of creativity, the generation of new ideas and understandings, diversification in areas of specialization, increased documentation and output abilities, and shared knowledge. Shared writing generates a unified voice, increases feelings of satisfaction and pride in integrating the personal voice into the voice of the group and expresses respect for individual knowledge. Therefore, in this study the writing took place in pairs or in small groups as part of the process of developing skills in argumentative mathematical writing.

Read (2010) proposed the IMSCI model for supporting the writing process, with writing serving as a pedagogical tool for assimilating learning. In the IMSCI acronym, "I" stands for inquiry, "M" for modeling, "S" for shared writing, "C" for collaborative writing and "I" for independent writing. This scaffolding model was integrated into the intervention process in the current study.

### **Spoken or written mathematical discourse**

According to Sfard (2008a; 2008b), discourse has four characteristics: vocabulary, visual mediators, unique routines and customary utterances. In the communicative approach, thinking constitutes an individual's discourse with the self. Such a discourse can yield ideas that express the thinking of those participating in the discourse. In contrast to those who talk, some people express themselves through writing and symbolic mathematical representations and have difficulty expressing their ideas verbally. Such individuals may eventually become teachers whose skills in developing and conducting mathematical discourse are not sufficiently developed. In most cases, this does not point to a lack of mathematical knowledge but rather to the difficulty teachers experience in translating this knowledge, which perhaps is represented in their minds through nonverbal symbols, into verbal tools. Mathematics teachers must generate significant discourse in their classrooms. Such discourse constitutes an organized and connected collection of all their students' and their own intellectual ideas. The job of the teacher is to conduct a discourse that reflects ideas and encourages participants to discuss these ideas, to endorse or refute them and to arrive at valid and agreed-upon mathematical rules that can be implemented in new situations that are similar or different. How can we promote and cultivate teachers who have the awareness and skills to cultivate this type of classroom reality?

Waggoner (2015) proposed five strategies for supporting meaningful math talk in class. First, teachers must talk with their students and arrive at common insights regarding the importance of math talk in the classroom. Second, teachers are responsible for teaching their students to listen and respond appropriately to one another. Third, teachers must teach their students to write sentence stems to emphasize their responses. Fourth, teachers must teach and demonstrate the difference between explaining and justifying what someone else says. Finally, teachers must provide examples of all these actions in class. The current study implemented all of Waggoner's ideas with pre-service and in-service teachers in the general context of group mathematical discourse and the particular context of written mathematical discourse in unexpected situations in the mathematics classroom.

## **Methodology**

### **Participants**

The research participants included undergraduate students taking a course that taught didactic and pedagogic skills for teaching math in elementary and junior high school and graduate students in mathematics education who teach math to all ages and at all levels. The two groups together totaled 35 students, as half of them were teachers were in fact teachers.

### **The research tool**

Intervention design –The two courses comprised the same several stages. First, the students read the article by Zazkis and Koichu (2015) about fictional dialogues in order to understand and define fictional dialogues in the context of their unique methodological role in the original article. Next, we adopted the skill of writing fictional dialogues as a tool for developing spoken and written

mathematical discourse in lesson planning for unexpected situations in the math classroom. We embraced the following quote with the understanding that we as students also seek interesting learning methods. "People are eager for stories. Not dissertations. Not lectures. Not informative essays for stories" (Haven, 2007, p. 8).

Third, we defined and formulated conditions determining whether a potential fictional dialogue met the objective. In this stage, we read mathematical dialogues from various sources that resembled fictional mathematical dialogues and we reworked their mathematical discourse so it matched our definition of a fictional dialogue. Fourth, the students independently wrote fictional mathematical dialogues. In the fifth and final stage, the students showed their dialogues to their classmates. This generated an evaluative argumentative discussion and, if necessary, led to redesigning the dialogues. Throughout the course, we documented the sessions and their outcomes *focuses on fictional Mathematical dialogues*.

### **Definition of "fictional dialogue" in the current study**

The definition of fictional dialogue emerged from agreement among all course participants and included the following characteristics: The dialogue must take place between two people with some sort of major gap between them. This gap may be rooted in culture, age, expertise, historical period (e.g., one speaker lives in contemporary times and the other lived 700 years ago), mathematical knowledge and more. One speaker is an expert in the field and should be able to bridge the gap through argumentative dialogue that leads the two speakers to understanding, definition and agreement on the mathematical topic they are discussing. The expert presents the mathematical explanation using formal intra-mathematical tools and extra-mathematical or other simple, practical and concrete examples and explanations. The non-expert participant's dialogue develops in unexpected directions, so that this participant can surprise the expert with questions or examples that seemingly contradict the mathematical concept under discussion or that present a challenge to the clear, simple and popular explanation. In the dialogue, the two participants express their perceptions of the mathematical topic being discussed, and each attempts to enrich the other's world through the mathematical knowledge at his or her disposal. Through the dialogue, the gap between the speakers becomes smaller in that all the relevant mathematical nuances in the field find expression in the dialogue.

### **Data analysis**

The data analysis focused on the process of establishing the conditions for fictional dialogue.

### **Findings**

In this paper, I describe one mathematical event representing two stages of the intervention period. Because the research focuses on the final product—"writing"—I give two examples of writing and discuss the processes involved in creating them. These two examples show that writing fictional mathematical dialogues can serve as a training and professional advancement tool for pre-service and in-service math teachers. The first finding refers to the third stage of the intervention period, in which we redesigned a dialogue and rewrote it as a group fictional dialogue. At this stage, each student individually redesigned the dialogue by writing a new dialogue based on the existing dialogue and thus creating a new personal product that conformed to the required conditions. In the next stage in the joint group work, the students showed their dialogues to their classmates for

evaluation, leading to writing an agreed-upon group product. The dialogue is the unified product after the group discussed their differences and went through the entire learning process.

### **Group design of a given dialogue and its transformation into a fictional dialogue**

The given dialogue is from an Abbott and Costello movie titled *Buck Privates*:

Abbott: You're 40 years old, and you're in love with a little girl, say 10 years old. You're four times as old as that girl. You couldn't marry that girl, could you?

Costello: No.

Abbott: So you wait 5 years. Now the little girl is 15, and you're 45. You're only three times as old as that girl. So you wait 15 years more. Now the little girl is 30, and you're 60. You're only twice as old as that little girl.

Costello: She's catching up?

Abbott: Here's the question. How long do you have to wait before you and that little girl are the same age?

Costello: What kind of question is that? That's ridiculous. If I keep waiting for that girl, she'll pass me up. She'll wind up older than I am. Then she'll have to wait for me!

In order to determine whether this qualifies as a fictional dialogue, we mapped it to see whether it fulfills the conditions for fictional dialogues formulated in the second stage of the course. The mapping results indicate that the dialogue does not meet the conditions to qualify as a fictional dialogue. Hence, we redesigned the dialogue to fulfill the necessary conditions. Each course participant individually designed and wrote a fictional dialogue. In the next stage, the students as a group combined these individual dialogues into a fictional group dialogue. The group dialogue features an expert "player" called Achilles, provides intra- and extra-mathematical explanations, stresses the perceptions of each of the speakers so that it is clear who represents the erroneous perception and who represents the appropriate perception and stresses the unexpected situation. Using the ideas from the individual dialogues, the group wrote an argumentative fictional dialogue that gap the discrepancy between the speakers to the point of generating an unexpected situation in which the speakers "reverse" their roles, so that the rookie, Costello, triumphs over the expert, Achilles. The following lines from the dialogue demonstrate compliance to condition (4) as written by the group.

.....

Achilles: I, Achilles, run at a speed of 10 meters per second. My friend the turtle runs 1 meter per second. I decide to give the turtle a head start of 100 meters at the beginning of the race.

Costello: Wait a minute. This is a fable, right? So I want to convert it to apply to me. I gave the girl a forty-year head start. Wow, that's a lot. I am four times older than she is! And you run ten times faster than the turtle. Great, I get it.

.....

Costello: So let's assume I'm 240 years old. How old will she be??? She will always be 30 years younger than me, so she'll be 210 years old. So her age will be seven-eighths of my age. It appears we are slowly advancing to the point where we're the same age.

Achilles: No. That's not right. Let's go back to my turtle.

Costello: I'm not going back to your turtle because I've discovered the problem and also the solution. The girl and I will never get married because there will always be a fixed difference of 30 years in our ages. But there is not a fixed difference of 100 meters between you and the turtle because around 12 seconds after the beginning of the race you will already catch up with the turtle. In ten seconds you run 100 meters and in another two seconds you run another ten meters, so the race is over because the turtle continues to trail behind you.

Achilles: Does that mean that the age difference problem is not representative of infinity.

Costello: Now we've switched roles. I'm the mathematician. What are you? The concept of infinity can be represented if the beautiful girl and I live forever and do not die. From a situation in which I'm four times her age and then three times her age, we get to a situation where the ratio is 7:8, and we can go on to 8:9 and even further. While the discrepancy in our ages is still thirty years, with time the relative difference in our ages gets smaller. In contrast, when you race against the turtle, a quick calculation tells me that you'll overtake your opponent after 12 seconds. The 100-meter difference between you is not fixed because you "grow at different rates" That is, you each run at a different speed and you are ten times faster than the turtle.

### **Dialogue analysis "Age difference problem"**

In the above dialogue, the students completed all the conditions that were missing from the original given dialogue. They created two fictional characters and delineated a significant historical and mathematical gap between them. They defined an expert speaker who led the dialogue. They formulated intra-mathematical explanations (e.g., speed as the ratio between distance time) and extra-mathematical explanations (e.g., representing the concept of infinity by means of the girl and Costello, who grow forever and never die) for the age problem and for the paradox of Achilles and the tortoise. Furthermore, they created two unexpected situations in the dialogue. One was the comparison between the age problem and the Achilles paradox. The other was that Costello understood the difference between the problems and claimed that the turtle problem differs from the age problem ("Now we've switched roles. I'm the mathematician. What are you?"). They created a specific explanation for the problem and its concepts and accurately differentiated between the two problems. Using the dialogue, they understood that the age problem demonstrates Costello's misconception about the age gap, as he thought the gap would decrease over time.

In contrast, the turtle paradox shows that the gap between the turtle and Achilles is not fixed and that the distance decreases with time. Using numbers, the students demonstrated the two situations, showing that the gap in the age problem remains constant while the distance between the turtle and Achilles continues to diminish. At this stage, they reduced the gap between the speakers' dialogue.

During the group formulation, the students explored ideas and mathematical explanations. They designed and formulated the dialogue as a group exercise, so that in cases of disagreement they stopped and sought a consensus in the group.

### **Discussion and conclusions**

The current study is a pioneer in this field. The research was inspired by studies that examined student writing in math classrooms (Bostiga et al., 2016) and writing-based pedagogies (Korkko et al., 2016; Zazkis, et al 2009). The study implemented Read's (2010) method using the IMSCI

model. Implementing this model one-step at a time was found to be effective and to validate the results of studies claiming that only theories that are practically applied in the training process can be properly implemented in the field (Anderson & Stillman, 2013; Bråten & Ferguson, 2015; Cheng, Tang, & Cheng, 2012; Gomez Zwiép,. & Benken, 2013). That is, it would have been more effective to teach the theory of fictional dialogue in the course and then to practice it step by step (IMSCI) through actual writing.

# Tensions in the role of mathematics coaches

Annette Rouleau

Simon Fraser University, Canada; [annetterouleau@gmail.com](mailto:annetterouleau@gmail.com)

*The use of mathematics coaches as a means of professional development for teachers is an increasing phenomenon in North American schools. The research presented here identifies tensions experienced by mathematics coaches and how they cope with those tensions. Utilizing a framework that characterizes tensions as dichotomous pairings, the results indicate that there are tensions that are unique to mathematics coaches. This adds to a growing body of research into the role of mathematics teachers.*

*Keywords: Tensions, mathematics coaches, professional development.*

## Introduction and background

In their search for school-wide models that support improvements in the teaching and learning of mathematics, districts are, “embracing coaching as a model of authentic professional development wherein teachers can learn in the context of their schools and their instructional practice” (Campbell & Malkus, 2014, p. 213). Underlying this development is the recognition that schools need to become places where both students and teachers can learn (Hawley & Valli, 1999). With this in mind, districts have begun placing mathematics specialists in their schools to work directly with practicing teachers (Anstey, 2010).

Bearing a variety of labels, such as mathematics specialist, numeracy specialist, lead teacher or learning coach, a mathematics coach is generally a highly knowledgeable teacher hired to support the improvement of mathematics teaching and learning within a district (Anstey, 2010). An effective mathematics coach would have a deep understanding of mathematical content combined with pedagogical expertise and strong interpersonal skills. Usually they are former classroom teachers, recognized for their abilities and promoted from within (Campbell & Malkus, 2011).

Mathematics coaches are responsible for providing ongoing professional development of the inservice teachers in their districts by “advocating for their change, nurturing their performance, advancing their thinking, increasing their mathematical understanding, and saluting their attempts” (Campbell & Malkus, 2011, p. 459). To reach this goal, mathematics coaches’ work varies from modeling mathematics lessons in a teacher’s classroom to observing and supporting a teacher as they teach (Campbell & Malkus, 2014). This is a varied, demanding role that Campbell and Malkus (2011) suggest “the profession does not understand and is only beginning to examine” (p. 449).

The tensions experienced by mathematics coaches is one such unexamined area. A review of the literature reveals little information about the dilemmas mathematics coaches face. Literature regarding generalist coaches is much richer and suggests several common tensions. For instance, Neufeld (2003) identified a series of tensions experienced by generalist coaches that begins with a lack of time. This is a frequently experienced tension, whether it is a lack of time to conference with teachers or lack of time to prepare for working with teachers. Leaving the classroom environment causes tensions for some generalist coaches, as does the switch to working with adults. Tensions also occur when teachers are slow to uptake change or are actively opposed to its implementation. Finally, Neufeld (2003) suggests tensions for generalist coaches arise from working with uncooperative

school cultures or administration and from a lack of opportunities for personal professional development. While there are perhaps some commonalities between these tensions experienced by learning coaches in general and those experienced by mathematics coaches in particular, it would be of benefit to identify whether there are any tensions specific to mathematics coaches. Jones (1995) suggests that “members of the mathematics education community, whether in schools, colleges, or universities, have a responsibility to help one another recognize and deal with tensions in a productive way” (p. 233). The intent of this paper then, is to identify some of the tensions experienced by mathematics coaches.

## **Theoretical background**

Endemic to the teaching profession, tension encompasses the inner turmoil teachers experience when faced with contradictory alternatives for which there are no clear answers (Adler, 2001; Berry, 2007). Building on the work of Berlak and Berlak (1981) who identified sixteen dilemmas that illuminated the relationship between everyday school events and broader social, economic, and political issues, it was Lampert (1985) who first suggested the notion of teachers as dilemma managers who accept conflict as useful in shaping both identity and practice.

For the purposes of this study, I turn to the work of Berry (2007) whose self-study of tensions in her role as a teacher-educator resulted in a binary categorization of tensions. Seeking to depict the inner turmoil she experienced from the competing pedagogical demands in her practice, she proposed a framework for both identifying and understanding tensions. Isolating the following six pairs of interconnected tensions, Berry used these as a lens to examine her practice: (1) Telling and growth—between informing and creating opportunities to reflect and self-direct (2) Confidence and uncertainty—between exposing vulnerability as a teacher educator and maintaining prospective teachers’ confidence in the teacher educator as a leader (3) Action and intent—between working towards a particular ideal and jeopardising that ideal by the approach chosen to attain it (4) Safety and challenge—between a constructive learning experience and an uncomfortable learning experience (5) Valuing and reconstructing experience—between helping students recognise the ‘authority of their experience’ and helping them to see that there is more to teaching than simply acquiring experience (6) Planning and being responsive—between planning for learning and responding to learning opportunities as they arise in practice (Berry, 2007, pp. 32–33).

Although initially used as a framework to isolate tensions in the work of teacher education of pre-service teachers, Berry’s (2007) framework has been used in other contexts as well. As part of a larger, ongoing project, of which this paper is a part, Liljedahl, Andrà, Di Martino, and Rouleau (2015) applied Berry’s tensions framework to a fictional composite of a mathematics teacher that comprised a collection of data sets. Their work expanded Berry’s framework by identifying new tension pairs and they concluded that some tensions may be the driving force behind a teacher’s pursuit of professional development by fueling a desire for change in practice.

While considered relative newcomers, mathematics coaches are part of a mathematics community that includes both pre-service and inservice teachers. Given that developing a shared understanding of the tensions teachers face gives them the power to shape the course and outcomes of their teaching practice (Adler, 2001); it is likely the same would be true for mathematics coaches. Bringing the

challenging aspects of their work to light would offer mathematics coaches the opportunity to recognise, talk about, and act on the tensions in their practice.

My goal then, in this article, is to isolate some of the tensions experienced by mathematics coaches. Specifically, using Berry's (2007) framework, I will identify and describe the tensions they face and how they cope with them. Thus, my research questions are as follows: (1) What are some of the tensions experienced by mathematics coaches? (2) How do mathematics coaches cope with those tensions?

## **Context and method**

This study is part of an ongoing research project regarding tensions in teaching. In particular, it is the first look into the tensions experienced by mathematics coaches. This is a small scale, qualitative study that involves only three participants. As such, I am focusing on proving the existence of a phenomenon rather than its prevalence. It is important to note, however, that I chose to report only on those tensions that were experienced by more than one participant. While aware that a single instance of a tension can be as revealing as multiple instances, it is less likely to be seen as representative of a generalizable pattern. In keeping with that, the data corpus comprises interviews with three mathematics coaches working in three separate school districts.

Tara is employed by a small urban school district that employs 430 teachers in 17 schools. She has been in the role of K-12 District Numeracy Coordinator for 4 years. Prior to that, she worked as an elementary classroom teacher for 18 years. Having had negative experiences as a learner of mathematics, Tara's interest in math was only ignited 14 years ago after attending a mathematics professional development workshop. During the ensuing years, she attended every mathematics professional development opportunity offered and developed a passion for the teaching and learning of mathematics. She is about to begin a Master's degree program with a numeracy focus.

Pam works for a small rural school district with 23 schools and 320 teachers. Employed as a classroom teacher for over 30 years, she has taught all grades K-7. Pam completed a Master's degree with a numeracy focus in 2011 and left the classroom in 2012 to take on the role of Numeracy Helping Teacher. She has always enjoyed and had a passion for math.

Ray is employed by a large urban school district that employs over 1000 teachers in 49 schools. He worked for his district for 18 years as a secondary math teacher before taking on the role of Math and Science Program Consultant 4 years ago. During his time in the classroom, Ray completed a Master's in secondary mathematics education and was involved with his province's math teachers' association. Ray went on to serve a term as the association's president, while working as his district's math consultant. Like Pam, Ray has always enjoyed math and wants to recreate that experience for the teachers and students in the classrooms he supports.

Data was collected from the participants during semi-structured interviews that were transcribed in their entirety. The data corpus was then scrutinized using Berry's (2007) framework as an a priori frame for identifying and coding tensions. To begin this was done by searching the interview transcripts for evidence of tensions. In particular, I looked for evidence of utterances with negative emotional components such as "I think what's been difficult..." or utterances that conveyed doubt or uncertainty such as "I wasn't 100% sure, but...". The identified tensions were then grouped according

to the pairings described by Berry. Additionally, the framework was extended to encompass a tension that did not fit within her established framework.

## **Analysis**

In the following analysis, Berry's (2007) framework will be used to identify and analyze the tensions experienced by the three participants in their roles as district mathematics coaches. During the analysis, the following four tensions pairs were evident.

### **Safety and challenge - Unwelcome in the classroom**

All three of the participants mentioned the conflict they experienced between their desire to be working with teachers in their classrooms and not having that support seen as threatening. They describe the teachers as uncomfortable in having someone observe them and therefore are unable to utilize this valuable learning opportunity. A tension arises for the mathematics coaches who, like Berry (2007), want the teachers to feel safe, but who also recognize the value in challenging the teachers to open their doors. This is evident in the following excerpts:

Ray: And I think that teachers are a little reluctant to have people in their classroom and do, sort of team teaching or have someone observe them... that hasn't happened as much as I kind of thought it would or as much as I'd sort of like.

Pam: The kind of biggest piece, I think, for us, is how do you support those teachers that are too nervous or too anxious about having someone come in?

Tara: If I get invited in, I'm in, I go. Absolutely. But unless I'm invited in, it doesn't, like, I don't just, well, I shouldn't say I don't just show up.... but to be actually modelling in a classroom and doing observations, that's all by invite.

As a rationale for the teachers' reluctance, both Pam and Ray offer related possibilities. Pam suggests that the teachers' reluctance stems from a fear of being evaluated even though she feels she makes it clear that her role is one of mentorship and has no evaluative elements stating, "They haven't shifted away from that fear yet, that I'm there to judge. I'm not, I'm there to support them." Ray suggests that the teachers are concerned with the overall quality of their lesson, which then becomes a barrier to observation, "When it comes down right to it, you know, we're all a little bit unhappy with every lesson we ever do so I don't really want you seeing me because, you know, it's got its warts and all that stuff. And so, a lot of good people, but not necessarily wanting people in their classrooms."

For all three, this appears to be an unresolved, ongoing tension in that none have successfully found ways to make classroom visits an accepted part of their roles. Pam, in particular, mentions that this tension leads her to consider ways of presenting this opportunity to learn as risk-free noting, "Well, I'd really like to be in more rooms and influencing more teachers. I'm trying to think of ways I can do that to support them."

### **Valuing and reconstructing experience - Resistance to change**

Another of the tensions that was apparent for all three participants was similar to Berry's (2007) tension of valuing and reconstructing experience. The mathematics coaches experienced a dilemma between acknowledging the authority of the teachers' experience and helping them to see that there

is more to teaching than simply having acquired a requisite amount of experience. This is best exemplified by Ray in the following excerpt:

Ray: I think the biggest barrier tends to be, as teachers, we've gone through a system a certain way that we can visualize how it looks in the classroom. We've taught that way and we see successes in that, in either ourselves or some students, and we hang onto those successes as sort of validation for doing what we do. And we tend to say, 'Well, those other kids just aren't being successful. They're not working hard enough. They're not trying hard enough. They need to do things differently. They need to change.' And I don't think a lot of teachers are as good at saying, 'Well, what do I need to do differently? What do I need to do to change?'

The mathematics coaches value the experience their teachers have, but know that experience can always be broadened and improved. None of data from the participants suggest they use a deficit model approach to coaching teachers, but rather they believe there is always room for growth. This belief perhaps stems from their own experience with life-long learning. They want the teachers they work with to consider which areas of their practice would benefit from further learning and support. As Ray suggests, "And, I think if teachers just come out a little bit more with the willingness that, you know, as good as I am, (laugh) I probably could be a lot better. That would be very helpful."

The data suggests that all three mathematics coaches see this tension as a resistance to change and this manifests in different ways. For Tara, who described her own career in terms of ongoing growth and change, the tension stems from the assumption that her colleagues would be open to similar experiences. She finds it difficult to accept that change is slow stating, "So I made the assumption that was once other teachers kind of have these a-ha moments [as she did], they would just fly and I've come to realize that's not the case."

Ray also experiences tension in slow change, but notes that, while "teachers can be very confident about some things and don't necessarily challenge themselves as much as they could", it is possible that "as much as we sometimes want to change, it's a lot of work to change and people only have so much time in the day so they sometimes just don't even get started." Ray's view suggests that outside influences play a role in teachers' readiness or willingness to change.

Pam views the resistance to change as more of a readiness factor. Her tension lies in the fact that the teachers she works with are not as ready to reconstruct their teaching experiences as she would like them to be. She recognizes that she "wants them to try more than they're capable of trying" and is aware that she's "not giving them time to slowly implement what they're comfortable with". She values the experience they bring, but struggles to encourage them to consider new practices.

This too appears as an unresolved tension that all three mathematics coaches deal with on an ongoing basis. Pam was the only participant to offer a partial solution, albeit unsatisfactory to her. She approaches this tension with perseverance tinged by frustration saying, "Well, I think, you kind of got to persist, but it can kind of get a little frustrating at times."

### **Confidence and uncertainty - Questioning role and ability**

A tension that surfaced for both Tara and Pam correlates closely with Berry's (2007) tension pairing of confidence and uncertainty. Both coaches mention having had colleagues question their role and their qualifications. This created a tension between the necessity of exposing their vulnerability and

maintaining the confidence of the teachers they mentor. Tara mentions, “You get the naysayers in the room that might, you know, question you on things. The biggest thing I get is what are your qualifications to do this job. That's what I get all the time.” And Pam adds:

Pam: I've had people that have said to me, I know enough that I don't really need you and I don't understand why the district is wasting money on your job. It's the senior math people, the 10, 11, and 12, that are the hardest to influence and they don't want to be influenced by me. I've been told many times by them that I have not the experience.

For both Pam and Tara, this appears to be a managed tension. Although the questions regarding their qualifications continue to be asked, neither seem to regard it as an ongoing source of tension. Both admit to limiting their role to elementary and junior high school and, for Pam, holding a Master's in Numeracy was perhaps sufficient to manage any remaining tension. Tara chose two other methods, which appear to offer the credibility she needs to answer any questions—she outlines her credentials and acknowledges the research behind best practice in mathematics:

Tara: So what I started to do more of after that was, whatever I was giving a recommendation for, I always had research to back up my recommendation. So I was always presenting what the research was saying. Always. [...] I lay out what courses I've taken, the journey I talked to you about, and why it's a passion. They seem to be a little better once they hear that story.

### **Initiative and systemic barriers - Working with learning assistants**

This is a tension pairing that extends Berry's (2007) framework as it does not have a counterpart within her original set of tensions. It surfaced when the mathematics coaches were asked what they would like to implement in their role but have not been able to as of yet. Both Pam and Ray mentioned working with learning assistants. A strong desire to support every adult involved in the learning of students in their district drives them to want to work more closely with the learning assistants. Yet to do so would disrupt an existing functioning system. Ray expresses this clearly in the following excerpt:

Ray: I've got a few things that are sort of happening, but not as deeply as I'd like. One of them is the learning support group in our district. They all work a little bit differently and it's kind of hard to connect with them the way we're set up in the system.

Their initiative meets with resistant in the form of systemic barriers. In Pam's case, it is a result of an administration system that limits her contact with colleagues to only classroom teachers. For Ray, it is a result of different priorities. Like Pam, the learning assistants in his district provide both numeracy and literacy support — and that support tends more towards literacy. Ray notes, “They tend to be very heavily focused on reading recovery/writing kind of stuff over the years and they just haven't had a lot of time to get together and talk about anything around math.”

Both Pam and Ray mention wanting to circumnavigate the systemic barriers and provide professional development to the assistants, who, in their respective districts, tend to work one-on-one in pullout environments with students. Ray wants the opportunity to offer more effective resources. Pam agrees, adding, “They are sending these support people out to work with students, but they're working same old, same old. The child gets the same kind of repetitive practice over and over again and it never moves them forward.”

This is an unresolved tension that has both mathematics coaches searching out solutions. Ray offers the vague “hope” that he will be able to connect with the learning assistants this coming school year, but does not go deeper into his plan. Pam plans on speaking with her assistant superintendent to seek her assistance in convincing the learning assistant teachers that she is capable of providing them with support.

## **Discussion and conclusion**

The first goal of this study was to identify tensions experienced by mathematics coaches. Three tensions emerged that closely aligned with the tension pairings in Berry’s (2007) framework. The fourth was a tension the mathematics coaches experienced in their desire to support learning assistants. With no obvious parallel in Berry’s work, likely due to her role as a pre-service teacher educator, the presence of this tension requires the framework to be extended when considering tensions experienced by mathematics coaches.

The findings also revealed tensions that could be considered unique to mathematics coaches, as there were two tensions they experienced that were not included in the list of tensions identified by generalist coaches. The first finding suggests that mathematics coaches may experience tension regarding their qualifications. This could be explained by the expectation that a specialist in one subject would be expected to have specific skills that a generalist, who works across all subjects, would not be expected to have. Additionally, given that many of the mathematics coaches are pulled from teaching positions within their districts (Campbell & Malkus, 2011), their former colleagues might question their abilities. Interestingly, Ray, who was a secondary mathematics teacher has never experienced this tension. Despite having no elementary experience, he stated that he has always been “well received” by the elementary staff. His status as a high school mathematics teacher appears to offer him credibility across all grade levels. The second tension experienced by mathematics coaches, but not generalists, was working with learning assistants. This might be the result of the relative newness of the role of mathematics coaches (Anstey, 2010). Districts are still in the process of determining the scope of the responsibility of the mathematics coaches in their employ. As Tara suggests, “As for the job itself, it was pretty much I just had to build the airplane as I was flying it.”

The second goal of this study was to identify how the mathematics coaches coped with the tensions they experienced. The findings suggest that they appear to fit Lampert’s (1985) image of dilemma managers who accept and cope with continuing tension. This means that the mathematics coaches initially manage the tensions that surface while never fully resolving their competing conflicts. What was interesting was the managed tension that Pam and Tara, both of whom are elementary trained teachers, experienced regarding questions about their role and qualifications. Their method for managing this tension was avoidance of interactions at the high school level. Similarly to the finding in Liljedahl et al. (2015), this suggests that this tension is managed on some levels but there is a possibility it could resurface at some point. While both are only required to work with teachers who volunteer and are willing, both of their roles encompass grades K to 12.

While the small number of participants in this study may limit its generalization, the findings do indicate the presence of tensions experienced by mathematics coaches. This language of tensions could be useful as a means for discussion and reflection on the practice of mathematics coaches. Whether managed or unresolved, identifying and describing these tensions will contribute to a small,

but growing body of research into mathematics coaching. If employing mathematics coaches in schools is to be a viable complement to professional development, more study will be necessary.

*Students often have difficulties with the content area of functions. If their teachers are not aware of these problems and lack of adequate teaching methods, they cannot counteract pointedly in their classrooms. This paper presents a project developing and evaluating a coaching to foster teachers' pedagogical content knowledge about several learning difficulties with functions and about how to respond to them. As this work is still in progress, we here focus on the project description as well as on the development of the survey to measure teachers' corresponding knowledge.*

*Keywords: Mathematics education, teachers' professional development, functions, learning difficulties, teacher survey.*

## Introduction

Being able to adequately reason with functions is considered to be a central goal of mathematics education (e.g. Eisenberg, 1992; KMK, 2003; NCTM, 2000). More precisely, reasoning with functions characterizes a specific way of thinking in interdependencies, relationships or changes (Vollrath, 1989) that is especially required when working on inner- and extra-mathematical problems (Hinrichs, 2008; NCTM, 2000).

However, several studies show that learners have particular difficulties in this domain (see for an overview Nitsch, 2015 or Vogel, 2006). For instance, they may experience problems with the meaning of the parameters (e.g. Schoenfeld et al., 1993), conceive graphs as pictures (e.g. Monk, 1992), confound the slope and the height of graphs (e.g. Hadjidemetriou & Williams, 2001) or have difficulties with word problems in the sense of the word-order-matching-process (e.g. Clement, 1982). Often, their teachers are not aware of these difficulties (Hadjidemetriou & Williams, 2002; Sproesser et al., in press) and therefore cannot counteract explicitly. Moreover, the study of Nitsch (ibid.) revealed systematic differences between school classes referring to learning difficulties with functions. She concludes from this finding that some teachers are more successful than others in responding to such difficulties.

## Theoretical background

The findings mentioned above raise the assumption that teachers' professional development (TPD) focusing on such typical learning difficulties may enhance teachers' pedagogical content knowledge (PCK, see e.g. Shulman, 1987), their instruction and mediate also students' learning in this field. This is also in line with the general understanding that teachers need TPD in order to meet the challenges that they encounter in their professional lives as university studies cannot satisfy all of demands from practice (cf. Mayr & Neuweg, 2009). To our best knowledge, there is no empirical

evidence about the effects of a TPD related to learning difficulties with functions, especially taking into account the interplay between the teacher and student level, yet.

Particular TPD-characteristics that have already proven to be effective in general can be implemented in a TPD referring to dealing with learning difficulties in the domain of functions. In this context, Lipowsky (2013), for instance, found that TPD should be related to one specific domain instead of focusing on different domains. Furthermore, long-term TPD courses enable to integrate input, practice and reflection phases. The study of Lipowsky (ibid.) additionally confirmed that giving feedback (e.g. Shute, 2008) supports learning also in the context of TPD. Teacher coaching represents a specific form of TPD that can also implement the mentioned characteristics. In adaptive (teacher) coaching (Leutner, 2004), the coach refers back to the teachers' statements and activities. If teacher coaching focuses on a concrete classroom situation, it is, for example, possible to encourage teachers to reflect on this situation (West & Staub, 2003) or to train them in giving supportive feedback to students showing a particular learning difficulty.

In several studies, such a focus on responding to students' difficulties or errors (e.g. through giving feedback) has already shown to be useful in order to measure or promote teachers' PCK concerning different mathematical content areas: For instance Biza et al. (2007) propose to measure (pre-service) teachers' PCK by requesting them to analyze wrong student solutions and to formulate supportive feedback. The study of An & Wu (2012) revealed that teachers' PCK can be fostered through asking them to analyze students' errors and to develop approaches how to correct them.

## Research goals

The teacher coaching developed in this project aims at building up teachers' pedagogical content knowledge related to learning difficulties with elementary functions and hence to support also their instruction and students' achievement in reasoning with functions. As a narrow content focus has proven to be a characteristic of effective TPD (Lipowsky, 2013), we here refer to specific PCK components as defined by Ball et al. (2008): In the case of 1) knowledge of content and students (KCS), we focus at fostering teachers' knowledge about typical learning difficulties and about students' thinking related to functions; in the case of 2) their knowledge of content and teaching (KCT), we train them in "adequately" responding to such specific learning difficulties. Within the content area of functions, we concentrate on linear functions and on the understanding of the concept of a bivariate functional relationship in order to assure a narrow content focus. The emphasis on this subdomain also takes into account that viable concepts about elementary functions appear to be crucial for understanding higher-order functional classes later on.

As the majority of existing TPD courses is not carried out in an experimental design, it cannot be clearly identified which of their characteristics would be responsible for a certain effect (e.g. Yoon et al., 2007). Therefore, this teacher coaching is brought out via two variations, namely with and without focus on feedback. This procedure takes into account findings from other studies showing positive effects of giving feedback (see above) but additionally evaluates the effectiveness of this characteristic (explicitly training to give feedback to students showing concrete learning difficulties). In this sense, the main goal of the project described in this paper is to prove what effective aspects of an adaptive teacher coaching are.

More precisely, we evaluate the following research questions:

- What do teachers know about typical learning difficulties in the domain of functions and what ideas do they have how to react to them (pretest)?
- To what extent can teachers' KCS and KCT related to functions be fostered through two variations of teacher coaching (pre- and posttest)?
- Which impact do the coaching treatments have on students' domain-specific competence?

## Methods

### Pilot study

The content of the coaching was identified via a pilot study in the academic year 2014/15 (see Figure 1 for an overview of the project's structure): Part I of the pilot study revealed that all of the learning difficulties derived from the literature (see Introduction) occurred among students within our learning settings (paper-and-pencil-tests in 4 classes of grade 7 and 8). Moreover, we found that their teachers only knew some of these learning difficulties and that their knowledge about them and about how to respond to them was very heterogeneous (interviews with 4 teachers). Therefore, TPD in this domain appears to be useful. A summary of these results can be found in Sproesser et al. (in press). As to our knowledge there is no consensus about how to "accurately" respond to such learning difficulties or how to largely prevent them, teacher trainers and university educators were interviewed about these issues within part II of the pilot study. Via these expert interviews, we collected and further developed teaching ideas, methods and material for the coaching.

### Main study

Within the main study, the teacher coaching (3 modules) accompanies the instructional unit of linear functions in grade 7 or 8, respectively: Module 1 is held before, module 2 during and module 3 after this unit. This structure enables to implement the content of the coaching in the teachers' classroom as well as to reflect on the teachers' experiences within the TPD. About 60 teachers of grade 7 or 8 are assigned to one of two treatment groups or to a control group. Both treatments contain input, reflection and activity phases in order to foster teachers' KCS and KCT related to learning difficulties concerning elementary functions. Only in one of the two treatment groups, teachers are specifically trained in giving supportive feedback to students facing a particular learning difficulty.

In order to gain empirical evidence about effective characteristics of the coaching, the teachers' PCK as well as their students' knowledge related to elementary functions are assessed before and after the coaching / teaching unit. This data structure allows using analysis tools such as multilevel analyses and hence to evaluate the interplay between the two levels. The student survey (pre-, post- and follow-up-test) contains large parts of the test instruments developed by Nitsch (2015): Via a number of tasks referring to elementary functions, several learning difficulties (see above) can be identified. Moreover, covariates such as students' cognitive abilities (Heller & Perleth, 2000) or motivational variables (Pekrun et al., 2002) are gathered.

In order to measure KCT and KCS of the participating teachers, we developed a survey that particularly refers to several tasks of the student test. The development and the structure of the teacher survey will be presented in more detail in the next section.

**Figure 1: Outline and content of the project**

## Teacher survey

The participating teachers are requested to complete before and after the coaching a structurally identical paper-pencil-survey. This procedure allows directly investigating teachers' KCS and KCT developed in the course of the coaching. The PCK items of the teacher survey are all structured in the same way (see Figure 2 for a sample item): The teachers are shown a task of the student test and they are asked about typical mistakes or learning difficulties referring to this task (questions a) and b) in Figure 2) and how they would respond to them (question c) in Figure 2). Hence, according to the classification of Ball and colleagues (2008) the questions a) and b) are part of the knowledge component KCS as "Teachers must anticipate what students are likely to think and what they will find confusing" (ibid., p. 401). These authors propose to measure teachers' KCS for instance via questions about what students may find difficult or about interpreting students' thinking. Within our survey, teachers in question a) are asked which mistakes and learning difficulties they had already noticed concerning the given type of task; in question b), on the basis of a wrong student solution they have to put themselves in a student's position in order to make transparent his or her thinking process when working on the task. Hence, these tasks require knowledge of typical student (mis)conceptions and errors as well as about students' thinking. The third PCK item (question c) in Figure 2) corresponds to the knowledge component KCT (Ball et al., ibid.): Teachers need to know about mathematics and about teaching in order to sequence their instruction and hence to promote students' understanding. For instance, they need to know different methods and procedures and choose appropriate ones for their instruction. This means that KCT is particularly relevant when teachers respond to students' mistakes and difficulties or when they aim at building up viable concepts through their instruction. Ball et al. (ibid.) propose to measure KCT e.g. by asking for examples for simplifying particular content or how learning of a specific content can be facilitated. As displayed in Figure 2, such KCT items are also included within our test instrument: In question c), teachers are asked to outline how they would react to a concrete student mistake.

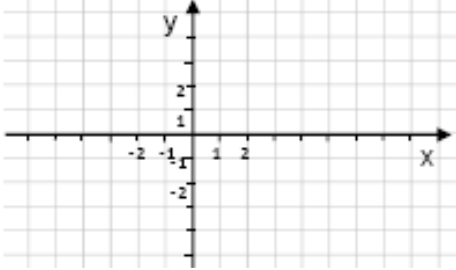

Within the whole survey, the sequence of PCK items is always as displayed in Figure 2: The first question a) is open-ended in order to collect the teachers' ideas and experiences without being influenced by specifications of the survey. Afterwards (question b)), teachers are confronted with a concrete students' mistake referring to this task and they are requested which (mis)conception could cause the mistake. As in real classroom situations, responding to a student mistake (cf. KCT) happens after its noticing (cf. KCS), the question sequences are always ended up by the KCT item (question c) in Figure 2).

This sequence of questions (a) open-ended, b) referring to a concrete mistake) was chosen to gather data about teachers' knowledge and experience concerning several student problems in general and related to specific mistakes. Within the teacher interviews of the pilot study, this sequence was also

used and proved to provide essential findings. However, one particular limitation of this sequencing should not be disregarded: Teachers could add the mistakes and learning difficulties displayed in b) to the open-ended question in a) even if they had not thought of them without the indication of the survey. We decided to accept this possible drawback that may occur in field studies as the our rather than in laboratory studies because interviews instead of the paper-pencil-survey would be extremely time-consuming for the numerous participants of the main study and could irritate them; furthermore, a digital survey with time markers could hardly be implemented as the coaching is brought out in different schools where we cannot count on a safe internet-connection. In the teachers writings it can mostly be identified if they have come back to a previous item or not.

We consider the relevance and the validity of these PCK items as relatively high because of several issues: First, empirical studies show that the presented learning difficulties are common among students and hence they are relevant for teachers. In their research Ball et al. (2008) similarly have drawn typical student mistakes and learning difficulties from the literature. Furthermore and as pointed out above, the kind of questions that we use are also proposed by these authors. Hence, our approach is not arbitrary but systematical and can also be applied in other content areas.

<p><b>Student task</b></p> <p>Draw the graph according to the functional equation</p> <p><math>y = 5x - 2</math></p> <p>in the given coordinate system.</p> <p>Explain briefly how you proceeded.</p>	
<p>a) Which typical mistakes or learning difficulties would you expect from your experience in this student task?</p> <p>b) A student solved the task as displayed on the right. Which concept could underlie this solution? Please justify your answer.</p> <p>c) Imagine you would be confronted with this learning difficulty. How would you respond to it in your mathematics classroom?</p>	

**Figure 2: Sample item of the teacher survey**

In addition to the mentioned PCK items, the teacher survey contains covariates for instance about their professional background (e.g. university degree, teaching experience), beliefs related to mathematics education (e.g. their constructivist conviction (Stern & Staub, 2002), assumed determinants for mathematical ability (Stipek et al., 2001) or their experience with and motivation for TPD (see several scales in Jerusalem et al., 2007).

## Current status and future steps of the project

As mentioned above, the pilot study has already been carried out in the academic year 2014/15 and its evaluation is almost concluded. Student assessment and teacher interviews revealed that a TPD referring to dealing with learning difficulties related to elementary functions would be useful for teachers within our learning settings. Moreover, the expert interviews were helpful to gather “best-practice-methods” and material for the coaching.

Concerning the content of the coaching, both treatments focus on the same learning difficulties (problems with the parameters, graphs-as-picture-mistake, slope-height-confusion, emphasis on the word-order in word problems). Teachers get information about their prevalence in empirical studies. Moreover, we illustrate the best-practice-methods and material how to prevent or overcome them that we have gathered through the pilot study. There are also active phases for the teachers: On the basis of the presented methods / material, they are asked to further develop tasks and material for their own classroom. Moreover, based on described classroom-situations showing concrete student mistakes, they are requested to think up a reaction to support the student to overcome his problem. In these tasks, the variation with / without focus on giving feedback comes into play: In the treatment with focus on feedback, teachers are asked to concretely formulate the feedback and explicitly explain the hints that they would use when being confronted with the corresponding student difficulty (e.g. “How would you respond to this learning difficulty in your mathematics classroom? Please be explicit: Verbalize your feedback and illustrate other ways to support the student.”). In the treatment without focus on feedback, teachers are simply requested to mention adequate ways of responding to these learning difficulties in a more general way (e.g. “How would you respond to this learning difficulty in your mathematics classroom?”). Furthermore, in both treatments teachers’ experiences in the course of the learning unit are discussed and reflected as well as their classes’ results - if the teachers agree with students testing before and after the unit.

The coaching has already been carried out in the academic year 2015/16 and it is still offered in the year 2016/17. Hence, the main study is in progress at the moment and data will be gathered at the student and teacher level. Results are expected from the end of the academic year 2016/17 onwards.

## Acknowledgment

This study is supported by the Ministry of Science, Research and the Arts in Baden-Wuerttemberg (Germany) and by research funds from Heidelberg University of Education.

*This paper draws from a qualitative exploratory case study that aimed at exploring the learning experiences of teachers as they engage in professional learning project. The case study involved three elementary school teachers' professional learning experiences as they engaged in developing a practical, research-based approach to differentiated instruction using a flipped classroom and student-centered pedagogical approaches that would result in enabling students to be engaged with mathematics..*

*Keywords: Professional learning, flipped classroom, student-centered, engagement, intermediate mathematics.*

## Introduction

Research indicates that professional learning, which is job-embedded (Joyce & Showers, 2002), collaborative (Garmston & Wellman, 2003), occurs over time, and is driven by the needs of the teachers involved (Fullan, 1995; Lawler & King, 2000; Little, 2002), is effective. Furthermore, effective professional learning is focused on student outcomes, integrated into the teacher's day-to-day culture, and often tied to the school's improvement process (Way, 2001). The paper draws from a study that aimed at exploring the learning experiences of three teachers engaged in a professional development project in Ontario at an Intermediate level (grade 6, grade 7 and grade 8). The professional development project is part of an initiative of The Elementary Teachers Federation of Ontario (ETFO). ETFO invited and provided support for teams of teachers from the same school or in similar roles at different schools to come together and conduct professional learning projects relevant to their specific professional needs, circumstances and interests. In addition to the three teachers a university researcher was invited to collaborate with the group and conduct a case study of the professional development project. The three teachers in the professional development project collaborated in developing a practical, research-based approach to differentiated instruction *using a flipped classroom approach and student-centered pedagogical approach* that would result in enabling students to be engaged with mathematics. This flipped classroom approach and student-centered approach involved the use of grade-appropriate math centers where students would engage in a variety of math problems and/or topics; have opportunities to practice and consolidate basic facts and operational skills; use technology and manipulative as learning tools; become efficient communicators in math; and develop a sense of self-awareness toward their own math skills. Students would also grow in their ability to work independently and cooperatively as they work through various math centers, allowing the teacher(s) to conference with individuals and small groups of students. In this paper we describe some of the findings from the case study. The case study is guided by two questions: How did the professional development project facilitate teachers' understanding of the use of math centers in a flipped classroom and student-centered approach for

teaching and learning mathematics? How did the teachers negotiate constraints and possibilities as they engaged in their professional development project? .

Research has demonstrated that engaging students in the learning process increases their attention and focus (Jonathan & Aaron, 2012). Further it motivates students to practice in higher-level of critical thinking while promoting meaningful learning experiences. Chickering & Gamson (1987.), states that

“learning is not a spectator sport. Students do not learn much just by sitting in classes listening to teachers, memorizing pre-packaged assignments, and spitting out answers. They must talk about what they are learning, write about it, related it to past experiences and apply it to their daily lives. They must make what they learn part of themselves”.

In this sense, a flipped classroom and student-centered learning is essential. Educators who adopt to a flipped classroom and student-centered approach as a pedagogical method find that it increases student engagement, which allows for learners to successfully achieve the learning objectives (Jonathan & Aaron, 2012). For a flipped classroom and student-centered mathematics class to be effective, a shift in the role of the teacher and students in the classroom must be adapted. On the one hand, teacher’s role is viewed as a guide for students’ constructive processes towards mathematical meanings and mathematical ways of knowing. On the other hand, learning is viewed as an active, constructive activity in which students wrestle through problems that arise as they participate in the mathematical practices in the classrooms (Cobb, Yackel & Wood, 1992). Recently, there has been an upsurge of interest in instruction that focuses on flipped classroom approach for teaching mathematics.

### **Type of Math Centers**

There were various types of math centers that each participating teacher used in their classroom. The choice of a math center was based on teachers’ professional judgment of the students and students’ needs.

*Inquiry based Center:* - A group of 4-5 students rotated from one station to another to learn about various topics. Examples of these topics included: explore and connect station, “what happens when...”, various word problems, “Reflection on this”, “Test your knowledge.” Each station had the option of students either working by themselves and/or in their respective groups. Teachers used as one or more of inquiry based centers to develop curiosity of a given topic among the students.

*Resource Center:* - This center was available for students all the time. This station consisted of graph papers, blank papers, mathematics dictionaries, mathematics textbook (e.g. *Math on call*, *Math on hand*, and *Math makes sense* 8). This center also included measuring tools such as meter -sticks, rulers, weight measuring scale and measuring tape. This center gave student the opportunity to select an appropriate tool for themselves in order to learn a topic/concept at hand.

*Online Research Center:* - Students had the opportunity to use their own technology or/and the computer station located in class to deepen their understanding of topic/concept at hand. Students also had the option of exploring a given topic at home via online research.

*Debriefing Center:* - This is usually available at the end of a lesson, where students come back into their respective groups. Here students are given the opportunity to consolidate their learning as a group, clarify any misunderstandings and learn from one another.

### *An example of inquiry based math center*

Students were given the opportunity to solve a real life problem, using a task called, “how big is a trillion?”. In this problem, students were asked two open-ended questions: 1) Is it possible for trillion rice to fit into this room? Explain your solution 2) How much distance around the Earth can the rice cover if each rice is lined up in a line? Compare this with another non-metric unit. Students were asked to solve this problem in group of 4-5. Each group was given 6-7 classes (40 minutes each) to solve the problem in class. Students were allowed to do any background inquiry that they thought was necessary at home. The purpose of working on this problem in class was to have a common working place as a group, where they negotiated their learning and solution. At the end of the 7th class, groups were asked to submit their solution in form of poster which each group presented in the following class. Mathematically, this problem required students to learn about how to measure a unit in real life, length, metric versus non-metric units, volume, and capacity. Other than the mathematical knowledge, students had to discuss their ways of solving the problem, which means selecting appropriate tool to solve the problem in most efficient way, while self-regulating their learning and progress as a group. By the time this particular problem was given, students often became competitive. Teacher noticed that while students helped members of other groups with background mathematical knowledge, groups often tried to keep their solution a secret. This was because groups often wanted their solutions to be a unique solution.

Preparing the students for flipped classroom with math-center included teacher presenting and discussing math center code of conducts, where the purpose and the importance of self-regulation for one’s own learning was discussed in depth as a class. In order to utilize various centers, students were divided in groups of 4-5 students, these groups were often changed and redesigned either by the teacher or the students. Students were informed that they may seek help support from their teacher at any point, however they are encouraged to first discuss it with the members of their respective groups.

### **Flipped classroom**

Flipped classroom approach for teaching mathematics is considered as an effective way for engaging students in active learning as well as in meaningful peer-to-peer and peer-to-teacher interactions during the in-class learning process (Forsey, Low, & Glance, 2013; Pluta, Richards, & Mutnick, 2013). Moreover, Bergmann and Sams (2012) indicated that flipped classrooms enable teachers to take individual students’ needs into account as well as to facilitate more interactions among peers and teachers in the classroom. The teaching and learning context of flipped classroom approach consists of two kinds of activities: in-class and out-class. In-class time is utilized for inquiry, application and assessment in order to better meet the needs of the individual learners. Technology-assisted out-of-class time involves personal instruction, where students acquire responsibility for their own learning, through studying course material on their own, using various sources (self-discovered and/or provided by teacher). The main goal in flipping a class is to cultivate deeper, richer, and active learning experiences for students where the instructor is present to coach and guide them. Further, emphasis is on higher-order thinking skills and application to complex problems, and which might include collaborative learning, case-based learning, peer instruction and problem set. In this sense the role of the teacher is to facilitate the learning process by helping students

individually and in groups. According to Bergmann & Sams (2012), there are many ways of implementing a flipped classroom approach. For this study, the participating teachers utilized various math-centers (discussed previously in the article) where students self-regulated their own learning in a math class.

## Methodology

A qualitative research methodology was used to conduct this case study. According to Yin (2003) a case study design should be considered when: (a) the focus of the study is to answer “how” and “why” questions; (b) the behavior of those involved in the study cannot be manipulated; (c) you want to cover contextual conditions because you believe they are relevant to the phenomenon under study; or (d) the boundaries are not clear between the phenomenon and context. A case study was chosen because the study could not be considered without the context of flipped classroom approach, and more specifically the math centers classroom settings.

This case study involved three mathematics teachers at a Canadian middle school, who taught intermediate level (grade 6, 7 and 8) students. Two of the teachers were intermediate level mathematics teachers with their own classroom. One teacher was the resource teacher assigned by the district school board. The role of the resource teacher was to support the two classroom teachers by finding necessary resources needed to run the project. The two classroom teachers applied the flipped classroom approach in their mathematics classes. In preparation for the project, all three teachers sought opportunities to enhance their professional knowledge of using technology in mathematics teaching and learning. Further, each teacher read a number of monographs provided by the Ontario Ministry of Education in order to develop efficient knowledge of the Ontario elementary school mathematics curriculum, in particular knowledge of the mathematical processes such as problem solving, communicating, reasoning and proving.

Data was collected from:

- 1) Participating teachers’ observation of their teaching and learning experiences. Each teacher recorded field notes based on their own reflections as well as observation of their students in-class events related to math-centers (e.g., counting the number of students being engaged per center, how teachers guided the off track students to get back to work, etc.). In addition to these data was collected from teachers’ notes of their conferencing with students as individuals and in groups.
- 2) Transcriptions and field notes of group meetings (selectively audio-recorded). Each teacher’s observations were shared, discussed and reflected upon by teachers as a group for professional growth while focusing on their own professional growth and their students’ engagement in respective mathematics class.
- 3) Teachers’ artifacts such as lesson plans and assessment rubrics, and the teacher team’s final project report.

## Findings and discussion

All transcribed data, field notes and teachers’ artifacts were analyzed by the university researcher and one teacher independently to identify major themes related to the guiding questions— How did the professional development project facilitate teachers’ understanding of the use of math centers in

a flipped classroom and student-centered approach for teaching and learning mathematics? How did the teachers negotiate constraints and possibilities as they engaged in their professional development project? The findings will be discussed in the following themes which emerged from the analysis: time for teachers to meet; awareness of initial resistance from parents and students; enhancement of student learning; and challenges. Findings from the study suggest that in order to sustain a collaborative professional development project teachers need time and need to meet. Teachers in this study were able to plan collaboratively and develop a practical, differentiated math program based on flipped classroom and student-centered pedagogical approach using math centers. The flipped classroom approach using math centers allowed students to engage in purposeful practice while freeing up the teacher to meet with individual and/or small groups of students for teaching and/or learning. However the two participating teachers taught different grades in different buildings of the same school, which became somewhat challenging to coordinate schedules for sit-down meetings. Often, the conversation between the three teachers would occur either in between classes (as the teachers would pass by each other's classroom) or through email (keeping each other informed on their status with the project). Although the teachers planned collaboratively, they had fewer time to compare what they had initially planned. This however, had an unexpected positive outcome which ended up by providing teachers with two different ideas of math-centers and student engagement. Both classroom teachers did utilize flipped classroom, student-centered pedagogical approach, however during their final group meeting, teachers discovered that they had each taken a different approach to the math center idea. This allowed for each teacher to talk about their thought process behind their choice for developing the math centers the way they did. Further, this provided both teachers to learn from one another's professional learning experience with their respective math centers. As different as each participating teachers' math centers were, the participating teachers observed that there were common themed categories to the math centers (these categories were presented earlier in this paper).

Another theme that emerged from the case study is that the professional development project provided opportunity for participating teachers to be aware of and understand about the initial resistance from the students and their parents toward flipped classroom and student-center pedagogical approach. Teachers developed awareness of the fact that both the students and their parents perceived mathematics teaching and learning in a traditional manner. And that for both the students and their parents, mathematics was a subject where the teacher taught a lesson, the students completed assigned tasks like doing practice questions from a mathematics textbook related to the lesson, followed by an assessment in form of a test. The students in participating teachers' classes and their parents' perception of how mathematics should be taught presented with complex challenges. This resulted in the professional development project allowing teachers to learn about strategies for alleviating these challenges including having to do a lot of community building exercise in class, while also having conversation with parents through emails, phone calls and/or one-on-one meeting, about the importance of math centers for their child's learning. These conversations with parents often revolved around the topic of how math centers not only helped students to become more engaged with mathematics but also helped to develop importance skill set of becoming more self-regulated toward their own learning.

Another theme that emerged is how the professional development provided opportunity for teachers to enhance students' learning and development through using math centers. Teachers noticed that

after the initial resistance, the students began to be engaged with math centers and by the end of school year, they began to self-regulate their learning. One teacher noted about a grade 8 student who reflected on his journey with math centers and stated that it helped him to become more resilient to mathematics learning.

First, I did not know why we were doing math centers. I felt that the teacher did not want to teach anything.... but now, when I go through different centers in class I know that I am able to do things on my own...I feel happy.... I have done these many [math centers] today...which means I can do math...I just have to take my time with each center and not worry about how much time my group members are taking with centers.

In relation to the same theme, another teacher expressed how her grade 8 student commented,

I used to think that my teacher should know everything...you know, like all the answers...but now I know that I can find all the answers...and if I am stuck, I can take help from my friends...which is okay, because we are learning together

Both of the participating teachers experienced a sense of fulfillment in terms of their professional development experiences in relation to their impact on growth in their students in terms of both mathematical understanding and self-regulation toward their own learning. Teachers noted that many of their students grew stronger in their ability to self-regulate, as they had to make choices toward their learning in terms of what to work on, how long to work for and with whom. Teachers expressed satisfaction on how the one-on-one time with the teacher allowed the struggling learners to take risk and seek clarification without feeling restricted by the classroom environment.

Given the many positive outcomes of the professional development project that focused on flipped classroom and student-centered pedagogical approach through math centers, there were some challenges. These were mainly due to the fact that teachers became aware that some students needed more time with this approach, which was not possible given that there was a limited time that these students were with their mathematics teachers and that the teachers were expected to cover the curriculum expectations. Also teachers in the professional development project realized that for a small number of students, it was extremely difficult to adapt to this approach, even if they loved mathematics. This was because these students had only experienced learning only from a textbook teaching approach in mathematics, and flipped classroom and math centers approaches were a significant departure from their past mathematics learning experiences.

## Implications

This project utilized a case study research design and was conducted at one Canadian middle school. Hence, the findings of the study should not be read in terms of generalizability, but of transferability to other cases (Creswell, 2008). Recently, mathematics educators have realized the potential for a flipped classroom and student centered pedagogical approach for enhancing student engagement and learning. However, very little is known in terms of the implementation of this approach in elementary schools. This study explored the mathematics professional learning experiences of elementary school teachers as they implement the flipped classroom and student centered pedagogical approach. The professional development project provided opportunity for teachers to enhance their understanding of flipped classroom and its impact on students' learning. Teachers noted that their students became engaged with mathematics and self-regulated toward their own

math learning. The findings suggest that given opportunity to learn in a professional development setting that ensures autonomy, teachers learn and are capable of teaching through flipped classrooms and student centered pedagogical approach. The study also suggests that professional development project provides opportunity for teachers to be aware of the need for communication and collaboration among teachers, parents and students regarding the benefits and implementation of flipped classroom. As a result, further research is needed on how professional development can facilitate teachers' learning about how to communicate and collaborate with parents and students in flipped classrooms.

*This paper investigates promoting knowledge of example use in mathematics education by way of analyzing a case using theoretical tools. Participants were both prospective and practicing teachers attending a university course. An event taken from a tenth grade geometry class was analyzed in terms of example use, and then discussed. Participants related to the type of example given, the timing of the example, agency, what the example was an example of, and the aim of giving the example.*

*Keywords: Examples, case analysis, teacher education, theoretical tools.*

### Introduction

Examples and non-examples are an integral part of learning and teaching mathematics. They are used in concept formation, when seeking relations between elements, abstraction, and generalization (e.g., Smith & Medin, 1981; Watson & Chick, 2011). Acknowledging the importance of example use in mathematics education, Shulman (1986) included knowledge of examples within the category of pedagogical content knowledge (PCK). This knowledge, he claimed, is essential for representing the subject, so that it will be comprehensible to others. Rowland, Huckstep, and Thwaites (2005) also included teachers' use of examples in their description of 'the knowledge quartet', a framework for thinking about the ways subject matter knowledge comes into play in the classroom. In their framework, the ways teachers use examples and the types of examples they use, are manifestations of teachers' own content knowledge, their meanings and descriptions, being transformed and presented in order for students to learn the mathematics. Ball, Thames, and Phelps (2008) also noted the importance of teachers' knowing how to sequence examples.

Although example use is a complex matter and promoting teachers' knowledge of example use could be quite challenging, few studies specifically investigated this aspect of teacher education. This study proposes fostering prospective and practicing teachers' knowledge and awareness of example use by applying research and theoretical tools to analyze cases, helping to bridge theory and practice for mathematics teachers. The material, which is the focus of this paper, is a case based on a classroom event, and used as an exemplar. The case material consisted of a classroom transcript, along with guiding questions to be answered by each participant. This was followed by a group discussion with the teacher educator. Specifically, we ask: What aspects of example use do individual participants notice when studying an authentic case? Can those aspects be traced back to theories learned during the course? What additional aspects arise during group discussion?

### Example use in mathematics education

There are many aspects of example use which have been investigated. To begin with, there are different types of examples. Arcavi (2003) discussed visual representations, while Tabach et al.

(2010) focused on numerical examples. In addition to the form of the example, studies have categorized examples by how they are identified. For instance, there are intuitive and non-intuitive examples and non-examples (Tsamir, Tirosh, & Levenson, 2008). Intuitive examples are those examples which students immediately identify as such and are often derived from practical experience. Likewise, intuitive non-examples may encourage visual, rather than analytical thinking. On the other hand, it seems that non-intuitive examples and non-examples can encourage students to use reasoning based on critical attributes. Tsamir, Tirosh, and Levenson (2008) also discussed the sequencing of examples and non-examples and its effects on students' learning.

The difference between examples and non-examples is dependent on the mathematical lens one is looking through. When looking for polygons, a triangle is an example; when looking for quadrilaterals, a triangle is a non-example. In other words, another aspect of example use to consider is the way an example is being used. Zazkis and Chernoff (2008) introduced the idea of pivotal examples which can cause the learner to change his or her cognitive perception or way of approaching a problem. Rowland (2008) differentiated between two uses of examples in teaching. The first is when examples are used to motivate generality. In this case, the examples are examples *of* something where the aim is to teach a general procedure or to support abstraction and concept formation. The second type of example use is for students to practice what was taught. That is, students are given many examples to practice some procedure. This type of example use allows students to experience variation and can lead to additional awareness and understanding. Watson and Chick (2011) found that examples can be used as templates for dealing with other class members, indicating a relation between classes or to express equivalence.

If we take into account that the way an example (or non-example) is used by a learner is determined by the focus of that learner, then it becomes the teacher's task to choose examples and set them up in such a way that students will view those examples through the intended lens and focus on the intended pedagogical aim. Zodik and Zaslavsky (2008) identified six types of considerations employed by teachers when selecting or generating examples: starting with a simple or familiar case, attending to students' errors, drawing attention to relevant features, conveying generality, including uncommon cases, and keeping unnecessary work to a minimum. They found that the most frequent consideration was choosing to begin with the simple or familiar example. They also found that on the spot, teachers often choose an example that will attend to an error which arose in class, whereas pre-planned examples tend more to consider uncommon cases.

To notice something means to make a distinction, to stress some perceived feature and ignore others (Mason, 1991). As shown above, various aspects of example use can be considered when analyzing a classroom event. In this study we investigate which of these aspects, and perhaps other aspects of example use, practicing and prospective teachers notice when analyzing a case.

## Methodology

The participants in this study were 13 practicing teachers (denoted as T) with between 1 and 11 years of experience (mean years of experience was four) and 10 prospective teachers (PTs) who had completed their first degree in mathematics or a mathematically rich field of study, such as engineering. The specific course which is the context of this study, aimed to promote participants' knowledge of explanations and examples, and the relationship between them in mathematics

education. The course consisted of a total of 13 lessons which took place once a week for a period of 90 minutes each. The first six lessons were devoted to explanations in mathematics education. Different types of explanations were reviewed, such as conceptual, procedural, mathematically-based and practically-based explanations (e.g., Levenson, Tsamir, & Tirosh, 2010), and theories concerning the roles of explanations in mathematics education were discussed (Levenson & Barkai, 2008). The last seven lessons were devoted to examples in mathematics education. Theoretical perspectives of examples, like those described in the background of this paper, were read and discussed.

During the fourth course lesson on examples (lesson #10), the teacher educator handed out a transcript of a geometry lesson which took place in a tenth grade classroom. The geometry lesson had taken place within a few weeks of the course lesson and was observed by three of the prospective teachers attending the course, lending the case authenticity and relatedness. The overall aim of the geometry lesson was to introduce students to Thales' theorem and show its connection to similar triangles. The students had previously learned about similar triangles in ninth grade. The case transcript began with the classroom teacher stating Thales' theorem. This was accompanied by a drawing on the board, made by the teacher, of two similar triangles, under the headline: Geometry – Thales' theorem. Next to the drawing it says that if the given is  $BC \parallel DE$  then from Thales' theorem we conclude proportional line segments (see Figure 1).

**Figure 1: Presenting Thales' theorem on the board**

The case transcript was handed out in the beginning of the course lesson with instructions to read it from beginning to end, without interruption, in order to understand the context and get a feel for the classroom. After reading through the transcript, participants were asked to reread the transcript and fill out a worksheet with the following questions: What did you learn about the use of examples during mathematics instruction from the examples given in the case presented? What would you do the same as the teacher did with regard to examples? What would you do differently from the teacher with regard to examples? After the participants wrote their answers and handed them in, a discussion followed. This discussion was audio-recorded and transcribed.

### **Data analysis**

When analyzing participants' responses to the worksheet, our guiding question was, what aspects of using examples did the participants relate to when studying the case. We then used the literature background to help form a categorization scheme of those aspects. For example, we examined participant's responses for comments related to various types of examples that were discussed in class and were present in the case, such as intuitive examples, non-examples, familiar examples, and uncommon examples. Participants also commented on didactical aims of giving examples, such

as responding to a student's error. Because participants wrote freely, it happened that one sentence could encompass more than one aspect of example use. For instance, one teacher (T12) wrote "the teacher gave a numerical example, which in my opinion served the purpose of making it easier for the students to understand and generalize the idea." T12 refers to the type of example (numerical) as well as the purpose of the example (to help students generalize). Participants' comments that were thought not to be related to the giving and use of examples were categorized as 'unrelated'. Table 1 lists the categories along with examples from the data of each category.

Aspect of example use	Sample data
Type: What type of example is given?	The example uses simple numbers; it is a visual example of Thales' theorem.
Agency: Who is giving the example?	Only the teacher gives examples.
Aim: what seems to be the aim of giving the example?	The example is given to explain it again; the example shows the students how the theorem works.
Timing: When is the example given?	The example is good for the beginning of a lesson.
Example of: What is the example an example of?	The teacher gives examples of proportions.
Unrelated	The teacher presents a dry definition of Thales' theorem.

**Table 1: Categorizing participants' comments**

## Findings

This section analyzes participants' comments from the worksheet on two segments of the case along with excerpts from the discussion which focused on those case segments. Thus, we review what participants noticed individually and what they discussed collectively. Analysis of participants' comments is carried out according to the aspects of examples listed in Table 1.

### Segment one- Introducing Thales' theorem

The case transcript began a picture of the teacher at the board presenting to his students an example (see Figure 1). Accompanying the picture were the following lines from the case transcript:

- 1     T:             In Thales' theorem, it is given that BC is parallel to DE. The conclusion is... wait, guess. If the length here (pointing to AB) is 6 and here (pointing to BD) is 2. And let's say that the length here (pointing to AC) is 12, what is the length of CE?
- 2     S:             4!
- 3     T:             Right!

There are several ways to look at the examples in the above segment. One way is that there are two explicit examples. First, there is the drawing on the board (see Figure 1). Second, there is the numerical example given by the teacher in Line 1. However, the drawing on the board can be an example of Thales' theorem or an example of similar triangles, and indeed, that is what the teacher is trying to convey. In addition, depending on one's point of view, the example on the board and the

numerical example may be considered one complete example, with the example on the board written in a general matter, using parameters (a, b, c, and d), and the oral example, a specific example given with numbers.

The most frequent aspect of examples mentioned by participants was example *type*. Participants used such descriptions as: a simple example (PT2), an unfinished example (T8), a visual example (T12), a numerical example (T12, T13), and an intuitive example (PT 22). Although most participants wrote that the teacher gave the example, we do not take this as commenting on the *agency*, but rather as a description of what is going on. On the other hand, for a different segment, one participant wrote, “Only the teacher gives examples... but he should have requested examples from the students.” This participant is not merely describing the situation, but commenting on who is and who should be giving the examples. The *aim* of giving the examples was mentioned by T8 who wrote, “In Line 1, the teacher gives an example that students have to finish. He is checking to see if the students are listening and if they understand.” T13 wrote, “The teacher gave a numerical example so that the students could understand the example and draw on their previous knowledge of similarity and proportional triangle sides.” *Timing* of the example, that the example was appropriate for the beginning of the lesson, was noted by PT2. Two participants commented on what the example was *an example of* – T12 wrote that it was an example of the theorem, meaning that the example showed how the theorem could be applied. PT22, referring to the numerical example in Line 1, wrote that it was an example of equivalent ratios.

### Segment two – Proportional segments

The following case segment is a direct continuation of the first one:

- 4-6. (The teacher and students review the concept of similar triangles.)
7. T: So, what is the ratio of their corresponding sides (referring to the example given in Line 1)?
- 8-10. Students: 1 to 3. 3 to 1. It depends on how you look at it.
11. T: The ratio is ... 3 to 4 because BD and CE are not sides of the triangle. So 6 is to 8 like 12 is to 16. Now, ..., what came first in Euclidian geometry? First, there was Thales’ theorem and only after that came the similar triangles theorems. So, let’s say we are in ancient Greece and we don’t know yet about similar triangles, but we do know Thales’ theorem. With that theorem, we can prove proportional sides in similar triangles.

In lines 4-11, no new examples are given. Instead, the teacher and students still refer to the first examples given on the board. Like the comments on the first segment, here too, most comments related to the *types* of examples being given: simple numbers (PT7), a non-intuitive example (T11), a general example with parameters (T17), and a numerical example with familiar numbers (T19). None of the participants mentioned aspects of *agency*, *aim*, or the *timing* of examples. T11 noted that the example was an *example of* ratios. Two PTs wrote remarks connected with the story of ancient Greece. PT23 wrote, “There is an example from real life that I like – in ancient Greece.” PT16 wrote, “In Line 11, the teacher made the material come alive when she told the story about Thales’ theorem from ancient Greece ... This example raises the question of why the students first learn about similarity and then about Thales.” T23 calls it an example from real life. Yet, it is not a

mathematical problem related to real life. The term ‘example’ when describing the ancient Greece story is not in line with the notion of examples discussed in the course.

### Discussing the case

After the worksheets were handed in, the teacher educator (TE) opened up the discussion by asking who wished to comment on the case. After nine minutes of discussing general ideas, the discussion turned to the example given in Line 1 of the case transcript. Note that PT21 was present during the geometry lesson as part of their field work.

TE: Let’s look at Line 1.

PT21: But it’s not complete... He wanted to give an example of a ratio, but... Instead, he asked the students... He told the students to guess. And they did. He didn’t really give an example, in my opinion. But, in the next example...

TE: Where is the next example, in your opinion?

PT21: Line 11... In my opinion, it’s an explanation with a few numbers and that’s so you can see... I can’t decide. It’s, like, a numerical example. Here (in Line 11) is what was missing beforehand (in Line 1).

TE: Is it an explanation or an example? Can an example also be an explanation?

PT21: No. An explanation can be accompanied by an example. There can be an example and then the explanation generalizes it.

T8: I felt that way about Line 1. It feels like an explanation, and also like an example. On the one hand, there are numbers. On the other hand, it’s not complete.

The above excerpt gives us a glimpse into PT21’s and T8’s concept image of an example. Both infer that an example has numbers, but it must be complete, without any missing parts. There is also the question of the different roles an example may play in the classroom. Can an example be an explanation? Must all examples be specific and only the explanation can generalize it? These are some of the questions that the participants are grappling with. In the following excerpt, PT22, who was also present as an observer of the geometry lesson, tells what he observed.

PT22: He was trying to show how Thales’ theorem is really intuitive. That is, he gave an intuitive example.

TE: An intuitive example of what?

Many voices: Equivalent fractions.

PT22: And most answered correctly. The teacher was trying to show how easy it is.

TE: But what was it an intuitive example of?

T12: Of proportions. I know that it’s proportional because I know, I recognize it. It doesn’t really have anything to do with Thales’ theorem. Simply, 6 is to 2 as 12 is to 4. That’s it. That’s the example.

As stated in the background, what an example is an example of, depends on your focus and point of view. PT22 claims that the examples in Line 1 and Line 11 are examples of Thales’ theorem and

that the teacher used intuitive examples to simplify the concept for his students. However, other participants, those not necessarily present during the geometry lesson, see those examples as intuitive examples of equivalent fractions or of a proportion.

## Discussion

During teacher preparation and professional development, participants are introduced to various theories. While field work is important, theories can help prospective and practicing teachers make the most of their field work by focusing their attention on different elements of practice. Findings showed that analyzing the case gave participants a chance to apply their knowledge of example theory when examining a classroom situation. Findings also showed that participants did not necessarily draw on the same theories when analyzing the same event. The example given in Line 1 of the case transcript was described alternatively as simple, numerical, visual, and intuitive. Each of these types can be traced back to different theories discussed in the course, but they focus on different issues. An intuitive example may also be numerical, but if the prospective teacher specifically comments on its intuitiveness, then that participant is remarking that a student will easily recognize it as an example (Tsamir, Tirosh, & Levenson, 2008). In other words, that participant is integrating knowledge of students (Ball, Thames, & Phelps, 2008) when analyzing example use and has appropriated a specific theory to accompany this integration. As teacher educators, we wish to encourage such integration of knowledge.

During the discussion, additional aspects of example use arose. Participants grappled with the nature of examples, and whether or not an example can be an explanation. This link between examples and explanations could have stemmed from the first half of the course which dealt with the topic of explanations in mathematics education. In any event, this question can help teachers and prospective teachers focus on the roles examples may play in the greater picture of teaching and learning mathematics. Finally, we also note how the integration of an authentic case, one that at least some participants actually observed, can help bridge theory and practice. In the discussion, participants held different views regarding what the example in Line 11 was an example of. Those who had actually observed the lesson had a chance to review the lesson again, focusing now on example use. They were also able to share with others some background of the lesson, perhaps adding to everyone's sense of 'being there'. This excerpt illustrates how fieldwork may be integrated into course work. It also reminds us, as teachers and as teacher educators, that it is not enough to offer examples. As Goldenberg and Mason (2008) said, exemplification is dependent on one's point of view. Analyzing a case using theories, and then discussing these analyses with participants, can raise awareness of how students may view examples and encourage planning example use in mathematics classrooms.

# Researching the sustainable impact of professional development programmes

Stefan Zehetmeier

University of Klagenfurt, Austria; [stefan.zehetmeier@aau.at](mailto:stefan.zehetmeier@aau.at)

*Impact analyses and evaluations of professional development programmes are mainly scheduled during or at the end of a particular programme. They aim at and provide results regarding immediate and short-term effects. However, apart from and beyond that, an analysis of sustainable effects is crucial. To address this issue, this contribution deals with the central question: What is the sustainable impact of professional development programmes? Theoretical models and empirical findings are introduced. In particular, this contribution provides two case studies' results regarding Austrian professional development programmes' impact. Here, the factors which foster or hinder the sustainability of impact are in the focus. Finally, implications for professional development programmes' implementation and research are discussed.*

*Keywords: Impact, sustainability, professional development programme, case study.*

## Introduction

The question of how to promote mathematics teachers' professional development has been discussed in various papers (e.g. Krainer & Zehetmeier, 2013; Loucks-Horsley et al., 1996; Sowder, 2007; Zehetmeier, 2010, 2014a, b; Zehetmeier & Krainer, 2011). In this context, the question of impact is of particular relevance. Evaluations and impact analyses of professional development programmes are mostly conducted during or at the end of a project and exclusively provide results regarding short-term effects. These findings are highly relevant for critical reflection of the terminated project and necessary for the conception of similar projects in the future (Fullan, 2006). However, apart from and beyond that, an analysis of sustainable effects is crucial (Loucks-Horsley et al., 1996). Despite its central importance for both teachers and teacher educators, research on sustainable impact is generally lacking within teacher education disciplines (Datnow, 2006; Rogers, 2003). This kind of sustainability analysis is often missing because of a lack of material, financial and personal resources (McLaughlin & Mitra, 2001; Hargreaves, 2002).

## Theoretical framework

The expected impacts of professional development programmes are not only focused on short-term effects that occur during or at the end of the project, but also on long-term effects that emerge (even after some years) after the project's termination. Effects that are both short-term and long-term can be considered to be sustainable. Sustainability may refer to both system and/or individual level. Sustainability can be defined as the lasting continuation of achieved benefits and effects of a project or initiative beyond its termination (DEZA, 2002).

Empirical evidence concerning the impact of professional development programmes points to the finding that "prior large-scale improvement efforts (...) have rarely produced lasting changes in either teachers' instructional practices or the organization of schools" (Cobb & Smith, 2008, p.

232). Thus, it seems reasonable to focus on factors which might foster the broad effects and scale-up of professional development programmes' innovations. Cobb and Smith (2008) highlight networks, shared vision and mutual accountability as key factors.

Teacher networks are described, for example, as groups of colleagues who provide social support in developing demanding instructional practices; this affords time built into the school schedule for collaboration among teachers and access to colleagues who have already developed relatively accomplished instructional practices.

Moreover, a shared vision of high quality instruction fosters the scale-up of impact: this includes a shared vision concerning the question of instructional goals (what pupils should know and be able to do) and the question of how pupils' development of these forms of knowing can be supported.

Another key factor which fosters the scale-up of innovations and impact in teacher education is mutual accountability. This means, for example, that if school leaders hold teachers accountable for developing high-quality instructional practices, then – in turn – school leaders are mutually accountable to teachers for supporting teachers' learning.

## **Examples of Austrian professional development programmes**

This paper deals with the analysis of sustainable impact of professional development programmes. In particular, two Austrian professional development programmes are in the focus: the IMST project and the PFL courses:

### **IMST project**

In Austria, a national initiative with the aim to foster mathematics and science education was launched in 1998: the IMST project. Since then, this initiative has undergone several adaptations and is still running.

IMST was implemented in three steps:

1. The task of the IMST research project (1998–1999) was to analyse the situation of upper secondary mathematics and science teaching in Austria and to work out suggestions for its further development. This research identified a complex picture of diverse problematic influences on the status and quality of mathematics and science teaching: For example, mathematics education and related research was seen as poorly anchored at Austrian teacher education institutions. Subject experts dominated university teacher education, while other teacher education institutions showed a lack of research in mathematics education. Also, the overall structure showed a fragmented educational system consisting of lone fighters with a high level of (individual) autonomy and action, but little evidence of reflection and networking (Krainer, 2003; see summarized in Pegg & Krainer, 2008).
2. The IMST<sup>2</sup> development project (2000–2004) focused on the upper secondary level in response to the problems and findings described. The two major tasks of IMST<sup>2</sup> were (a) the initiation, promotion, dissemination, networking and analysis of innovations in schools (and to some extent also in teacher education at university); and (b) recommendations for a support system for the quality development of mathematics, science and technology teaching. In order to take systemic steps to overcome the “fragmented educational system”, a “learning system” (Krainer, 2005) approach was taken. It adopted enhanced reflection and networking as the basic intervention

strategy to initiate and promote innovations at schools. Besides stressing the dimensions of reflection and networking, “innovation” and “working with teams” were two additional features. Teachers and schools defined their own starting point for innovations and were individually supported by researchers and project facilitators.

3. The IMST3 support system started to continuously broadening the focus to all school levels and to the kindergarten, and also to the subject German language (due to the poor results in PISA). The overall goal of IMST is to establish a culture of innovation and thus to strengthen the teaching of mathematics, information technology, natural sciences, technology, and related subjects in Austrian schools (see e.g. Krainer et al., 2009). Here, culture of innovation means starting from teachers’ strengths, understanding teachers and schools as owners of their innovations, and regarding innovations as continuous processes that lead to a natural further development of practice, as opposed to singular events that replace an ineffective practice (for more details see e.g. Krainer, 2003).

For the future, the ministry expressed its intention to continue IMST. The overall goal is setting up and strengthening a culture of innovations in schools and classrooms, and anchoring this culture within the Austrian educational system.

### **PFL courses**

In Austria, in-service professional development courses (PFL - Pedagogy and Subject-specific Methodology for Teachers) support teachers in developing their teaching skills and updating their knowledge of the subject they teach. The participants systematically reflect their professional work. PFL started in 1982, has undergone several adaptations, and is still running (for more detail, see Rauch et al., 2014). The programme is designed for teachers from all types of schools across the nation, including all age groups of pupils. The overall focus of PFL is on the professional development of teachers in the fields of content, didactics and pedagogy. School development plays a central role without losing sight of classroom instruction. The PFL concept is based on the implicit knowledge, which teachers possess concerning their work in class, their experience and their individual strengths. The course is intended to contribute to the further development of the teachers as professionals. Teachers are introduced to the methods of action research (Altrichter & Posch, 2009). They investigate different aspects of their teaching by defining research questions of relevance to their work, by collecting data, interpreting and drawing conclusions and writing down their findings in reflective papers.

The major goals of the teaching process should be primarily achieved through – and not detached from – the subject-related design of teaching and learning. PFL takes two years and focuses on the individual teachers’ own reflective practice using action research methods (Altrichter & Posch, 2009). By the end of the course, each participant is obliged to write a reflective paper using the data he/she has gathered throughout the process using qualitative and quantitative research methods. Participants are part of a community of practice (Wenger, 1998), since their work is embedded in a structure of mutual assistance and external support.

### **Case studies**

Within both professional development programmes (IMST and PFL) several case studies were conducted, with the aim to research the sustainability of the programmes’ impact. The case studies

presented here were based on data from various sources and time periods to gain validity by “convergence of evidence” (Yin, 2003, p. 100): data collection contained documents (e.g. teachers’ project reports, which were written during and at the end of teachers’ participation in the project) and archival records (e.g. author’s field-notes, which originate from author’s activities as teacher educator in the project). Moreover, interviews were conducted from an ex-post perspective with former participating teachers, teachers’ colleagues, principals, and project facilitators and teacher educators. Data analysis included both inductive and deductive elements (Altrichter & Posch, 2009) to analyse both the impact and the respective fostering (or hindering) factors. For example: document analysis aimed at gathering information concerning short-term impact which (a) occurred during and/or at the end of the teachers’ participation and (b) might hold the possibility of sustainability and scale-up. Subsequently, this document analysis formed the basis for the interviews series. The interviews were semi-structured, since they were based on the analysis of existing data (document analysis), which identified various levels of short-term impact which occurred during and/or at the end of teachers’ participation. The interviews were designed accordingly (a) to gather data concerning the sustainability and scale-up of impact and (b) to reveal other types of impact which were not already coded. Data was analysed by qualitative content analysis (Mayring, 2003) in order to identify common topics, elaborate emerging categories, and gain deeper insight into teachers’ professional growth over time. The case studies’ results were validated by means of member checking.

### **Exemplary case study from IMST**

The case of Barbara, a former participant of the IMST<sup>2</sup> project, provides exemplary results concerning the issue of sustainable impact:

Barbara’s beliefs regarding inquiry based learning (IBL) and open learning environments were changed during her participation in IMST<sup>2</sup>: Due to her participation in the project, she regularly used IBL settings (which she did not before her participation) and experienced positive effects on students’ content knowledge, as well as on their self-confidence. In particular, she stated that there were positive changes regarding low-performing students’ self-esteem, as well as the further development of high-performing students’ competencies. This change was evidenced by data (both document analysis and interviews). In the interview, Barbara highlighted that this impact was sustained and enabled her to create and implement innovative teaching methods in a long-term way.

Besides this impact, she also developed (due to her participation in the IMST<sup>2</sup>) an inquiry stance towards the content and the method of her teaching. This inquiry stance was mirrored by her new belief about the value of feedback: due to the teacher education programme, topics such as classroom atmosphere and teaching quality were discussed with and evaluated by her students on a regular basis. This impact on her own IBL was sustained: Barbara stated in the interview, that she was convinced of the importance of critically evaluating her teaching. Even after the programme’s termination, she continued to actively facilitate her students’ communication and discussion about her teaching practices.

One of the central factors that fostered the sustainability of impacts was the engagement of the school’s principal. The school had an efficiently organized management and school development structure, which represented another fostering factor. Additionally, Barbara experienced personal

benefit, which also helped the impact persist after the programme's termination. Both the teacher and principal highlighted (in the interviews) the role of the IMST<sup>2</sup> project facilitator as a fostering factor. Yet another fostering factor was represented by the IMST<sup>2</sup> workshops and seminars, where Barbara (according the interview data) got support and opportunities to share her experiences and to make her success and remaining challenges visible.

### **Exemplary case study from PFL**

Eve participated in the PFL course and had the goal to promote open learning settings by implementing new teaching approaches in her mathematics classes. Document analysis showed that she aimed at enhancing pupils' inquiry-based learning opportunities. During her participation in PFL, Eve changed her teaching practices and implemented innovative teaching approaches to enhance her pupils' self-directed and independent learning. Interview data clearly shows that this impact was sustained: the changes in Eve's teaching practices stayed effective even after the termination of PFL. Core fostering factors were the school principal's support and a high level of mutual appreciation within the school staff, and pupils' benefit. In particular, Eve highlighted in the interview that the pupils' joy and success are core reasons for her to keep this impact sustained.

Document analysis further showed that Eve conducted various self-evaluations during her participation in PFL and gained new knowledge concerning action research methods. In the interview, she stated that she continued to reflect on her teaching practices, even after the end of her participation. This impact was sustainable, due to Eve's direct advantage (by getting information on her classroom performance) and the support of the school's principal (who was convinced that reflections and self-evaluations are important steps on the journey to school quality). This impact was also fostered by Eve's colleagues' joint reflection and communication. Interview data shows that teachers cooperated beyond school subjects and held similar values and standards concerning pedagogical or subject-related issues. The school's principal showed great interest in, and provided support for, the teachers' activities. He participated in the school's mathematics study group and shared his perspective with the teachers.

### **Discussion**

The factors that fostered the sustainability of the case studies' impacts are mirrored by the theoretical framework (see above):

IMST and PFL enabled networking (Cobb & Smith, 2008) by community building, mutual appreciation and joint reflection. A particular factor was the principals' content knowledge (Cobb & Smith, 2008). Teachers' colleagues provided communication and social support in developing and reflecting instructional practices (Cobb & Smith, 2008). Moreover, a shared vision (Cobb & Smith, 2008) of values and standards regarding high quality mathematics instruction was established. In particular, the case studies' results highlight that the promotion of reflection and networking as key interventions (Krainer, 1998) turned out to be supportive for the sustainability of the professional development programmes' impacts.

# **The impact of professional development on teachers' autonomy-supportive teaching practices**

Janette Bobis<sup>1</sup>, Jenni Way<sup>2</sup> and Judy Anderson<sup>3</sup>

<sup>1</sup>*The University of Sydney, Australia; [janette.bobis@sydney.edu.au](mailto:janette.bobis@sydney.edu.au)*

<sup>2</sup>*The University of Sydney, Australia; [jennifer.way@sydney.edu.au](mailto:jennifer.way@sydney.edu.au)*

<sup>3</sup>*The University of Sydney, Australia; [judy.anderson@sydney.edu.au](mailto:judy.anderson@sydney.edu.au)*

*Keywords: Professional development, autonomy-supportive practices, teacher beliefs.*

## **Description of the research topic**

The benefits to student academic and dispositional outcomes when exposed to autonomy supportive learning environments have been acknowledged for more than a decade (Assor, 2012; Reeve, 2009). Autonomy supportive teaching practices nurture students' internal motivations to learn, resulting in learning that is self-directed and both cognitively and emotionally engaging (Wolters & Taylor, 2012). While research affirms the benefits of instruction incorporating autonomy-supportive practices (e.g., Assor, 2012) it also shows that the mathematical beliefs of teachers can be an impediment to their commitment and enactment of such practices (Bobis, Way, Anderson, & Martin, 2016). With this in mind, an intervention study was conducted with mathematics teachers (grades 5-7) that aimed to enhance their use of engagement supportive teaching strategies in their mathematics classrooms. The intervention was a year-long professional development program that focused on shifting teachers' beliefs about student engagement and building knowledge of instructional strategies for promoting student autonomy in the mathematics classroom. The specific research question addressed was: What impact did the professional development program have on teachers' beliefs and practices that promote learner autonomy in mathematics?

## **Theoretical framework and methodology**

Self-determination theorists (SDT, Deci & Ryan, 1985) advocate that autonomous motivation will improve students' academic and dispositional outcomes because activities undertaken for autonomous reasons are likely to increase students' willingness to apply effort when learning. According to SDT, students will be more intrinsically motivated to learn when teachers adopt autonomy-supportive pedagogy rather than controlling pedagogical approaches. SDT was used to guide our examination of self-reported data regarding mathematics teachers' instructional beliefs and practices as a result of their involvement in the professional development program.

Pre- and post-intervention data were collected from 32 grade 5 to 7 teachers of mathematics from four secondary and ten elementary schools located in Sydney, Australia. Participants included five male and 27 female teachers. Data were collected via focus groups and a 20 Likert-type item questionnaire that measured the extent to which teachers were committed to instructional beliefs and practices considered supportive of student engagement, including learner autonomy.

## Findings and conclusion

Dependent T-tests were used to determine whether there were significant differences between teachers' pre- and post-intervention responses on each dimension of the questionnaire. Results for two dimensions pertaining to teachers' autonomy supportive beliefs and practices—discovery (the construction of ideas through student discovery) and teacher's role (co-learner and constructor of a learning community) are presented on the poster. During the pre-intervention focus groups, most teachers described their roles as a 'giver' of knowledge to students. However, in the post-intervention focus groups, teachers reported how they now tried to develop more autonomous learning strategies in their students and to encourage them to take greater responsibility for their own learning. The results indicate that teachers expressed beliefs and practices that were more supportive of student autonomy at the end of the intervention than prior to undertaking the professional development program.

## Presentation of the poster

The poster is structured in four major sections: Section one provides a succinct introduction to the literature, providing a justification for the study and presents the research question. Section two presents a visual representation of the theoretical framework (SDT) underpinning the study and our analysis of results. Section three presents results from the questionnaire and focus groups. The final section presents implications of the findings and argues that such shifts in teachers' beliefs/practices can have practical consequences in terms of improving students' autonomy for learning mathematics.

# Supporting teachers' practices: A teacher educator-embedded professional development model

Scott A. Courtney

Kent State University, United States of America; [scourtn5@kent.edu](mailto:scourtn5@kent.edu)

*The poster describes preliminary results from ongoing professional development with two U.S. mathematics teachers, one Algebra 1 and one eighth grade mathematics teacher, designed to increase and enhance teachers' content knowledge and transform their classroom instruction by embedding the author (i.e., researcher) in teachers' practices. The poster also articulates the embedded PD model. Preliminary results show participating teachers are engaging their students in more rigorous mathematics, teachers are demonstrating increased self-efficacy and are more frequently engaging students in mathematical sense making, reasoning, modeling, generalizing, and communicating.*

*Keywords: Mathematics instruction, mathematics teachers, theory practice relationship.*

## Description of research topic

The poster describes ongoing professional development (PD) in the United States with one eighth grade math teacher (students 13-14 years) and one ninth grade Algebra 1 teacher (students 14-15 years) designed to increase and enhance teachers' content knowledge and transform their classroom instruction by embedding the author (i.e., researcher) in teachers' practices. The poster focuses on the following research questions: How does embedding a mathematics teacher educator in a mathematics classroom (embedded PD) impact (1) participating teachers' content knowledge, (2) participating teachers' instruction, (3) students' self-efficacy, and (4) student achievement?

## Theoretical framework

The embedded PD model is grounded in a constructivist approach to learning mathematics and aligns with Simon's (1995) Mathematics Teaching Cycle and Thompson's (2013) interpretive framework for the development of powerful Mathematical Meanings for Teaching (MMT).

## Method

Throughout embedded PD, the author (i.e., researcher) and participating teachers relied on: participating teachers' prior assignments, assessments and notes; textbooks and district generated documents (e.g., curriculum maps); state-level standards and documents; and a variety of Internet resources (e.g., GeoGebra, NRIC Project). Throughout the planning of a lesson, which may take multiple in-person or online meetings (or both), the researcher attempts to motivate the teacher to make explicit (and objects thought, discussion and subsequent reflection) her (i.e., teacher's) understandings of: the mathematics inherent in the lesson, hypotheses of their students' knowledge, theories of mathematics learning and teaching, activities and assessments (Simon, 1995; Thompson, 2013). As such, notions of meanings, ways of thinking and the need for the teacher and her students to articulate their meanings, thinking, and reasoning are consistently addressed (Thompson, 2013).

## Participants

Participating teachers reported on the poster involve Tami (eighth grade math) and Jeremy (Algebra 1). Tami's eighth grade class contained 15 students of both genders and multiple races. Five (of the

15) students were on individual education plans. Jeremy's Algebra 1 class contained 25 students of both genders and multiple races.

## Data and analysis

Data consisted of: (1) video- and audio-recordings of and physical documents related to lesson co-planning sessions; (2) video- and audio-recordings of lesson implementations (i.e., co-teaching); and, (3) video- and audio-recordings of and physical documents related to teachers' reflection on student work and classroom instruction. Two embedded co-teaching descriptions will be described on the poster, one involving a co-planning session with Tami, the other involving co-teaching with Jeremy. Analysis will serve to characterize some of the differences exhibited in tasks, activities, and classroom interactions highlighted as a result of the embedded model.

## Preliminary results

Teachers engaged in embedded PD have indicated their participation has provided them the support to do what they believe is best for their students and their practice while not feeling constrained by district and state demands. Rather than feeling the need to rush through content and focus on skills and procedures, embedded co-teaching has allowed participating teachers to focus on understanding, coherence, and discourse. Preliminary results show participating teachers are engaging their students in more rigorous mathematics and both students and teachers are demonstrating increased self-efficacy and are more frequently engaging in mathematical sense making, reasoning, modeling, generalizing, and communicating.

# **Teachers learning through participatory action research – developing instructional tools in mathematics primary classrooms**

Margareta Engvall

Linköping University, Department of Behavioural Sciences and Learning, Linköping, Sweden;  
[margareta.engvall@liu.se](mailto:margareta.engvall@liu.se)

*Keywords: Mathematics education, action research, teacher professional development, multilingual classrooms, instructional tools.*

## **Introduction**

In many classrooms, from first grade through the whole school system, there are many students whose mother tongue is not the same as the teachers' language used for instruction (Khisty, 2001). In Sweden, newly arrived immigrant children with limited Swedish language knowledge are learning Mathematics together with children who have spent their entire life in a Swedish context. Considering the large number of students with limited knowledge in the language of instruction one of the most important tasks for teachers in Swedish primary education is to create conditions to support the development of mathematical knowledge in these students.

Lately, the role of language in mathematics education has received a profound interest in educational research. Researchers have emphasized the importance of teachers using specific strategies to facilitate the classroom communication to and support students' mathematical thinking (O'Connor & Michaels, 1993).

Specifically, in the syllabuses (Skolverket, 2011) it is particularly prominent that mathematics is dominated by discourse-intensive approaches, and the use of instructional tools such as talk moves, give ample opportunities for student learning (Chapin & O'Connor, 2007). Similar strategies for supporting students' learning in mathematics have received attention among effective teachers of second language learners in mathematics (Khisty, 2001).

This study uses action research which is characterized by ongoing processes of self-reflection, which can be thought of as a spiral of self-reflective cycles on planning a change, followed by acting and observing the process and reflecting on the process and then re-planning and so forth (Kemmis & Wilkinsson, 1998). Using PAR gives an attempt "to help people investigate and change their social and educational realities by changing some of the practices which constitute their lived realities" (Kemmis & Wilkinsson, 1998, p.22).

## **Method**

The poster gives a brief presentation of a one-year research project where four primary teachers at the same school (year 2, 4 and 5) have been working together with a researcher, using participatory action research (PAR) (Kemmis & Wilkinsson, 1998) to develop their instructional tools in order to support students' mathematical development in multilingual classrooms. Data collection has continued throughout the whole action research process during the academic year. The empirical data includes teachers' logs, teacher questionnaires with open answers, researcher's notes, audio-

recorded discussions from the meetings twice a month in the project group and 3-4 video-taped mathematics lessons in each classes, 14 lessons altogether

## Results

Although the focus in this project has been on instructional tools for supporting students' talk in order to enhance their development in communicating and reasoning mathematically, it is noteworthy that the teachers express their development, not only in terms of (1) instructional tools but also regarding other aspects such as (2) classroom organization and (3) focus on mathematical content.

Methods structured in these three themes above constitute a teacher *tool kit* to support students' learning mathematics in multicultural classrooms.

## Conclusions

By using PAR, the teachers had the opportunity to reflect critically, analyze and act as coparticipants in the challenge to change the practices in which they interact, which also challenged their approach to teaching.

When teachers act and reflect on their use of specific strategies of classroom talk they also start reflecting and acting on other aspects of teaching, such as classroom organization and how to keep attention to the taught content. Thereby, the change in practice became more than just temporary changes.

### Introduction

TWG19 is one of three TWGs at CERME10 dealing with issues related to teaching and teacher education (the others being TWG18 and TWG20). The group is particularly interested in studies that aim to understand the development of classroom practices and teachers' contributions to them. This includes the roles of other factors such as the available teaching-learning materials, modes of teacher collaboration at and beyond the school(s) in question, and school cultures as they relate to, for instance, teacher-student relationships, teachers' individual and communal responsibilities, and the role of curricular materials and testing. Finally, studies concerned with how micro-level interactions are informed by macro-level structures (society, culture and the political) are also of TWG19's interest.

A total of 27 contributions were initially submitted (26 papers and 1 poster), involving authors from at least 14 different countries, primarily in southern or northern Europe. The papers were grouped in five thematic areas, each assigned to one of the five team leaders for overseeing the reviewing process. Each proposal was reviewed by a team leader and two authors, and 24 contributions (22 papers and 2 posters) were accepted for presentation at the conference. Participants were expected to read the papers before the conference sessions. In the time slot allocated to each group of papers, the authors each gave a short presentation (5–7 minutes), sketching the key ideas of the work reported. This was followed by a reflection by the group leader on common themes and cross-cutting issues (15 minutes), which were subsequently discussed by the participants in small groups. Ultimately, 22 papers and 1 poster are included in the conference proceedings.

The five thematic areas according to which the TWG19 contributions were grouped are: (a) problem solving and general issues related to teaching practice, (b) lesson planning, lesson study and curriculum, (c) instructional quality and assessment, (d) in-the-moment teaching actions and decision making and reflection and (e) instructional practices. In the next two sections, we discuss the contributions first within and then across these thematic areas.

## Substantive issues

In this section we present research considerations and concerns in the papers in each group, including the range of theoretical perspectives and methodologies employed.

### (a) Problem solving and general issues related to teaching practice

Dominant perspectives on the teachers' knowledge have changed and now focus on content knowledge closely connected to the profession. This is fueled by current reform initiatives that emphasise processes of mathematics, for instance in terms of problem solving.

Three of the four papers in this section deal with problem solving. The paper by Kleve and Ånestad concerns a Norwegian teacher, who seems inspired by a process view of mathematics. The class works with subtraction and initially uses informal mental strategies. The authors argue that there is a need to link such methods to a standard algorithm, that the flexible use of both methods is needed, and that it should become socio-mathematical norm that both are acceptable. However, the teacher's mathematical knowledge for teaching seems too weak for her to support the students in the transition from informal strategies to standard procedures. This makes it impossible for her to support socio-mathematical norms in line with the reform.

Odindo's study from Kenya is based on the expectation that problem-solving approaches may alleviate secondary students' difficulties with their final exams. He uses Learning Study (LS) to support teachers in using problem solving when teaching algebra. The paper to some extent focuses on the students, but mainly asks what the learning opportunities are for the teachers. Odindo argues that the LS format allows teachers to consider general issues of, for instance, time management, but also to focus on patterns of task variation closely related to the contents. At least implicitly, then, the paper is concerned with how LS may support mathematical knowledge for teaching.

The study by Villalonga and Andrews is also on problem solving, but less on mathematical knowledge for teaching. In fact, the teacher is conspicuously absent, as the paper deals with how Catalan students may self-scaffold when engaged in problem solving. The students use a resource, an Orientation Base (OB), which is to help them monitor their problem solving. The teacher is almost obsolete, and the OB may be read as a response to the problem that many teachers find it difficult to support their students' problem solving. OB may be seen as an attempt to circumvent this difficulty and transfer responsibility to the students.

The last paper in this group, by Mosvold and Hoover, report on a literature review of studies on mathematical knowledge for teaching. The 12 studies in the review address questions of what, how and why such knowledge plays a part for the quality of instruction. The studies argue that mathematical knowledge for teaching is important for instance for teachers' selection and adaptation of tasks, for their planning of instruction, and for how they listen to students and pursue student thinking. Based on the review, however, Mosvold and Hoover argue that the results are mixed and that there is a need to shift the emphasis towards more dynamic understandings of the relationship between mathematical knowledge for teaching and teaching.

The discussions of these papers focus on what it may mean to adopt a dynamic perspective on the knowledge-teaching relationship. How, then, we may change the emphasis from teacher characteristics (e.g., their knowledge or beliefs) to the acts of teaching? The latter perspective

requires greater attention to issues of context, to what we mean by practice, and possibly to alternative frameworks that allow us to reconsider what we mean by knowledge.

### **(b) Lesson planning, development and curriculum**

This group of papers focuses on planning for teaching, utilizing lessons learned in other contexts, and dealing with curricula and textbooks. Four papers approached these issues.

In her case study of a Swedish mathematics teacher, Grundén targets the practice of planning. Reflecting on her own planning, the teacher conceptualizes planning as making informed decisions regarding the teaching of the mathematical content in different contexts, and she relates planning to other practices of the teacher as well as practices of other teachers. Relating to the practice of other teachers is also an issue in the study of Runesson Kempe, Lövström and Hellqvist, who investigate how experiences from a Learning study can be shared and used by teachers in other contexts. Applying the results from a previous Learning study in new classrooms, the authors investigate some necessary conditions for learning about negative numbers and indicate possibilities for cultivating more effective professional practice in mathematics classrooms.

Although development and change in mathematics teaching might be teacher-driven, it is sometimes prescribed by curriculum reforms. Klothou and Sakonidis investigate the implementation of a new curriculum reform among primary mathematics teachers in Greece. They argue that contradictions in teachers' own discourses can be explained by recontextualization procedures that appear when teachers attempt to implement the reform, and inconsistencies may abide in the very discourses that teachers draw upon. Whereas some countries have official textbooks that everyone must use, French teachers are free to decide if they want to use a textbook and how – if they adhere to the national curriculum. In their study on how two experienced French teachers use and adapt the content of mathematics textbooks and teacher manuals, Priolet and Mounier analyze how the teachers use the same textbook when teaching the same mathematical content. None of them follow the recommendations from the textbook completely in their lesson, and the adjustments they make tend to reduce the difficulty of textbook tasks.

These four papers provide compelling glimpses into the complex work of teaching mathematics. They discuss how authorities, schools and other teachers may provide resources that are intended to support the work of teaching, and how adapting and using such resources introduces mathematical, didactical and social demands on teachers' work. Mathematical knowledge for teaching can be described as knowledge required to deal with such demands (Ball et al., 2008), and these four papers thus indirectly contribute to investigating more dynamic relationships between knowledge and teaching.

### **(c) Instructional quality and assessment**

The five papers in this thematic group describe qualities of teaching. Three papers concern instrument development for assessing qualities. One such instrument is the Realization Tree Assessment tool (Weingarden, Heyd-Metzuyanim & Nachlieli). This tool is particularly interesting in the way it reduces the complexity of the lesson into a picture of the mathematical concepts discussed in order to describe qualities of the lessons. This picture organizes mathematical ideas related to what Sfard (2008) calls saming and objectification. A second instrument presented is an innovative tool to observe, describe and evaluate metacognitive practices in mathematics

(Nowinska & Praetorius). Six out of the seven dimensions developed had highly reliable ratings. A third instrument developed by Jentsch and Schlesinger starts from three established dimensions (classroom management, personal learning support, cognitive activation) and aims at adding a subject-specific dimension. This dimension includes nine characteristics – such as teachers' mathematical correctness, explanations and mathematical depth – and produces results with good interrater agreement and satisfying reliability measures.

In addition, two papers study qualities of teaching using observation and interviews. Tuset investigates pre-service teachers trying ambitious teaching, allowing students to exercise authority while staying accountable to the discipline. The study finds that the pre-service teachers are able to create opportunities to engage in explorative discourses, but that their talk moves seem to be ritualized and therefore constrain students' participation. Kaldrimidou, Sakonidis and Tzekaki attempt to identify crucial elements shaping classroom mathematical meaning construction. To achieve this, they study three highly motivated and professionally active teachers' instructional practices and reflections. Findings reveal that the teachers' choices restrict the mathematical meaning because they desire to provide an easy, safe and pleasant learning environment.

These five papers illustrate two main issues for further research. The first issue regards the challenges of low and high inference observations. Low inference observations, like talk moves, explain little in themselves. On the other hand, high inference observations require extensive rater training that might result in simplification and even ritualization of the rating. What could we lose then? The second issue is that these articles illustrate the need for an instrument review. Which instruments are available for assessing qualities of teaching, what do they intend to measure, what theories do they build on, how reliable are they, and how much data and extent of rater training is needed to make them reliable?

#### **(d) In-the-moment teaching actions and decision making and reflection**

The studies in this group address mathematics instruction in a variety of ways: as teachers' management of actions and moments determining students' learning (Ferreira & da Ponte); as an activity shaping and being shaped by teachers' professional enactment in intervention or reform settings (Stouraitis; Sterner); as a practice being intentionally problematized to support teachers to develop (Potari & Psycharis; NicMhuirí). A different approach is to distinguish between papers that look at mathematics instruction as a learning-to-teach site through scrutinizing yourself or others acting it (Ferreira & da Ponte; Potari & Psycharis), as a professional activity developed through collaborative action (Sterner; Stouraitis), or through individual reflection via literature (NicMhuirí).

A range of theoretical or conceptual frameworks – mostly of sociocultural origin – are at work in the studies reported, and reflection (on teaching practice) and collaboration are at heart of these frameworks. In particular, NicMhuirí employs a reflective practitioner's perspective in combination with a model allowing for levels of teachers' reflection to be identified. Reflection is also of concern in Potari and Psycharis' work operationalized through the construct of 'critical incidents' within a community of inquiry framework. The theoretical underpinnings of the community of practice approach are adopted by Steiner, with reflection being seen this time as a professional learning enterprise developing collaboratively. Drawing on a CHAT perspective, Stouraitis views reflection as an aspect of teachers' decision making which interacts with teaching activity. Finally,

the study by Ferreira and Ponte employs features related to tasks assigned to the students and the communication established in the classroom to evaluate teaching actions.

Most papers in the group report on small, qualitative studies. Empirical data include observations of teaching, meetings and/or interviews audio-taped and transcribed. These data are predominately analyzed based on categories indicated by the literature (content analysis) or by the data themselves (grounded theory like analysis). One study uses no data, but analyzes two empirically tested constructs to exemplify the tool indicated (NicMhuirí). The results of the studies highlight various levels of mathematics teaching interacting with teachers' professional activity.

Overall, the studies in the group seek to understand how mathematics classroom teaching feeds teachers' professional practice, focusing on teachers inquiring into specific aspects of it. The relevant discussions carried out during the conference sessions raised concerns about the clarity of the terms and constructs used, the appropriateness and the functionality of the theoretical frameworks employed, and the boundaries between teaching action/practice and teacher practice.

### **(e) Instructional practices**

The four papers in this thematic group approach instructional practices from different sociocultural perspectives. Two papers investigate teacher change during professional development programs. In particular, Venkat and Askew employ variation theory and example spaces to understand how teachers mediate primary mathematics, mainly how they generate and validate solutions as well as build mathematical connections. Şeker and Ader, on the other hand, focus on maintaining the cognitive demand of mathematical tasks, teachers' attention to students' mathematical ideas and intellectual authority in the classroom. Using the aforementioned frameworks makes it possible to illuminate different aspects of teacher practices that seem to improve based on research recommendations. Future research concerning both papers may entail a close look into the nature of professional development that influences instructional practices.

The paper by Baldry focuses on the development and viability of an analytical framework aiming to understand a 'typical' mathematical classroom in the United Kingdom. The analytical framework *Orchestration of Mathematics* portrays the quality of mathematics orchestration combining several theoretical constructs including cognitive demand of mathematical tasks, sociomathematical norms, hypothetical learning trajectories and professional noticing. The framework thus seems closely related to the scheme of analysis adopted by Şeker and Ader. A common theme of the two studies is teachers' difficulty in noticing and building on student thinking as well as maintaining cognitive demand of the tasks.

The importance of discourse in understanding instructional practices is evident across all papers. Drageset and Allern use drama as an innovative tool, allowing students to gain mathematical authority and engage in productive discourse patterns in making sense of mathematics. Instructional practices shaped and were shaped by student participation and responses. Future consideration for this work is to explore how teachers might implement such drama-based interaction patterns in their classrooms with the help of teacher educators.

A general trend identified in this group is using interviews together with observational data to understand teacher instructional practices, including teacher decisions and professional noticing abilities, closely connected with student participation and sociocultural norms. It would be

productive to define boundaries of instructional practices and how to incorporate pre- and post-observation interviews with teachers in analysing relevant data.

## **Trends and developments**

The studies in TWG19 address a wide range of features and factors that regulate the quality and development of classroom mathematics teaching as well as its relation to teachers' professional growth. A systematic attempt to understand, assess and trace contributions to teacher and classroom practices can be identified across the papers. Issues pursued along each of these three directions are discussed below. The section concludes with some critical considerations related to the studies hosted by TWG19.

In trying to understand teachers and classroom practices, some of the studies look at mathematics teaching in challenging circumstances (e.g., Kaldrimidou et al.; Kleve & Ånestad; Priolet & Mounier). Their results suggest that adapting teaching to effectively respond to such occasions is a difficult endeavor often leading to poor and even contradictory teaching practices. Teaching is also seen in relation to teachers' professional knowledge and practices/perspectives, with the relevant studies indicating a complex but dynamic and fertile relationship (e.g., Mosvold & Hoover; Grundén; Stouraitis). Finally, some studies consider the influence of contextual factors upon teaching practices (e.g., Baldry; Venkat & Askew). The findings reveal teachers' difficulties in administering the mediational role of these factors in order to develop effective teaching practices.

The qualities of teachers and classroom practices are assessed by focusing quantitatively or qualitatively on subject-specific rather than generic features. Studies adopting quantitative instruments highlight the value of such approaches when able to assess high inference valuations with the necessary inter-rater agreement (e.g., Jentsch & Schlesinger; Nowinska & Praetorius). The qualitative instruments, like interviews and observations (e.g., Weingarden, Heyd-Metzuyanim & Nachlieli; Tuset), found to face the same challenges of assessing high inference valuations. To do this with trustworthiness, the qualitative research typically focuses on depth of scrutiny rather than inter-rater agreement.

Certain ways of contributing to teachers and classroom practices are identified in the papers, mainly in some form of collaboration, reflection or intervention. In particular, opportunities to collaborate with other teachers to explore various aspects of teaching mathematics seem to offer possibilities for teachers to develop their professional practice (Sterner; Runesson Kempe et al.; Odindo). Teachers' reflection on classroom practice is a central constituent of this collaboration facilitated by inquiry tools. When exercised on varied levels and at specific aspects of classroom practice, affordances and constraints of this practice become evident (NicMhuirí; Psycharis & Potari). The latter appears to be also the outcome of intervention studies supporting teachers to transfer more learning responsibilities to students (Drageset & Allern; Şeker & Ader; Villalonga & Andrews).

The research activity on teachers and classroom practices included in TWG19 reflects some interesting steps forward, but it also reveals at least five sets of issues in need of critical consideration. Firstly, issues related to the methods adopted, for instance, the issue of generalizing across contexts, the role of using multiple methods, and the (dis-)advantages of different teacher-researcher relationships. Secondly, concerns about the theoretical frameworks employed, for example, selection criteria, levels of generality targeted, issues of compatibility, questions (not)

addressed, ‘own’ frameworks. Thirdly, there is a need to carefully consider concepts and terms used. For instance, terms like ‘practice’, ‘context’ and even ‘teaching’ need clarification, whereas constructs like ‘stability of knowledge’ require further consideration. Fourthly, it is important to adopt clearly defined criteria for assessing the quality of teaching with reference to the learning of mathematics achieved as well as the wider educational goals targeted. Finally, it is necessary to consider quality criteria for research adopted, contribution to theory or practice, coherence, and sufficiency of evidence to warrant an empirical claim.

## **Concluding remarks**

The work reported in TWG19 is part of the research on mathematics teachers and classroom practices developed in recent years employing a predominately sociocultural perspective. Within this perspective, teaching is seen as a social practice in which teachers are practitioners (Jaworski, 2006). Classroom practices are viewed as regular activities and norms continually developed by teachers’ involvement in multiple simultaneous activities, “taking into consideration working contexts, meanings and intentions (...) the social structure of the context and its many layers – classroom, school, community, professional structure and educational and social system” (Ponte & Chapman, 2006, p. 483). These activities mutually structure and frame each other to constitute the practice of the classroom (Skott, 2013).

There is a range of issues addressed by the studies reported that concern teachers’ contribution to classroom practice in various contexts, mostly related to critical aspects of instruction-in-action and teachers either inquiring into their own teaching or working towards developing it. Collectively these contributions appear to suggest that it is valuable to shift the emphasis in this line of research from teachers to teaching. Several theoretical and analytical frameworks are used often in combination (rather than in coordination) providing multiple lenses through which certain constructs (rather than structures) are examined within particular contexts. Along the same line, different methodological approaches are pursued, mainly qualitative, seeking to capture the complexity and richness of the practices unfolding within mathematics classroom life shaping students’ learning of mathematics and teachers’ learning to teach mathematics alike. The findings of the studies offer some notable insights into this shaping, highlighting the importance of focusing on the micro-level of classroom practice, on the resources teachers draw on as they engage in it, and their (intentional or unintentional) professional activity.

The plurality of theoretical perspectives, constructs and analytical tools employed in the studies of teacher and classroom practice reported in TWG19 underline the dynamics of the research activity aiming at ‘unpacking’ teaching practice. It might be the time for the research community working in this area to consider what is already known, what is to be further examined and to develop on the basis of this evaluation a research agenda to fill the gaps. How different tools may be used considering different theoretical perspectives, decisions of whether to use an existing tool or to develop a new one and how to report the added value of using different tools require special attention in moving forward. To this end, the emphasis should be on teaching rather than on teachers, as suggested by the work presented and discussed in the context of the conference sessions.

# A teacher's orchestration of mathematics in a 'typical' classroom

Fay Baldry

University of Leicester, UK; [fb128@le.ac.uk](mailto:fb128@le.ac.uk)

*This paper explores the complexity of interpreting teachers' practice in relation to mathematical meaning making in 'typical' classrooms in England. An observation framework has been developed to interpret classroom activities that draws on a range of theoretical perspectives, including variation theory (Marton & Pang, 2006) and notions of classroom norms (Cobb, Gresalfi, & Hodge, 2009). This paper focusses on the analysis of two lessons in order to discuss the potential of this framework to foreground the mathematics made available to students and the pedagogical moves made by the teacher to bring this about. In England, class composition for secondary mathematics is usually decided by measures of prior attainment, with students of similar 'ability' grouped together. A wider study is exploring shifts in teachers' pedagogical approaches when they teach classes with different attainment profiles. Consideration here is given to whether observation of a few lessons using this framework can identify stable mathematical characteristics, so that in future the framework would allow comparisons between classes to be made.*

*Keywords: Observation, teaching methods, sociomathematical norms, variation theory.*

## Introduction

In England, ongoing attention is paid by politicians and educators to the mathematical attainment of students, and this includes analysing the progress of different groups (Easby, 2014). At secondary level, class composition in mathematics is often determined by measures of prior attainment, with students grouped with others of similar 'ability' and is referred to as *setting* (Ireson, Hallam, & Hurley, 2005). Whilst findings from research into the impact of setting do vary, the predominant view is that setting does not improve overall attainment and may indeed act as a suppressant (e.g. Hattie, 2002). Moreover, setting does increase the spread of attainment, resulting in students placed in lower attaining sets being disproportionately affected. Issues of equity are raised further as students from lower socioeconomic groups are over-represented in low sets, even when prior attainment is taken into account (Muijs & Dunne, 2010). In spite of these concerns, setting in secondary mathematics classrooms appears to be firmly entrenched, with many teachers perceiving setting as the only practical way to teach a range of 'abilities' (William & Bartholomew, 2004).

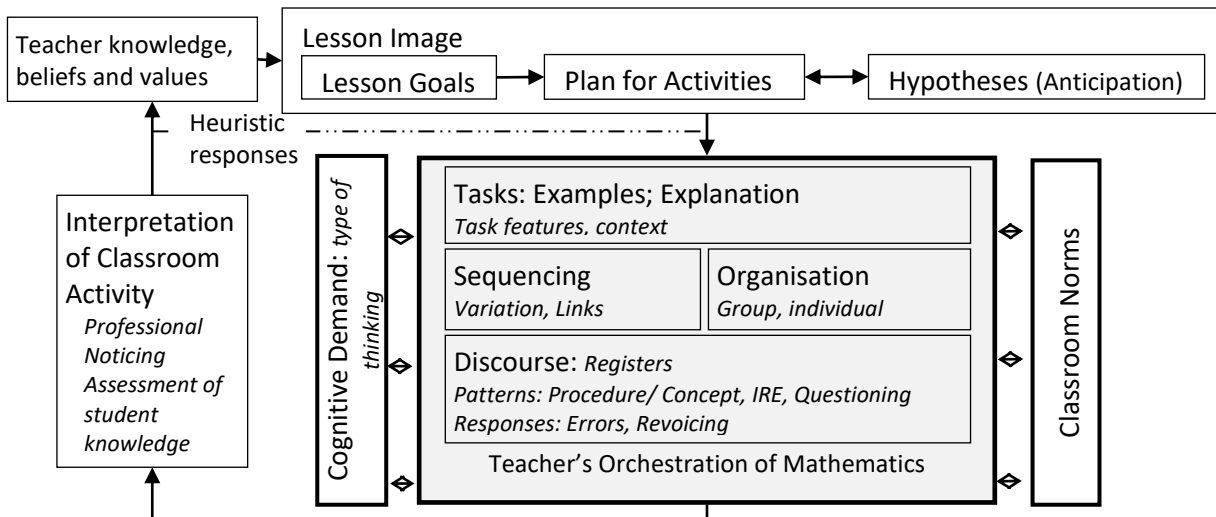

There is a tendency for the teaching of sets with different attainment profiles to have distinctive pedagogical characteristics; for example, contextualised language is more common in low attaining sets, shifting to more formalized mathematical language in higher attaining sets (Dunne et al., 2011). The aim of a wider ongoing study is to explore how individual teachers shift their pedagogy when they teach classes with different attainment profiles. It is anticipated that this will offer insights into how they tailor practice for different sets and the impact this has on the mathematics made available to students. In that larger study, a conceptual framework has been developed to interpret teachers' actions in relation to their orchestration of mathematics (figure 1); in this study the framework is employed to capture practice that the teacher considers typical for them with a particular class (set).

## Theoretical framework

Classrooms are widely acknowledged as dynamic environments, where the complexities cannot be captured in a simple model (e.g. Potari & Jaworski, 2002). Goodchild and Sriraman (2012) argue that the didactic triangle, where vertices represent teachers, students and mathematical content, “serves as a starting point to theorise the dynamics of teaching–learning” (p. 581). For researchers, this raises a question as to how that practice could be understood without taking into account the actions of individual students. This study utilises the notion of classroom norms as a mechanism for taking into account student activity whilst maintaining a focus on the teacher.

Underpinning much of the recent research relating to teachers’ practice appears to be the notion that good practice is related to an inquiry orientation (Boesen et al., 2014; Schoenfeld, 2013). Termed the ‘reform agenda’ in the US, an inquiry orientation is associated with the development of conceptual understanding through the use of rich mathematical tasks, discussions and problem solving approaches (Stein, Engle, Smith, & Hughes, 2008). This is often contrasted with a ‘traditional’ approach, characterised as students working on individual tasks that focus on the efficient application of algorithms, and delivered through transmission style teaching. Many of the existing analytical frameworks are linked to inquiry-oriented goals for the professional development of teachers (e.g. Boesen et al., 2014; Schoenfeld, 2013). Others focus on particular aspects of classroom practice that are considered important, such as the design of rich tasks and the management of discussion (M. Simon et al., 2010; Stein et al., 2008). However, with evidence that traditional approaches to teaching are still common in England (S. Watson & Evans, 2012), the applicability of affordances of inquiry-oriented frameworks to the analysis of ‘typical’ lessons has to be questioned. For example, inquiry-orientated contexts place more value on discussion, explanation and justification, with the potential to make students’ meaning making more visible, than do more traditional approaches.

The Orchestration of Mathematics Framework (OMF) was developed as a tool to build a picture of teachers’ classroom practice (figure 1). Whilst there is insufficient space here for a detailed discussion, an iterative process of development was undertaken, where concepts with traction in interpreting classrooms were considered from the teachers’ perspective, and their relationship to each other. For example, Stein, Grover, and Henningsen (1996) tracked the cognitive demand of tasks as lessons unfold; a notion that has subsequently been drawn on by many researchers (e.g. Schoenfeld, 2013). Here, the focus was on linking the teachers’ activities with other theoretical perspectives, such as relating problems with multiple solution strategies with variation theory (Marton & Pang, 2006) or the press for explanations with patterns of discourse (Imm & Stylianou, 2012). In addition to demonstrating that a wide range of classroom features can have a critical effect on the learning of mathematics, research has indicated that it is not the presence or absence or particular features *per se* that influences the mathematics experienced by students, but rather the nuances of implementation and interdependency (Hiebert et al., 2003). The OMF has been designed to offer a range of lenses that can be brought into play as classroom activity unfolds. As part of this development process, the OMF was used to analyse three publically available video lessons from the TIMSS studies. Whilst not reported on here, the OMF orientated the data analysis and distinct lesson profiles were identified.

**Figure 1: Orchestration of Mathematics Framework**

The central dimensions relate to in-class activity, and in particular the teacher's orchestration of mathematics: that is, the mathematics made available in the shared space of the classroom and the actions taken by the teacher to bring this about. Two significant elements of teachers' practice are the selection of tasks and the management of classroom discourse (e.g. Ainley, Pratt, & Hansen, 2006; Stein et al., 2008). Within each dimension, there is a range of significant elements, such as the role of multiple representations and management of student responses. Variation theory draws on the idea that learning requires variation set against a backdrop of invariance (Marton & Pang, 2006); A. Watson and Mason (2006), amongst others, have drawn on this theory to explicate how the sequencing of questions or activities can make visible critical features of a concept and hence support generalisation. Moreover, variation theory also offers a mechanism as to how other previously identified beneficial features could support learning. For example, multiple representations and multiple solution strategies could be seen as holding the concept constant whilst varying representations and processes.

The notion of cognitive demand offers a way to categorize the "the level and type of thinking that a task has the potential to elicit" (Boston & Smith, 2009, p. 122). Stein et al. (1996) introduced a rubric where 'memorization' and 'procedures without connections to concepts' are classified as low demand, whereas 'procedures with connections to concepts' and 'doing mathematics' are classified as high demand. As such, this can be viewed as potential of the teacher's orchestration of mathematics to influence student learning. Cobb, Stephan, McClain, and Gravemeijer (2001) offer an interpretative framework that coordinates social and psychological perspectives, where the social aspect is framed in terms of norms. All lessons and all interactions are unique, but norms offer a way to interpret interactions as typical or atypical, which offers the possibility of generalising beyond particular incidents. In particular, their notions of sociomathematical norms and mathematical practices can identify what is considered legitimised mathematical activity in that particular context.

The lesson image, activity and interpretation cycle draws on Simon's (1995) work on hypothetical learning trajectories, but extends the focus to include performance and engagement goals, as evidence indicates that not all teachers focus on learning (Amador & Lamberg, 2013). This captures

the iterative planning, activity and interpretation that starts before the lesson and continues as the lesson unfolds. Teachers' interpretations of mathematical activity are predicated on what they notice; the conceptualisation of professional noticing by Jacobs, Lamb, and Philipp (2010) is one construct drawn on here. Taken together, the dimensions offer a way to build a picture of the classroom based on the features as they occur and interact in the course of a teacher's normal practice.

## **Methodology**

This paper reports on a section of a pilot study, undertaken as part of a larger ongoing qualitative case study, following the interpretative tradition. The research question explored in this paper is how viable the OMF is as an analytical tool for charting a teacher's pedagogical approaches and the mathematics made available to students.

For a pilot study, two secondary mathematics teachers known to the author have been recruited. Decisions regarding selection of classes and the timing of observations resides with the teachers, in order to minimize the imposition on them and their schools. So far, data have been gathered from one teacher and two lessons with a year 8 class (12 to 13 years old), taught ten days apart. The author acted as a non-participant observer, with the OMF used as an observation pro forma. The lessons were recorded by two static video cameras and lesson artifacts, such as students' work and teaching resources, were collected. Pre- and post- lesson semi-structured interviews were conducted with the teacher, focusing on how and why the lesson was planned in the manner chosen, and on moments the teacher thought important for learning, including whether these were as anticipated or unexpected.

The audio data from lessons and interviews was transcribed. Lesson activities were coded as being mathematically relevant, organisational or not mathematically relevant. The mathematically relevant sections of the videos were then reviewed; interactions were mapped to the OMF and cross-referenced with the observation notes. The interviews were analysed for evidence of the teacher's interpretation of classroom activities and their lesson image. The analyses of the two lessons were compared; consistencies and contradictions in the dimensions of the OMF were sought, to see whether there was evidence that observation of a few lessons could build a sufficiently representative picture of a class to allow comparison with others (Staub, 2007). All the analysis in this pilot study has been conducted by the author; it is anticipated that another researcher will review the dimensional analysis before the next stage of the wider study.

## **Findings and discussion**

In this section, two linked extracts from the first lesson will be used to illustrate how the dimensions of the OMF were populated (figure 3). Then the comparison of the two lessons will be discussed.

### **Lesson 1**

The students individually attempted to calculate the areas of six different shapes. The numerical answers were shown, in a mixed order, alongside the questions at the start. After nine minutes solutions were discussed as a whole class.

**Figure 2: Questions projected onto classroom whiteboard**

- 78 Teacher: OK number one, what did you do and what answer did you get?
- 79 Azariah: I got five times two.. ten meters.. centimeters meters squared
- 80 Teacher: Ten centimeters squared, perfect, units are really important ok. Finley second one then.
- 81 Finley: I did four add eight, twelve divided by two, six.. times five makes thirty centimeters squared.
- ⋮ [the last question]
- 113 Teacher: Sixteen centimeters squared, what did you do to get it?
- 114 Sam: It was just the last...
- 115 Teacher: Just the last answer, did anyone manage to do it with the maths? Raj
- 116 Raj: Three times.. three times four so it's the bottom rectangle
- 117 Teacher: Yep
- 118 Raj: and that's 12 meters squared, but then you triangle the top bit, which is three times four meters and divide by two
- 119 Teacher: So what Raj did, and I'm guessing what most people did who managed to get that was to draw a little line there to do our 3 times 4 which is 12 meters squared and work out the triangle on top which was 4 meters squared ok good.

### Analysis of Lesson 1

Line 78 is an example of the teacher indicating that a procedural explanation was expected as part of a response. When answering subsequent questions, most students provided a procedural explanation without prompting but other types of explanations were not offered, indicating an established sociomathematical norm. Line 78 was also the start of an IRE sequence (teacher initiation, student response, teacher evaluation), which was the predominant form of teacher-student interaction in the whole class context. In lines 80 and 113, the teacher repeated correct answers, and in line 119 reworded a more complex student explanation, claiming understanding of student reasoning. In terms of social norms, this contributed to accountability residing with the teacher.

Interpretation of activity: <i>errors, explanations not explored</i>	Tasks: Examples; Explanations: <i>Multiple solution strategies possible but no acknowledgement. All questions standard format.</i>	Classroom Norms: <i>Social Norms: Agency and <b>accountability</b>: resides largely with the <b>teacher</b>. SM norms: <b>procedural explanation</b> counts as explanation. Mathematical practices: area equates to multiplication; units vital</i>
	Sequencing: <i>Unsystematic variation and links were not explored.</i>	
	Organisation: <i>Individual working</i>	
Cognitive Demand: <i>Potential- high; As enacted- low</i>	Discourse: <i>Teacher led; Teacher requested (procedural) explanation (line 78), followed up when not provided (line 113) IRE with teacher evaluation (lines 78-80, 80-81, 113-119) Teacher re-voiced contributions; repeating correct answer (lines 80, 113), rewording more complex explanations (119)</i>	

**Figure 3: Extract from lesson 1 OMF summary**

## Integrated OMF for Lesson 1 and 2

When the two lessons were compared the overall profiles were very similar, and the differences in use of context and mathematical practices could be explained by the different lesson topics. More important is the fact that contradictions between the two lesson analyses were not apparent. From these profiles a summary OMF was formed (figure 4) specific to this class. The central core, consisting of tasks, sequencing, organisation and discourse, located specific instances of the teacher's activities, with their impact interpreted in the wider framework. For example, questions were posed that could have been solved in multiple ways or with the integration of multiple representations. However, the IRE pattern of interaction, focusing on a single procedural calculation, was mirrored by the students in their work and led to the categorization of low cognitive demand.

Links between dimensions did emerge. For example, there were two occasions where pseudo-contexts were used: that is real-world objects such as cars or apples were introduced, but in contrived and unrealistic ways. Students made errors in the whole class discussion that were not explored; the teacher focused on explaining the abstracted mathematical procedure whilst the students involved focused on interpreting the context. Follow-up questions were asked by the teacher, but when students' responses did not conform to the abstracted mathematical solution the teacher moved on by offering a direct demonstration of the 'correct' procedural answer. In the post lesson interview, the teacher expressed surprise that errors were made on those questions and was unclear as to why this had occurred. The activities related to the use of pseudo-context can be traced through the dimensions, contributing to the conclusion that the teacher did not explore student thinking and that mathematical competence equates to efficient production of standard solutions.

OMF	Lesson Image		
Interpretation of classroom activity: <i>Professional noticing - no evidence of exploration of student thinking when it was not directly relatable to a standard solution.</i>	Goal: <i>Performance</i>	Plan: <i>Exam style questions</i>	Hypotheses: <i>Familiarisation</i>
	Tasks: <i>Multiple solution strategies were possible, but rarely explored. (4 occasions students offered alternative calculation- not evaluated or compared)</i> <b>Lesson 1: No context; Lesson 2: Pseudo-context 2/6</b> Sequencing: <b><i>Questions sets unsystematic variation. All questions dealt with in isolation; links between questions were not explored [Dimensions of variation and range of permissible change not made explicit]</i></b>		Classroom Norms: <i>Social Norms: Agency and accountability: resides predominantly with the teacher.</i> <i>Sociomathematical norms: procedural explanation counts as explanation.</i> <b>Mathematical competence equates to obtaining correct answers efficiently (errors to be avoided).</b> <i>Mathematical practices: Lesson 1: Area equates to multiplication. Lesson 2: Proportional reasoning equates to multiplication</i>
Cognitive demand: <i>Potential - high As enacted - low</i>	Organisation: <i>Individual working- tables in groups of four; peer to peer discussions were had.</i>		
	Discourse: <i>Registers: teacher used colloquial language with no evidence of inducting students into a ‘vertical discourse’. Patterns: IRE dominant form of interaction. Correct answers acknowledged, often repeated or extended. Errors often ignored; when acknowledged focused on moving to standard solution, reverting to direct explanation if initial follow-up failed. Extended student explanations taken over by the teacher.</i>		

Figure 4: Summary OMF for lesson 1 and 2

## Conclusion

When the dimensions of the OMF are considered, distinctive patterns of discourse consistent across both lessons were identified, and the classroom norms indicated that these were regular patterns of interaction. Moreover, the same restricted range of task features were utilised throughout both lessons and the sequencing of questions was classified as unsystematic variation. This provides some evidence that the framework was effective in characterising a teacher's pedagogical approaches. However, whilst the teacher indicated that these lessons were 'typical', the timing of the data collection meant that they were focused on reviewing previously met material. As such, there may be features that are part of the teacher's usual repertoire but are not captured here. For the larger study, when comparisons between classes is sought, collecting data at the same time of year and when the classes are being taught similar material could ameliorate some of these issues.

All elements of the lesson that were classified as being mathematically relevant were mapped to the OMF. It may be tempting, therefore, to say that the model is sufficient to capture mathematically significant classroom events. However, the dimensions of the framework have been populated by features identified as significant in the literature and these have orientated the data collection and analysis, therefore a complete mapping could be anticipated. Instead, the question is whether the orientation this framework offers provides insights into the characteristics of teachers' pedagogical moves more powerful than a list of features and with sufficient validity to allow comparison. The evidence presented here indicates that this may indeed be the case, but further research is needed.

# Using drama to change classroom discourse

Ove Gunnar Drageset<sup>1</sup> and Tor Helge Allern<sup>2</sup>

<sup>1</sup>UiT – The Arctic University of Norway, Norway; [ove.drageset@uit.no](mailto:ove.drageset@uit.no)

<sup>2</sup>Bergen University College, Norway; [tor.helge.allern@hib.no](mailto:tor.helge.allern@hib.no)

*This article provides insights about a project studying how process drama can be used to change classroom discourse in mathematics. The idea is to use process drama to help students practice with roles relevant for mathematics discourse, and then use these roles to help students become active participants of learning during regular mathematics lessons. This article reports from the first lesson conducted after the process drama, and finds a lesson where the students dominate talk, especially asking for and explaining methods and reasons, and where the teacher acts as a moderator.*

*Keywords: Classroom discourse, process drama, communication.*

## Introduction

Based on our own studies (Drageset, 2014; 2015) we have observed that mathematics teaching in our area is typically teacher dominated with students rarely contributing to the discourse beyond answering questions. We wanted to find ways to activate students as participants of the mathematical work of the classroom. In drama methods we found tools to develop roles and then rehearse them during a process drama. To develop and rehearse, we designed a process drama called Out of Syria with the students grouped as families. The play was set in Damascus and the families had to escape the war. Although process drama may be used as a subject of its own, emphasizing the artistic process more than the learning outcome, change of attitudes and knowledge will always be important. Thus, applied drama often deals with topics in need of change, and the purpose of drama is to empower the participants (Bolton, 1998; Landy & Montgomery, 2012; O'Neill 1995).

During the travel the families had to solve both practical and mathematical tasks. Simple scenery, sound effects, music, costumes and the physical actions of the participants were used to create fiction. Different rooms were used for home, bus, apartment in Egypt, border crossing and boat travel. Dramatic effects were used by lightening contrasts, sound effects and by the researchers playing different roles such as police, smugglers and coastal guards. An important goal for the process drama was to create a reference among the pupils to role aspects such as the authority, the skeptical, the curious, and the mediator. Each member of the families was assigned one of these roles. We wanted to examine if and how the reference to these roles would contribute to a change in classroom discourse, i.e. to create discussions, argumentation and reasoning. The elder should always ask all members of their meaning, and try to enlighten their reasoning for this, before deciding. The curious should ask why as often as possible, while the skeptic should try to oppose and suggest alternative solutions or decisions. Using the situation of refugees from Syria as our topic might seem insensitive. It was, however, conducted with care and related to learning about other areas than mathematics.

A few weeks after the process drama, the researchers returned to the classrooms to use the roles in ordinary teaching. An important point is also to change the teacher role, avoiding to play the elder (authority) and thus open a space for the students to use. The aim with this article is to do an analysis of the first lesson after the process drama in order to characterize the lesson as a whole and describe qualities of the discourse.

## Theoretical framework

Studies related to classroom discourse often describe different ways teachers dominate the discourse. Normally these fit into a pattern described as IRE (initiation-response-evaluation) where the teacher initiates the questions, the students respond to them, and the teacher evaluates the response (Cazden, 1988; Mehan, 1979). IRE is often related to procedure-bound discourse, with little emphasis on ‘students explaining their thinking, working publicly through an incorrect idea, making a conjecture, or coming to consensus about a mathematical idea’ (Franke, Kazemi, & Battey, 2007, p. 231). Other teacher-dominated patterns are described, such as uni-directional communication (Brendefur & Frykholm, 2000) and conventional text-book classroom culture (Wood, Williams, & McNeal, 2006). However, the teacher domination appears in different ways, which might be illustrated by the four types of communicative approaches suggested by Mortimer and Scott (2003). Three of these approaches can be seen as illustrations of different types of teacher dominance. In B – the non-interactive / dialogic approach – several points of view are paid attention to but without allowing others to participate. This could occur when a teacher presents several points of view and discusses these without allowing students to participate actively. In C – the interactive/authoritative approach – the participants are allowed to participate but only one point of view is paid attention to by the teacher. In D – the non-interactive / authoritative approach – only one point of view is attended to and the teacher does not allow others to participate.

The alternative to teacher domination is found in A – the interactive / dialogic approach – where several points of view are paid attention to and people are allowed to participate actively. Others have also described communicative approaches where students are actively engaged. One such type of approach focus on sharing ideas, such as strategy-reporting classroom culture (Wood et al., 2006, and reflective communication (Brendefur & Frykholm, 2000). Another type of classroom communication reported is where the students work alongside the teachers solving problems, such as inquiry/argument classroom culture (Wood et al., 2006) and instructive communication (Brendefur & Frykholm, 2000).

While the above are examples of characterizing entire practices, other scholars have studied single utterances in more detail. In one such approach, Alrø and Skovsmose (2002) identified eight communicative features: getting in contact, locating, identifying, advocating, thinking aloud, reformulating, challenging and evaluating. While all these eight communicative features were present in both student-student and teacher-student interactions, others describe different types of student participation, such as Drageset (2015) describing five types of students interactions; initiatives, explanations, partial answers, teacher-led responses, and unexplained answers. Students explanations might be particularly interesting, consisting of explaining reason (why), explaining concept and explaining method (how and what).

There also exists frameworks and concepts describing how teachers orchestrate discourses in the classroom. Ponte and Quaresma (2016) suggest a framework to analyze discussions that distinguish between management actions and actions related to mathematics. The four teacher actions related to mathematical aspects are inviting, informing/suggesting, guiding, and challenging. Fraivillig, Murphy and Fuson (1999) also focus on similar teacher actions by describing how a teacher use students’ ideas to lead them towards more powerful, efficient and accurate mathematical discussion by eliciting, supporting, and extending children’s mathematical thinking. While Fraivillig et al.

(1999) developed the concepts from a study of a particularly skillful teacher, Drageset (2014) developed a framework based on a study of five rather ordinary teachers. The result was that the redirecting, progressing and focusing framework (Drageset, 2014) that describes actions where the teacher actively involves the students (such as enlighten details and justify), and also describes actions where the teacher is more authoritative and less interactive (such as simplifying, closed progress details and demonstrating) than described by Fraivillig et al. (1999). Teacher dominance is also described by others, such as through funneling (Wood, 1998), the Topaze effect (Brousseau & Balacheff, 1997) and guided algorithmic reasoning (Lithner, 2008).

## Method

This study is part of a larger study on how the use of drama and roles can change the classroom discourse. The study includes classes from primary, secondary and pre-service teachers. The data in this article comes from a primary classroom.

The long term goal of this project is to develop knowledge that can be used to educate teachers in changing classroom discourse. With the lesson reported in this article, we wanted to try out a lesson with the students to understand what is possible using roles exemplary. To achieve this, the lesson was led by one of the researchers. This means that we are exploring the potential to change students' participation using roles, analyzing qualities of students' participation. We will also look at the teacher's (researcher's) actions in order to understand the reason for any changes in student participation. To see how students normally participated, we filmed a few lessons before the process drama.

The selected classroom was chosen of convenience and consisted of 17 students from a typical upper primary school in Norway aged 11-12. None had been refugees or had any first-hand knowledge of Syria or refugees. Their teacher has a typical Norwegian four-year teacher education with some specialization in mathematics.

The lesson was filmed and transcribed. The data was then analyzed using conversation analysis (Linell, 1998), describing qualities of single utterances from student and teachers, grouping them together to establish categories.

## Findings

The lessons before the process drama showed a traditional IRE-classroom. The students answered the questions they were asked, often answering tasks and sometimes explaining concepts and methods. The teacher dominated the talk.

The lesson in focus here is the first lesson after the process drama. The teacher of this lesson, which was one of the researchers, started by discussing the roles learned during the process drama. The students suggested important features from each role, especially the elder, the skeptic and the curious. They then agreed to use these roles actively during the coming lesson. Sometimes during the lesson, the teacher reminded the students of their roles, or challenged some of them to use one specific. The following excerpts are carefully chosen to illustrate the typical discourse of the lesson.

The students were given two tasks about decimals and told that they should use two different methods to solve them. Prior to this, the students had worked with informal methods to operate on decimals. The tasks used names from the process drama, Omar and Samira, and told them that Omar had 3,2

liters of water while Samira had only 2,6 liters during a travel in the desert, and asked how much Omar had to give to Samira to get level. The other task was similar, but with Omar and Samira having 0,7 and 5,3 liters, respectively. Early in the lesson, one student volunteered to tell how he solved the first task of sharing water (figure 1):

Student: Here I only thought, first I made a number line, and then I thought... what was it? Two comma ... six? (draws a number line with 2,6 to the left and 3,2 to the right)... And then I took as many markers as it was... between the two (points out 2,6 and 3,2, and draws a marker for every tenth, see figure 1)... three comma zero, three comma one, and then three comma two (points)... and then... and then I just jumps like this, this, this, there (draws three jumps from each side towards the middle, marks the middle with a vertical line). And then I see how long it was from the middle to there (points out 3,2), it was three... or it was three to the middle. And then I thought that it just were zero comma three.

**Figure 1: Solving the first task – first strategy**

When explaining an alternative method for solving the same task as above, a student said this:

Student: 2,6 and 3,2 (writes them on the blackboard, look at figure 2) then I just jumped... then it became 3,0 there (writes it below 3,2) and 2,8 there (writes it below 2,6, and draws an arrow from 3,2 to 2,6 with 0,2 above the arrow). And after that I just jumped one there (draws a line between 2,8 and 3,0). And then it became 2,9 and 2,9 (writes 2,9 below both 2,8 and 3,0, and writes 0,1 above the line between 2,8 and 3,0). And then I just added these two (0,2 and 0,1) and then I got 0,3 (writes =0,3 to the right).

**Figure 2: Solving the first task – second strategy**

These two explanations are similar as they seek to explain every step from task to answer, telling others how the answer was found. Such explanations naturally occur following a request to tell what had been done or how a solution were found, and were the most common type of explanations during the lesson.

However, this was not the only type of explanation observed during the lesson. An interesting exchange of meaning came when a student disagreed to the first solution (figure 1):

- Student A: Yes, but I found another answer
- Student B: What did you get?
- Student A: 0,6
- Student C: Me too, but then I found out that I had got wrong
- Student D: 0,3
- Student B: Why did you get 0,6?
- Student A: Because I counted on both sides
- Student E: Me too
- Student B: Yes, but in the middle. Thus when you jump with both of them then you should not count it and, because, the question was thus, the question was not how much was between them, it asked how much it was, how many liters Omar had to give Samira then. You should not count how far, it was only like, when they met. Where they met you should stop counting, you should not continue counting... and down. That was only therefore.

There are several things worth noticing in this discourse. First of all, a student challenges another. When the two opposing answers are presented, student A is asked why she got 0,6. The answer is short, but explains the reason for the answer clearly as the student points at the drawing on the blackboard. We can also see two instances of support for the answer 0,6, even though one had changed meaning. In the end student B explains the reason why he means 0,3 is correct and 0,6 is incorrect. It is a long explanation, and the student struggles to find the words, but ends up convincing the other students that 0,3 is correct. And during all this, the teacher is not participating.

Explaining reason is different from explaining method (Figure 1 and 2) as explaining reason seeks to argue for and justify the solution, explaining why instead of how or what. Explaining reason occurred frequently during the lesson. Sometimes the reason was explained quite clearly, other times more struggling (like the long explanation of 0,3 being the correct answer), and some times the explanation was insufficient. Explaining reasons naturally came as a result of someone asking why a solution is correct, or as above as an argument when challenged with an alternative solution.

The examples above illustrate the discourse of the lesson, where the students frequently ask questions to each other (why, how, what) and frequently explains method and reason. Also, student challenges and clarifications are observed.

The teacher did participate during the lesson in different ways, mainly by asking questions such as these five examples from different parts of the lesson:

- 1) On the first task, is there anyone that wants to tell the method used on that one?
- 2) Can you show us on the blackboard?
- 3) Were there anyone else that got three comma zero?
- 4) Okay. Are there anyone that has done it in another way?
- 5) Yes. And what was the answer then?

The first two is about enlightening details, either by asking a student to tell the method or by using the blackboard so that it is easier to follow the line of thought. The third and fourth are examples of how the teacher asked for alternative strategies, and the fifth is an example of how the teacher sometimes requested clarifications. Evaluations or support from the teacher were observed, but rarely. Funneling and guided algorithmic reasoning were simply not observed at all.

## Conclusion

This first lesson after the process drama contained considerably more student than teacher talk, as exemplified by the excerpts. The most frequent types of student interactions were questions (why, what, how) and explanations of method and reason. The questions can be related to the roles of skeptic and curious, and the result of these were explanations and arguments. These questions and explanations played out as a discourse where the teacher acted as a moderator. The teacher did not take the typical role of the elder (authority) but instead allowed the students to take this role. This type of discourse has similarities with both interactive/dialogic communication (Mortimer & Scott, 2003), strategy-reporting classroom culture (Wood et al., 2006) and reflective communication (Brendefur & Frykholm, 2000) as the focus is on sharing different strategies. But the lesson goes beyond these where the students' request explanations and the discourse goes on with explanations, questions and clarifications without teacher participation. In these cases, the lesson might be defined as instructive communication (Brendefur & Frykholm, 2000), where the teacher requests details, asks for alternative strategies, and requests clarifications. However, it is not an inquiry/argument classroom (Wood et al., 2006) as the teacher is not really working together with the students to solve problems.

Reduction of complexity, such as funneling, guided algorithmic reasoning and the Topaze effect, which are the most frequently used teacher actions in other classrooms at upper primary level in the same area (Drageset, 2015) were not observed at all. It is also evident that the lesson does not follow an IRE-pattern, as students both initiate (ask questions) and evaluate (agrees, requests explanations, and challenges).

A majority of the student interactions, especially their ability to ask, explain and challenge, is similar to the roles practiced upon during the process drama, especially the curious through the students' use of questions (why, how, what), but also the elder through the willingness to listen to alternative strategies and assess which is the best, and occasionally the skeptic through questions and challenging.

The role of the teacher was withdrawn and might seem of little importance. But this change does not happen by itself, the teacher is the key to the change. First by leaving the typical 'elder' role and inviting students to fill this role by asking them to decide right and wrong and assess each others'

suggestions. Secondly, by acting as a moderator to encourage the use of other roles such as being curios and skeptic.

Further study of the process drama itself, and the lessons filmed before the process drama, is needed to understand how much the students' involvement changed and if it is possible to explain any changes by our use of process drama. In general, there is a need for research related to the use of roles to establish different types of discourse, and also how teachers can learn, rehearse and use roles to develop their practice.

*In different moments of teaching, such as in launching, exploring and discussing a task, teachers carry out different actions, which have a critical influence on the classroom dynamics. Our aim is to identify and understand the actions that Berta, a prospective teacher, undertakes in instructional practice to promote students' conceptual learning of rational numbers. For this paper, data were collected and analyzed from classes observed and videotaped. To promote and organize an exploratory environment, Berta launched the task, strived to promote interactions, organized students' solutions, and attempted to promote a discussion environment with inviting, supporting and challenging actions in order to lead students to learn rational number concept.*

*Keywords: Teachers actions, moments of practice, prospective teachers, rational numbers.*

## Introduction

Rational numbers are a topic that raises many difficulties for students. Teaching rational numbers leading to conceptual learning is a challenging task for teachers. This topic, very important in the elementary mathematics curricula, requires the exploration of different representations to support students' learning. In fact, the complexity of these numbers is related to the different meanings (such as part-whole, quotient, measure, and operator) and representations (such as decimals, fractions, percent, active and pictorial representation) that they may assume (NCTM, 2007). To foster students' understanding of mathematics concepts teachers are challenged to promote an exploratory learning environment (Ponte, 2005). Research has given attention to prospective teachers' knowledge about how and why to teach rational numbers in different ways. For example, a study by Isiksal and Cakiroglu (2011) indicates that prospective teachers have different perceptions of children's mistakes and different suggestions of strategies that may be followed including using multiple representations, using problem solving strategies, making clear explanations of questions, and focusing on the meaning of concepts. However, it is important to understand the practice that prospective teachers, with these teaching views, accomplish and what kind of action takes place in the classroom. There are few studies focusing on the teaching practice of prospective teachers, paying attention to their actions in different moments when they explore different tasks with their students and to the communication that entails. So, in this paper we aim to identify the actions that a prospective elementary school teacher (Berta) accomplishes in different moments of instructional practice, as she strives to promote students' conceptual learning of rational numbers.

## Prospective teachers instructional practice

Teachers' practice could be analyzed with different approaches (cognitive or sociocultural). Ponte, Quaresma and Branco (2012) reconciling the two approaches attend to curricular and social context, teacher knowledge, actions and teachers reflection. In this regard they propose to analyze teachers' practice with reference to two main aspects: the tasks proposed to students and the communication

established in the classroom. In respect to tasks, teachers may choose to just offer simple exercises or also propose challenging exploratory tasks, problems and investigations in which the students need to design and carry out solving strategies based on their previous knowledge (Ponte, 2005). Communication may be oral or written, and it includes both linguistic and mathematical representations. One important aspect of communication is questioning, involving confirmation, focus, and inquiry questions (Ponte et al., 2012). Communication also includes those representations that are used to aid in solving a task, such as building or illustrating objects, concepts, and mathematical situations (NCTM, 2007). Another important aspect of communication is explanations. Instructional explanations may have different purposes and characteristics and may be carried out at different times during a lesson (Charalambous, Hill & Ball, 2011).

Shaped by communication we have the teachers' actions that influence the classroom dynamics. In different moments of work the actions address the development of mathematical concepts and processes (Ponte, Mata-Pereira & Quaresma, 2013) and management of the learning environment (NCTM, 2007). In an exploratory environment the work with a task may develop in three fundamental moments: Launching, exploration and discussion (Stein, Engle, Smith & Hughes, 2008). In launching the teacher organizes the students and the materials (NCTM, 2007) and proposes the *task informing, inviting and guiding* (eliciting) the students to solve it (Lobato, Clarke, & Ellis, 2005). The students have to understand the task, identify conditions and data. To promote the quality of the discussion of the task and knowledge that may be built, the teacher must discuss key aspects of context and verify if the students recognized them. Further, the teacher must discuss and relate mathematical ideas with key contextual characteristics and build a common language clarifying the unknown or confusing vocabulary for students. Note that teachers should take care of maintaining the challenge of the task (Jackson, Garrison, Wilson, Gibbons & Shahan, 2013). When students begin their work, in pairs or groups, it is important that the teacher *guides and challenges* them to build together their solutions, promoting productive interactions, and register solutions in an organized way (NCTM, 2007). During this time the teacher monitors students' work, questions them and clarifies doubts related with content or the task context *informing*. Again, the teacher supports students, questioning or even explaining, but must not decrease the level of demand of the task and give the opportunity to different solutions to emerge by challenging students. During this moment the teacher selects solutions and structures the sequence of the discussion with a focus on the purposes of the task (Stein et al., 2008). The third moment is the discussion of the task where the teacher orchestrates students' ideas, organizes and supports oral and written communication, promotes interaction between students, connects ideas and guides students towards a powerful mathematical solution (Stein et al., 2008). Addressing the development of mathematical concepts and processes Ponte, Mata-Pereira and Quaresma (2013) consider four main types of actions: *inviting*, to begin the discussion; *supporting/guiding*, leading the students through different kinds of questions; *informing/suggesting*, giving information or validating students' ideas; and *challenging*, encouraging students in interpreting situations, finding new representations, making generalizations and justifications, making connections, and evaluating their work. At the end of the discussion, the teacher must promote reflection on the work accomplished, the new concepts and procedures that emerged, and institutionalize the expected learning. The teacher may also review other concepts and connect with other situations reinforcing the main ideas (Stein et al., 2008).

## Research methodology

This paper emerged from a larger study of an exploratory nature and takes a qualitative and interpretative approach, following a case study design (Stake). We analyze the supervised practice of three different prospective elementary school teachers to characterize it and to understand the challenges and options that they face in different moments of instructional practice, as they strive to promote students' conceptual learning of rational numbers. Data were collected from semi-structured interviews and video-stimulated recall interviews after class. Four lessons were observed, videotaped and fully transcribed. We also collected documents produced (lesson plans and written reflections). For this paper we analyze one prospective teachers and her instructional practice in one of her lessons. Data were analyzed based on categories that emerged from the above framework, namely teachers action in launching, exploring the task and in discussion of the task combining the actions *invite*, *inform*, *guide* and *challenge*. Bertas' case, a prospective elementary school teacher, could represent the teachers that suggest an exploratory approach to develop conceptual knowledge of their students. So, we aim to identify the actions that she accomplishes in different moments of instructional practice, as she strives to promote students' conceptual learning. In the Teacher College last semester, Berta considered important that students understand the concepts and develop mathematical communication through an exploratory approach, valuing contextualized situations and open tasks. In the mathematics education course she analyzed the video of a class and its teacher's plans and reflections. When she was about to teach the notion of percentage selected the task of the video to explore with her students. We should note that her practicum takes place in a 6<sup>th</sup> grade class with 20 students who don't have experience in discussing open tasks. Comparing the knowledge and skills of her students with the students of the video, she defined her teaching purpose and decided to promote her students' conceptual learning of percentage, the development of mathematical communication, and problem solving skills.

## Actions of a prospective teacher in different moments of teaching practice

### Launching the task

Berta introduced the task "Petrolex" distributing the worksheet to each student and asking one student to read it (figure 1). In order to promote "a short discussion with students about the thematic of fuels price" (WR), she highlighted key aspects of the context of the task, ensures that the students recognize them, and reinforces the main question:

As you may have already noticed, fuel prices vary depending on the price of oil.  
The fuel pumps Petrolex increased the price of gasoline by 10%, which meant that drivers protested a lot. Given this, the Director of Petrolex changed his mind and lower the price of gasoline by 10%.  
Did the gasoline returned to the previous price? Justify your answer.

**Figure 1: Berta Percentage Task**

Let's see. The gasoline has a price... Next you will discuss that but... The gasoline has a price, right? You will increase the price in 10%. But the drivers don't like the new price and protest... Then the director decreased again the price in 10%. What does this mean... Diana [as others] is telling us that gasoline returned to the same price ... And they say no... Who thinks that the price returned to the same value?

Berta invites, informs and guides the students in understanding the task and feel challenged. In response to some students said that the price went back to the original price and others disagreed. The discussion began and Berta provided information about the organization of the work and stressed the importance of making written records of the solving processes to support the discussion. The prospective teacher invited the students to solve the task, organized students' time and reinforced the importance of recording their different ideas about the challenge proposed. Berta ended the initial discussion and emphasized that it has to be made in pairs:

So what will you do? We will not say more and join your partner and try to understand what would be the price of gasoline be... Will it return or not to the initial price? We have five minutes and I will circulate between the tables to try to understand... Attention, what you have written. Say yes, say no, do not erase anything! Leave everything as it is! Then we will see what you thought, what do you see and what is the final decision.

### Exploring the task

The students began to work in the task and Berta circulated around the pairs, observing solutions and supporting struggling students. One student requested her help and she highlighted the main question posing different questions:

Student 1: This is a tricky question!

Berta: Why? I do not say anything... I'm only asking if it is the same value of the beginning? There is no trick!

Student 2: It returns to the initial price!

Berta: So we can see it... Can you try a way to view it?

Student 2: Calculating!

Berta: You can do it!

Student 2: Can I make up a price?

Berta: You can make up a price! But look carefully what the price is...

Student 1: 60 euros.

Berta: You did not have to say an actual price but do you think that this price is so...?

In this dialogue Berta posed an inquiry question reinforcing the main question. The students' idea was not right and the prospective teacher guided students' work by suggest/informing them to try different values and verify the conjecture. The students suggested a price, she confirmed the idea and reinforced and focused students on the nature of the price. Before Berta letting the students work on their own, she tried to promote students' interactions and warned the class about the importance of the written record of the solution:

Okay... So you are working in pairs and therefore you can talk about that and make up a price . . .

[To the class] Attention of what you write down... Do not erase so we can see how you thought!

Berta wanted the students to discuss their options and insisted that they had to work in pairs, promoting interactions. Anticipating and preparing the moment of whole class discussion, she

emphasized the importance of recording all the ideas. As she asked not to erase any solutions we can assume that she wanted the wrong solutions so that the errors and different ideas could be discussed. Berta observed the students' work and supported and guided, in a provoking way, other students. However the class ended and the discussion happened in the next day.

### Discussing the task

Berta began the class by organizing the students in the same pairs and distributing back the solutions that she had already analyzed at home. One pair had a good solution but it was not well organized. The prospective teacher numbered the different steps and checked with the students her proposed organization. She informed the pair of the importance of organizing written communication to clarify their ideas to others and skipped the opportunity to discuss it with all students. After this, she began the discussion of the task.

To promote a discussion environment and to invite students to the work, Berta recalled the first idea of many students. She asked a student to present his first idea and then the second solution he built when he realized the error. We notice the sequence of solutions presented:

Most of you [initially] considered that the price of gasoline would return to the initial value. After the increase and after the decrease! So your colleague will start by explaining the first part. Why did you think that the price returns to the same? . . . Do not copy anything, first let's see...

After the students registered their solution in the white board, one student explained their idea (figure 2):

**Figure 2: Tomas first solution**

I did... a friend and I... I lent pens [to a friend] and I went back and ask him for the pens. [It is the same situation] and so the price is back to the same!!

Berta guided the presentation and asked the students if they tested their idea with a value. She challenged the students by asking "Have you verified if it gives you the same value!?" establishing connection with the second solution of the same pair. The student recorded the second solution with 10 euros as a starting value and explained his ideas with the support of Berta:

**Figure 3: Tomás' second solution**

Tomás: The gasoline costs 10 euros and 10% of 10 euros is 1€.

Berta: . . . Why did you do 10% of 10?

Tomás: To know how much is the value we have to add up to 10 €.

Berta: Exactly! And then?

Tomás: Then I added 1 euro to 10 and gave 11 euros. And then people protested...

Berta: . . . How much was the increased value of fuel? . . .

Tomás: It increased 1 euro.

After Berta made a supporting question the student replied:

Tomás: Then it decreased by 10% and 10% of 11 is 1.10 euros.

Berta: And here Tomás did very well... Because Tomás calculated 10% of 11 euros and did not calculate (as some students did) 10% of 10 €? . . . Because we had to see 10% of what we had again! Right? So the amount of the discount is 1.10 €. OK? So the fuel is 9.90 €. If you were a driver, would you prefer this to happen or not?

The students presented their work and to support their presentation Berta posed an inquiry question, challenging Tomás to explain why he and his partner did multiply 10% of 11 euros. After that she focused the students to the specific procedure. At the end she recalled Tomás' explanation and reinforced the students' focus on the main question. Others pairs of students presented their work with a more realistic value. To help students' presentations, Berta organized their computations and clarified issues related to mathematical language. At the end of the presentation, she recalled the task and the two solutions and focused students' attention on the reference unit. For that, she built a representation in hard paper and related it to the students' solutions. However she struggled with the students' difficulties in "seeing" the difference between before and after the rise of gasoline. Berta first explained the conceptual idea of the difference between 10% of the first unit (brown) before of the increased price and the 10% of the second unit (pink) after the decrease of the price:

**Figure 4: Final synthesis scheme**

The 10% will now relate to another unit, not the same as before? Now we have a different unit . . . And this 10% is bigger than that one . . . We have a new price with plus 10%. You are thinking well! I stay with this unit but now I have to withdraw the 10%. But the 10% are not the same! . . . Because the value of the unit is different.

Given the difficulty of some students in understanding the explanation, Berta assumed that maybe other percentages would allow the students "to see better" and presented a new representation with 20% making more evident the difference between the increase and the decrease in the final price. In the synthesis she said:

- Berta: If you noticed the starting price was up here (bigger heavy paper). But the final price is already here (less heavy paper). What does it mean? The final price will always be lower than the initial price, right? . . . We had seen it here for € 1.5 that gave us € 1.48, right?
- Student1: And this part here, brown, is the 0,15€.
- Berta: Yes! This part here, brown, is the 0,15€...
- Student1: And this one is 0,02€...
- Berta: And this piece is the 0,02€! Very well!

For the synthesis, to guide students on building the percentage concept, Berta prepared a hard paper in order to represent the problem situation. She struggled with the representation prepared and students had difficulties in realizing the difference between the rectangles. Some students understood the explanation but others did not. The prospective teacher was referring to the problem posed and connected her representation with the procedural solution of the students. We notice that she was returning to essential aspects like reasonability of the price value and the influence of the unit of reference on percentage.

## Conclusion

Berta's lesson was based on launching, exploring and discussing one task. She organized students and materials, encouraged and valued students' ideas and discussion among pairs. She combined invited, informed and guided actions reinforcing the main question and focusing students' attention on the fuel value and the impact of the increase and decrease of fuel by 10%. During the exploration, she suggests students to try real values of the fuel, supported, guided and challenged students' ideas and finally promoted solution recording. Berta also highlighted the importance of the discussion among students but, in this lesson, we couldn't see students posing questions to each other or actions consistent with the idea of developing mathematical argumentation. So, during students' autonomous work, Berta mainly challenged students. Berta organized and selected several solutions sequencing them for the discussion. We cannot say that Berta accomplished a dialogic discourse and students really discussed the task but as it is her first teaching practice, her effort can be valued with respect to sequencing students' presentations to enable connections among solutions (incorrect, correct and mathematically powerful). During the task exploration and discussion she posed put different questions with different focuses: from more open and challenging to more supportive and focused. In the final synthesis, although the main ideas were not recorded on the board, she focused the students' attention on the solutions of the task, establishing connections and explaining the main idea but not discussing the percentage concept. So, at different moments of the instructional practice, Berta carried out different management of the learning actions and of the learning environment actions. Berta's actions in launching and exploration moments created opportunities to learn when she supported students in solving the task and didn't decrease the task demand. As a result different solutions emerged to be presented and analyzed in whole-class discussions (Jackson et al., 2013). In different moments of practice we can identify different actions combined. Berta's aim was to challenge students to build their knowledge together. However maintaining the mathematical demand during questioning and promoting the task discussion could be a complex practice for prospective teachers as we can see with Berta's case.

# Practice of planning in mathematics teaching – meaning and relations

Helena Grundén

Linnaeus University, Växjö, Sweden; [annahelena.grunden@lnu.se](mailto:annahelena.grunden@lnu.se)

*Understanding the complexity of teaching also means understanding issues outside classrooms, including planning in mathematics. Although planning is part of a mathematics teacher's everyday life, there is no shared understanding of it, and little is known about how teachers' planning is related to other practices. In response, to explore what planning means to mathematics teachers and planning's relations to other practices, interviews were conducted with teachers and their contents analyzed in several steps to generate a story of each teacher's experiences with planning. For one teacher, Fia, planning meant decisions and considerations about mathematical content and teaching situations, as well as navigating the decisions and opinions of other actors. Fia's planning is related to practices of management, mathematics teaching, and mathematics teachers, all of which influenced her planning and how her students encountered mathematics in the classroom.*

*Keywords: Planning, teaching, meaning, practice, interview.*

## Introduction

Teaching in mathematics is complex and cannot be isolated from students' learning or context. To acknowledge that complexity, "deeper explanations of teacher's decisions and actions" (Potari, Figueiras, Mosvold, Sakonidis, & Skott, 2015, p. 2972) are necessary. The decisions that mathematics teachers make and the considerations they take into account before entering teaching situations influence what happens in the classroom and thereby students' opportunities for learning. To explore those considerations and decisions, the planning in mathematics teaching is vital in order to understand the complexity of teaching and to improve students' possibilities to learn. However, research has demonstrated a lack of consensus about the concept of planning in mathematics. Former studies focus mainly on the planning itself and not how planning in mathematics is a part of a complex whole and related to other practices. The lack of shared understanding, as well as of studies addressing the complexity of teaching and planning, are thus inevitable stumbling blocks when studying planning in mathematics. Still, knowledge about what teachers actually do when they plan and their constructed meaning about planning might be important information that contributes to an understanding of teachers' work. However, examining only individual aspects of teachers' work is not enough to overcome gaps in research. Teaching is complex not only because it consists of many parts, but also because those parts are framed by "contextual, epistemological, and social issues" (Potari et al., 2015, p. 2972). To elucidate those issues, it is helpful to conceive planning in mathematics as a practice in which individual teachers act in a specific time and place, and in which their habitual ways of acting are related to other practices within "a network of practices" (Chouliaraki & Fairclough, 1999, p. 23). By acknowledging planning in mathematics as a practice, the aim of this study was to explore that practice as a part of a network of practices. To that end, it was necessary to know how teachers construct meaning while planning and reflecting upon their planning in mathematics, to what practices they relate planning and reflection, and how they express them in stories about their planning. An interview study with six teachers was designed to answer those questions. This paper recounts the story of one teacher, Fia, that includes several of the aspects and relations described by the other teachers interviewed.

## Background

### Planning in mathematics teaching

Although planning done by mathematics teachers bears consequences for students' learning, studies in the topic remain scarce. Research about planning in mathematics that does exist address three chief aspects: design research including learning and lesson studies, teachers' mathematical knowledge in relation to their planning, and models and templates for planning. Few studies, none of them conducted in Sweden, have focused on what teachers do in their everyday lives as teachers. National documents based on the Swedish curriculum advocate that planning should be done in a systematic way (Skolverket, 2011) similar to that in models emphasized in research (e.g. Gomez, 2002; Superfine, 2008). However, conversations with Swedish teachers and student teachers have indicated that planning means deciding what to do with a focus on activities, not goals or mathematical content. Such a focus on activities also appears in international research on the topic (Akyuz, Dixon, & Stephan, 2013; National Research Council, 2001). In sum, when people talk about planning in mathematics teaching, they demonstrate no shared understanding of what it means.

### Practice

One way of describing the complexity of teaching is to use the term *practice*, which captures both individual people's actions and more habitual, common ways of acting within a practice (Chouliaraki et al., 1999). Accordingly, conceiving planning in mathematics as a practice can afford a way to conceive teachers' actions both as individual actions and actions shared by other mathematics teachers, as well as a way to conceive the relationship between those actions and abstract structures, that is how social structures govern people's possibilities to act (Lund & Sundberg, 2004). Since each practice is determined from others within a network of practices and since power relations always are present (Chouliaraki et al., 1999), knowing more about teachers' planning practice becomes a way of knowing more about how the process of planning is related to other practices and how power relations are working within the network of practices. In that sense, using practice as a concept to explore planning in mathematics is a way of considering "contextual, epistemological, and social issues that frame mathematics teaching" (Potari et al., 2015, p. 2972).

### Meaning

In this study, meaning referred to "a (collectivity of) subjects' way of relating to – making sense of, interpreting, valuing, thinking, and feeling about – a specific issue" (Alvesson & Kärreman, 2000, p. 1147). How teachers relate to planning, makes sense of planning, interprets planning, values planning, and thinks and feels about planning were thus of interest in interviews and their analysis. The meaning that teachers expressed was both transient – that is, constructed and emergent in interactions in interview situations – and durable – that is, connected to cultural and individual ideas. By conceiving meaning as partly durable, it was possible to explain how previous experiences and more habitual ways of acting formed part of the meaning that teachers expressed in interviews.

### The study

An important starting point when designing the study was an interest in considerations that teachers' have and the decisions that they make that precede and influence what happens in the mathematics classroom, here called *planning in mathematics teaching*. With the notion that planning is both a

focused, time-bound activity and what emerges from reflections and thoughts that can occur at any time, as well as given the aim to explore a concept about which there is no shared understanding, it was necessary to approach the phenomenon as unprejudiced as possible. Since all teachers have heard about and applied the concept of planning it was important to listen to the voices of teachers, hence the decision to use interviews as a method. In the larger study, from which Fia's story was taken, teachers' reflections on planning were explored. Each of six participants was asked to keep a notebook for a period of two weeks before the interview in which they were asked to record actions, reflections, and thoughts that for them were related to planning in mathematics. In the interviews, teachers referred to their notebooks and chose topics to talk about. The interviewer's role was to listen affirmatively by uttering encouragement and nodding, asking for clarification when something was unclear, and asking follow-up questions. By not using predetermined questions, teachers were afforded freedom in the discussion about planning, which made it possible to see beyond pre-understandings and the normative speech of planning that dominates mathematics education research. The use of notebooks provided a possibility for each teacher to return to the notebook on several occasions, and the interview situation where the notebook was used as stimuli, was a way to experience meaning as durable. In the interview situation, transient meaning was constructed and emerged in interactions both with the interviewer and with the notebook.

### **Analysis**

Conducting interviews with notebooks as stimuli was a way of foregrounding teachers' experiences and meaning. To continue in that spirit, analysis needed to be based on the material, not predetermined categories. Along with reviewing the stories of each teacher separately, aspects hidden in stories as a whole were also sought. Those somewhat contradictory motivations required staying close to the material and keeping a distance from it. Consequently, analysis proceeded in several steps, the first of which involved reading each utterance per se, and noting what discursive action was performed by making the utterance. During that initial coding memos were written to record spontaneous reflections and ideas, as inspired by Charmaz (2014). In another version of the transcripts, meaning units (that is, units considered relevant to considerations and decisions that preceded and influenced what happens in the mathematics classroom) were marked. Each unit was paired with the activity belonging to the unit in the first transcript, and by interpreting the meaning unit and the activity together an aspect of planning, considering, or decision-making emerged (Table 1).

Meaning unit (from step 2)	Activity (from step 1)	Aspect
We have a template that we should stick to.	Expresses requirements from school administration	Formal requirements
...that talented students and parents would say that it [special educational approach] was wrong... or the parents of those students	Expresses unspoken expectations from parents and students	Discourse of mathematics education
Why have I not talked about... talked with colleagues about this movie before?	Reflects on telling each other	Colleagues

**Table 1: Examples from analysis step 1**

To see aspects hidden in the stories as a group, distance from the material was necessary. Inspired by Szklarski (2015), meaning units were therefore transformed from the first- to the third-person perspective (Table 2).

Meaning unit	Transformed meaning unit
When will I be able to plan with my colleagues? The work turns into working alone although I don't want it to. It is a lot... We make these big, long-term plans, but we never have time to see each other once we've started [implementing the plans].	When will she be able to plan with her colleagues? The work turns into working alone although she doesn't want it to. It is a lot... They make these big, long-term plans, but they never have time to see each other once they've started.
Do I dare consider it [special education approach] from the beginning? Do I have the energy? Do I have the time?	Does she dare consider it from the beginning? Does she have the energy? Does she have the time?

**Table 2: Examples from analysis step 3**

The transformed meaning units were organized so that units dealing with the same aspect were grouped and read as a whole. As a result, meaning was identified and could be expressed as a product of synthesis (Table 3).

Sorted and transformed meaning units (per aspect)	Synthesis of transformed meaning units
<b>Content</b>	In her planning Fia sees that there are several parts to decide upon: what mathematical area the planning should cover, how to connect that to the everyday lives of students, and how to work with and make assessment in relation to students. Good activities can be reused with different foci. Fia thinks about how she will be able to apply an overall special education approach to her long-term plans.
Area [mathematical]	
Planning in detail and thinking... how	
Relation to everyday life: How to get it [mathematics] related to the students.	
At examination, it [thoughts about students] comes	
How does Fia apply a special educational approach in her long-term plans?	
They watched a movie again. Fia has done that several times... The story of 1[name of the movie], but that one focuses on different things. Finding... find activities that you can say, that you can get the most out of... and maybe dare to weed out those that really do not give anything.	

**Table 3: Examples from analysis step 4**

The synthesis of the transformed meaning units were organized and assembled into stories, one of each teacher. This paper presents the story of Fia, since it emphasizes several aspects visible in the other stories.

### **Fia's story**

Fia is a mathematics-, science-, and technology teacher in compulsory school grades 7–9. She used the notebook for reflections on her planning, teaching, and decisions. In the interview, she referred to her notebook and chose topics to discuss. At several times, she also reflected upon her reflections and reached new insights – for example, when she referred to “pedagogical plans” in her notebook and discussed how constrained she feels when she has to do her planning with a template.

Fia: I have had exactly that [referring to the template] content before, but it has not been so formal... That formality... everything has to look the same. It makes me constrained, or I don't feel free to think, or... 1,2,3,4: that must come first, then that, then that... But actually... It is also up to me! I can start to think about paragraph 4 if it's about how we should work.

In her story Fia referred to the template several times. She discussed how her school management has decided that a specific template has to be used when planning, largely to be able to collect the plans and thereby “see what is happening”. Time is another constraining factor for Fia, regarding both

individual and collaborative planning. Colleagues are resources in Fia's planning, and she would like more cooperation with them, also in her short-term planning. She also highly values spontaneous exchanges of ideas and experiences.

Fia's work with planning varies throughout the year. At the beginning of the school year she generally has more energy, but in the final weeks, particularly for the for the ninth graders, Fia tends to perform what she calls "spontaneous planning" – that is, decides immediately before lessons what she will do. Fia argues that "spontaneous planning" can be good; the creativity that she sacrifices with templates can bloom in "spontaneous planning", and this also affords greater opportunities for student participation.

Having two groups of the same grade level at different times of the day has made Fia aware of how much the schedule influence her planning. She has also experienced how other activities planned for the students (including field days, theater visits, project periods) steal time from her mathematics teaching and thereby affect her planning. If Fia were allowed to decide upon the schedule, then she would plan for more teaching situations with one or two students. One year she had opportunities for such occasions in her schedule and felt that they helped the students very much.

The availability of materials is another factor that influences her planning. Fia discussed an occasion when she was sitting with a small group of students in a room beside the main classroom while the rest of the class was supposed to work in pairs with problem solving and show their solutions on small white boards. However, since there were enough white boards for all students, each student took one and worked individually instead. For Fia, that occasion exemplified how a teaching situation is a meeting between planning and reality and how the outcome can differ from what was intended.

When planning, Fia makes several decisions, including what mathematical content to cover, how to relate that content to students' everyday lives, and how to work with the content. Referring to a film that she has shown several times, she expressed how good activities can be used several times with different focuses. Besides decisions directly related to the concrete teaching situation, Fia has considered how to adopt an overall special education perspective in her long-term planning, which she thinks can benefit all students' learning. Planning can help to "play it cool" and break norms about mathematics teaching. Fia gave examples when she has planned for working with a couple of students at a time although she had a lesson for the whole class, or when she has used the same film on several occasions for the same students. For Fia, planning is always about prioritizing and is related to feelings. She expressed how care for the students and their learning is critical when making decisions and how her own fears and energy level influence how the planning is done. Fia is constantly reflecting on previous experiences and how those experiences can be applied in future plans. She believes that even more reflection for example, after spontaneously planned lessons can be a good way to take advantage of good experiences instead of letting them go to waste.

Fia describes a practice in which the way of talking about planning in mathematics is frustrating. Some ways of planning are more valuable than others, and Fia almost excuses herself for sometimes doing what she calls spontaneous planning. Knowing that other actors might have comments influence her way of thinking, and, according to Fia, changes in teaching can lead to questioning from for example parents and students. In her notebook, she had written about how she wanted to include a special education approach in her long-term planning. She had also written: "Do I dare? Do I have

the energy?” Fia said that those considerations represented fears that not all students will be challenged and that she will have to argue for her choices. Fia thinks that she has the authority to make decisions about the teaching, but that exercising that authority takes energy.

## Analysis and discussion

Reading Fia’s story in the light of *meaning* defined as “a (collectivity of) subjects’ way of relating to – making sense of, interpreting, valuing, thinking, and feeling about – a specific issue” (Alvesson et al., 2000, p. 1147) makes it possible to conceive how she constructs meaning and makes sense of planning in mathematics by choosing topics to discuss, by interpreting the practice of planning, and describing what she is doing and what is important for her. She discussed how choosing mathematical content and ways to present and work with that content always are part of her planning, as well as how good activities can be re-used with a different focus. Also related to the *practice of planning* is how she uses, and wants to use, reflections to benefit from past experiences, and how planning can help her break norms about mathematics teaching.

Besides describing the practice of planning itself, Fia constructed meaning by, for example, discussing how decisions by school management regarding schedule, availability of materials, and templates influence her planning. From her story it is clear that she perceives models often emphasized as a support for planning (Goméz, 2002; Superfine, 2008) as constraints. This is possible to interpret as she is referring to a *practice of management*.

Visible in Fia’s story are also norms about how mathematics teaching “should be done.” Those norms influence her considerations and decisions and emerged in her story as an invisible idea of what counts as teaching in mathematics, but also as concrete examples related to opinions of students and parents. Interestingly, Fia has ideas that she thinks would benefit students’ learning, but she contemplates to abandon them because she worries about parents’ and students’ reactions. When referring to thoughts of mathematics teaching, Fia relates the practice of planning to a *practice of mathematics teaching*.

Closely connected to practice of mathematics teaching are the colleagues that Fia referred to several times. She talked about a desire to make more collaborative planning, and how colleagues can be resources also in spontaneous exchange of ideas and experiences. Those parts of the story can be interpreted as her referring to a *practice of mathematics teachers*, in which she sees herself as a part. In reality, the practice of management and the decisions made there to some extent determines how she can participate in the practice of mathematics teachers. The degree to which co-planning is valued in the practice of management clearly affects Fia’s schedule and how much time she has with her colleagues.

Fia’s story makes it clear that her actions and reflections within the practice of planning relate to other practices in different ways. Some of those relations are constraining and hinders Fia from planning the way that she wants, whereas others contribute positively to her planning in mathematics. Since those other practices influence her planning they also implicitly influence her students’ possibilities to learn. Although the teacher is ultimately responsible for the teaching, results show that there are other aspects that influence the planning and, in turn, what happens in the classroom. That dynamic needs to be taken into account when discussing mathematics teaching and forming development initiatives. Viewing teachers and situations in the classroom as isolated entities poses the undesired

consequence that other important aspects that also influence students' possibilities to learn mathematics are neglected.

# Measuring instructional quality in mathematics education

Armin Jentsch<sup>1</sup> and Lena Schlesinger<sup>1</sup>

<sup>1</sup>University of Hamburg, Germany; [armin.jentsch@uni-hamburg.de](mailto:armin.jentsch@uni-hamburg.de)

*Instructional research has recently become more important within the framework of teaching effectiveness research. Various instruments have been developed within this research discipline in order to gain a better insight of what is really happening in the classroom. Most of these instruments mainly focus on generic aspects of instructional quality. In this paper we first describe a subject-specific dimension of instructional quality. Second, we show how these subject-specific aspects could be measured empirically with a standardized observational instrument. The results point out both good interrater agreement and satisfying reliability measures. The presented observational instrument has been developed within the study TEDS-instruct in which relations to teachers' competencies and students' achievement are analyzed.*

*Keywords: Mathematics instruction, instructional quality, classroom observation techniques, instructional improvement.*

## Introduction

In German instructional research, subject-specific aspects of instructional quality have been investigated rarely until now. Three generic dimensions have been introduced which are classroom management, personal learning support and cognitive activation (e.g. Lipowsky et al., 2009). Although these basic dimensions were developed for mathematics instruction in the first place, they are now deemed relevant for every subject at school (Baumert et al., 2010; Helmke, 2012). Other important aspects of mathematics instruction were apparently disregarded then (e.g. representations, examples, modelling, proof). Blum and others (2006) therefore ask for a high *mathematical* quality of the lesson beyond the three basic dimensions.

At the same time, several instruments for measuring subject-specific aspects of instructional quality have been developed within the American debate (e.g. Learning Mathematics for Teaching Project, 2011). However, some of these instruments do not contain generic aspects even though the prognostic validity of the three basic dimensions of instructional quality has been shown empirically more than once (see Baumert et al., 2010; Kunter et al., 2013; Lipowsky et al., 2009). In conclusion: to our knowledge there is no standardized instrument in existence that is based on a sound theoretical framework (e.g. the three basic dimensions) covering also subject-specific aspects regardless of the mathematical content discussed in class. Starting from these three basic dimensions, we would like to point out subject-specific characteristics of instructional quality that are deemed relevant in the literature and show how these characteristics can be measured with a standardized instrument. The purpose of this paper then is to describe the development of an observational protocol that is used to assess instructional quality in secondary mathematics classes and to present first empirical results.

## Theoretical framework

In recent years educational research has shown a great scientific interest in teacher knowledge and instruction (see Hattie, 2012). At the same time, the relation of teacher competencies and students'

achievement has been analyzed (Baumert et al., 2010; Hill, Rowan & Ball, 2005; Scheerens, 2004). The so-called process-mediation-product-paradigm is regarded as a theoretical framework in which these research questions are grounded. This framework describes a relation between students' learning and instruction which has to be *offered* by teachers and *used* by students (Brophy, 2000; Brophy, 2006; Helmke, 2012; Oser, Dick & Patry, 1992).

### **Three basic dimensions of instructional quality**

As mentioned before, three generic dimensions of teaching quality have been developed in recent instructional research which are classroom management, personal learning support and cognitive activation. These dimensions were shown to have a positive impact on both students' learning and their motivation in class (Baumert et al., 2010; Lipowsky et al., 2009).

*Classroom management* focuses on quality-oriented learning time provided for students and on how effectively the teacher deals with disciplinary conflicts (Brophy, 2000). Effective classroom management is also characterized by a lesson that is organized well and has clear routines (Lipowsky et al., 2009). The second dimension, *personal learning support*, includes the individual support provided by the teacher, the relationship between students and teacher as well as constructive feedback (e.g. Rakoczy, 2008). Finally, *cognitive activation* refers to how problem-solving tasks are used to activate learning processes (Baumert et al., 2010; Brophy, 2000). This dimension includes the activation of previous knowledge and whether challenging tasks and questions are presented that foster students in high-level thinking activities (Lipowsky et al., 2009; Praetorius et al., 2014).

Although the three basic dimensions focus on generic aspects of instructional quality, the question remains whether they could be operationalized in subject-specific way. This holds specifically for cognitive activation (Drollinger-Vetter, 2011; Schlesinger & Jentsch, 2016). Moreover, it is not clear which subject-specific aspects are missing in this framework and how its dimensionality changes when generic and subject-specific aspects are measured simultaneously (Drollinger-Vetter, 2011). Due to these concerns, most instruments that have been developed for the analysis of instruction are only suitable for a very small number of situations (e.g. regarding the mathematical content, see Steinweg, 2011; Schoenfeld, 2013).

### **Measuring instructional quality**

We will now focus on the question how instructional quality can be measured both reliably and validly. Praetorius and colleagues (2012) see classroom observations as a straight-forward way to do so, especially compared to the analyses of material or minutes conducted during the lesson. Helmke (2012) even claims that one can only speak of instructional research in a narrower sense when classroom observations are performed. The reliability of classroom observations is always an issue since observer ratings are often heavily biased and the stability of the measurement is sometimes questioned (for an overview see Praetorius, 2014). Most authors suggest analyzing variance components beyond measures of interrater agreement to understand better which sources of error have added to the variance of the observed score (e.g. Praetorius et al., 2012; Praetorius et al., 2014).

Observational instruments may contain both low and high inference items (Praetorius, 2014). Codings with low inference are operationalized in a way that is strictly observable. High inference

items, in comparison, need the observer to interpret what he or she sees which makes the observation much more complex (Hugener, 2006). However, at the same time one gains a higher validity because instructional research has shown that low inference items explain only little variance when students' achievements are measured as outcome variables (e.g. Baumert et al., 2010). This is because the surface structure of instruction (e.g. which method is used by the teacher) and its quality may sometimes vary independently from each other (Kunter & Voss, 2013).

## **Developing an instrument for measuring instructional quality**

The observational instrument that is presented in this paper was developed within the study of TEDS-Instruct which is a Follow-Up Study of TEDS-M (Teacher Education and Development Study in Mathematics). The main goal is to empirically investigate teachers' competencies in mathematics education at the secondary level and their influence on students achievement mediated by instructional quality. As a matter of fact, students' achievements will be collected to describe the prognostic validity of both teachers' competency tests and the observational protocol that is presented here.

### **Subject-specific aspects of instructional quality**

For developing a subject-specific dimension of instructional quality we first analyzed which subject-specific aspects of instruction are assumed to have an impact on students' learning which has to be examined empirically. The main goal for developing a fourth dimension with subject-specific aspects was hence to extend the existing generic theoretical framework of instructional quality. Such an extension with subject-specific aspects is not established until now (e.g. Steinweg, 2011). During the development of the fourth dimension it became apparent that it is necessary to discuss the subject-specificity of some aspects that are included within the former three-dimensional generic framework. This discussion leads to the assumption that the three basic dimensions of instructional quality are not completely generic. However, in the fourth dimension there were included only such subject-specific aspects that were not already used to operationalize the other three dimensions.

For conceptualizing this dimension, a systematic literature survey within the databases of Web of Science, ERA and ERIC was conducted (see Schlesinger & Jentsch, 2016 for more detail). At the same time, the national debate on mathematics education and the German common core standards was reviewed. Based on the described approach, the following aspects were operationalized for the observational instrument:

- the teacher's mathematical correctness
- the use of representations
- mathematical competencies (modelling, problem-solving, the use of mathematical language, argumentation and proof, training mathematical tools and operations)
- a constructive approach to students' mathematical errors
- the quality of exercises and tasks
- sense-making
- teachers' mathematical explanations
- appropriate examples
- mathematical depth (e.g. generalizations)

## Method

Based on the three basic dimensions of instructional quality and the subject-specific aspects that were condensed into a fourth dimension, we developed an observational instrument that can be used for in vivo ratings without needing videos of the lesson and that can be utilised independently from both the specific mathematical content and the academic year. Instructional quality was rated by assessing the items on a four-point scale ( $1 = \text{“not at all true”}$ ;  $4 = \text{“completely true”}$ ). The instrument consists of four dimensions which are classroom management (five items), personal learning support (seven items), cognitive activation (five items) and mathematics educational quality of instruction (nine items). The data for TEDS-Instruct was collected in Hamburg from a sample of 38 teachers at the secondary level. The teachers participated on a voluntary basis. Therefore it can be assumed that they were greatly motivated to have their lessons observed. Each teacher was observed for two lessons (90 min each). Within one lesson, the instructional quality was assessed four times (every 22.5 min).

Example items	Indicators
<b>Mathematical depth</b>	<ul style="list-style-type: none"> <li>• The teacher provides generalizations</li> <li>• The teacher provides mathematical connections</li> <li>• The teacher deepens and structures mathematical knowledge</li> </ul>
<b>Representations</b>	<ul style="list-style-type: none"> <li>• The teacher provides various representations for mathematical objects</li> <li>• The teacher illustrates the linking between different representations</li> </ul>

Table 1: Two example items for the subject-specific dimension

Altogether, there were six observers involved in the classroom study, all of which held at least a university degree from a mathematics teacher program. The observers were trained for the classroom observations in advance which took around 20 hours. The training had three main goals: 1) a joint understanding of the theoretical underpinnings of each rating dimension, 2) familiarizing with the observational protocol, 3) ensuring a satisfactory amount of interrater reliability. By doing so, all items and indicators were discussed thoroughly with the help of a rating manual. The goal of a joint theoretical understanding also involved the *object of measurement*, i.e. instructional quality. Based on the process-mediation-product-paradigm, instruction is regarded as a learning opportunity that is individually adapted to students' skills and dispositions. Even though the focus of the observations lies mainly on the teachers' behaviour, the latter is dependent of the students' behaviour and student-teacher-interactions. Students' reactions to the learning opportunities are crucial to understand and assess the *quality* of instruction and are hence part of the observation, too. Nonetheless, due to pragmatic reasons no student self-reports or cognitive tests have been collected.

Before stepping into real classrooms, the observers trained their skills on videotaped lessons until they reached a certain amount of interrater agreement. Finally, a pilot study was conducted with 13 teachers in three German federal states. After each observation, the ratings were discussed intensively between the two raters. For the data collection the lessons were observed directly without using videotapes, i.e. the raters assessed all items within the lesson in vivo. Two raters were chosen randomly and rated the lesson independently from each other. For this reason it was possible to avoid systematical agreement between certain raters. In addition to these ratings, there were also produced minutes for every lesson. These minutes included teaching methods, teacher-student-

interactions, students' behaviour and reactions, the mathematical content and provided materials and tasks from the lessons for a detailed description of the learning opportunities.

## Results

As a first step we calculated descriptive statistics for the data that was collected by external observers. The following table contains the results of all items from the three basic dimensions and the newly developed subject-specific dimension. For ensuring interrater reliability *Spearman's*  $\rho$  was calculated. This is a common measure since in educational research one is more often interested in relative than in absolute decisions (Praetorius et al., 2012; see also Shavelson & Webb, 1991). In the present study we reached satisfying results of  $.75 \leq \rho_{inter} < .97$  which can be interpreted as high or very high correlations between both observer ratings. In order to calculate the descriptive statistics the data was aggregated to a single datum per person ( $N = 38$ ). By doing so, we first took the average rating of both observers and then calculated the mean of all eight measurement points per teacher.

Items	<i>M</i>	<i>SD</i>	<i>r<sub>it</sub></i>
Classroom management ( $\alpha = .83$ )			
Effective use of lesson time	3.58	.33	.59
Clear rules and routines	2.97	.19	.66
Preventing disruptions	3.39	.45	.83
Advance organization	2.89	.49	.55
Working atmosphere	3.23	.51	.77
Personal learning support ( $\alpha = .714$ )			
Students' individual support	2.05	.45	.37
Approach to heterogeneity/differentiation	1.26	.38	.64
Self-regulated learning	1.48	.35	.58
Teacher's feedback	3.07	.37	.49
Teacher approval	3.10	.38	.49
Students' feedback	1.05	.11	.22
Fostering cooperative learning	1.75	.46	.27
Cognitive activation ( $\alpha = .821$ )			
Challenging tasks and questions	2.54	.47	.79
Supporting metacognition	1.25	.29	.42
Activating prior knowledge and co-construction	2.66	.37	.76
Quality of teaching methods	2.81	.41	.66
Securing knowledge	2.43	.48	.50
Mathematics educational characteristics ( $\alpha = .820$ )			
Constructive approach to students' errors	2.79	.56	.69
Teacher's mathematical correctness	3.64	.37	.54
Representations	2.29	.65	.39
Exercises and tasks	2.37	.52	.63
Examples	2.99	.42	.54

Mathematical competencies	1.62	.15	.44
Sense-making	2.09	.49	.32
Teacher's explanations	2.93	.54	.62
Mathematical depth	2.34	.40	.69

Table 2: Descriptive statistics for all items

When looking at the measures in table 2, we see that correctness has reached the highest values in the subject-specific dimension. Even though this could be seen as a ceiling effect, the statistical discrimination is quite high. The same holds for the items in the first dimension. Nonetheless, these ceiling effects are not surprising as the sample consisted of professional teachers only (Baumert et al., 2010; Blömeke et al., 2010). On the other hand, the average individual support that was observed in the lessons is quite low which is also supported by the low measures of the items “Self-regulated learning” and “Differentiation”. Finally, the standard deviation of most items is high enough to conclude that a decent amount of variance was measured.

Altogether we can conclude that an acceptable internal consistency could be reached for all four dimensions. When  $r_{it} = .25$  is regarded as a threshold for acceptable measures of statistical discrimination, the item “Student’s feedback” did not reach acceptable values and was thus excluded from further analyses which is also due to a floor effect. All other items show at least mediocre correlations to the corresponding scale which supports the claim of three generic dimensions. This is, however, supposed to be confirmed by factor analyses. Recent both exploratory and also confirmatory approaches once again support the hypothesis of three generic dimensions but suggest dividing the subject-specific dimension into two sub-dimensions which will be discussed in more detail in the presentation (Blömeke et al., submitted).

To sum up, this present study has mainly an explorative character concerning the mentioned subject-specific aspects. However, from a more content-related standpoint one can conclude that fostering specific mathematical competencies like modelling or proof has often been disregarded during lessons. Precise analyses of the used material might then be fruitful to understand better what has happened in the classroom.

## Discussion and outlook

The presented instrument for measuring instructional quality shall finally be discussed concerning advantages and disadvantages compared to other instruments in the field. Since this instrument has been developed in order to be used in classrooms without analyzing video there is a chance that it could possibly be used in a broader way than instruments from video studies. Second, measuring instructional quality more than once in a given lesson may describe the learning process in more detail and can lead to more reliable data because certain aspects of instructional quality may change a lot during the lesson. The ratings then tend to be biased heavily since the observer has to give a single rating for the whole lesson (Praetorius et al., 2012). Third, the instrument is suitable for most mathematics classes, academic years and mathematical contents. Finally, in this instrument generic and subject-specific aspects are combined which, in addition, can then be analyzed on their relation.

The question remains whether the present instruments’ prognostic validity can be shown by analyzing the relation of instructional quality and students’ achievements. It should be tested whether instructional quality can be seen as a mediator variable between teachers’ competencies and

students' learning, too. This might especially be interesting for mathematics educational scholars since the impact of generic aspects of instructional quality has already been shown in some studies (Baumert et al., 2010; Helmke, 2012; Lipowsky et al., 2009). The important mathematical or mathematics educational aspects of instructional quality and their impact on both learning and other outcome variables as motivation or metacognition have still to be found. Here, our study could help to gain a little more insight.

<sup>3</sup>Aristotle University of Thessaloniki, Greece; [tzekaki@auth.gr](mailto:tzekaki@auth.gr)

*Research on classroom teaching practices is mainly focused on teachers' knowledge, beliefs and practices paying limited attention to a crucial aspect of the instructional activity, that is, on the mathematical meaning constructed in the classroom. The present study examines three highly motivated and professionally active primary teachers' instructional practices and their reflections on them in an attempt to identify critical elements shaping classroom mathematical meaning construction. The results show that all three teachers, intentionally or not, make instructional choices, which tend to restrict the mathematical meaning under negotiation. These choices could be attributed to their desire to provide children with an 'easy', 'safe' and 'pleasant' learning environment.*

*Keywords: Teacher practices, teachers' reflections, epistemological features*

## Introduction

Significant research has been carried out on classroom teaching practices. An important part of this research examines teachers' mathematical knowledge, beliefs and practices employing different theoretical as well as empirical lenses and aiming to understand its impact upon students' learning. Although the importance of the mathematical meaning constructed in the classroom is widely recognized and implicitly implicated in all the different approaches, relatively little attention has been paid to a detailed analysis of this construction.

In previous studies, we attempted to systematically examine this important aspect of mathematics teaching and learning, analyzing teaching episodes of different teachers, mathematical topics or age students. Lately teachers' reflections on their teaching decisions and practices drew our attention, because of the interest in understanding the value teachers attribute to the nature of the mathematics knowledge shaped in the classroom (Linares and Krainer, 2006). Thus, in this study, after analyzing three primary teachers' classroom practices with respect to the mathematical meaning constructed, we focus on their reflections on this construction. Our aim is to examine each teacher's decisions and practices related to the mathematical meaning construction process.

## Classroom mathematical meaning construction

We first attempt to define “*classroom mathematical meaning construction*” and then present framework related to the epistemological features of this meaning used to analyze teaching practices.

Mathematics is a very special discipline and the nature of the mathematical knowledge and the way it operates are among the main objectives of the subject matter curriculum worldwide. The mathematical way of developing (ideal, theoretical) objects and processes reveals ideas' attributes and relations as well as definitions and theorems to identify objects, to produce new, to relate them and to justify properties and relations. One of the most significant aspects of mathematics education is the understanding of this mathematical way of operating to which students gradually become acquainted by the way teachers manage mathematics within the classroom. Thus, the *mathematical meaning construction* concerns the significance that teachers' classroom management attaches to different mathematical contents and procedures. *How does this construction appear to be omitted from different studies?*

The considerable body of research focusing on the so called 'mathematical quality' of teaching employs terms such as '*connection to worthwhile mathematical ideas*', '*richness of the mathematics*', '*accuracy*' and so on (Ball, et al., 2008) to describe various dimensions of the mathematical meaning shaped in the classroom. Kilday and Kinzie (2009) report on different dimensions related to the 'quality of mathematics instruction' for classroom observation verifying the absence of clear designation for these terms. They report on various tools used to examine this quality summarized along the following dimensions: *teaching aspects* (roles, strategies, classroom setups, tasks, time, etc.), not necessary related to mathematical content; *teachers' knowledge* (e.g., mathematical content); *teachers' and students' functioning* (for example, interactions, behavior, engagement, expectations, etc.) and *learning aspects* (such as cognitive demands). Only one rather unclear term can be identified among the above referring to the mathematical meaning constructed in the classroom that could be seen as relevant, '*clarity and correctness*', without though any specific relation to the mathematical content.

Within our perspective (Kaldrimidou et al, 2008; 2013), the term '*mathematical meaning construction*' is oriented to the epistemological features of mathematics. These features concern 'definitions' to identify and differentiate the theoretical mathematical objects, 'attributes and relations' to study them and special 'processes' for the management of these objects and relationships. Students are expected to gradually approach these ideas, objects and properties through the meaning assigned to them by the teacher's classroom management. This aspect of the classroom '*mathematical meaning construction*' is only partly approached by the research, which examines the mathematical quality of teaching.

### **Theoretical Perspectives**

Most of the studies examining the mathematical knowledge at play in the classroom focus indirectly on this knowledge, often adopting a teachers' knowledge perspective. This section discusses some of these studies with respect to the way these examine the shaped mathematical meaning.

Ball et al (2008) studied teachers' mathematical knowledge for teaching (MKT) arguing that this special knowledge, in addition to other, like the knowledge of content and students, content and teaching, content and curriculum and so on determine the quality of teaching and thus the learning outcome. They propose a framework for examining this quality including features like *richness* and *rigor* of the lesson, presence of *mathematical explanation* and *justification*, *mathematical representation*, etc. Their approach allows the study of certain features of the mathematical

knowledge present in teaching practices but not the exact mathematical meaning shaped in the classroom.

Turner & Rowland (2010) focus on teaching practices and examine teachers' mathematics knowledge based on their instruction. Four categories of situations revealing teachers' mathematics knowledge are identified: '*foundation*' referring to the knowledge, beliefs and understanding acquired during teachers' education, '*transformation*' and '*connection*' explaining the ways teachers present the relevant mathematical topic and '*contingency*' related to the ways teachers react to 'unanticipated events'. Their framework named Knowledge Quartet (KQ) mostly relates the mathematical knowledge in teaching to teachers' mathematical expertise or to principles of classroom management in different types of situations. Thus, it is less connected to the mathematical meaning shaped in the classroom as a result of teachers' management of this meaning.

Some studies attempted to examine teachers' knowledge based on teaching practices, errors and teachers' reflection on these, the use of representations and examples (Lin & Rowland, 2016) without deepening, however, into the impact of this knowledge in the classroom management of the mathematical meaning. Also others examined teachers' knowledge from a cognitive point of view, without concentrating on specific contexts and the nature of mathematics (Davis & Simmt, 2006).

From a decision making perspective, Schoenfeld (2013) proposed a framework for classroom observations related to effective instruction analyzed along three basic dimensions: *access*, *accountability* and *productive dispositions*. Here the focus is on mathematics and opportunities for their learning, thus on mathematical meaning construction: "Students are given a chance to learn mathematics... This requires making mathematics learning practices explicit and accessible ... Mathematical exploration and discussion should be accurate. Reasoning and justification should be tied to mathematics" (p. 611). Terms like 'mathematical reasoning', 'mathematical accuracy', 'richness and integrity' are used to describe the mathematical character of the knowledge built. However, although the framework is thoroughly and accurately presented, it leaves unclear the meaning of each term and its connection to the epistemology of mathematics.

Mathematical meaning and the understanding of the nature of the mathematics constructed in the classroom have been also seen as an important aspect of classroom management encountered as a complex multi- dimensional phenomenon and studied in varied ways. Relevant research indicates that teachers make decisions based on multiple perspectives, often less mathematical and mostly pedagogical or didactical (Bednarz & Proulx, 2009).

For a number of years, our studies have been looking at teachers' classroom management, teaching practices in various mathematical contexts and students' learning in relation to the epistemological status of the knowledge under construction in the classroom. The results indicate that "in most cases the activity developed in the classroom had none of the epistemological features characterizing mathematics, thus affecting students' mathematical understanding" (Kaldrimidou, Sakonidis & Tzekaki, 2013, p. 306). Below, an episode from our data is analyzed within different perspectives to exemplify the aspects of the mathematical meaning under consideration. In this episode, a primary teacher offers an introduction to fractions and deals with definitions:

T(eacher). ... Tell me, what is the difference between fractions and natural numbers? ... How do they differ? ... Are they the same numbers?

S(tudent). The fractional numbers ... can b... That is, we have a cake and we cut it in six pieces and take one. This is  $1/6$ . The natural numbers are 1, 2, 3, ... up to infinity!

T. Good! ...

The student presents fractions using a specific example making reference to descriptive characteristics and then simply names natural numbers; the teacher accepts his answer (although a description rather than a definition is provided) and even praises him. What is the meaning of definitions constructed by the students? Is at all connected to the mathematical meaning of definition? The teacher's urge to offer a familiar context to the students destroys the accuracy of the definition, and, thus students' understanding of it.

What could we detect examining this episode through the *mathematical quality* lenses? Error, richness, rigor, or presence of mathematical explanation (Ball, et al., 2008)? There is no error, while the student's explanation (accepted) has no rigor or any other mathematical quality. Similarly, using Schoenfeld's framework we could identify less *opportunities for mathematics learning*. However, both analyses cannot explain the meaning constructed by the students. In an analogous manner, the KQ lenses would examine the connection between the initial question, the specific response, the descriptive explanation and the teacher's decision to accept it, but wouldn't explain the meaning constructed by the students. Examining the episode from the teacher's knowledge perspective (Davis & Simmt, 2006), her management provides no hints about this knowledge, because her decisions are consciously aiming to create a familiar environment for the students.

The above suggest that studies examining teachers' classroom management of the epistemological features of mathematics as well as the ways in which they understand and interpret this management play a central role in the improvement of mathematics teaching and learning. In the present study we look at teachers' reflections, interpretations and justifications related to the teaching decisions shaping the mathematical meaning constructed in the classroom.

## Methodology

The data presented here come from a large project following the development of a new mathematics curriculum promoting mathematical literacy through active learning in social contexts. Here the focus is on three primary teachers, members of a small group chosen on the basis of their substantial teaching experience and promising professional development record, implementing units of the new syllabus over a school year. There were all females with more than fifteen years of experience each, teaching in an experimental primary school in the northern part of the country. Over the year, they discussed, designed, implemented and evaluated a series of lessons in collaboration and under the supervision and support of an advisor/consultant. The lessons, the meetings as well as a number of interviews were taped and transcribed providing the data for the study. For the purposes of this report, three transcribed lessons and a follow up semi-structured interview on certain aspects of the teaching session for each teacher are considered.

The research problem pursued was to explore different meanings constructed in these teachers' classrooms related to mathematical objects, their definitions, attributes and relations to other mathematical objects based on their teaching actions/ management as well as reflections on them.

A combination of content analysis and grounded theory techniques were used to analyze the transcribed lessons and the discourse developed in the interview. In particular, we first identified critical episodes in the teachers' practices related to the above mentioned features and then analyzed their reflections on these, seeking to identify teachers' acknowledgement of the mathematical nature of this knowledge.

## Results - Analysis

In this section, the results for each teacher participant according to the aforementioned scheme of analysis are presented. Due to the limited space, for each teacher, a critical episode is first provided and commented and then her reflection on it is discussed.

**(1) Teacher A (5<sup>th</sup> graders):** The episode below concerns the notion of percentage. Classroom activity concentrates on the completion of a 2x2 table, its rows representing games and its columns the number of students out of 100 voting favorably for each game, in three forms (fraction, decimal or percentage), partly completed. Teaching management focuses on the calculation procedure needed to move from one number representation to the other, especially on division, paying no attention to the equivalence of these representations.

- T(eacher): Because, 100 divided by 4 makes 25!! Hence, we have 25 out of 100! ... Do you agree?... She had the fraction  $\frac{1}{4}$  and wanted to turn it to decimal... Because here we have 100 students.
- T: Danae said before that the decimal fraction is what?
- Danae: A fraction with denominator 10, 100, 1000 ...!
- T: And since I want 100 as denominator, what am I going to do?
- Thanassis: I will multiply it by ...
- S(tudent): By hundred!!
- T (to Thanassis): By what? (She writes on the board simultaneously)
- Thanassis: ... (noise increasing in the room) ... By 25! I will do the same with the numerator
- T: (She writes on the board) That is, 25/100! ...
- T: How did you come up with this 0,25? Thano?
- Thanos: We got 0,25 from the fraction 25/100
- T: It was very easy for you to do the decimal number from the decimal fraction ...
- Adriana: We will perform the division of 1 by 4 and we will find 0,25!
- Teacher: Why shall I divide 1 by 4?
- S: Because, if I divide the numerator by the denominator, I make decimal!
- T: Because it is very easy to make decimal fractions, but it suits me to get numerator with denominator, to divide them, because I am very good at division! ... The percentage! ... Have we met the percentage only in graphs so far, eh? We haven't really worked with percentages ... What does 25% mean? This is the new idea that came up there!

Teacher A claims that the mathematical focus of her session is on % and then on pupils becoming able to see the three different number representations (fraction, decimal, percentage). However, the way in which she manages group work and outcomes (dominance of question - answer practice and vague transitions between representations) destroys the mathematical equivalence between representations envisaged by the task. Nevertheless, in her reflection on this she appears unaware that this equivalence should be at the heart of her teaching. At the end of the interview, explaining why

children tended to ‘calculate the decimal to be able to deal with the number’s, she even argues that this might be her fault as she also does this in everyday life.

**(2) Teacher B** (2<sup>nd</sup> graders): The episode comes from an introductory session on fractions. The task here focuses on fair/even sharing of certain objects and materials depicted on paper, including a loaf of bread, a lolly-pop, some candies and a pizza. Children adopted strategies of folding and measuring, with the latter being mostly praised by the teacher.

- Fotini: I took the ruler and I measured it! I found its half!  
 T: That is, how much is the biscuit ... Take first the biscuit ... Let your co-students see... The way the biscuit is, what did you measure? (She shows) ... Aaaa! You measured this side from above! And how much did you find that the biscuit is?  
 Fotini: Twelve centimeters!  
 T: Oh, you found that the biscuit is 12 centimeters!  
 Fotini: I cut it into six! ...  
 T: Ah! Go and bring your notebook and show us how you shared your loaf! ... Because I haven’t seen many to share this way! ... Look, please how did George share his loaf!! Do you agree?  
 S: Yes!  
 T: Did he share into two equal pieces?  
 Students: Yes!  
 Joanna: Yes! And then I cut it in the middle!  
 T: How did you cut it in the middle? What did you think? ...  
 Joanna: ... I cut it! ...

Teacher B explained in her interview that she wanted pupils to ‘explore and discover’ for themselves how this even sharing is carried out, almost forgetting that this was all about fractions. Although we tried to draw her attention to the interesting strategies pupils came up with while trying to share, she insisted in the interview on the importance of children getting familiar with the ‘sharing procedure’ which they had recently discussed in the class. She was stuck with material and kinesthetic activities promoting no connections and generalizations related to the idea of fractions, because “they were familiar, manageable by the children” and therefore appropriate. This interpretation is apparently context-specific, that is, concerns this particular occasion of the teacher’s management. Nonetheless, it is difficult to deny that this occasion can frame students’ conceptions specifically and possibly inappropriately with respect to the mathematical meaning under construction. Even if this is seen as an ‘effective’ introduction to the concept of fractions, it is possible to keep both the teacher and the students stuck to this action driven approach in the future, which allows for a partial conceptualization of the concept at hand.

**(3) Teacher C** (5<sup>th</sup> graders): The episode selected comes from a teaching session on comparing fractions. The teacher is closing the lesson by attempting to help students generalize and draw a conclusion. However, both she and the students remain faithful to referring to pizzas and to the quantity “we eat”.

- T: But there must be something in order to be able to compare! What have you noticed? How did I place the fractions in order to be able to compare? What is common in each case?  
 S: Either the denominators or the numerators are the same!

- T. When the numerators are the same, which fraction is larger?  
 Spyros: When the numerators are the same, you eat more when there are fewer pieces!  
 T: Listen ... When the denominators are the same, when do you eat more?  
 S: When the denominator is smaller!  
 T: Smaller!! Whereas, when the denominators are the same, when do you eat more?  
 S: You look whether the numerator is bigger!

The episode above is typical of what we would call a classroom ‘destruction of the mathematical meaning’ case. While working on ordering fractions, teacher C (a Mathematics degree holder, actively involved with research) keeps holding on to pieces and pizzas. Reflecting on this in her interview, she appears aware of the epistemological issues related to the knowledge managed in the classroom, but she is prepared to “sacrifice them”, to deal loosely with these, because of her priority to motivate students, to allow them accessing the mathematical idea to “any cost really” even though distorted (Kaldrimidou, Sakonidis & Tzekaki, 2013, p. 309).

## Discussion and concluding remarks

We presented the cases of three professionally active and highly motivated teachers with different, however, mathematics education background and varied awareness related to the nature of the mathematical meaning emerging in the classroom during instruction. The first of these teachers seems to be unaware of this aspect, while the second attempts to allow for mathematical elements to emerge, but through teaching practices of practical and partial character. Teacher C knows the importance of the mathematical content but prioritizes accessibility and manageability. In other words, all three teachers, intentionally or not, make choices concerning tasks, elements to highlight and approaches to manage which tend to reduce the mathematical meaning under teaching negotiation. These choices could be attributed to their desire to provide children with an ‘easy’, ‘safe’ and ‘pleasant’ learning environment. Their reflections on their teaching practices indicate that these decisions are strongly influenced by their own experience, regardless of their training and involvement with the pilot project and in accordance with Ponte & Champan’s (2006) position that “teachers eventually develop their own PCK ... shaped by their own experiences” (p.469).

In concluding, we would highlight two issues. First, that an analysis revealing classroom construction of the mathematical meaning requires, in addition to the study of teachers’ knowledge, of the mathematical content elaborated and of the tasks employed (Ball, et al., 2008) as well as of the management of students’ actions and thinking (Turner & Rowland, 2010; Davis & Smitt, 2003), a detailed analysis of the epistemological features of the content under construction (Kaldrimidou Sakonidis & Tzekaki, 2013). Teachers need to be aware of the importance of such an analysis of the mathematical meaning construction because they tend to either ignore or underestimate it. It is imperative to become aware that their management of the mathematical objects within the classroom connects or dissociates students from what should be at the heart of their instruction, that is, learning epistemologically legitimate mathematics.

# The interplay between sociomathematical norms and students' use of informal mental strategies or standard algorithms

Bodil Kleve and Gerd Ånestad

Oslo and Akershus University College of Applied Sciences, Norway; [bodil.kleve@hioa.no](mailto:bodil.kleve@hioa.no)

*In a year 4 classroom, we studied students' presentations of their solutions of problem-solving tasks. Sitting in pairs (learning-partners), they solved the tasks before presenting their solutions orally in class. Based on transcripts from video recordings of the lesson, students' written notes and post interview with the teacher, the role of sociomathematical norms related to students' use of informal mental strategies and standard algorithm for subtraction is discussed. For students flexibly to carry out arithmetic operations, we suggest to develop switching between informal mental strategies and standard algorithm as a sociomathematical norm. In that respect, attention is put on mathematical knowledge for teaching (MKfT) and emphasis on place value system is suggested as amalgam between different strategies.*

**Keywords:** Subtraction, place value system, learning-partners, mathematical knowledge for teaching,

«Ah, mental (informal) algorithms are all very well, but they must learn the standard methods sooner or later» **Or must they?** Plunkett (1979, p 4).

## Background and introduction

This paper is based on a study which purpose was to identify situations in a classroom where development of existing sociomathematical norms or establishing new norms may create potential for students' learning. A video research study was carried out in a year 4 classroom (9-10 years). An earlier publication reported situations in the classroom related to argumentations, and development of existing sociomathematical norms and establishing new norms were suggested in order to increase the potential for students' learning. (Kleve & Ånestad, 2016).

Based on students' (learning partners') written and oral presentations of a problem-solving task, where a three digits subtraction had to be carried out, sociomathematical norms (Yackel & Cobb, 1996) are identified and we discuss development of sociomathematical norms in light of mathematical knowledge for teaching (Ball, Thames, & Phelps, 2008; Rowland, Huckstep, & Thwaites, 2005). Our research question is: What role does mathematical knowledge for teaching play in order to develop sociomathematical norms, which can bridge the gap between informal mental strategies and standard algorithm for subtraction so the children can flexibly switch between different strategies?

Raveh, Koichu, Peled and Zaslavsky (2016) presented an integrative framework of knowledge for teaching the standard algorithm of four arithmetic operations. Studying connections between the four basic algorithms for arithmetic operations, they encouraged teaching the standard algorithm with emphasis on conceptual understanding, putting weight on connections between the four algorithms. In our study, the focus is on the relation between informal mental strategies and the standard algorithm for subtraction.

Torbyns and Verschaffel (2016) analyzed students' use of mental strategies and standard algorithm on subtraction. They found that when having been introduced for the standard algorithm:

Children presumably became gradually more efficient in this algorithm, while their mastery of mental computation in general, and compensation in particular, may have stagnated or even *declined* (p. 112, italics in original).

Even when numbers involved were suitable for and “strongly invited to mental computation strategies”, (ibid.) they found that students, when first having been introduced to the standard algorithm for subtraction, used this instead of mental strategies.

Torbyns and Verschaffel (2016) suggested that when the standard algorithm was introduced, the students would think that this newly introduced method was “the superior way to subtract larger number” (p.112). Referring to Yackel and Cobb (1996) they linked this to socio-cultural classroom norms in the classroom. Furthermore they referred to international efforts to reform elementary mathematics education which emphasizes children's abilities to flexibly apply informal mental strategies before they are introduced to the standard algorithm, and the claim that children then will continue to efficiently apply informal strategies. Torbyns and Verschaffel therefore encouraged research in more reform-oriented classrooms, comparing children from these with children taught in traditional oriented classrooms.

The classroom, in which our study took place, was reform oriented. There was a strong focus on children's use of own informal strategies and an extensive use of learning partners. The focus in this paper is on sociomathematical norms related to their use of informal mental strategies and/or use of standard algorithm for subtraction. Related to sociomathematical norms we also discuss what role mathematical knowledge for teaching play in the development of children's flexibility in using different mental strategies and the standard algorithm.

## **Theoretical perspectives**

“Sociomathematical norms are normative aspects of mathematical discussions that are specific to students' mathematical activity” (Yackel & Cobb, 1996, p. 458). Yackel and Cobb focused on sociomathematical norms when studying “how students develop specific mathematical beliefs and values and consequently become intellectually autonomous in mathematics [ ] how they come to develop mathematical dispositions” (p. 458). They distinguished sociomathematical norms from general classroom social norms in that they are specific to the mathematical activity carried out in a classroom. In our study, we focus on an episode where use of informal mental strategies and/or standard algorithm for subtraction as mathematical activity is discussed.

Sociomathematical norms can be what counts as an efficient mathematical solution, different mathematical solution and a sophisticated mathematical solution (Cobb, Stephan, McClain, & Gravemeijer, 2001). Cobb et al. emphasized that both social norms and sociomathematical norms are dealing with what is «Taken as shared» in the classroom.

Classroom norms are developed in collaboration between the teacher and students or between students. However, the teacher is the key person when norms are changing or new norms are established (McClain & Cobb, 2001). In our study, we consider that the teacher has great influence on sociomathematical norms, whether the norms are already established, in the process to be

weakened or under development in the classroom. We therefore want to link development of sociomathematical norms to mathematical knowledge for teaching.

Ball, Thames and Phelps (2008) developed a framework for mathematical knowledge for teaching, MKfT. They distinguished between *Common content knowledge*, which is mathematical knowledge possessed not necessarily for teaching, and *Specialized content knowledge for teaching*, which is about the teacher's way of 'unpacking' mathematics, neither necessary nor desirable for others to do. They also included a third category, *Horizon content knowledge*, which is about making connections between different areas and topics. "Horizon knowledge is an awareness of how mathematical topics are related over the span of mathematics included in the curriculum [ ]. It also includes the vision useful in seeing connections to much later mathematics". (Ball et al. 2008, p. 403).

In order to investigate how aspects of the teacher's mathematical knowledge surfaced in the lesson observed, the Knowledge Quartet (KQ) developed by Rowland, Huckstep and Thwaites (2005) has been a valuable tool. The KQ has four dimensions: Foundation, Transformation, Connection, and Contingency. Foundation is informing the other three dimensions, and Connection is the dimension, which we see as linked to "Horizon content knowledge".

Plunkett (1979) discussed pros and cons with regard to use of informal mental strategies and standard algorithm in school, and questioned whether standard algorithms necessarily have to be taught and learned. He claimed that unlike standard algorithms, which only deal with separated digits, informal mental strategies are holistic in that they work with complete numbers and thus requires understanding. Liping Ma (2010) emphasized regrouping rather than technical use of standard algorithm. When regrouping, the subtraction algorithm will be understood on a holistic number level, rather than as separate digits. False mathematical statements as "we can't subtract a bigger number from a smaller" will be avoided. Such false statements are related to teachers' horizon content knowledge (Ball et al., 2008).

Anghileri, J., Beishuizen, M., & Putten, K. v. (2002) compared the Dutch approach to written division calculations in school, which extensively built on children's own informal strategies, to the English approach which was schematic and focused on separate digits. Based on the results from their study Anghileri et al. (2002) warned against replacing informal strategies with standard algorithms. Rather one should give support to structuring informal approaches in a written record.

Referring to Plunkett (1979) and that calculations are carried out in real life, Anghileri (2006) emphasized children's mental strategies as a starting point for developing more formal methods.

Based on the above, one can suggest that when introducing a standard algorithm, teachers should focus on regrouping numbers and take children's informal mental strategies as a starting point. This puts demands on the teacher's mathematical knowledge for teaching, which again will constrain the sociomathematical norms in the classroom.

Referring to among others Ball et al. (2008), Raveh et al. (2016) proposed a framework consisting of four components: Procedural Knowledge (PK), Knowledge of Underlying Concepts (KC), Knowledge of Similarity between the algorithms (KS) and Knowledge of Representations (KR). In our analysis, we will use components from this framework, mainly PK and KC, and some of KR. PK is about carrying out the steps correctly in the (subtraction) algorithm, while KC refers to

knowledge about mathematical concepts underlying different algorithms as place-value and number regrouping. Rather than analyzing different representations of the subtraction algorithm as KR refers to in Raveh et al's framework, we emphasize the relationship between informal mental strategies, and the standard algorithm for subtraction.

In our study, we will not argue for not introducing the standard algorithm. However, we consider bridging between informal mental strategies and standard algorithm as valuable features of mathematics, which may influence students' mathematical beliefs. Development of flexibility and children's ability to switch between informal strategies and standard algorithm are linked to sociomathematical norms and to the aspects of teachers' mathematical knowledge for teaching.

## Methods

We observed two mathematics lessons in a 4th grade (mixed ability, 9-10 years old) classroom. Prior to the classroom observations, we had come to know the teacher. Her educational background was a pre-school teacher. She described her teaching as being reform oriented and that her students performed well on "transition tests". She had established an extensive use of learning partners in her classroom. She put her students together in pairs at random, same partner in all subjects, and changing partners every week. According to the teacher, the students never complained or protested against whom they received as their partners. This was established as a social norm in the class. With regard to Eli's view on mathematics teaching and learning, she emphasized the process rather than the product, saying: "For me it is not so important if the answer is correct. I am more interested in the strategy they use, that they have understood the principle behind solving such tasks". She also told us that she encouraged students to develop their own strategies in solving arithmetic problems and to discuss their strategies with their learning partner. Against this background, we wanted to study sociomathematical norms in Eli's class.

During our first visit in the class, we observed and wrote field notes. The second time we video recorded a 90 mins mathematics lesson. We used two cameras. The students were sitting in pairs and should solve different tasks, which were written on the board. After having solved the tasks, and written down their solutions, they presented their solutions orally. Towards the end of the lesson, they had some ('warm ups') whole class activities where they "worked with concepts" (teacher's expression). One of the activities was linked to the place value system.

Our analysis here is based on transcriptions of video recordings of their oral presentations and on their written work, which we collected. We also studied the video recordings together with the teacher several weeks afterwards. We interviewed the teacher and asked her to comment the different pairs' written sketches and oral presentations.

The task, on which we base our analysis, was written on the board:

Tobias has two 200 NOK notes and six 10 NOK coins. He spends half on a gift, 142 NOK on a book and then he buys "pig ears" to Doffen. One ear costs 11 NOK. How many ears can he buy?

## Analysis

The subtraction  $230-142$  had to be carried out to solve the task. Eleven out of twelve pairs of students had used the standard algorithm, however with different degree of detail in their oral presentations. The standard algorithm had become the "taken as shared" method (Cobb et al.,

2001). First, we discuss four pairs' written calculations (sketches) together with their oral presentations, illuminated with the teacher's comments to the presentations, then we go further into the teacher's comments from the interview. The teacher did not comment on any of the presentations in the lesson.

**Figure 1: Four pairs' written calculations**

The pairs' oral presentations:

- Pair 5: 230, it was easier to do 230 minus 130 equals 100 and then we did minus 12 because 130 plus 12 is 142, and that made 88
- Pair 9: 230 – 142 is zero minus two, doesn't work. We have to exchange from the three, and ten minus two is eight and then we have two left there. So then we take, however four minus two doesn't work either, so then we will have to exchange from the two. Ten minus four is six plus two is eight and then we have only one left, which makes one minus one is zero. So then it is 88".
- Pair 8: We did 230 minus 142 using the standard algorithm. We got 88
- Pair 7: 230 minus 142 is 88

Studying Pair 5's calculation, both their written work and oral presentation, we see that they did not use a standard algorithm for subtraction. The students regrouped the subtrahend 142 into 130 and 12. This way of calculating is flexible and requires understanding and a holistic way of thinking. They treated the complete numbers rather than separated digits (Plunkett, 1979).

The interview with the teacher Eli, with regard to Pair 5, revealed that she did not see the way of solving and presenting this as a potential for further development. The teacher expressed her acknowledgement of different ways of doing subtractions, but that this was a cumbersome and much lengthier way. She considered one of the students in the pair as a "funny one", and that "you need to be much sharpened to follow his thoughts. However, I keep telling him that he ought to start using another strategy in order to make things go faster. So after a while you' will have to do that". This is in line with Plunkett's (1979) characterization of informal mental strategies: "often difficult to catch hold of" (p. 3). This comment revealed that the teacher did not see the potential in her students' mental calculations for further development. She now looked upon the standard algorithm as the most efficient and sophisticated way of carrying out subtraction, and using the standard algorithm was in the process of being established as a new sociomathematical norm.

As we can see from figure 1, the three other pairs used the standard algorithm for subtraction. All correctly written out, displaying decomposition (exchange or borrowing). This can also be interpreted as regrouping of the minuend based on the place value system. However, the students did not express any regrouping. Studying their oral presentations reveals that the students were on different levels in using the algorithm. “Standard algorithms are *not easily internalized*. They do not correspond to ways in which people tend to think about numbers” (Plunkett, 1979, p. 3, italics in original). The pairs only referred to digits between 0 and 10. We suggest that this is why Pair 9 presented a detailed explanation of the algorithm as such. Their claims: “zero minus two, doesn’t work” and “four minus two doesn’t work reveal either”, reveal a misconception or a “false mathematical statement” (Ma, 2010, p. 3). These students have not been presented for negative numbers yet, and false mathematical statements like these may lead to later misconceptions about negative numbers. The students in this class (except Pair 5) used the term “exchange” when regrouping the minuend 230 into  $220 + 10$ , and when they later regrouped 220 into  $120 + 100$ .

A question here is whether the students know what they are doing. According to Plunkett, use of standard algorithms encourage suspended understanding. Pair 9’s explanation reflects procedural knowledge in carrying out an algorithm rather than conceptual understanding. Ma (2010) encourages regrouping rather than exchanging or borrowing (decomposing) when introducing the standard algorithm. Because then they will be working on a holistic number level rather than with separate digits.

With regard to Pair 8, they only said they had used the standard algorithm, whereas Pair 7 only presented the answer. They can be considered as having internalized the algorithm, and as Plunkett (1979) puts it: “While the calculation is being carried out, one does not think much about why one does it in that way” (p. 3).

In the interview with the teacher, Eli said that when starting a new arithmetic operation, she encouraged everyone to do it his or her own way, and that she used to present all students’ different informal strategies on the board. She expressed a great concern about these differences when a new arithmetic operation was being introduced. Thus, we consider that use of mental strategies for subtraction was earlier established as a sociomathematical norm. However, after having introduced the standard algorithm, this sociomathematical norm was in the process of disappearing, or at least fading, and a new sociomathematical norm was about to be developed. About the introduction of the standard algorithm, Eli said, “We practiced memory numbers and exchange in detail”. Consequently, we consider such detailed explanation as a new sociomathematical norm. This sociomathematical norm is also in the process of disappearing. Everybody was now expected to use the algorithm without further explanations or comments. As we see from our data, some students used the standard algorithm naturally without further explanation, while others still explained the procedure in detail. Only one pair (5) explained the subtraction as use of mental strategies without mentioning the standard algorithm. Hence, eleven out of twelve pairs looked upon the newly learnt algorithm “as a superior way” (Torbeys & Verschaffel, 2016, p. 112).

## Discussion

Our findings suggest that although Pair 5’s way of doing subtraction was not acknowledged (“he ought to start using another strategy in order to make things go faster”), the students displayed both

number sense and a well-developed subtraction concept. Of those who had used the standard algorithm, some explained the procedure in detail, Pair 9, while others just referred to the algorithm. Although they might have had conceptual understanding, they did not display it. Their focus was on the skill carrying out the subtraction *procedure*. According to Eli, the students who used the standard algorithm had developed a more mature number sense than those still using mental strategies. Although being influenced by reform-oriented working methods, Eli expressed the necessity of learning the standard algorithm, both as a tool, an assurance to always have a method to use, and as an efficient way of doing subtraction. She looked upon standard algorithms as a supplement to informal mental strategies. However, she was not aware what research has shown; when first have been introduced to the standard algorithm for subtraction and exposed to instruction emphasizing mastery of the standard algorithm, children will gradually become more efficient in using the standard algorithm, while their use of informal and mental strategies will fade (Torbeyns & Verschaffel, 2016). The challenge is to bridge or close this gap. A goal must be to develop sociomathematical norms where students are able to switch between different strategies dependent on the nature of the numbers involved. This puts demands on the teacher's MKfT, and especially the Horizon knowledge.

There was no indication in what the teacher said in the interview that the informal mental strategies the children earlier had used had been taken as a starting point when introducing the standard algorithm. The teacher's mathematical knowledge for teaching seemed too fragile to give her courage to rely on students' mental strategies, and thus to bridge the gap. The mathematics presented for her students seemed to be fragmented. During the place value activity towards the end of the lesson students should answer questions as "what value does 1 have in 5129?" If this had been linked to the standard algorithm for subtraction, regrouping, based on place value system, could serve as an amalgam between informal strategies and the formal algorithm. This refers to Raveh et al.'s (2016) KR, which we see as knowledge about connections between informal strategies and mental strategies. Attention could here be brought to the foundation and connection aspects of the teacher's knowledge (Rowland et al., 2005). Knowledge of the mathematical concepts underlying the algorithm, KC (Raveh et al., 2016) did not surface in what she said. However, she demonstrated procedural knowledge (PK) related to correct computations and the steps in the algorithm.

Our findings suggest that the teacher did not see the potential in taking earlier established sociomathematical norms about students' use of mental strategies as a starting point. We claim that linking informal mental strategies to the place value system in introducing the standard algorithm for subtraction would enhance students' ability to switch between informal strategies and the standard algorithm, dependent on the numbers involved. Regrouping based on the place value system could then serve as an amalgam between informal mental strategies and the standard algorithm.

Based on our data, we cannot say anything about the sociomathematical norms related to other areas of the mathematics in this classroom. However, the students had not yet been introduced to the standard algorithm for division. We saw that in carrying out the necessary division operation to solve the task (how many ears can he buy?) 88:11, the students used either repeated subtraction or repeated addition as (informal) mental strategies.

Encouraging teachers to rely on and see the potential in earlier established sociomathematical norms where students use informal mental strategies, are important issues for further research. In that respect, attention must be directed towards teachers' mathematical knowledge for teaching, with special focus on Horizon knowledge and the connection dimension of the teacher's mathematical knowledge (Ball et al., 2008; Ma, 2010; Raveh et al., 2016; Rowland et al., 2005).

*The recontextualization taking place during the implementation of a new curriculum are identified through different discourses teachers draw on in order to attribute meaning to the ideas promoted by the new curriculum. The paper studies the ways in which thirteen Greek primary school teachers who participated in a one-year pilot implementation of a new mathematics curriculum recontextualized its innovations through the discourses they drew on. The analysis of the data revealed contradictions within the teachers’ discourse that can be attributed to the recontextualization procedures activated during the implementation of the new curriculum and indicate inconsistencies within or/and between the various discourses available to them.*

*Keywords: Curriculum, mathematical processes, reform, recontextualization, teachers.*

## **Introduction**

A number of studies examining mathematics curriculum reforms reveal the complex nature of the change in the teaching practices and the agents operating at the institutional level (State) as well as at the individual level (teachers), constituting obstacles to the implementation of the innovations promoted. The results of these studies indicate distortion of the innovations promoted, mainly because of the dominance of traditional teaching approaches and only partial adoption of innovative features, usually of those that can be painlessly integrated into existing teaching practices. While teachers’ beliefs can be considered critical for the implementation of a mathematics curriculum, there are difficulties in using beliefs to interpret effectively the outcomes of the implementation. According to Lerman (2002), research should keep distances from such “personalized” views on the relations between beliefs and practices, so that the “conflicting” ways in which promoted reforms are reflected in the practices of teachers can be understood and interpreted as social phenomena (e.g. Morgan, Tsatsaroni & Lerman, 2002). Research to this direction, although still very limited, is of particular importance for making sense of the problems arising while implementing a mathematics curriculum that goes beyond the concept of belief. We argue in this paper that Bernstein’s concepts of recontextualization and recontextualization fields have much to offer in understanding how intervention programs employing socio-cultural approaches succeed or fail because of teachers’ ways of interacting dynamically with curriculum reforms (e.g. Jaworski, 2007).

## **Implementing a new mathematics curriculum: recontextualization in practice**

Each new curriculum is unavoidably being ‘altered’ during its implementation by the action of institutional factors as well as of the teachers themselves. This situation does not differ from that of the distortion of academic mathematics during their transformation to school mathematics and of the academic knowledge related to mathematics education when ‘translating’ it the knowledge needed to

support mathematics teaching in practice (Morgan, 2010). More specifically, the actions of those involved with school mathematics aim to develop students' relevant knowledge rather than to extend mathematical knowledge itself. Moving from academic mathematics (production field) to school mathematics (reproduction field) presupposes a reframing process of the discourse established both in the first and in other areas (e.g., in relation to learning theories) [the term 'discourse' refers to a social construction that establishes a person's social hierarchy (Koulaidis & Tsatsaroni, 2010)]. This is similar to the transition from mathematics education research and theory production field (academic) to the reproduction field (school). Teachers are generally not engaged in producing new knowledge about teaching and learning, but are expected to acquire knowledge and skills that enable them to teach effectively. The development of curricula, the production of teaching materials that support a curriculum and the professional development activities play an important role to this. The field of reproduction here is embedded in many fields of teachers' professional life, creating a more complex environment for developing discourses related to their practices.

The adoption of a sociological agenda for examining the process of implementing a new curriculum, which prioritizes the notion of 'recontextualizing knowledge', could provide an operational framework for understanding and interpreting problems arising because of the complexity of the task. Such a framework is being proposed by Bernstein (2000), who focuses on a pedagogical mechanism that structures and organizes the educational contents and their distribution based on the dominant process of recontextualizing. That is, the transfer of knowledge through selection procedures from the fields where it is produced (e.g., universities) to areas of formal or informal training (e.g., classroom). Bernstein (2000) distinguished the Official Recontextualizing Field (ORF), established and dominated by the State for the construction and supervision of the State pedagogical discourse, and the (official) Pedagogic Recontextualizing Field (PRF), in the formulation and management of which agents such as teachers' trainers, more or less independent of the State, are involved. The relationship between the two fields and the curriculum reform processes depends on the degree of the PRF autonomy, the extent to which the discourses produced by these fields differ and the source of reproduction of the revised curriculum (Morgan, 2010). Teachers act as agents in the PRF, reproducing the official pedagogical discourse established in the ORF. However, their practices cannot be completely regulated externally. What is being reproduced at school and in classroom depends on the principles of recontextualization that arise from "the specific context of a particular school and the effectiveness of the external control in the reproduction of the official pedagogical discourse" (Bernstein, 2000). That is, from the operation of the complementary resources that are being produced locally (Local PRF, in distinction to Official PRF). This suggests that, despite the independence between them, the recontextualization fields influence each other, with the agents playing an important role in more than one fields (e.g., researchers who teach in universities, in professional development programs, in the formation of a new curriculum etc). This complex relationship creates differences between pedagogical discourses established in different fields of recontextualization and, consequently, between the practices adopted on the basis of these discourses. The interaction between the fields of recontextualization on the one hand and the interpretations of the discourse developed in these fields on the other generates the resources used by teachers to legalize their practices in classroom.

In the Greek educational system the State has almost absolute control over the curriculum, its implementation at school level, the production of educational materials and teachers' professional

development. There is not, therefore, a truly independent PRF. However, there are differences between individual fields of recontextualization and the discourses these produce, providing diverse resources of curriculum interpretations for teachers in the field of reproduction. Teachers draw on discourses arising from teaching and learning processes experienced during their own mathematics education and within the context of their professional activity. The absence of a discernible pedagogical recontextualization field, independent of the Greek State's control, influencing mathematics classroom teaching practices and the meaning attached to them by teachers as well as the occasion of a new mathematics curriculum being implemented in the country, offered a situation seen as worth studying.

### **A new mathematics curriculum in Greek schools**

Studying the curriculum reform of Mathematics undertaken in Greece, various levels of the development and the structure of the administrative control exercised by the State can be identified. It appears that different agents occupy different positions within this structure and are involved in recontextualizing the curriculum, having different interests and different relationships with schools and teachers. The Greek recontextualization field can be considered to consist of three official sub-fields: (a) the Official Recontextualization Field (ORF) - the curriculum itself and its authorities are set up at a national level by the Ministry of Education, (b) the Official Pedagogical Recontextualization Field (OPRF), where the production of all educational materials like textbooks is directly controlled by the Ministry of Education, (c) the Local Pedagogical Recontextualization (LPRF) field related to the implementation at the school level, where schools and teachers interpret the new curriculum through training and additional resources produced locally. Although both the OPRF and the LPRF have a degree of autonomy, this is quite limited. The discourses produced by the agents in these two fields (e.g., in the form of mathematics textbooks, public examinations or teachers' training programs) should be approved by the Ministry of Education. Unlike the educational systems in most Western countries, there is no Recontextualization Pedagogical Field independent from the Greek State to influence the adoption of instructional practices. However, even when the State does not encourage the development of independent discourses relating to the curriculum, the different individual fields that make up the field of recontextualization and the generated discourses act as sources on which teachers can draw to 'interpret' the curriculum in the field of reproduction. In addition, teachers can draw on previous discourses related to mathematics, for instance produced locally, at school and in the wider community.

As it has been already mentioned, the Greek educational system is highly complex, its administration is being exercised centrally and the hierarchical structure of its organization and management are characterized by high concentration of powers at the top. Every educational activity, be it the identification of educational objectives, the implementation of the curriculum, the educational materials used to support teaching and learning or the evaluation of teachers' work, is centrally controlled. The heavily complex and centralized nature of the Greek educational system creates differences between the pedagogical discourses produced at different levels of the recontextualization fields. In turn, differences between the pedagogical texts, between the practices adopted by these different pedagogical discourses and between the ways in which teachers might legitimize their practices are evident. Morgan (2011) states that the interaction between recontextualization fields and the interpretations resulting from the production of different discourses create space for teachers to

place themselves in the position of a ‘good teacher’, legitimizing a number of different classroom practices.

The above situation is quite different from that met in well known educational systems like the British, where the curriculum is strongly controlled by the State and is being regulated by tests and inspections. There is an organized pedagogical recontextualization field that holds a high degree of autonomy and is being developed mainly at universities and educational communities. The Pedagogical Recontextualization Field produces alternative discourses related to the curriculum by setting up different sets of recontextualization authorities and plays an important role in reframing the discourse of the curriculum produced in the Official Recontextualization Field (Morgan & Hu, 2011). Despite the fact that the two fields are independent in structure, they affect one another (for example, mathematics education academics participate in working groups for the design of the mathematics curriculum or in national exams committees using State-defined standards). Given the tight control exercised by the Greek State on the whole educational process, no independent Pedagogical Field can be ever expected.

### **The study**

The context of this study is provided by a recent reform effort in the Greek compulsory education system concerned with the development of new curricula, completed in 2011, piloted for two years and presently utilized primarily in experimental schools. A central innovative element with respect to mathematics education has to do with students’ active involvement with activities that enhance processes such as a) mathematical reasoning and argumentation, b) creating bonds between concepts, c) communicating through the use of different tools and d) promoting metacognitive awareness (Institute of Educational Policy, 2014). Utilizing Bernstein’s theoretical framework, the study focuses on the impact of this reform on teachers’ recontextualization practices. In specific, the aim of the study is to examine the ways in which primary teachers participating in a one-year pilot implementation of the new curriculum recontextualized its innovations, especially the mathematical processes promoted, based on their pedagogical discourse.

The sample consisted of 13 primary teachers who worked in three schools in the north-western part of the country. Most of the teachers had considerable teaching experience (10–25 years) and were involved in professional development activities, such as participating in in-service training programs and research projects. During the study, five teachers were teaching to upper, four to middle and four to lower primary school classes. The teachers were all involved in the implementation process of the new mathematics curriculum because their schools were selected by the State as pilot units. The extent of their involvement was determined by their sense of ‘duty’ to meet the requirements set by the new curriculum but also by their interest to participate in activities promoting their students’ learning and their professional development.

The study included two phases. In the first, a non-participant observation of teachers’ reformed mathematics teaching took place. The teachers were observed for two teaching sessions and were then interviewed mainly in relation to the ways they exploited the mathematical processes promoted by the new curriculum in designing and implementing their instruction. The second phase included a semi-structured interview with each of the teachers aiming to study the pedagogical discourse developed and through that the recontextualized process that possibly took place in relation to the

mathematical processes promoted by the new curriculum. Each teacher was interviewed for four hours in four meetings.

To describe the procedures of recontextualization of the mathematical processes taking place, techniques of Grounded Theory and Content Analysis were utilized. In particular, articulations associated with each of the recontextualization fields were identified, coded, grouped and merged, providing meaning to its content and structure. Specifically, the analysis of the data from the semi-structured interviews was carried out at two levels. First the researchers held multiple and careful readings of the interview transcripts, identifying phrases for each mathematical process within each recontextualization field. The recorded phrases in each recontextualization field were then coded and those indicating a ‘special’ aspect of the corresponding field were identified and marked with a new code. When a phrase that reflected a field reappeared, it was also noted. So, gradually, the phrases that were part of each first level domain were organized into second level categories, based on the ‘special’ theme. In the following, some results from the second phase of the study are presented and discussed.

## Results and discussion

In the following, the participant teachers’ conceptualizations of each of the four mathematical processes promoted by the new curriculum as emerging through their discourse are briefly presented and discussed.

(a) Mathematical reasoning and argumentation: Teachers interpreted mathematical reasoning and argumentation in a way that is consistent with the official discourse, as aiming to promote classroom interaction. This interpretation is related to the professional official discourse and is supported by tasks demanding cooperation and communication included in the mathematics textbooks produced and distributed by the State. Consistency in the recontextualization between the Official Pedagogical Recontextualization Field and the Local Recontextualization Field with respect to this process is identified (e.g., difficult to apply in practice).

But there is a problem ... it is the textbooks we use, they do not help us at all. We must follow the material and we do not anticipate. Of course, I give more exercises; beyond the textbook ... the textbook does not cover us. And moreover, you know something? We have the pressure from parents who want more exercises. They are pushing us and they do not understand what we do (teacher with 11 years teaching experience, moderate professional activity, teaching to a lower primary class).

Time often forces me not to be able to give the time needed so that the student loses the opportunity to communicate, but communication is essential (teacher with 19 years of teaching experience, moderate professional development activity, teaching to a middle primary class).

The ‘objections’ raised drew mainly on a local discourse concerning classes, especially size of classes, the time pressure and parents’ demands. Teachers also drew on elements from the conventional discourse facing mathematics as a ‘discipline’ which is not always available for discussion because of its ‘absolute nature’.

(b) Creating bonds between concepts: Teachers appeared to be aligned with the official discourse with respect to this process, giving however little value to it. They only deviated from it when referring to opportunities of exploiting this process in classroom. To this direction they made reference to a pedagogical recontextualization often governed by informal, local factors (e.g., the importance of knowing ‘good’ mathematics, of repetition, of continuous emphasis on conceptual understanding) and not by official “routes” (e.g., attending courses on issues of teaching mathematics).

I’m not sure about what you mean ... relate to other mathematical concepts, that is what? Now we do fractions, what should I do, then? It sounds important .... Solving exercises, repetition, this must be done, otherwise mathematics would be forgotten (teacher of 21 years of teaching experience, moderate professional development activity, teaching to a lower primary class)

(c) Communication through the use of different tools: Teachers’ discourse concerning mathematics classroom communication utilized different tools mainly related to the importance of tasks requiring the use of manipulatives, through which students are able to use their hands to ‘do things’ (for example, to cut a piece of paper, to take cubes from a bag etc).

We are working with manipulatives in the class every day. But if you do maths in an experimental way, when will you understand that maths is not a game? We need to be accurate (teacher of 11 years of teaching experience, moderate professional development activity, teaching to a lower primary class)

The same idea seems to prevail when reference is made to the use of technology and digital materials. No distinction was made between the presence and functionality of colors, virtual objects, sounds and other digital ‘goodies’ that do not have themselves any mathematical meaning but exist to invigorate the general ‘elegance’ of software (Institute of Educational Policy, 2014). As argued in the “Teacher’s Guide” (2014), in cases where digital technology ‘provides’ a patchwork of mathematical and non-mathematical representations, the importance of mathematical representation deteriorates.

I personally deal successfully with technology because I like it. It facilitates our work when we are going to teach difficult mathematical concepts. It is impressive with all these shapes, colors, the environment, but also it is functional, a tool to work (teacher of 21 years of teaching experience, moderate professional development activity, teaching to an upper primary class)

Teachers’ discourse drew also on their own mathematical education and the experience gained from the previous curriculum.

We are the generation of the book, but we can do things with the computers. It would be nice for us to be familiar with it, but so far it was not provided, nor from the previous curriculum (teacher of 17 years of teaching experience, moderate professional development activity, teaching to an upper primary class)

This mix of ‘conformity’ to the official discourse with opposition to it was expressed implicitly by teachers who were resisting to the official discourses (but one teacher), although they seemed to be in favor of it.

(d) Metacognitive awareness: Teachers argued for this process and ‘wished’ they could foster more of its components into their teaching. On the whole, they aligned with the relevant official discourse.

However, they deviated from it when referring to the conditions set for the use of this process in class, moving to a pedagogical recontextualization determined predominately by informal, local factors (e.g., the effectiveness of mathematics learning and the coverage of the appropriate content) and less by official agents.

For me it is important for students to really have the desire to explore and then teachers will guide them effectively...However, for students who are less 'comfortable' with this, it is a great challenge, but I'm disappointed...If these conditions are met, then it is a good idea, but I can say that especially for my class, to be honest, it is difficult (teacher with 16 years of teaching experience, university degree, moderate professional development activity, teaching to a lower primary class).

## Concluding remarks

Teachers drew mainly on the resources provided by the official discourses when arguing about the four mathematical processes promoted by the new curriculum and tended to align to these discourses. However, they deviated from them when interpreting these processes in relation to their own classes. The official discourses shape the range of the new curriculum interpretations in relation to teaching and learning, while the conventional and local discourses fuel teachers' pedagogical discourse with further resources for understanding the new mathematics curriculum having an impact on the options available to teachers and adopted by them in the classroom practice. This finding raises the question why some discourses are more powerful than others regarding the influence they have on teachers. The strength of the local school discourse of other teachers, parents and pupils can also be related to the regulatory effect exerted by the school administration, which requires certain standards in student performance. As the official discourses, such as the discourse promoted by a curriculum, do not 'recognize' the difficulties in implementing key curriculum principles or the recontextualizations activated during classroom implementation in different students or groups of students, teachers need a 'way of facing' the difficulties experienced in their classroom, seemingly provided by the resources of the local discourse.

In the Greek educational reality is evident the parallel operation of recontextualization fields, often mutually incompatible, which influence contradictory ways in which teachers select and transform the official discourse. Teachers utilize the discourses produced in these fields and place themselves in relation to them, being affected by their official or non-official nature, thus creating the potential for resistance and for the use of alternative discourses. The study of the implementation of a new mathematics curriculum will benefit from the analysis of the structures that rule the recontextualized fields and their discourses as this will help us understand the ways in which the choices and the transformations taking place within these discourses shape teachers' professional practices in educational contexts similar to but also beyond the ones studied here.

*This paper reports on a review of 12 empirical studies framed to address the problem of whether and in what ways mathematical knowledge for teaching influences teaching practice. From a larger review of literature on mathematical knowledge for teaching, this qualitative synthesis examines the theoretical foundations, methods applied and claims made. Most of the studies reviewed are small-scale qualitative studies. There is variability in the language to describe teaching and in how focused the studies are on teaching. We suggest that the tendency has been to focus on the question of the knowledge that teachers need, but that it would be more useful to focus on the mathematical entailments of doing teaching, which will require more detailed and shared conceptualizations of the mathematical work of teaching.*

*Keywords: Mathematical knowledge for teaching, teaching practice, literature review.*

## Introduction

In a review of literature on mathematical knowledge for teaching from 2006 to 2013, with colleagues we identify a number of studies that argue that mathematical knowledge for teaching influences teaching practice (Hoover, Mosvold, Ball, & Lai, 2016). The connection between mathematical knowledge for teaching and the quality of instruction is, however, complex. Hill, Umland, Litke, and Kapitula (2012) report evidence that weak mathematical knowledge for teaching predicts low instructional quality, and strong mathematical knowledge for teaching predicts high instructional quality, yet they also report that there is much more variation in teaching quality as well as in student achievement with teachers who perform in the midrange on measures of mathematical knowledge for teaching. Likewise, Hill et al. (2008) suggest that professional development, supplemental curriculum materials and teacher beliefs are all factors of potential influence, but these factors may cut both ways depending on the teachers' mathematical knowledge for teaching. In addition, efforts to clarify the conceptualization of mathematical knowledge for teaching continue to be concerned with the dynamic nature of mathematical knowledge for teaching, the usefulness of knowledge, and whether, when, and how it plays in teaching (Ball, 2016; Kersting, Givvin, Thompson, Santagata, & Stigler, 2012). From these different lines of work, it seems clear that decisions about teacher education or policy cannot be made simply by establishing *that* mathematical knowledge for teaching correlates with teaching practice. Although these correlational studies are arguably important, in this review we draw attention to the need to refine our understanding of *how* mathematical knowledge for teaching influences teaching practice.

## The literature review

The present paper draws on results from a larger literature review of empirical research on mathematical knowledge that is specific to teaching (Hoover, Mosvold, Ball, & Lai, 2016). That

review included a total of 190 articles that were coded for the following categories: 1) genre of study, 2) research problem used to motivate the study, 3) variables used, 4) whether or not and how causality was addressed, 5) findings. A research problem is an issue, topic, or question that motivates a study, indicating why the results would be of interest and how an investigation is linked to the literature. In most instances, the research problem was the same as what was specifically investigated, but at times there were tensions between the research problem and the research questions or the specific focus of the analysis. Distinguishing between research problems and the genre of the study helped us understand what a paper argues and how. In coding the research problem, we paid specific attention to the introduction and conclusion as opposed to the statement of the research questions or the specifics of the research design. In general, differences between the research problem and the research genre or design reflected inevitable tensions in the interrelated components of empirical research publications and provided useful insight into the approaches used in the study and the arguments made in the article. When considering the research problems that motivated the studies in our larger review, 12 studies focused on the ways in which teachers' knowledge contributes to practice. In this paper, we analyze these 12 studies with a particular focus on the theoretical frameworks of the studies, the methods applied and the claims made.

### **Studies of the influence of mathematical knowledge for teaching on teaching**

The 12 studies framed to address the problem of whether and in what ways mathematical knowledge for teaching influences teaching practice have different characteristics. Seven studies investigate effects of mathematical knowledge for teaching on teaching practice (absent a specific intervention), one is an intervention study and four studies investigate mathematical knowledge for teaching as a construct in relation to teaching. Only one of the studies is quantitative, whereas most studies are small-scale qualitative studies. The participant teachers in the studies teach mathematics in primary, middle, and secondary schools, as well as at the university level — most of them are practicing or experienced teachers (see table 1).

Study	Sample size	Type	Causal design	Experience and level of teachers	Region	Teaching studied
Bansilal (2012)	Small (n=1)	Effect	Qualitative	Practicing secondary	Africa	Identifying key ideas, organizing explanations, listening to students
Cengiz et al. (2011)	Small (n=6)	Effect	Qualitative	Experienced primary	North America	Extending student thinking
Charalambous (2010)	Small (n=2)	Effect	Qualitative	Practicing primary	North America	Using representations, giving explanations, Interpreting and responding to student thinking
Choppin (2011)	Small (n=1)	Nature	None	Experienced middle school	North America	Engaging students with challenging tasks
Izsák et al. (2008)	Small (n=1)	Effect	Qualitative	Practicing middle school	North America	Using number lines for fraction addition
Johnson & Larsen (2012)	Small (n=1)	Effect	Qualitative	Practicing tertiary	North America	Listening to student thinking

Nardi et al. (2012)	Medium (n=11)	Nature	None	Practicing secondary	Europe	Identifying task objectives, interpreting and responding to student thinking
Rowland (2008)	Medium (n=24)	Nature	Qualitative	Future primary	Europe	Selecting and using examples
Speer & Wagner (2009)	Small (n=1)	Nature	Qualitative	Practicing tertiary	North America	Social and analytic scaffolding
Steele & Rogers (2012)	Small (n=2)	Effect	Qualitative	Practicing secondary	North America	Integrating different ideas of proof and positioning students as observers, creators, and explainers
Sullivan et al. (2009)	Large (n=97)	Intervention	Statistical	Practicing all levels	Oceania	Converting tasks to lessons
Tanase (2011)	Small (n=4)	Effect	Qualitative	Practicing primary	Europe	Connecting place value to other mathematical concepts, setting objectives, challenging students

**Table 1: Studies investigating influences of mathematical knowledge for teaching on teaching**

Next, we describe these studies with a focus on what they investigate, their methods, how teaching is conceptualized, and what we can learn from them. Cengiz, Kline and Grant (2011) focus on how teachers' MKT supports their teaching. They develop an extending-student-thinking framework based on analysis of instructional actions within episodes. In their investigation of six experienced elementary teachers, they draw upon Ball et al.'s (2008) conceptualization of mathematical knowledge for teaching. It is assumed that the participating teachers, due to their experience, have well-developed MKT. From analysis of video-recorded classroom observations and teacher interviews, these researchers provide detailed accounts of teaching and “demonstrate that MKT matters in the way teachers pursue student thinking” (Cengiz et al., 2011, p. 372). Their analysis of data from one of the participating teachers “provide evidence that a lack of certain aspects of knowledge can negatively impact a teacher's pursuit of student thinking” (p. 372). Similarly, Izsák, Tillema and Tunç-Pekkan (2008) provide fine-grained details in their analysis of the cognitive structures used by a teacher and her students when using number lines as a representation for fraction addition. Audio- and video-recorded interactions of a practicing middle-school teacher and her students formed a starting point for interviews with three pairs of students. Excerpts from lesson and student interviews were then used in a video-elicited interview with the teacher. They argue that subtle variations in the teacher's approach to partitioning unit intervals matter for the students' opportunities to learn.

Several studies are situated in the teaching of particular mathematical content. Steele and Rogers (2012) investigate the relationship between mathematical knowledge for teaching proof and teaching practice by combining clinical assessments with classroom observations of two secondary teachers — a novice and an expert teacher. Data collection included lesson observations, pre- and post-lesson interviews, written assessments and semi-structured interviews after the observation. The authors argue that the more experienced and MKT-knowledgeable teacher not only enacts a stronger and more nuanced lesson on mathematical proof, but her students end up having more mathematical authority. They argue that their use of MKT as a frame for examining practice provides an innovative

method for investigating both MKT and features of instruction, such as student positioning as a key, mediating factor between MKT and opportunities to learn.

A study by Tanase (2011) investigates the connection between four Romanian first grade teachers' mathematical knowledge for teaching place value and their classroom practice. The participants are selected from a well performing and an average performing school in Romania. One experienced and one less experienced teacher from each school is selected for participation, and data collection includes teacher interviews, classroom observations and student assessments. Although all four teachers display good understanding of place value, Tanase suggests that teachers' knowledge goes beyond their own mathematical understanding. Differences are observed in teachers' ability to make connections between place value concepts and other mathematical concepts, how they set different objectives for students as well as the extent to which they challenge students in their mathematical work. Tanase also observes that although teachers have strong mathematical knowledge for teaching, and this knowledge impacts the quality of their instruction, their students may still not perform well. She suggests that student achievement is also influenced by external factors inside and outside of school.

Among these initial investigations of the specific influence of mathematical knowledge for teaching on teaching, most studies focus on teachers in primary, middle or secondary school. Two studies focus on mathematics teaching at university level. Speer and Wagner (2009) examine one undergraduate instructor's use of constructs of social and analytic scaffolding as a frame, the authors argue that aspects of pedagogical content knowledge are important for helping students find productive ways of solving particular problems and for understanding which student contributions, whether correct or incorrect, are important to emphasize in a discussion. They trace ways in which teachers' particular knowledge of students' understanding aids them in assuring that the lesson reaches intended mathematical goals and in understanding the role of particular mathematical ideas in students' development.

Another example is Johnson and Larsen's (2012) study of how a university teacher's mathematical knowledge influences her ability to listen when teaching abstract algebra. Their investigation focuses on how this particular aspect of mathematical knowledge for teaching supports mathematics teachers' listening when implementing a reform curriculum. Their theoretical framework distinguishes among three types of teacher listening: hermeneutic, interpretative and evaluative. Drawing on Speer and Wagner's (2009) argument that teacher listening requires particular types of mathematical knowledge for teaching, Johnson and Larsen examine the role of knowledge of content and of students in hearing tertiary students as they engage in reinventing the group concept in abstract algebra. Based on analyses of three teachers' classroom interactions when implementing a particular reform curriculum, Johnson and Larsen report on a teacher whose classroom interactions contained several episodes where the students were confused and the teacher was unable to make sense of their struggles. They observe that this teacher's ability to listen to her students draws on her knowledge of content and students. Johnson and Larsen posit that teachers need not only knowledge of students' misconceptions, but also knowledge of when and why students are likely to be confused and display misconceptions and of the consequences of such misconceptions when students engage in new activities.

The focus on teacher listening is also prevalent in Bansilal's (2012) investigation of how a South-African mathematics teacher's poor mathematical knowledge influences her classroom interactions. In this case study, the focus is on the process-object understanding of ratio. Based on narrative analysis of field notes and transcripts from five lesson observations with interviews, Bansilal organizes her claims around three emerging themes. First, she argues that the teacher displays limited understanding of ratio in her teaching. Second, she argues that the teacher fails to identify key ideas and organize her explanations in a way that enables the students to notice the big ideas involved in the mathematical task. Third, Bansilal points to the stressful environment that the teacher experiences in this classroom and suggests that this environment is caused by her lack of knowledge of the students as well as her preference for evaluative rather than interpretative listening.

In his study of mathematics teacher knowledge and its impact on how teachers engage students with challenging tasks, Choppin (2011) explores pedagogical content knowledge as situated in an instructional sequence. From his study, he aims at exploring teachers' "local theory of instruction". Choppin investigates an experienced middle-school mathematics teacher while she is teaching a particular curriculum unit over two years. In order to investigate the teacher's knowledge, interview data are analyzed with a focus on her articulation of "(1) how student thinking develops over time, (2) the process by which that thinking develops, and (3) the resources that facilitate the development of student thinking" (p. 12). Based on his analysis of data, Choppin claims that the teacher develops her local theory of instruction from teaching. The teacher's knowledge appears to influence her teaching in several ways, for instance in her adaptation of tasks.

Engaging students with challenging tasks is an important component of the work of teaching mathematics, and so is the selection and use of appropriate examples. Rowland (2008) focuses on mathematics teachers' purposes for using examples in elementary mathematics teaching. Video recordings from 24 lessons taught by 12 pre-service elementary teachers are analyzed from a grounded approach, and codes are developed that focus on aspects of their teaching practice. The resulting 18 codes — one of the most common codes is "choice of examples" — are then placed in four overarching categories that constitute Rowland's conceptualization of mathematical knowledge in teaching, commonly referred to as the knowledge quartet.

Although eight of the studies reviewed investigate effects of mathematical knowledge for teaching on mathematics teachers' classroom practice, only one applies standardized measures of mathematics teacher knowledge. In his exploratory study, Charalambous (2010) investigates the connection between two primary teachers' mathematical knowledge for teaching and their use of mathematical tasks. The two primary mathematics teachers had different levels of mathematical knowledge for teaching — as measured by MKT measures — and notable differences were found in how they planned, presented and implemented mathematical tasks. Charalambous applies Stein and colleagues' mathematical tasks framework to examine the cognitive level of enacted tasks, and he formulates three tentative hypotheses about mechanisms of how mathematical knowledge for teaching impacts teachers' selection and use of mathematical tasks. First, he hypothesizes that strong mathematical knowledge for teaching may contribute to a use of representations that supports students in solving problems, whereas weaker mathematical knowledge for teaching may limit instruction to memorizing rules. Second, he proposes that mathematical knowledge for teaching appears to support teachers' ability to provide explanations that give meaning to mathematical procedures. Third, he proposes that

teachers' mathematical knowledge for teaching may be related to their ability to follow students' thinking and responsively support development of understanding.

The study of Nardi, Biza and Zachariades (2012) differs from many of the other studies on how teachers' knowledge influences their teaching practice in that they do not study observed teaching. Instead, these researchers analyze teachers' argumentation about hypothetical classroom scenarios in task-based interviews. From their analysis of eleven teachers, they suggest that the teachers' warrants for the claims made about these classroom scenarios are not always mathematical. Their argument, which has potentially interesting methodological implications, is that analysis of the argumentation provided by teachers in such task-based interviews may provide insight into how the teachers' knowledge and beliefs influence their classroom interactions.

Sullivan, Clarke and Clarke (2009) also investigate the influence of teacher knowledge on the planning phase of teaching. In particular, they investigate the assumption that teachers are able to convert tasks to lessons easily. From their analysis of 107 primary and secondary teachers' responses to questionnaire items — and interpreting the responses by using the subcategories of MKT — they observe that many teachers find it difficult to translate tasks to lessons. For instance, many teachers find it difficult to convert the task of determining which of  $\frac{2}{3}$  and  $\frac{201}{301}$  is larger into a worthwhile learning experience for students.

## Discussion

With regard to research design and choice of methods, we observe that most of the studies are small-scale qualitative studies that explore the connections between mathematics teacher knowledge and teaching practice in different ways. Although many studies draw on a similar conceptualization of mathematical knowledge for teaching, only one study applies one of the existing standardized measures of such knowledge (Charalambous, 2010). Several studies present innovative methods to investigate contributions of teachers' mathematical knowledge to teaching practice, such as video-elicited interviews and hypothetical classroom scenarios in interview prompts. As we have argued elsewhere (Hoover et al., 2016), given that research in this arena is in early development and to date we lack clear, replicable methods, scholars' efforts to innovate seem well placed. Ideas proposed in these dozen papers contribute to that development.

Each of the 12 studies reported is concerned with uncovering what, how, and why mathematical knowledge for teaching matters for teaching, yet the overall picture is unclear. One issue may be that an effort to show *that* mathematical knowledge for teaching matters (a focus on impact) may lead to holding knowledge and teaching at arms length in ways that obscure the dynamic nature of the role of that knowledge in teaching. For instance, several papers argued that teachers' lack of knowledge constrained what they were able to see, hear, and do, without taking the additional step of elaborating what knowledge arises in the work, when, where, and how. We suggest that the field would profit from studies that examine the interplay between knowledge and teaching practice and that impact studies are better conducted at a larger scale once clear conceptual and measurement tools are in place. Another issue may be that the conceptualization of and focus on *teaching* in these studies is underdeveloped. Some of the studies examine what might be better described as features of instruction than as teaching practice. For instance, Steele and Rogers (2012) examine the degree to which different ideas of proof are integrated into instruction and how students are positioned in

relation to mathematical explanation. We agree that these are important, but would like to understand more fully what it is that teachers need to do to integrate ideas and position students and what the mathematical entailments are for doing so. Some of the studies address constrained, specific tasks of teaching (cf. Hoover, Mosvold, & Fauskanger, 2014), such as selecting and using examples, while others are broad and general, such as engaging students with challenging tasks. What is meant by “teaching” and its role in these studies vary.

Progress on the problem of whether and in what ways mathematical knowledge for teaching influences teaching practice will require building more shared language for talking about teaching, starting with more explicit attention to how it is conceptualized and continuing through the development of more widely shared conceptualizations of the work of teaching. It will require more focused examination of what it takes to do teaching, conceptualized as meaningful work, supportive of learning and doing the work in professional community. As we have argued elsewhere (Hoover et al., 2016), this may need to go hand in hand with developing the theoretical foundations of research on teaching. Teaching is a professional practice engaged in human improvement work. While there are other important aims of education, teaching is centrally about supporting the learning of subject matter. Understanding the theoretical implications of these observations and acting on them may strengthen research and practice.

## Acknowledgement

The larger review of research on mathematical knowledge for teaching reported on here was funded by the National Science Foundation under grant DRL-1008317 and was conducted in collaboration with Arne Jakobsen, Yeon Kim, Minsung Kwon, Yvonne Lai, Lindsey Mann, and Rohen Shah, who we wish to thank for their assistance with searching, conceptualizing codes, coding, and analysis. The opinions reported are those of the authors and do not necessarily reflect the views of the National Science Foundation or our colleagues.

# Considering research frameworks as a tool for reflection on practices: Grain-size and levels of change

Siún Nic Mhuirí

Dublin City University, Ireland; [siun.nicmhuiri@dcu.ie](mailto:siun.nicmhuiri@dcu.ie)

*Reflection is widely recognized as essential to teachers' learning but questions remain about what exactly teachers should reflect on and how effective reflection might be facilitated. This paper considers how research frameworks might be used as a tool to facilitate reflection on mathematics classroom practices. It will be argued that frameworks which facilitate planning and analysis of classroom practices at different levels of specificity may also target reflection at different levels. This will be illustrated with reference to frameworks which relate to talk in the mathematics classroom. It will also be argued that for research frameworks to be effective in facilitating reflection on mathematics classroom practices, they must target different levels of reflection.*

*Keywords: Reflection, research framework, classroom practice(s), grain size.*

## Introduction

A growing body of literature recognizes the importance and complexity of the practices involved in effective mathematics teaching (e.g., Ball et al., 2009; Potari et al., 2015). Classroom practices have been described as “the repeated actions in which students and teachers engage as they learn” (Boaler, 2002, p. 114). Dooley, Dunphy and Shiel (2014) identify five overarching practices as essential in promoting mathematical thinking and understanding. These meta-practices are the development of a productive disposition; emphasis on mathematical modelling; the use of cognitively challenging tasks, formative assessment, and the promotion of mathematical talk. In each of these areas, research frameworks exist which may hold potential for teacher development. By ‘research framework’, I mean either a theoretical framework or methodological tool which ‘frames’ or structures a coherent set of understandings about a particular theme. For example, consider how the Math Talk Learning Community (MTLC) framework (Hufferd-Ackles, Fuson & Sherin, 2004) might offer a coherent set of understandings about the nature of talk in classrooms or how the Mathematical Tasks Framework (Stein, Grover, & Henningsen, 1996) offers a similar set of understandings for the use of cognitively demanding tasks. Such frameworks illustrate teacher actions that contribute to desirable meta-practices for mathematics teaching and learning.

The growing emphasis on mathematics classroom practices is occurring at a time when reflection has been widely established as a guiding principle within teacher education (Hatton & Smith, 1995; Zeichner, 2008). Mathematics education research frameworks have been used to facilitate teachers' reflection (e.g., Stein & Smith, 1998). However, there is little literature to offer guidance on how frameworks might be used as a tool for reflection on mathematics classroom practices, or to guide researchers investigating this area. This paper offers a consideration of this theme. First, I will outline some key issues from the literature on reflection and will discuss the theoretical perspective from which teachers' use of research frameworks is understood. Then I will outline Korthagen's (2004) model of levels of reflection and change. Finally, I will argue that grain-size, or level of specificity, is of key importance when research frameworks are used to facilitate teachers' reflection on practices. I will illustrate this with reference to two frameworks relevant to the practices involved the promotion

of mathematical talk. I will argue that for frameworks to be effective in facilitating reflection on classroom practices, they must target different levels of reflection.

## **Reflection and research frameworks**

It is generally accepted that experience alone may not result in learning and reflection is considered to be integral to learning from practice (Loughran, 2002; Schön, 1983; Zeichner, 2008). The widespread adoption of reflection in teacher education programs has resulted in conflicting conceptualizations and many efforts to develop reflective practitioners are often underpinned by different ideological stances (Hatton & Smith, 1995; Zeichner, 2008). Despite the multiplicity of interpretations, there is some agreement that reflection should involve finding solutions to real problems of practice (Hatton & Smith, 1995) with some authors suggesting that the initial stimulus should be a problem arising from practice (e.g., Jaworski, 1998). Loughran (2002) maintains that learning arises from framing and reframing the initial problem. Research frameworks may be helpful in the reframing process and towards the goal of problematizing teaching, a key component of reflective practice (Jaworski, 1998). This problematizing of teaching may arise from considering a situation from another point of view (Loughran, 2002). Research frameworks can facilitate consideration of alternate or multiple viewpoints. For example, the MTLC framework (Hufferd-Ackles et al., 2004) addresses both the student and teacher experience.

The reflective practice literature includes much attention to the process of reflection. Eraut (1995) critiques and extends Schön's (1983, 1987) stages of reflection-in-action and reflection-on-action to also include reflection-for-action. The extent to which research frameworks might inform teachers' reflections-in-action is limited due to the many pressures of real-time teaching but frameworks can be used to support reflection at both the planning and post-teaching phase either as a tool for formal analysis, or as a means of troubling accepted understandings of practice. The literature also highlights links between reflective practice and action research. Jaworski (1998) describes a mathematics teacher research project where the theory of the teachers' research activity aligned with a view of action research being connected to critical reflective practice. Critical reflective practice has also been conceptualized in different ways (Hatton & Smith, 1995). Larrivee (2000) maintains that critical reflection is an essential part of becoming a reflective practitioner and defines it as encompassing critical inquiry and self-reflection. Critical inquiry is described as "the conscious consideration of the ethical implications and consequences of teaching practice" (p. 293).

## **Theoretical perspective**

Zeichner (2008) suggests that often the obligatory content of reflection is around how well practice conforms to what is expected. This issue might arise when using research frameworks for the purposes of teacher reflection. If a research framework is considered to be an example of what has been sanctioned as 'acceptable,' then teachers' interactions with frameworks might actually serve to undermine their agency. This is not the stance that I adopt. Instead, I understand reflective practice as "the making explicit of teaching approaches and processes so that they can become the objects of critical scrutiny" (Jaworski, 1998, p. 7). I view the teacher as knower and agent for educational and social change (Cochran-Smith & Lytle, 2009). The research framework is understood as a tool for teacher inquiry and reflection rather than a prescription for action. Inquiry is taken to be "a critical habit of mind that informs professional work in all its aspects" where the data arising from practice

is continually interrogated (Cochran-Smith, Lytle 2009, p.121). It is from this perspective that a teacher's use of research frameworks is understood.

## Levels of reflection

Models of reflection often emphasize process or chronological phases, e.g., Gibbs (1988). In contrast, Korthagen's (2004) model (Figure 1) emphasizes the teacher as person. Korthagen describes the levels as "different perspectives from which we can look at how teachers function" (p. 80). This model should be of interest to researchers seeking to investigate the nature of teacher reflection and teacher-educators seeking to support the same process. For teacher-researchers, it may offer an overview of the landscape of reflection and serve to frame and contextualize the inquiry process. The umbrella-nature of the model is powerful because the individual levels commonly exist as distinct research domains within mathematics education. This scope is challenging to address and only key issues and contradictions are highlighted here. Korthagen explicates his model largely with reference to the literature of psychology. Some concepts may not align with sociocultural approaches present in much current mathematics education literature.

**Figure 1: Korthagen's (2004) model of levels of change**

Korthagen maintains that the inner levels influence the outer levels just as the outer levels can influence the inner levels, e.g., *behavior* can be influenced by external environmental factors as well as personal *competencies*, *beliefs*, *identity* and *mission*. A teacher's *competencies* will determine the *behavior* he/she is able to show but Korthagen suggests that *competencies* contain also the potential for behavior though this may not be enacted. He maintains that competencies are determined by *beliefs*. The mathematics education literature has also explored links and discontinuities between teacher beliefs, competencies and classroom practices (e.g., Stipek et al., 2001). Korthagen suggests that complete alignment between the levels may take a lifetime to achieve and is unlikely to occur without careful reflection on practice and self. Recently, the mathematics education literature has questioned the value of research on beliefs without due attention to teachers' participation in social practices (Skott, 2013). Though Korthagen's model does not address this directly, he does situate teachers' beliefs within a complex framework, with the levels of *environment* and *mission* in particular premised on the individual's engagement in a social world.

Recent research emphasizes the importance of understanding mathematics teacher competencies as personally, situationally and socially determined (Blömeke, 2016). Where ‘situational’ might be connected with the *environment*, ‘personal’ and ‘social’ suggest links with the *identity* and *mission* levels respectively. The identity level is concerned with the personal singularity of the individual, and the mission level (or spirituality level in earlier versions of the model) is intended to acknowledge the individual’s participation in both local and global communities. Korthagen (2004) describes *mission* as being “about becoming aware of the meaning of one’s own existence within a larger whole, and the role we see for ourselves in relation to our fellow man” (p. 85). Reflection at this level necessarily encompasses consideration of the short and long term influence of teaching on students and the larger goals of mathematics education or education more generally. This level must be considered to be important in relation to critical reflection (Larrivee, 2001). Some commonalities also exist with critical mathematics education or values education (e.g., Bishop, 2008).

While noting the importance of *identity*, Korthagen admits to a certain ‘vagueness’ around the definition of professional identity as the concept has been informed by many different research traditions. The concept has also been understood in different ways in the mathematics education literature though Boaler (2002) and others contend that the identities students develop are strongly related to the classroom practices they have opportunities to participate in. In relation to teacher identity, it is likely that a more complete understanding of teachers’ engagement with research frameworks might arise from a perspective which foregrounds the social and situated nature of identity, and acknowledges that teachers engaged in such work may be working at, or across, the boundaries of various communities of practice (Lave & Wenger, 1991).

Korthagen positions his model as particularly useful to the teacher-educator. He suggests that a teacher’s behavior may imply reflection is needed on a particular level and the teacher-educator can orchestrate his/her interactions with the teacher accordingly. It is likely that relevant research frameworks could be introduced to focus a teacher’s reflection on a particular level. It has long been accepted that research frameworks may provide an impetus to question taken-for-granted assumptions and a language to describe, analyze, and interpret practice (e.g., Erikson, 1986). The novel element here is that the grain size, or level of specificity of a research framework, becomes important as this may determine which of Korthagen’s levels the framework will relate to. Existing mathematics education research frameworks range from broad general theories about (mathematics) learning to very finely grained, highly structured frameworks concerned with the teaching and learning of particular mathematical content. Korthagen’s model provides a structure for considering how such differing frameworks might be used to facilitate effective reflection.

The model is particularly useful in the specific case where research frameworks are being used to facilitate reflection on and development of mathematics classroom practices. Despite classroom practices being enacted at the outer level of *behavior*, they are connected to both inner and outer levels and arise from a complicated interaction between *mission*, *identity*, *beliefs*, *competencies* and *environment*. Larrivee contends that a “deliberative code of conduct” (2000, p. 293), or conscious adoption of particular practices, results from the infusion of personal beliefs and values into a professional identity. If research frameworks, or teachers’ interactions with research frameworks, confine reflection to the outer levels of Korthagen’s model, there is a danger that rationalization of practice (Loughran, 2002) may occur rather than inquiry and development. While an appropriate

research framework may provoke reflection across and between levels, frameworks which focus attention only on the outer levels are likely to have limited effectiveness. Teachers should have opportunities to question the relationship between inner and outer levels and reflect on how their practices align (or not) with inner levels such as *beliefs*, *identity* and *mission*.

A researcher interested in investigating teacher reflection who adopts the perspective outlined by Korthagen is likely to be interested in the relationships between the different levels of reflection and change. For example, if reflection appears to be occurring as a result of a perplexing situation arising from practice, then the researcher may be interested in attempting to track this to a particular level or a possible conflict between levels (e.g., a teacher is perplexed because she is struggling to implement in practice (*behavior*) what she believes (*beliefs*) to be true about ‘good’ mathematics teaching or in line with her *mission*. Similarly, a researcher investigating the extent to which research frameworks facilitate reflection may be interested in considering the extent to which a teacher’s interaction with the framework(s) aligns with the various levels of Korthagen’s model.

### **An illustration**

Two research frameworks that might be used to develop the practices involved in the promotion of math talk are discussed below. This topic has been chosen as classroom interaction emerged as a strong theme in TWG19 at CERME9 (Potari et al., 2015). The MTLC framework arises from research which tracked a classroom community transitioning from a traditional model to one in which students helped each other learn by engaging in meaningful talk about mathematics (Hufferd-Ackles et al., 2004). The framework describes four levels of mathematical talk and the overall community trajectory is described as growing “to support students acting in central or leading roles and shifts from a focus on answers to a focus on mathematical thinking” (p. 88). Associated with the levels are developmental trajectories for teacher and student actions across the areas of questioning, explaining mathematical thinking, source of mathematical ideas, and responsibility for learning. Table 1 shows teacher actions at the highest level of the framework.

The MTLC framework may facilitate reflection at all levels but it raises particular challenges at the levels of *beliefs*, *identity* and *mission* because it presents an alternative to traditional teaching. It may challenge the idea of teacher as sole-mathematical authority and it disrupts traditional conceptualizations of teacher and student roles by emphasizing student agency. In doing so, it may provoke reflection on personal *beliefs* about mathematics and the teaching of mathematics. It may also foreground issues of teacher *identity* and *mission*. I used this framework in previous research and while I never formally stated my ‘mission’, it did help me clarify what I wished to achieve as a teacher of mathematics: students who could think mathematically, and who valued their own thinking and their responsibilities within the classroom community. The framework details teacher actions and gives some direction as to how this mission might be achieved. However, used on its own, it is unlikely to provide sufficient support for developing the complex network of teacher *competencies* and *behavior* necessary for the promotion of productive math talk.

Description of Teacher Actions
Questioning: Teacher expects students to ask one another questions about their work. The teacher's questions may still guide the discourse.
Explaining Mathematical Thinking: Teacher follows along closely to student descriptions of their thinking, encouraging students to make their answers more complete. Teacher stimulates students to think more clearly about strategies.
Source of Mathematical Ideas: Teacher lets students explain and "own" new strategies. (Teacher is still engaged and deciding what is important to continue exploring.) Teacher uses student ideas as the basis for lessons or mini-extensions
Responsibility for Learning: Teacher expects students to be responsible for co-evaluation of everyone's thinking. She supports students as they help one another sort out misconceptions. She helps and/or follows up when needed

**Table 1: Teacher Actions at level 3 of the MTLC framework (Hufferd-Ackles et al., 2004, p. 88 -90)**

Teacher Question Categories		
1. Gathering information, leading students through a method	4. Probing, getting students to explain their thinking	7. Extending thinking:
2. Inserting terminology	5. Generating discussion	8. Orientating and focusing:
3. Exploring mathematical meanings and/or relationships	6. Linking and applying	9. Establishing context:

**Table 2: Boaler and Brodie's (2004) Teacher Question Categories**

The second framework I will discuss is Boaler and Brodie's (2004) teacher question categories (Table 2). This framework arises from analyses of practice and was developed to allow researchers investigate multiple lessons at a relatively fine grain-size. The framework directs attention to the level of *behavior*, specifically the questioning practices of the teacher, with scope for consideration of the learning opportunities that arise for the student. It may allow for consideration of the emphasis on relational (type 3 questions) and instrumental understanding (type 1 questions) or the opportunities created for student discussion (type 5 questions). This framework might be used as a tool for reflection, either to support planning of effective questions or to support analysis or reflection on practice. However, it is unlikely that this framework alone will hold meaning for the teacher unless its use is mediated by consideration of the 'bigger picture'. Teacher questions can only be considered effective or ineffective with reference to the overall goal for learning. This refers both to the specific mathematical goals for a lesson or unit of work, as well as goals that might be considered part of *mission*, such as the development of student agency and mathematical authority.

The frameworks described above are of different levels of specificity. The MTLC framework attempts to describe teacher and student interactions at a broad level while Boaler and Brodie's framework facilitates fine-grained analysis of teacher questions. For this reason, they offer different affordances and constraints when considered in relation to Korthagen's levels of reflection. It is argued, that for the purposes of facilitating teacher reflection, the use of either of the frameworks alone has limitations. Potential for reflection is maximized when such frameworks are combined. It is in the interplay between reflection at the inner levels and reflection at the outer levels that more profound development may occur.

## Conclusion

Many national curricula have begun to emphasize the practices, as well as the content, of mathematics education (e.g., Dooley et al., 2014). In this context, it is worth considering to what extent research frameworks might be used to support and develop teachers' reflection on practices. I have argued that any such work must strive to take into account the level(s) of reflection that a research framework might target. I also contend that the perspective outlined is of relevance to both teacher-educators and researchers. Further consideration of the methodological implications of a researcher adopting such a stance on teacher reflection is necessary. Theoretical and empirical work is also needed on teachers' use of broad and finely grained research frameworks. Such work should seek to identify the characteristics of research frameworks, and teachers' interactions with frameworks, that enable their use as tools for effective reflection.

*Metacognition plays an essential role in learning mathematics. However, due to the lack of observational systems for evaluation of metacognition in mathematics instruction, rarely anything is known about how metacognition is practised and fostered when teaching and learning mathematics in class. This paper presents an observational system (a rating system) developed to reliably assess metacognitive activities in mathematics instruction. It also explains the methodology used to evaluate the reliability of ratings achieved with this tool and to investigate the stability of metacognitive-discursive practices between lessons of an individual teacher/class. Despite the high inference of conclusions needed to assess metacognitive-discursive instructional quality in seven dimensions, highly reliable ratings have been achieved for six dimensions. The paper discusses reasons for and consequences of the high reliability.*

*Keywords: Metacognition, discourse, rating system, generalizability study, decision study.*

### The role of metacognition in teaching and learning mathematics

Metacognition has been ascribed an essential role in regulating students' cognitive processes in problem solving as well as in learning mathematics in general, in particular when constructing, organising, systematising, and connecting (pieces of) knowledge (cf. Schraw & Moshman, 1995; Wilson & Clark, 2004). However, hardly anything is known about how metacognition is practised and fostered in mathematics instruction. Assuming that enhancing learners' metacognition is essential for promoting learning, research on metacognition in this area definitely merits future research (cf. Mevarech & Kramarski, 2014; Depaepe et al., 2010). For this kind of research a tool is needed that allows to *reliably* assess metacognitive practices when teaching and learning mathematics in a class. This paper reports on a research project that aimed at developing such a tool, named the rating system for analysing and assessing the metacognitive-discursive instructional quality (Nowińska, 2016). This tool can be used to first *describe* metacognition during class discussion, and to second *evaluate* how metacognitive activities are used to foster understanding in mathematics, in particular by elaborating students' ways of thinking and reasoning, and by discussing them in a coherent and comprehensible way. One important research question underlying our work on developing and evaluating this tool was how stable metacognitive-discursive instructional quality is across lessons of an individual teacher in one class. In addition to advancing our knowledge about the occurrence of metacognitive-discursive instructional quality, investigating its stability allows identifying the number of lessons per teacher/class which would be needed to reliably measure metacognitive-discursive instructional quality.

Metacognition is often understood as *knowledge* about cognition and *regulation* of cognition (Flavell, 1976; Schraw & Moshmann, 1998). The groundwork for investigating metacognition in the domain of teaching and learning mathematics in a class has been done by Cohors-Fresenborg and

Kaune (2007) as they developed a category system for an interpretative, transcript-based analysis of metacognitive and discursive activities (CMDA)<sup>1</sup>. This category system decomposes metacognition in *planning*, *monitoring* and *reflection*. Examples are *planning* the structure of a proof or definition; *monitoring* the correctness of an argumentation; and *reflecting* on misconceptions or on difficulties experienced in interpreting a definition or in solving an equation. According to studies suggesting that the effects of metacognition on students' understanding when learning in class seem to depend on the quality of the class discussion (cf. Mevarech & Kramarski, 2014; Depaepe et al., 2010), it was necessary to combine the analysis of metacognition with a deep analysis of precision, coherence and accuracy of teacher's and students' contributions. For this purpose, CMDA also includes the categories *discursivity* and *negative discursivity*. *Discursivity* means activities enhancing precision, accuracy and coherence in a class discussion, e.g. by making connections between different answers, or between external concept representations and students' conceptions. *Negative discursivity* means activities with a negative influence on precision, accuracy and coherence. The results of many years research conducted on metacognitive and discursive activities led the authors of CMDA to the conviction that discursive ways of practicing metacognition are crucial for supporting students' understanding when learning mathematics in class. The term "discursive" does not simply mean "in a discourse" but is meant as a characteristic of discussions elaborating, explaining and linking students' ways of thinking in a coherent and comprehensible way.

The category system CMDA allows a detailed *interpretation* and categorization of local, single metacognitive and discursive activities, but it does not provide any additional tool for the *global, comprehensive assessment* of their instruction-related quality, thus of the extent to which they facilitate understanding of the mathematical subject discussed in class. The new rating system discussed in this paper is a result of extending<sup>2</sup> the category system CMDA to a video-based observational system aimed to analyse and measure 'metacognitive-discursive instructional quality' in a comprehensive way. For this aim, several dimensions of the metacognitive-discursive instructional quality as well as evaluation criteria to rate them have been developed (for details see Nowińska, 2016). To allow its application, the rating system needed to be valid and reliable despite the complexity and high inferences required for rating metacognitive-discursive instructional quality.

In the following, we first explain the design of the rating system. Second, we describe the methodology used to evaluate its reliability (G study), present the achieved results, and discuss their consequences for generalizable evaluation of metacognitive-discursive instructional quality. Finally, we discuss consequences of our study for further research aimed to deepen our understanding of metacognitive-discursive instructional quality and to improve teaching and learning practices in class.

---

<sup>1</sup> The complete German version of CMDA is presented in Cohors-Fresenborg, Kaune, & Zülzdorf-Kersting (2014).

<sup>2</sup> [www.mathematik.uni-osnabrueck.de/fileadmin/didaktik/Projekte\\_KM/Kategoriensystem\\_EN.pdf](http://www.mathematik.uni-osnabrueck.de/fileadmin/didaktik/Projekte_KM/Kategoriensystem_EN.pdf)

## The design of the rating system

Our conceptualization of metacognitive-discursive instructional quality and its decomposition in seven dimensions is based on research literature concerning relations between metacognition and learning gains (e.g. Mevarech & Kramarski, 2014; Depaepe et al., 2010), and on the preliminary research work related to the category system CMDA (e.g., Cohors-Fresenborg et al., 2010; Gretzmann, 2011). Furthermore, we analysed more than 20 videotaped lessons to deepen our understanding of these dimensions. Each dimension is described by means of a guiding question (GQ) focusing raters' attention on aspects to be analysed and evaluated, as well as of several answering categories. For each GQ, the answering categories describe particular aspects of classroom discussions that differ in quality. The categories are ordered so that they reflect increasing quality of the classroom discussion with regard to the relevant aspects, and constitute a rating scale. In the following, the seven guiding questions are described briefly (for the detailed version see Nowińska, 2016).

GQ 1 puts the focus on using metacognitive activities for an elaborate discussion of mathematical content and on supporting learners' autonomy in practicing such activities. To answer this GQ, the rater has to distinguish, among others, between metacognitive activities limited to monitoring results of calculations, on the one hand, and extended to reflection on mathematical ways of reasoning, methods, definitions, and conceptions related to them, on the other hand. Due to the essential role of argumentation in learning and understanding mathematics, GQ 2 focuses on justifications combined with metacognitive activities, and on supporting learners' autonomy in providing and analysing justifications. To answer this GQ, the rater has to distinguish between fragmentary justifications, on the one hand, and efforts made in class to orchestrate single justifications in order to produce precise comprehensive argumentations, on the other hand. GQ 3 aims at assessing to which extent the interplay of metacognitive and discursive activities foster students' understanding of subject-specific issues discussed in the particular lesson. The answering categories for this GQ distinguish among others between situations without any productive use of metacognitive and discursive activities, and situations in which (at least in the case of one single learner) metacognitive and discursive activities foster and express learners' understanding of the subject-specific issues discussed in the class. GQ 4 analyses the use of discursive activities in producing precise and coherent discussion. Such discussion is an essential precondition for an effective use of metacognition in class in order to foster learners' understanding. GQ 5, on the contrary, evaluates to what extent negative discursivity (e.g., not taking notice of inadequate mathematical vocabulary or of fragmentary answers as well as of answers not related to the discussed question) leads to ignoring students' cognitive and metacognitive processes, and hinders the reciprocal understanding in class as well as the understanding of subject-specific issues. GQ 6 evaluates to what extent metacognitive and discursive activities are used to build coherent and stringently guided discourse units (i.e., debates). The answering categories for this GQ distinguish between classroom situations without any debates, and situations with at least one remarkable debate led by the teacher or by students. GQ 7 aims at assessing to which extent metacognitive and discursive activities are related to challenging and complex subject-specific issues (e.g., related to meta-mathematics), used to elaborate such issues, and to foster learners' understanding of them.

To ensure reliable ratings despite the high level of inference needed to answer the guiding questions, the rating procedure was designed as a two-step procedure. In the first step of the rating process, the rater *categorises* each of the teacher and student contributions. Hereby, the rater uses the category system adopted from Cohors-Fresenborg and Kaune, and works with special software which at the end of the categorisation generates a graphic representation (i.e. category line; for more details see Nowińska, 2016). The category line includes all codes for metacognitive and (negative) discursive activities set by the rater, and distinguishes between codes for teacher and student activities. It serves as a basis for interpreting relations between teacher's and students' metacognitive and discursive behaviour, and for assessing students' autonomy in practicing these activities. Thus, the purpose of the first step is to get insight into the kind and quality of each single metacognitive and (negative) discursive activity, and to prevent the rater from rushed and inadequate ratings. In the second step, the rater uses the category line and the video transcript to evaluate the lessons by means of the seven rating scales elaborated on above.

In order to be able to carry out these tasks, three raters (students at the end of their master study course in mathematics education) participated in an intensive rater training (6 months, 180 h in sum). They were qualified to understand the purpose of the rating system, the foci of the seven rating scales, and the use the rating system. During the rater training (and also after it) the raters were obligated to justify their decisions regarding their interpretation of each single metacognitive and (negative) discursive activity as well as their final evaluation of the instructional quality. This allowed the trainer to discuss the answers given by the raters in detail, to discuss reasons for differences between the raters, and to provide each rater with detailed feedback. The videos and transcripts used during the training were separate from the ones used in the current study.

## Methodology

In the current study, sequences from 24 videotaped mathematics lessons (6 teachers/classes with 4 lessons per teacher/class) were analysed. For each teacher, four lessons were videotaped within two weeks, and should represent “normal” lessons in these classes. From each lesson, a 10-minute video sequence showing a discussion in the class was chosen. This was done by two independent experts who first analysed each lesson, and suggested the sequence in which the main topic of the lesson was discussed, and in which the students actively participated in the discussion. Finally, the experts agreed on one sequence. In many cases, however, only one 10-minute discussion could be indicated, whereas in the remaining time the students worked individually or in pairs. Each video sequence was evaluated by three independent raters, who had taken part in the rater training.

*Generalizability* theory was used (Shavelson & Webb, 1991; for an application to the instructional context, see Praetorius et al., 2012) for assessing the generalizability (which can be interpreted similarly to reliability in classical test theory) of the rating instrument. The reported relative G coefficient can be interpreted analogously to a reliability coefficient in the classical test theory. Thus, a coefficient  $\geq 0.7$  is needed for a satisfactory reliability. In addition to providing these G coefficients, generalizability studies (G studies) allow decomposing the variance in rating scores into different components (e.g., teachers, lessons, and raters), their interactions, and measurement error. Therefore, G study results provide more detailed and precise information regarding reliability than reliability coefficients used in classical test theory. Furthermore, decision studies (D studies)

can be conducted to estimate the reliability under multiple hypothetical measurement conditions, thus also allowing to analyse numbers of lessons per teacher/class higher than the number actually evaluated by the raters in our study. In the present study, it was investigated how many lessons per teacher/class would be necessary for a reliable assessment of the aspects of the metacognitive-discursive quality determined by the seven dimensions.

## Results

The results of the G studies indicated satisfactory reliability of ratings concerning six out of the seven dimensions of the metacognitive-discursive instructional quality (guiding questions 1 to 6), for which the relative G coefficient varied between 0,78 and 0,98 (see Table 1). The ratings concerning dimension 7 were not reliable, with a relative G coefficient of 0,38.

		GQ 1	GQ 2	GQ 3	GQ 4	GQ 5	GQ 6	GQ 7
Lesson-unspecific (stable) component	t	89	45	60	52	71	50	6
Lesson-specific component	l:t	0	46	21	39	22	30	14
Rater bias components	r	0	1	0	0	0	0	5
	r*t	3	0	0	2	1	3	51
Residual	r*(l:t); e	8	9	19	8	7	16	25
Relative G-coefficient		0,98	0,78	0,90	0,83	0,92	0,83	0,38

**Table 1: Relative G-coefficients and variance decomposition (in %) for the seven dimensions**

Based on the rating data, the variance in the ratings was decomposed in variance components attributable to the teacher/class (t), lessons nested in teachers (l:t), raters (r), the interaction between teachers and raters (r×t), and the unexplained variance, i.e. residual (r×(l:t),e). Table 1 shows the percentage of variance explained by the different variance components.

For dimensions 1 to 6, the amount of variance attributable to rater bias was very small (between 1% and 3% of the entire variance); this indicates that the raters do rarely differ in their ratings. However, further rater training would be needed to eliminate the very high amount of the variance (55%) attributable to rater bias for dimension 7 in order to get reliable ratings.

The ratio of t to l:t, which describes the stability of the given dimension across lessons of an individual teacher/class, indicates partly very high stability (see e.g., GQ 1) and partly very low stability (see e.g., GQ 7).

To determine how many lessons per teacher/class are necessary to measure metacognitive-discursive instructional quality in a stable and reliable way, D analyses were conducted with the hypothetical number of lessons per teacher/class varying between 1 and 10. The number of raters was fixed to the actual number in the study (i.e., three). Figure 1 illustrates the results of the D study for each of the seven dimensions.

**Figure 1: Relative G coefficients for D studies with 1-10 lessons per teacher/class for GQ 1–7**

To obtain relative G coefficients greater than 0.7, one lesson is needed for the dimensions related to GQ 1 as well as GQ 5. Two lessons are needed for the dimensions related to GQ 3, GQ 4, and GQ 6, and three lessons for the dimension related to GQ 2. Thus, three lessons are sufficient to achieve a G coefficient of 0.7 for GQ 1 to GQ 6.), whereas 5 lessons per teacher/class would be needed for the reliability greater than 0.8. Due to the high amount of the variance attributable to rater bias for GQ 7, no satisfactory reliability concerning this dimension could be reached, even with 10 lessons per teacher/class without further rater training.

## Discussion

The aim of our research project was to develop a reliable rating system for assessing *metacognitive-discursive instructional quality*. For this purpose, seven dimensions of metacognitive-discursive quality had been developed. Despite the high amount of inferences needed to rate these dimensions, highly reliable ratings were achieved for six of them. This rather unusual result (for an overview on the amount of rater effects found in prior studies, see Praetorius et al., 2012) can likely be explained, among others, with the intensive rater training, and with the two-steps procedure of the rating process. Both aspects prevented the raters from a superficial analysis, and instead forced well-reasoned scoring.

No satisfactory reliability could be achieved for the seventh dimension. The reliability analyses showed that this is due to high rater bias. Obviously, the meaning of “complex subject-specific” issues, which is at the core of the seventh dimension, has not been interpreted in the same way by all raters. Thus, additional rater training or other raters with a more substantial background in mathematics education would be needed to get reliable ratings for this dimension. Such efforts seem highly desirable as the seventh dimension plays an important role in a *long-term* evaluation of the metacognitive-discursive quality in a class. In general, complex subject-specific issues are discussed in mathematical instruction rarely. Discussing such issues indicates teacher’s efforts to deepen and systematise students’ cognition related to (meta-)mathematical questions, methods or ways of reasoning, and therefore it is a significant characteristic of instructional quality.

The seven dimensions of the metacognitive-discursive instructional quality vary in their stability between lessons in a particular class. The lowest variability could be determined for the dimension concerning the extent to which metacognition is practised in a class, in interactions between the teacher and the students (GQ 1), and the highest for this concerning metacognitive activities combined with justifications (GQ 2). The quite stable first dimension is based on GQ 1 which also takes some observable aspects of patterns in interactions between metacognitive and discursive teacher and students activities, whereas GQ 2 focuses more on metacognitive activities in relation to the content discussed in class and to students' reasoning concerning this content. The results indicate that the quite stable observational patterns in practicing metacognition do not necessarily imply the stability of metacognitive efforts to elaborate the mathematical issues discussed in class and to foster students' understanding. A deep analysis of videos is needed to explain this observation. Our preliminary analysis shows that in some classes, providing justification seems to be well established as a social norm. This means that the learners and the teacher are used to justify their answers, i.e. to practice monitoring or reflection. However, by doing so, not always the necessary attempts are made in the class to reflect on these justifications, to control and correct them, and to orchestrate *single* and fragmentary justifications in order to produce a coherent *global* explanation related to mathematical issues discussed in the class. This can be observed in particular when new concepts, definitions or strategies are introduced. Despite the high number of single justifications combined with metacognition, the lack of a well-orchestrated mathematical justification related to the new issues may hinder understanding. Consequently, this leads to a low score for the second dimension of the metacognitive-discursive instructional quality (GQ 2). The score can be higher when the tasks discussed in the class do not require a global well-orchestrated mathematical justification, and the lack of it cannot be evaluated negatively, with very low scoring. Thus, the variability of the second dimension seems to be related to the complexity of the mathematical content. This observation seems plausible but it must be investigated more deeply. Considering only the number of justifications combined with metacognitive activities would most likely enhance the reliability of the ratings in the second dimension but it would distort the validity of the instructional quality.

Our D studies are of crucial importance for further research on metacognition in mathematics instruction. Due to the variability of metacognitive-discursive practices between lessons in a particular class, at least three lessons per teacher/class and three qualified raters would be needed for reliable (generalizable) evaluation of the metacognitive-discursive quality with regard to six dimensions of this construct. Thus, given these relative small numbers, the rating system can be considered as a practicable research tool although intensive rater training is needed.

Given this result, a pivotal next step for research on metacognitive-discursive instructional quality is to investigate the effects of each of the six dimensions on students' mathematics achievement. In doing so, the empirical relevance of metacognitive-discursive instructional quality can be investigated, and implications for supporting metacognition to foster mathematical understanding can be suggested. Thus, continuing this research is highly desirable. It would shift the focus from measurement and evaluation to development and improvement. This would require the work *with* teachers, and not only research *on* teachers' instructional practices. Thereby, the rating system presented in this paper can be used as an analytical tool in teacher trainings for guiding teachers' reflection on their own practices and on learners' metacognitive and discursive behaviour.

# Teacher learning in teaching the topic of quadratic expressions and equations in Kenyan high schools: Learning Study design

Fredrick Odindo

University of East Anglia, School of Education and Lifelong Learning, Norwich, UK

[F.Odindo@uea.ac.uk](mailto:F.Odindo@uea.ac.uk)

*Performance in mathematics national examinations in Kenya has been weak and raises questions about the pedagogical approaches adopted by teachers. The purpose of this paper is to report on teachers' experiences of the application of a problem-solving teaching strategy in a Learning Study design to teach factorization of quadratic expressions. The study follows a qualitative and interpretive research approach with data collected through questionnaires, classroom observations, video replays and reflection sessions after lessons. The findings reveal teachers' appreciation of the application of problem-solving teaching in a Learning Study design, saying it helped them to observe the difficulties students experience in learning algebra and the shortcomings in their lesson preparation. In addition, they noted the importance of reflection in that it helped them improve the second lesson.*

## Introduction

Teaching is an activity that involves engagement of the teacher, the student and the content (Loef Franke, et al., 2007; Stigler, & Hiebert, 1999). In mathematics teaching, this engagement needs to be effective to create a productive learning environment for both teachers and students (Loef Franke, et al., 2007). However, Stigler and Hiebert (1999) note that levels of engagement among the three is not uniform due to different classroom cultures and teaching strategies in different countries. They observed, for example, that in some US classrooms, teaching strategies are so procedural and teacher-directed that students are passive recipients of knowledge, and that there is little interaction between student and content.

Stigler and Hiebert's (1999) finding concerning US mathematics classrooms seems to be relevant in other classroom cultures in countries such as Kenya (CEMASTE, 2010). Based on past performances, the Government of Kenya initiated an in-service education programme for high school teachers of mathematics and science in 1998. Among the strategies employed was Lesson Study approach, which implicitly applies constructivist theory (Elliot, 2014). However, a survey conducted to check the extent of the implementation of the programme, reported that about 65% of the teachers were not implementing the programme and were applying the teacher-directed method of teaching (CEMASTE, 2010). Teachers cited lack of clear guidelines and workload among reasons. Students continued to post weak results in mathematics in 2012 and 2013 from the Kenya national examinations (KNEC, 2014). This study adopts a Learning Study (LS) design which explicitly applies Variation Theory to support classroom learning. Little is known about LS in Africa, and the outcome of this present study may support the further development of LS in Kenya in particular.

The purpose of this study is to solicit teachers' views and experiences of the application of a problem-solving teaching strategy in a LS design to teach factorization and solution of quadratic

equations, one of the topics poorly performed by students (KNEC, 2014). My intention is to eventually extend the approach to other mathematics topics. The research question of the present study is “What are the teachers able to learn about the students learning of factorization of quadratic expressions in a Learning Study design?”

## Variation theory

Variation Theory is a theory of learning which asserts that to learn something entails experiencing it in a variety of ways. The theory proposes that learning is always directed towards an object, which could be a skill or a concept referred to as *the object of learning* in the ‘what’ and ‘how’ aspects of learning (Marton & Booth, 1997). The ‘what’ aspect is the content to be learnt while the ‘how’ aspect is concerned with the process of learning that enhances a student’s ability to apply the learned concept in a new environment (Elliot, 2014; Lo, 2012). The theory postulates that learning takes place when students focus on a *critical feature of the object of learning*. For example, suppose the solution of simultaneous linear equations by elimination were the object of learning: a critical feature to be discerned can be the collating of the equations so that one variable has the same numerical coefficient in both equations. To achieve this, Lo (2012) and Marton (2015) propose that teachers need to create learning opportunities by explicitly or implicitly offering patterns of variation in which some parts remain invariant as others vary. Four patterns of variation are identified, namely: contrast, separation, generalization and fusion. For example, to discern the concept of quadrilateral, a type of quadrilateral would be kept invariant and contrasted with other polygons such as triangles and pentagons. To discern a particular type of quadrilateral, for instance a kite, it is kept invariant as other types such as rectangle, trapezium are varied. The kite is separated from the whole and focused on. To generalize that the total sum of interior angles of a quadrilateral is  $360^\circ$ , each type of a quadrilateral is varied with its sum of interior angles calculated. To compare properties of different types of quadrilaterals, such as a kite and a rhombus, the two and their properties are brought into focus simultaneously, the fusion pattern of variation.

## Learning Study

Learning Study (LS) provides a framework for supporting learning in the classroom by applying aspects of Variation Theory, in which all the three categories of persons participating in the lesson (the teachers, the students and the researchers) could learn in the process (Marton, 2015; Pang, 2008). LS adopts a Lesson Study organizational structure in which a group of teachers prepare a lesson together, then one teaches the lesson while others observe as they collect research data and thereafter converge for a reflection session (Pang, 2008). LS focuses on *the object of learning* which points to the beginning of the learning process with learning ‘what’ and learning ‘how’ aspects (Lo, 2012). In this study, the topic of quadratic expressions and equations is the ‘what’ aspect while the ‘how’ aspect is addressed by small group discussion approach to learning. For ease of monitoring the learning process, the *object of learning* is categorized into: (a) *lived object of learning 1*, (b) *lived object of learning 2*, (c) *intended object of learning* and (d) *enacted object of learning*. Part (a) is concerned with prior experiences and awareness that students have about the concept and is monitored through a student’s diagnostic pre-test or interview whose outcome is considered in lesson preparation. Part (b) is the acquired experiences after the teaching of the lesson and is monitored through a student’s post-test or interview. Part (c) is the planned lesson and part

(d) is the taught lesson (Pang, 2008). Parts (c) and (d) are monitored through a post-test or interview and reflection session.

## Methodology

The study on which this paper is drawn follows a qualitative and interpretive research approach in a LS design conducted in two classes in Kenya. Three teachers planned the lesson together as explained earlier. Prior to the first lesson, a diagnostic pre-test was given to the students in both classes; a post-test identical to the pre-test was given to each class at the end of each lesson. The teachers will be addressed by pseudonyms as Dominic – head of mathematics, Peter – teacher of the first lesson and John – teacher of the second lesson. The two classes were for third year high school students (age 16-18 years) comprising 68 students altogether.

Data were collected through classroom lesson observation, pre-post questionnaires, video recordings of the lessons and transcribed reflection sessions. Teaching was approached through a small group discussion by the students. The *object of learning* was factorization of a quadratic expression with a unit coefficient of  $x^2$  (i.e.  $x^2 + bx + c$ ). The *critical feature* was the identification of factors of the constant term of a quadratic expression that sum to the coefficient of  $x$ , often expressed in textbooks as “sum and product”.

The items in the questionnaire, whose outcomes were considered in the preparation of the lesson, included: (1) Why is  $x^2 + 5x + 6$  called a quadratic expression? (2) What do we consider in attempting to factorize a quadratic expression such as the one given above? (3) How many factors do we expect from a factorized quadratic expression? Frequent student responses included: (1) the given expression is called a quadratic expression because it has unknowns, (2) we consider like terms, (3) two factors (considered the correct answer). The questionnaire responses were scored 1 for a correct answer and 0 otherwise.

**Figure 1: Paper cuttings for a hands-on activity aiming at the factorization of  $x^2 + 5x + 6$**

Based on the students' responses, the teachers prepared for *the intended object of learning* in a 40-minutes lesson, incorporating a hands-on activity intended to raise students' curiosity, and to motivate them to discuss in small groups as the approach was new to them. The first task on the activity was to form a rectangle using the pieces of paper shown in Figure 1, and to find the product of the sides of the rectangle formed. This was intended to lead to the factorization of  $x^2 + 5x + 6$ . The second task was to explain the relationship between the numerical terms from their expression of the area,  $(x + 2)(x + 3)$ ; and the coefficient of  $x$  and the constant term in the quadratic expression.

## First lesson
