In order to study students' thinking with geometrical shapes, the terms 'concept image' and 'concept definition', introduced by Vinner and Hershkowitz (1980) are useful. A concept definition is defined as 'a form of words used to specify that concept' and concept image as 'the total cognitive structure that is associated with the concept, which includes all the mental pictures and associated properties and process' (ibid, p. 152). When considering a parallelogram, at least two types of concept images are considered, i.e. one is 'conceptual images' such as 'parallelograms have two sets of parallel lines', 'opposite sides of a parallelograms are equal', and the other is 'visual images' (e.g. ). In relation to learners' concept image and definition, another useful idea is the prototype phenomenon (Hershkowitz, 1990). This theoretical idea claims that students' difficulty in seeing geometrical shapes flexibly is caused by the prototype example, which students often encounter in their initial stages of learning of geometrical figures. For example, as a concept definition, parallelograms are introduced as 'a quadrilateral with two pairs of parallel sides', but a typical 'slanted' visual image is often used. This 'visual images' will stay strongly in students' minds, and as a result their 'conceptual images' become "the subset of examples that had the "longest" list of attributes – all the critical attributes of the concept and those specific (noncritical) attributes that had strong visual characteristics." (ibids., p. 82). Thus, for many students, when the hierarchical relationships between quadrilaterals are required, they cannot accept that rectangles can be a member of parallelogram group as, on the one hand, rectangles have 90 degree angles, and on the other hand, parallelograms should be 'slanted' ('visual geometrical images') and not have such angles, and therefore rectangle are not member of parallelograms, stating 'rectangles have 90 degree angles and so they are not a member of parallelograms' as their 'conceptual image' (e.g. Fujita, 2012).

### Collective geometrical thinking process

Collaborative learning has been recognised as a key topic in mathematics education research, and the difficulties in geometric thinking described above might be overcome if students' undertake problems collaboratively. Martin and Towers (2014) apply Pirie and Kieren's model (1994), which describes the growth of mathematical understanding with eight potential layers; Primitive Knowing, Image Making, Image Having, Property Noticing, Formalising, Observing, Structuring and Investing. The learners' developmental paths from Primitive knowing to Investing would not be straightforward. For example, when an individual/a group of learners had difficulty in noticing properties during problem solving, they might examine their already made images, and as a result they re-make new images for exploring new paths for problem solving. This is what Pirie and Kieren call Folding back. Martin and Tower also suggest that this process is crucial in collective thinking process. For example, suppose a group of students are discussing whether a 'rectangle' can also be seen as a 'parallelogram'. In order to solve this (under a curriculum hierarchical relationships of geometrical shapes are assumed), they have to collectively make and have their conceptual and visual images of rectangle and parallelograms including their definitions, examine their properties collectively, and then formulate their reasoning etc. In this process, they might fail to collectively have useful conceptual and visual images of parallelograms and in this case they have to fold back to their collective image making stage in order to continue to examine this problem.

### **Dialogic process in collective geometrical thinking**

The framework for collective thinking process by Martin and Towers (2014) discussed above can offer useful ways of analysing collective thinking process which collectively made or had conceptual and visual images, held back, noticed properties and so on, but this approach can be strengthened by considering some of the dialogic processes involved in thinking. For example, Mercer and Sams (2006) studied how certain types of talk, which mediate conceptual knowledge, affect students' ways of collective thinking and problem solving. They particularly consider that the roles of exploratory talk, described as being critical friends each other and using explicit reasoning during problem solving, showing how it is crucial for developing understanding, comparing to the other types of talk such as disputational (being competitive or disagreeing with each other in egoistic ways) or cumulative talk (agreeing each other without constructive criticisms). Extending this talk type approach further, Kazak, Wegerif and Fujita (2015) report that an 'Aha!' moment occurred after learners had engaged in productive 'dialogues'. 'Dialogues' to which we refer include more than exchanging recognisable utterances, but it is in a Bakhtinian sense, which Barwell (2016) recently described as "a theoretical idea that defines the nature of many aspects of the relationality of language." (p. 6). Our view is that such 'dialogues' elucidate differences and gaps, and encourage learners to see their learning from a different perspective, which is based on Bakhtinian dialogic theory (1963; 1984).

From this point of view, in addition to effective collaborative practice such as building effective collective conceptual and visual images of geometrical figures for problem solving, seeing a problem 'as if through the eyes of another' is important for emergence and development of collective group thinking and understanding. This includes, for example, recognising multiple 'voices' in mathematical concepts, seeing ideas from an 'outside' perspective, establishing dialogic space, learners' attitudes to each other, laughter, and so on. This is what Wegerif (2011) refers to as dialogic process of conceptual growth. Barwell (2016) also states, in the context of the development of the concept 'polygon': "the process of making sense of the word and the concept 'polygon' arises through the differences between the two groups of shapes on the blackboard, between the different ways of classifying shapes that preceded this moment, and so on." (p. 9). Let us take again the example whether a 'rectangle' can also be seen as a 'parallelogram'. Here, in their utterances students will use 'rectangle' or 'parallelogram', but they will contain 'multiple perspectives and agencies, i.e. rectangles for their own definitions and conceptual and visual images, for peers' definitions and images, for the formal definitions which appear in the textbook or for definitions used by teachers, and so on. In their talk they might agree or disagree with their thinking and if the group of students do not see a rectangle from an 'outside' perspective, they might not be able to reach mutual agreements or reasonable answers, or extend their discussions and apply other contexts such as 'is a square a type of parallelogram?', etc.

### **Methodology**

The participants of our study were 27 Y7 students (12-13 year old) in a lower secondary school in South West England. Their abilities are recognised by their class teacher as the second highest group in the year group, meaning that their achievements are higher than the average students in the UK school context. They have also studied formal definitions of basic 2D shapes including parallelograms. The participants undertook the following tests in 2015-16, summarised in fig. 1.

Group thinking measure test	Geometry group test
<p>General group thinking test: We first identify groups' thinking by using the group thinking test which consists of two tests A and B of 15 graphical puzzles each, carefully matched to be of equal difficulty. We used this test as it was reported that the test provides useful insights into how groups work well in general. Students do one test working in groups of three and the other test working individually, assuming a measure of individual thinking correlated to a measure of group thinking with a measure of the difference between the individual scores and the group score (Wegerif et al, in press). In our study, the half of students in the chosen class individually undertook Test A, and then we formed groups of three in accordance with their test scores. Then each group undertook Test B. The other half did Test B as their individual and Test A as group test. All groups' work was video-recorded.</p> <div data-bbox="181 1032 687 1368"> </div> <p>For each question, students have to choose which graphical image should fit into '?' based on patterns and properties of the other 8. For the left the answer is 5, and the right one it is 4 (by seeing 'outside' as addition and 'inside' as subtraction).</p>	<p>Geometrical thinking tests: The same groups of students undertook geometry test which are derived by Fujita (2012) about hierarchical relationships between parallelograms. 4 of 9 groups were video-recorded for further analysis, informed by their group thinking test performances. Students undertake the following questions related to inclusion relations between quadrilaterals. For each question, 3 points will be given if students' choice is based on the hierarchical classification, but if it is prototypical then 1 point will be given. For example, for Q1, 3 points for '1, 2, 4, 5, 6, 7, 9, 11, 13, 14, 15' but 1 point for '1, 6, 9, 14' or for Q3, 1 point for choosing (b) and (c) are correct.</p> <p>Q1. Which of the quadrilaterals 1-15 above are members of the Parallelogram family?</p> <div data-bbox="842 770 1315 1016"> </div> <p>Q2. What is a parallelogram? Please write its definition.</p> <p>Q3. Read the following sentences carefully, and circle the statements which you think are correct.</p> <ul style="list-style-type: none"> <li>(a) There is a type of parallelogram which has right angles.</li> <li>(b) The lengths of the opposite sides of parallelograms are equal.</li> <li>(c) The diagonally opposite angles of parallelograms are equal.</li> <li>(d) There is a type of parallelogram which has 4 sides of equal length.</li> <li>(e) Some parallelograms have more than two lines of symmetry.</li> </ul> <p>Q4. Is it possible to draw a parallelogram whose four vertices are on the circumference of a circle?</p>

**Figure 1. Tests for group thinking and geometrical thinking**

In the data analysis, we first examined general relationships between general group thinking test and geometry test, focusing on whether geometrical thinking can be predicted from group thinking test performances. We then analysed the video data by considering what types of talk (disputational, cumulative, or explorative) can be recognised in their group work, what kind of 'voice' can be recognised in their collective Image Having/Making, Property Noticing and Folding Back processes (see the next section for the examples).

## Findings and analysis

### Overall performance in their group thinking test and collective geometric thinking

The test results for our sample of 27 students are as follows:

Test	Mean	S.D.
Group thinking test (Individual, N=27)	9.3 (out of 15)	2.07
Group thinking test (Group, N=9)	10.4 (out of 15)	1.24
Geometry test (N=9)	3.67 (out of 12)	1.66

There is no statistical significant difference between individual and group scores in the Group thinking tests (Mann-Whitney U test, p-value is 0.1063,  $p > .05$ ), indicating in this class in general collaborative learning did not positively affect test scores. Also, low scores from geometry tests indicate that the students' collective geometric thinking are also governed by prototypical examples of parallelograms, despite being given opportunities to share their ideas and to work collaboratively to solve the geometry test. Furthermore, statistical analysis of the data, using linear regression modelling, showed that the ability to predict geometry test scores from individual thinking scores, and group maths test scores was very weak ( $R^2$  of 0.046). Likewise, the relationship between individual group thinking scores and geometry test scores was very weak (Spearman Correlation 0.224). This might suggest that collective geometric thinking as 'measured' by the geometry test is different from the thinking 'measured' by the group thinking test at least in our sample (we will explain relationships between general group thinking and mathematical thinking in more detail in our presentation.)

### Examples of students' collective thinking process

Although quantitative analysis did not suggest strong relationships between general group thinking and collective geometric thinking, the video data suggest some interesting features relating to why students could not do well in the geometry test in their collaborative work. In total 340 interactions from students were examined in terms of stages of collective thinking process and dialogic theory. In this section we select examples from Group 1 and 5, whose obstacles were particularly related to not only their conceptual and visual images of quadrilaterals but also their dialogic relationships in their collaborative learning.

In the individual test, the three students BS, AC, and JC in Group 1 scored 14, 10, 11 but their group score was 12. This means their group work did not benefit very positively (in the context of group thinking measure test). In their geometry test, their interactions were rather disputational and they could not see their peers' ideas from the others' point of view in addition to influences from prototypical examples. For example, in their collective Image Making/Having stage, they discussed what a parallelogram was conceptually and visually, one of them questioned if rectangle or square can be a parallelograms based on the statement voiced by BS (line G1 49), but immediately after AC said "And a square and a rectangle. It's trash". This indicate in the line 54, the word 'square' or 'rectangle' by AC were very personal, and not accepting the 'voice' by BS or JC:

G1 47. JC      What is a parallelogram? Write the definition.

G1 48. AC      A squashed up rectangle.

- G1 49. JC      No both sides are parallel.  
 G1 50. AC      A squashed up rectangle.  
 G1 51. BS      So that would mean thirteen as well and two.  
 G1 52. AC:      And a square.  
 G1 53. BS:      And one and...  
 G1 54. AC:      And a square and a rectangle. It's trash.

They then continued their discussion, and it is evident that their understanding is influenced by the prototypical image of parallelogram (line G1 59, G1 60 or G1 70). In addition, it seemed that they could not see each other's positions. In the line 61, AC aggressively said 'That's what we got told in...', referring to authoritative voices. In the line 64, BS again held back to a definition "all the sides are parallel" and suggested rectangle can be a parallelogram (line G1 67). There was a dialogic gap between BS and AC/JC. However, JC and AC again referred to a (wrong) definition based on the prototypical image (line G1 68 and G1 69), and BS's voice was dismissed, and BS disappointingly said 'Oh no', and their collaborative explorations stopped.

- G1 58. AC      I think it's...  
 G1 59. BS      A squashed up rectangle.  
 G1 60. JC      No if it's a squashed up I need to know squeeze it.  
 G1 61. AC      That's what we got told in...  
 G1 62. BS      All sides are the same.  
 G1 63. AC      No they're not.  
 G1 64. BS      No, no, all the sides are parallel.  
 G1 65. JC      Yeah.  
 G1 66. AC      Yes so is a square.  
 G1 67. BS      So that will do one, two (pointing a rectangle image).  
 G1 68. JC      No because that's a quadrilateral not a parallelogram. A parallelograms are like...  
 G1 69. AC      A squashed up rectangle.  
 G1 70. JC      No parallelograms are like that they're like that they're messed up.  
 G1 71. BS      Oh no.

Let us see another group, Group 5. In the individual test, the three students JM, BH, and TF in Group 5 scored 9, 10, 7, but their group score was 11. This means their group work did not benefit either positively or negatively. In their collective Image Making stage of the geometry test, JM first voiced his own image and definition (line G5 12) which was influenced by the prototypical image and then TF agreed. Then BH added 'Two pairs of parallel sides' (line G5 14). This made JM question "a rectangle has two pairs of parallel sides as well?" (line G8 17), but after a moment he said "But it (parallelogram) doesn't have right angles" (line G5 18), indicating he could not see BH's point of view. TF then agreed with JM. BH did not argue back from here (a kind of cumulative talk), and they now had parallelogram as 'a rectangle without 90 degree angles' as their collective image of parallelogram.

- G5 7. JM      ...Ok what is a parallelogram?  
 G5 8. BH      Oh.  
 G5 9. JM      It's rectangle but...

- G5 10. BH It's like...
- G5 11. TF Erm like...
- G5 12. JM It's like, it's a rectangle but it doesn't, we're not, it doesn't have all ninety degrees. It doesn't have all right angles.
- G5 13. TF Yeah, yeah yes so it's a rectangle but it doesn't have...
- G5 14. BH Two pairs of parallel sides.
- G5 15. JM It's a rectangle.
- G5 16. BH Two pairs of parallel sides.
- G5 17. JM Yeah but that erm that a rectangle has two pairs of parallel sides as well.
- G5 18. JM ... (a moment) But it doesn't have right angles so it's rectangle without ...
- G5 19. TF Ninety degree angles.

After this, this shared definition used throughout the problem solving process in their Collective Property Noticing stage, resulting they only chose (b) and (c) of Q3 as true or in Q4 they formulated it would be impossible to draw a parallelogram whose four vertices are on the circumference of a circle because “the obtuse angles would not touch the circumference of the circle” (G5 line 56). The other groups (Group 2 and 8) also showed similar processes, i.e. definitions based on prototypical images were collectively made and had uncritically at first and then these were used to examine properties and formulate their answers.

## Discussion

In this paper we examined what obstacles will be identified when students are working together with geometrical problems. By answering our research question, our findings suggest that even collaborative learning settings prototypical images (Hershkowitz, 1990; Fujita, 2012) strongly influence when students were making/having conceptual and visual images of geometrical figures collaboratively, i.e. collective Image Making and Having stages (Pirie and Kieran, 1994; Martin and Towers, 2014). Also, when learners collectively had definitions based on prototypical images and missed opportunities to dialogically examine these (Bahktin, 1964; Wegerif, 2011; Barwell, 2016). Even if they shared ideas during their problem solving processes well, these students could not reach the correct answers by examining different ideas voiced in their collaborative work (Barwell, 2016). It is interesting to see that groups often had opportunities to examine their collective definitions (e.g. line G1 67 or G5 18-19), but they did not explore these opportunities because each member did not see what others were saying ‘as if through the eyes of another’ (e.g. line G1 67-71 or G5 16-19). Thus, in conclusion, in addition to prototype phenomenon, in collaborative learning settings it is necessary for students to dialogically examine their starting points of problem solving (in this case the definition of parallelogram).

In our research context, we did not find strong relationships between general group thinking and geometric thinking. As the sample size is relatively small, we would like to pursue this topic in our future research, together with developing effective pedagogical models for better collective geometric thinking.

# Double perspective taking processes of primary children – adoption and application of a psychological instrument

Cathleen Heil

Leuphana University, Lüneburg, Germany; [cathleen.heil@leuphana.de](mailto:cathleen.heil@leuphana.de)

*Perspective taking can be conceptualized in the framework of mental transformations in terms of subsequent egocentric transformations. Kozhevnikov and Hegarty's (2001) PTSOT is a test instrument for adults that investigates double perspective taking processes. Both perspective taking processes can be defined by certain egocentric transformations. An adoption of this test for primary children reveals that they are able to understand the test and verbalize easily their thinking processes. 8 items were solved by 254 fourth graders. Results show a variety of typical difficulties that can be interpreted in detail using the egocentric transformations framework. The theoretical framework and the straightforward way of item construction allow us to systematically generate items for various applications in psychology and mathematics education.*

*Keywords: Egocentric transformations, geometric thinking, perspective taking, spatial abilities.*

## Theoretical background

Spatial abilities have widely been debated within mathematics education, with a multitude of meanings and definitions (Mulligan, 2015). Discussions within WG4 in CERME highlight implicitly the implication of those abilities on all four geometrical competencies to support geometrical thinking that were proposed by Manschietto et al. (2013).

Psychometric studies on individual differences have shown that the construct of spatial ability is multidimensional and consists of several spatial ability factors (e.g., McGee, 1979; Linn & Petersen, 1985). Although the exact factor structure of spatial abilities remains a subject of intensive debate, some of these factors were studied in detail, both for adults and children. One of these factors, spatial orientation, also denoted as perspective taking in the literature, was proposed to measure the ability to imagine the appearance of a set of objects from different orientations (perspectives) of the observer (McGee, 1979).

In the experimental cognitive literature, spatial abilities have been conceptualized as the ability to engage different mental transformations that require the subject to update an encoded visual stimuli with respect to three different frames of reference: the intrinsic reference frame of objects, which encodes relations among objects, the egocentric frame of reference, which encodes object locations with respect to one's body, and the environmental frame of reference (Huttenlocher & Presson, 1973; Zacks et al., 2000). Perspective taking ability has been defined as the ability to perform a set of egocentric transformations on objects, in which the relationship between the environmental coordinate frame and those of the objects remain fixed, while each of their relationships with the observer's egocentric reference frame are updated. Although the conceptualization of perspective taking within the theoretical framework of mental transformations is logically equivalent to the qualitative description of the factor spatial orientation, it adds value for the deconstruction of complex perspective taking into separable, analyzable transformation processes.

Perspective taking abilities have been studied extensively in the developmental psychology literature (see Newcombe, 1989, for a full review). It has been highlighted that children demonstrate first perspective taking abilities even in infancy, show first achievements on more advanced tasks at around 4 or 5 years and improve performance considerably between the age of 6 and 8 (Frick et al., 2014). Complex perspective taking tasks that involve typically conflicting frames of references such as Piaget and Inhelder's (1956) *Three Mountains Task* are not fully mastered until the end of primary school. Although the involvement of conflicting frames of reference in perspective taking tasks, e.g. the involvement of a to-be-imagined frame of reference that conflicts with the child's direct relation to the visual stimulus, has received criticism (see Huttenlocher & Presson, 1973, for a detailed discussion), it is valuable from a spatial cognition point of view. Tasks with conflicting frames of reference are of high interest, because they demand for the ability to represent, maintain and coordinate multiple frames of references within one coherent spatial framework. This ability is meaningful and predictive for a whole range of everyday life spatial abilities, such as misaligned map reading (Lobben, 2004), environmental learning and wayfinding (Allen, 1999; Hegarty et al., 2006). A deeper understanding of perspective taking processes involving conflicting frames of references allows us therefore to discuss spatial abilities of primary children in a much broader context. This is consistent with the mathematics curriculum but also curricula of applied sciences and geography.

A qualitative re-analysis of typical markers of perspective taking ability such as the Guilford and Zimmerman (1948) Spatial Orientation Test for adults turned out not to be construct valid as being solved mostly by mental rotation strategies (Barratt, 1953). Kozhevnikov and Hegarty (2001) proposed a novel, psychometric paper and pencil perspective taking/spatial orientation test (PTSOT) for adults in order to overcome the drawbacks of the Guilford-Zimmermann task. The test instrument consists of 12 items that display an array of seven 2D-objects. On each item, the participant is asked to imagine being at the position of one object (anchor point), facing another object (defining the imagined perspective within the array) and is asked to indicate the direction to a third object (target). Item formulation stimulates therefore complex perspective taking processes with conflicting frames of references. The answer is noted on an "arrow circle" (see example item in Figure 1, left side, item adopted for better readability). Participants are neither allowed to rotate physically the object array nor the "arrow circle".

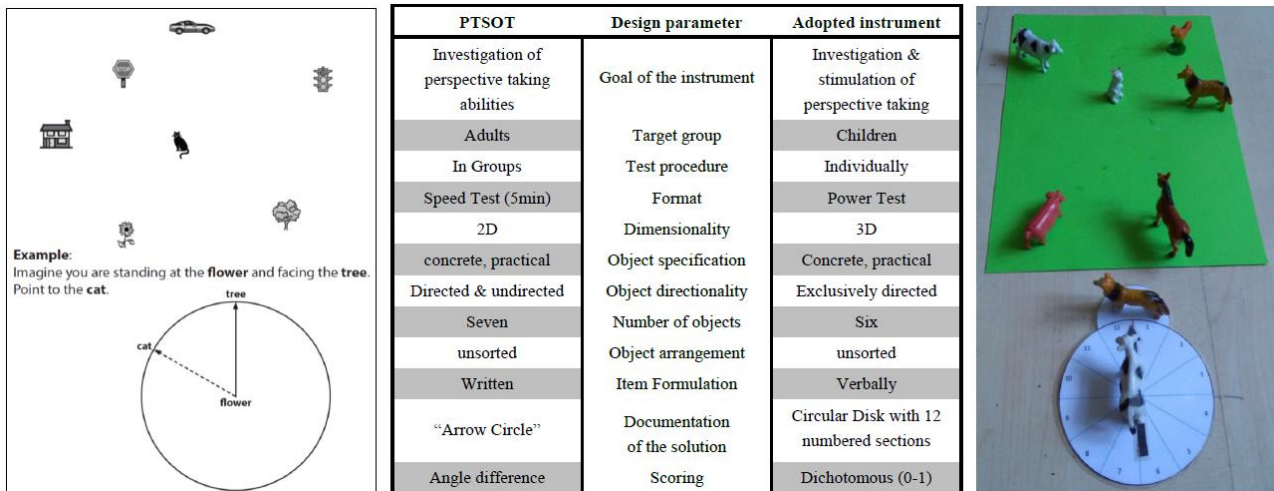

The PTSOT has been shown to be construct valid by the authors themselves, involving mostly self-reported perspective taking processes in adults (Kozhevnikov & Hegarty, 2001). Due to its accepted validity the test has been used to underline perspective taking abilities to be predictive for environmental layout learning in real world and virtual contexts (Hegarty & Waller, 2004).

The present study aimed to address the development of an instrument that stimulates complex perspective taking processes with conflicting frames of reference. One goal of the study was an adoption of the original PTSOT for primary children. A second goal was to describe the instrument with respect to test characteristics and typical error patterns that are caused by problems or failure in a set of mental transformations that are necessary to solve the items. Finally, an overall goal was to conclude potential applications of the instrument within the field of psychology and mathematics education.

## Adoption and item construction

### Design of an adopted instrument

The adoption process was conducted throughout a qualitative study with 25 fourth graders in a bachelor thesis project. We adopted the PTSOT with respect to 12 design parameters that are listed in Figure 1. We will elaborate in detail on the literature background in a following publication.

**Figure 1: Comparison between the PTSOT and the adopted instrument with respect to 12 design parameters. One item of the PTSOT is shown on the left, the whole adopted instrument is shown from a quasi-bird perspective on the right side, showing the object field and the solution answering disk**

The adopted instrument consists of a 3D, small scale array of six farm animals that are placed on a green sheet of paper (the "meadow"). The child is sitting in front of the fixed array of objects, taking an oblique view on the whole scene. Just in front of the child there is a fixed, circular disk with 12 numbered sections and a mobile arrow on it. Animals can be stuck on the disk using glue dots. Verbal item formulation is standardized as following:

Tutor: "Imagine that you are animal A (sticks animal A in the middle on the arrow of the disk) on the meadow and are facing animal B (places animal B on on the semicircle attached to the disk). In which direction do you have to turn in order to see animal C?"

The child turns the arrow of the answering disk at the section which corresponds to the right direction and the tutor notes the answer. During the solution process, the child is allowed to gesture but not to turn the array, the answering disk or itself.

### Item construction & framework for item analysis

We constructed eight initial items with the help of two parameters that describe two perspective taking processes within one item. In Figure 2 you can see that each item is defined by a set of four subsequent mental transformations of the egocentric frame of reference, which – pairwise – define one perspective taking process within the item.

**Figure 2: Item analysis for an arbitrary item showing the two mental viewing directions (dashed lines), the original viewing direction of animal A (black line), the egocentric viewing direction of the observer as well as the item construction parameters  $\alpha$  and  $\beta$**

## Exploratory Studies

We studied the range of strategies that children use to solve different items in a qualitative interview study with 16 fourth graders in the context of a second bachelor thesis. Interviews served as an aid for the interpretation of results of the exploratory study as well as verification of the goal of the instrument.

In a main study, we performed the eight items of our adopted test instrument with 254 fourth graders (mean age was 9.17 years; 116 boys and 138 girls) out of 11 classes in Lüneburg; forming a heterogeneous sample in terms of scholar achievement and social background. The test was administered in a separate room in a 1:1 situation with the experimenter. We documented children's solutions, but we did not film the children.

## Results and discussion

### Test theoretical considerations

In a first approach, Item Response Theory (IRT) analysis, we scaled the data using a Rasch-model<sup>1</sup> in *Conquest*. The characteristics prove that data fit well with dichotomous data from the exploratory study with a MNSQ within 0.95 and 1.07 for all items. EAP reliability is poor, 0.456, yet might be influenced by the small number of items. Discrimination values show poor discrimination (0.24 and 0.33) for two items and acceptable (0.42- 0.56) discrimination for the other items. Item difficulties are between -0.52 and 2.8 (0 being medium difficulty), yet showing a tendency towards a selection of very difficult items. We conclude that from a test theoretical point of view, our selection of eight items is still far away from been applied as a psychometric measure of perspective taking. However, a first analysis pointed out a set of items with good characteristic values.

### Quantitative results

<sup>1</sup> Rasch-models are one specific class of measurement models in IRT in which latent trait estimates depend on both persons' responses and the properties of the item (difficulty, discrimination).

In a second analysis, we interpreted the number of answers per section in the answering disk within the mental transformation framework that was presented in Figure 2.

(Item 6) “Imagine that you are the cow and you are facing the dog. In which direction do you have to turn in order to see the chicken?”

Item 6 is characterized by  $\alpha=250^\circ$ , thus demanding the child to rotate its egocentric frame of reference by more than  $90^\circ$  to the right while indicating the direction of the chicken ( $\beta=33^\circ$ ), thus asking for a clear left/right decision at this point of view. IRT analysis showed that the item is difficult (1.06) and has an acceptable discrimination value (0.55).

We performed the analysis of item solutions within our mental transformation framework. Errors were classified into “problems” (task is basically understood but there are a few inaccuracies within one transformation), “failure” (one transformation is not performed at all, but the item is solved within the general item structures) and “neglect” (the goal of the item is changed due to a misunderstanding/heavy problem with one of the two perspective taking processes) in order to stress the amount of difficulty that a child showed during the solution of an item.

A detailed analysis in Figure 3 demonstrates the depth in which item solutions might be interpreted with the mental transformation framework. Figure 3 shows typical error patterns, such as

- neglect of the first perspective taking process, thus solving the item from a fixed egocentric viewing direction
- failure at the last transformation  $\mathcal{T}_4$ , thus having left-right problems
- failure at  $\mathcal{T}_2$ , the item is thus solved by taking the initial, fixed heading of the first animal (cow) and the child fails to shift the viewing direction from  $\alpha_0$  to  $\alpha$
- problems with estimation of the angle  $\beta$  in  $\mathcal{T}_3$
- neglect of the first perspective taking process and projection of the egocentric viewing direction on the first animal (cow), thus pointing towards the relative position of the dog

Figure 3: Analysis of solutions for item 6.

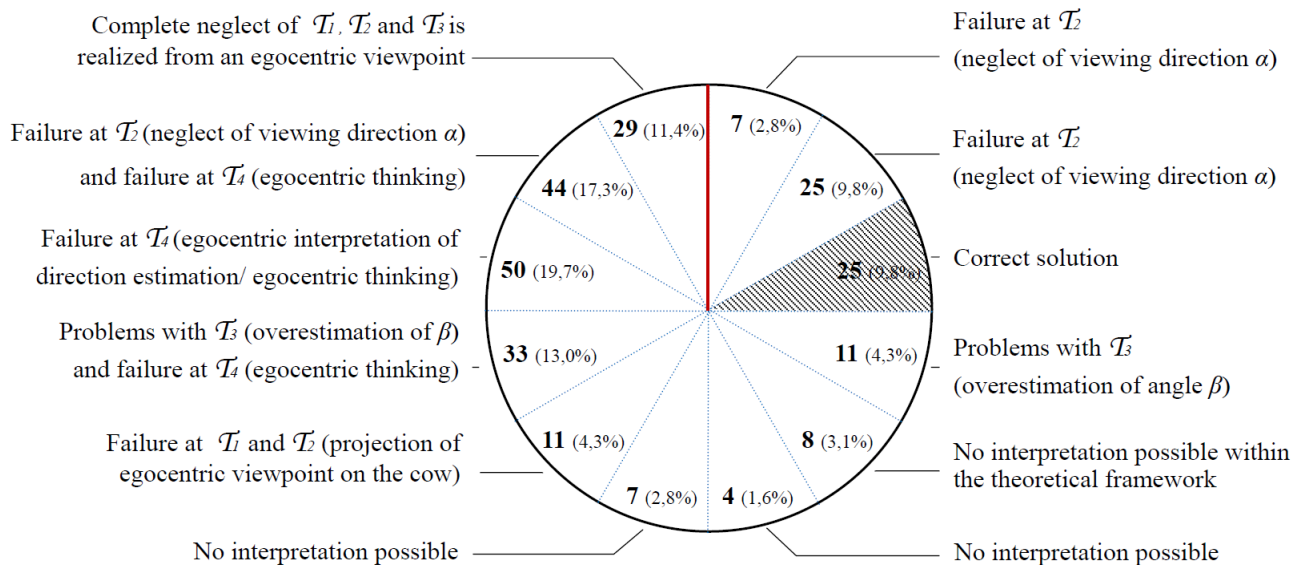

(Item 8) “Imagine that you are the chicken and you are facing the horse.  
In which direction do you have to turn in order to see the cow?”

Item 8 is characterized by  $\alpha=170^\circ$ , thus demanding the child to transform its egocentric frame of reference by almost  $180^\circ$  while indicating the direction of the cow ( $\beta=68^\circ$ ), thus asking for clear left/right decision at this point of view. IRT analysis showed that the item is very difficult (2.48) and has an acceptable discrimination value (0.53). The high difficulty of this item results from the need to take almost an opposite perspective while indicating to the front right.

For the analysis we expected therefore a large percentage of children to fail at the last transformation  $\mathcal{T}_4$  (thus producing right-left-errors) as well as a high number of children to neglect the first perspective taking process, thus solving the item from an egocentric viewpoint. Figure 4 demonstrates that the last item shows a whole range of typical difficulties.

However, although the solution rate is for this item was low, many children managed to perform most of the transition processes correctly. Almost 77% of the children succeeded on performing at least  $\mathcal{T}_1$ , 47% succeeded in doing at least  $\mathcal{T}_1$  and  $\mathcal{T}_2$  correctly, 30% managed  $\mathcal{T}_1$ ,  $\mathcal{T}_2$  and  $\mathcal{T}_3$  and almost 10% managed to do all the transformations correctly. Figure 4 shows that problems with the first perspective taking process may occur due to egocentric behavior, the failure to perform  $\mathcal{T}_2$  or due to the projection of the egocentric viewing direction on the chicken. We explain errors in the first perspective taking process by difficulties that are inherent to children at this age (see Huttenlocher & Presson, 1973) but also by problems in understanding the item formulation and the item structure itself. The latter might be improved by doing multiple examples with the children (we explained the item structure with only one example).

**Figure 4: Detailed analysis of item 8, revealing problems in the  $\mathcal{T}_4$  transformation process. Answer patterns that are not interpretable within our framework might be explained by counting in the field of animals or arbitrarily guessing the answer.**

## Applications of the instrument in different contexts

We analyzed performance on our adopted version of the perspective taking test at two different levels in order to underpin the argumentation on possible applications of the instrument.

### Diagnostics

We demonstrated that item construction is straight forward using the construction parameters  $\alpha$  and  $\beta$ . Our instrument allows therefore purposeful item construction in order to investigate individual differences and developmental issues in complex double perspective taking abilities. Children verbalized easily their thinking processes in our qualitative study, using gesture for showing viewing directions and the direction of the third animal. A combination of item solution and explaining aloud the solution process might help to diagnose the transformation processes that are still problematic for each child.

During construction and evaluation process, we identified two problems with our instrument that should be considered during item formulation: First, we measured angles from head to head of each animal. As the animals are quite large, the correct estimation of the angle  $\beta$  might depend on whether the child focuses on the head or the tail of each animal. Second, as the rabbit was placed at the center of the animal array, children had problems with taking the viewing direction of the rabbit. Instead, they projected their egocentric viewing direction onto the rabbit and answered items as giving relative positions of animal C to the rabbit.

### Learning environment

Our adopted instrument consists of easily purchasable, inexpensive material. Again, our study showed that children are able to verbalize their spatial thinking processes with ease, using a whole range of gestures. Our instrument might be used for teaching of complex perspective taking processes (children solve pre-formulated items by the teacher), in communicative settings (children formulate items on their own), in discussions that address the transformation processes explicitly (“Can you explain me why this item is so complicated?”), or in creative settings (formulation of own items within constraints, e.g. difficulty, or re-configuration of all animals on the meadow).

### Psychological test instrument

The original PTSOT has gained much attention concerning psychometric measurement of perspective taking ability because it is construct valid and reveals the predictive nature of perspective taking abilities for environmental learning. Another wishful application of our adopted version of the PTSOT is therefore in psychometrical measurement of children’s perspective taking abilities. IRT analysis revealed a poor reliability and pointed out some inappropriate items with low discrimination values. In a further study, an exploratory analysis on a larger set of items of intentionally different difficulties is planned. IRT analysis might then reveal good items for a psychometric test of spatial ability in children. An IRT analysis of the test instrument might then be linked to our analysis technique based on egocentric transformations in order to develop a typology of complex perspective taking in children.

## Traveling in spatiality, in spatial sense

Catherine Houdement

Université Rouen Normandie, Laboratoire de Didactique André Revuz (EA4434), Rouen, France

[catherine.houdement@univ-rouen.fr](mailto:catherine.houdement@univ-rouen.fr)

*What attention is given to spatial sense in Geometry? The outcome (2015) of a special ZDM issue, Geometry in the Primary School and the CERME conference is a good opportunity to think about and compare different approaches or frameworks regarding this topic.*

*Keywords: Spatial sense, spatial knowledge, geometrical thinking.*

### Introduction

A travel abroad enriches our way of thinking and furthers our understanding of the values and behaviours of his/her own culture. For us just the same an intellectual trip outside the country (or the language) helps deepen our knowledge and analysis of our way of thinking. The study initially aims to compare the perspectives of educational researchers regarding the notion of *spatial sense*. Along the way, it documents the conceptual frameworks which support research.

In ZDM issue 47, *Geometry in the Primary School*, the theme of *spatial sense* is common to all papers (Mulligan, 2015). Could it be that the study involves primary school or that the imagery in thought is a topical subject in recent neuroscience research? In the 36 papers of the ICMI Study *Perspectives on Teaching Geometry for the 21st Century* (1998) the word *spatial* was mentioned 353 times but never in a title. Our ongoing study is based on (not yet completely extensive) reading of ZDM 47 and CERME texts on Geometry since the first time (2003) that a specific group about Geometry exists. Such a group has persisted for all the CERME under the name *Geometrical Thinking* (except 2011 *Geometrical teaching and learning*).

In short, this paper provides an overview on spatial sense the difference theoretical frameworks regarding it, based on literature published in ZDM issue 47 and CERME papers of the last decade (2003-2015).

### First definitions and motivations for studies about spatial sense

Many expressions (*spatial reasoning*, *spatial sense*.....) are related to *spatial* when considering English papers from cross- and interdisciplinary fields of mathematics education, psychology, child development and neuroscience: In a first approach we consider these expressions as equivalent and agree the large definition quoted by Mulligan (2015), from Spatial Reasoning Group (2015)

“*Spatial reasoning* (or *spatial ability*, *spatial intelligence*, or *spatiality*) refers to the ability to recognize and (mentally) manipulate the spatial properties of objects and the spatial relations among objects. Examples of spatial reasoning include: locating, orienting, decomposing / recomposing, balancing, diagramming, symmetry, navigating, comparing, scaling, and visualizing.” (Mulligan, 2015, p. 513).

It should be noted that this definition considers *spatial* in a broader sense than 3D- situations or 3D-geometrical thinking. **In this paper we are interested in *spatial skills*, which are not associated with objects 3D.**

Many researchers stress the utility of *spatial reasoning* for mathematical learning and problem solving (Owens & Outhred, 2006; Sinclair & Bruce, 2015), and to Science, Technology, Engineering and Mathematics Education (Mulligan, 2015). Tahta (1980) and others note the ability to mobilize wisely spatial skills in mathematical and scientific thought, which Battista (1999, quoted by Mulligan, 2015, p. 514) named *spatial structuring* and defined as: “the mental operation of constructing an organization or form for an object or set of objects. It determines the object’s nature, shape, or composition by identifying its spatial components, relating and combining these components, and establishing interrelationships between components and the new objects” (Battista, 1999).

*Spatial structuring* is also an important component of the early learning of numbers, of measurement units, and well of geometrical thought (Van den Heuvel-Panhuizen et al., 2015; Mulligan, 2015). Van den Heuvel-Panhuizen et al. (2015, p. 347) outline the strong relationship between spatial and mathematical abilities. Mathematical performance and spatial abilities are positively correlated, not only in mathematical domains that are ostensibly spatial.

French scholars as Berthelot & Salin – with a long story of research on geometrical education – agree on the place of *spatial abilities* in geometry learning, also for geometrical proof. But they have always emphasised (since the 1990s) their interest for everyday life: “the treatment of spatial abilities is the main source not only of many of the further learning difficulties met by secondary school pupils, but also of some of the main deficiencies in spatial representation needs in everyday life” (Berthelot & Salin, 1998, p. 71). This point of view has encouraged them to define and elaborate, unconstrained by geometry (or dissociated by classical geometry), what they called *spatial knowledge*.

In conclusion it appears that spatial abilities are critical for learning mathematics and beyond. As these abilities are naturally associated with geometry, geometry seems the ideal niche for their teaching. It could even be read between the lines that it would be, nowadays, the main reason for teaching geometry in compulsory school education. Indeed, the present trend in some countries is to marginalize geometry in curricula in favor of probability and statistics (Maschietto et al., 2013).

Obviously *spatial reasoning* nourishes *geometric reasoning* (Mithalal-Le Doze, 2015), but *geometric reasoning* needs other abilities, like defining and classifying (in the sense of Brunheira & Ponte, 2015), axiomatic reasoning, and doesn’t take in account non-mathematical forms of deduction... Furthermore spatial problems, like finding one’s way in an unknown town, cannot be assimilated to geometrical tasks. Studying *spatial reasoning* for itself seems to be interesting.

### **Spatial sense in CERME papers (2003 to 2015)**

Let us first examine how the successive CERME (2003 to 2015) working groups named *Geometrical Thinking* deal with spatial sense.

The Group *Geometrical Thinking* worked within the continuity in the CERME3, 4 and 5 (2003, 2005, 2007). In CERME5 the topic *Spatial abilities and Geometrical tasks* was considered; it is

noted: if it seems possible to agree about Geometrical tasks, it is necessary to precise what *spatial abilities* mean. We try to do it in the next section.

In CERME6 (2009) *spatial abilities* is not a specific topic of the Group even though it could be present in the sub-theme *Teaching, thinking and learning 3D Geometry*.

In CERME7 (2011) *spatial abilities* is connected to *diagrammatic reasoning*. Deliyanni et al. (2011) explore spatial abilities in relation with 2D-geometrical figure understanding and consider the influence on reasoning of the different diagram's apprehensions (Duval, 1995): perceptual, sequential and operative. Braconne-Michoux (2011) proposes to intertwine the Geometrical Paradigms (Houdement & Kuzniak, 2003; Houdement, 2005) and the Van Hiele levels which integrates visualization, a spatial ability.

In CERME8 (2013) the Group introduction proposed four competencies (see Figure 1) to support geometrical thinking: reasoning, figural, operational and visual (Maschietto et al., 2013) and assume that the links between these competencies are more important for geometrical work. *Spatial abilities*, *spatial sense* are not explicitly mentioned but it seems (see above in Mulligan, 2015) to “have a place” in each competency. Two papers assume a *spatial* entry (other than 3D activities): in Sevil & Aslan-Tutak (2013) and particularly de Freitas & Mc Carthy (2013) emerges a new face of *spatial abilities*, the gestural / haptic ones.

**Figure 1: The geometrical competencies (Maschietto et al., 2013)**

CERME9 (2015) in the continuity of CERME8 is supported by the same model (Figure 1). The topic quoted in relation with spatial abilities is *visualization*. The authors (Ceretkova et al., 2015) stress the influence of geometric knowledge on visualization, beyond perceptive and psychological aspects.

How do educational researches deal with the issue of *spatial abilities*? More precisely what kind of theoretical frames do they use or construct for their research?

## Theoretical frameworks for spatial abilities

Specifying the frame the authors use in order to analyse spatial abilities is quite rare: only once in ZDM, only a few times in CERME papers before CERME9. Let us give some examples of such frames.

### Example 1

In Panaoura et al. (2007) *spatial abilities* are commonly addressed by three major dimensions **spatial visualization, spatial orientation and spatial relations**. These researchers use an analysis model for *spatial abilities* (Demetriou & Kyriakides, 2006) with three components, namely **image manipulation, mental rotation and coordination of perspectives** to investigate whether or not and to what extent primary and secondary school students' spatial abilities are related to their performance on geometry tasks involving 2D figures, 3D figures, or nets of solids.

### Example 2

In Berthelot & Salin's research (quoted in Douaire & Emprin, 2015) *spatial knowledge* is knowledge which enables to control one's relations to the surrounding space, the sensible world. This control may consist in recognizing, describing, manufacturing or transforming objects; moving, finding, communicating objects' position; recognizing, describing, constructing or transforming a route (Berthelot & Salin, 1999, p. 38). Children begin to integrate *spatial knowledge* before going to school while experimenting, and sharing with adults about their actions. Spatial knowledge cannot be reduced to geometrical knowledge but can be necessary to solve a geometrical problem.

It should be noted that this definition relies on problems (what Berthelot & Salin name spatial problems). In Brousseau's theory (the theoretical frame of Berthelot & Salin's research) knowledge is what enables to solve problems, and problems solving is a condition for learning. For instance how to define knowledge to be taught to use efficiently a map when lost in an unknown town? First identifying situations in which using plans and maps are necessary; second analysing the spatial interactions to solve them and thus indentifying the necessary knowledge.

Daily life interactions take place in space of different sizes which exert different constraints on the actions. *Microspace* is very close to the subject, like a sheet of paper, a computer screen, a touch screen; in this space objects can be moved, touched, turned; it corresponds to the usual grip relations. *Mesospace* is the surrounding space, inside a room, a building; the subject can move inside it, mesospace is the space of usual domestic spatial interactions. *Macrospace* is the broader space, unknown city, rural or maritime spaces; the subject has only local views, he had to conceptualize (Berthelot & Salin, 1998, p. 72; Douaire & Emprin, 2015, p. 532). Thus *spatial knowledge* is structured into three main conceptions, microspatial conception, mesospacial conception, macrospatial conception. For instance, following this frame, a straight line can be conceived as a print trace produced with a ruler, the edge of a door, or a set of trees properly aligned in a orchard.

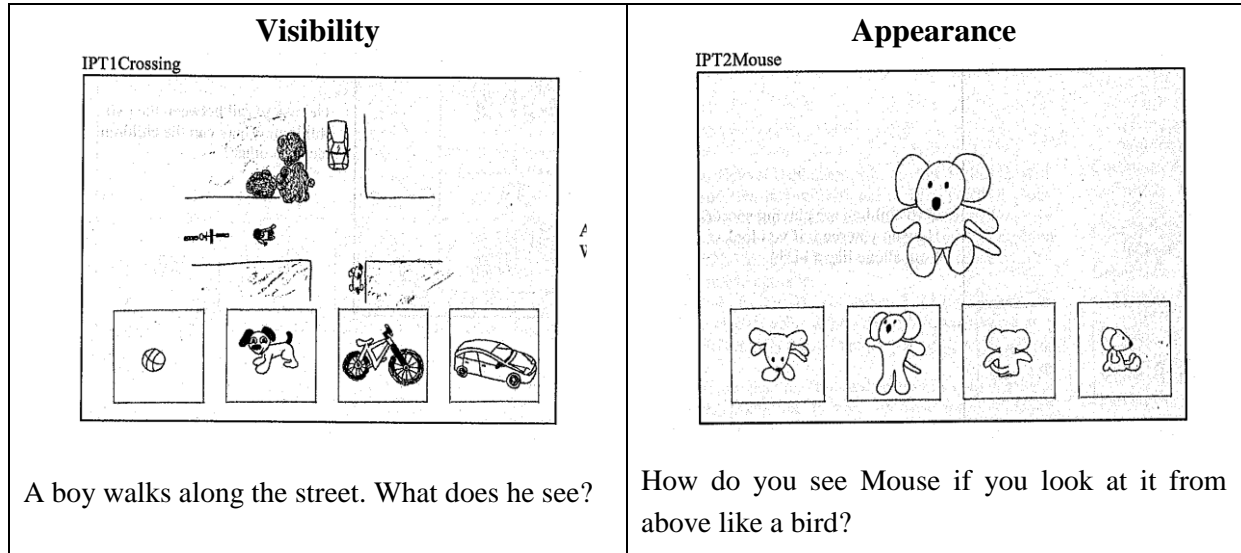

This framework has different functions: in Berthelot & Salin, as in Douaire & Emprin (2015) the framework allows them to construct situations as means to teach students spatial knowledge (as to alignment and straightness, through the good use of a map to navigate). In other described cases, the frame allows to evaluate and compare performances of students, or to map spatial abilities.

### Example 3

Following Newcombe et al. (2013), Van den Heuvel-Panhuizen et al. (2015, p. 346) distinguish between two kinds of spatial skills: **between**-objects representation and transformation skills (for

example in Perspective-Taking tasks –PT–, like the Three Mountains of Piaget & Inhelder, 1956) and **within**-objects representation and transformation skills (for example a mental rotation).

The aim of their research is to assess children's PT-skills focusing on the difference between two components of what they named IPT (Imaginary Perspective-Taking): **visibility** and **appearance**. These two competencies are highlighted by the items they proposed to the children.

**Figure 2: Examples of drawings and questions in the test (Van den Heuvel-Panhuizen et al., 2015)**

It could be noted that the 3D situation (meso- or macro-spatial) is communicated to the 2D representation (micro-spatial).

The analysis of their tests with more than 300 children of Netherlands and Cyprus (age 4-5) shows that kindergartners of the two countries can answer correctly: on average respectively 70% and 55% of the visibility items, and 40% and 30% of the appearance items; that the development of the IPT competence visibility precedes the development of the IPT competence appearance; that specific item characteristics of the evoked context could also influence the difficulty level of the item.

#### Example 4

In the 1990s Duval (1995, 2006) has brought an important contribution to necessary visualization of the drawing (implicitly in a microspace) for geometric reasoning. Some authors rely particularly on Duval's research, e.g., Mithalal-LeDoze (2009, 2015), Papadaki (2015) and Swoboda (2015).

With iconic visualization "the drawing is a true physical object, and its shape is a graphic icon that cannot be modified. All its properties are related to this shape (...)" (Mithalal-LeDoze, 2009, p. 797). With non iconic visualization "the figure is analysed as a theoretical object represented by the drawing, using three main processes: *Instrumental deconstruction*: in order to find how to build the representation with given instruments), *Heuristic breaking down of the shapes*: the shape is split up into subparts, as if it was a puzzle), *Dimensional deconstruction*: the figure is broken down into figural units — lower dimension units that figures are composed of —, and the links between these units are the geometrical properties (...)" (Mithalal-LeDoze, 2009, p. 797; Papadaki, 2015). Duval quoted two other processes *Change of Scale* and *Change of Orientation*.

Studying visually impaired students moving 2D objects to imagine 3D objects, Papadaki (2015) introduces a new source for mental images, the kinesthetic one. For these students visualization integrated many repetitions of the same gesture, cross-checking it with one's everyday life tactile experience and geometrical knowledge as objects' definitions. Visualization is clearly more than vision, what Duval wrote for a long time describing different ways (iconic and non iconic) of visualizing a figure. But Papadaki (2015) introduces a new dimension in visualization, a dynamic one; conceiving a figure 3D as the result of a reproducible movement of a figure 2D.

Swoboda (2015) stresses the rotation as a natural transformation for young students; mental rotation is a fundamental component of the frame of Demetriou & Kyriakides (2006), and of non iconic apprehension of Duval too. Maybe the rotary motion and the rotation as transformation could be studied sooner (than the line symmetry) in compulsory school to enrich visualization skills.

## Conclusion

Spatial sense and the different frames regarding it is now better mapped. We will not go back on what was discussed above, but just stress some difference between the frames regarding it.

1) The framework of Berthelot & Salin in relation with the size of space enables to realize that almost all the mentioned situations or items of the ZDM and CERME papers (except Douaire & Emprin, 2015) are located in the microspace; a priori they only request microspatial knowledge<sup>1</sup>. The existence and importance of mesospacial and macrospacial knowledge seem underestimated. For example in the paper of Van den Heuvel-Panhuizen et al. (2015) spatial apprehension of a picture (or a drawing, microspace) is considered as an apprehension of the evoked real world (meso- or macro-space).

2) Some papers try to isolate "basic" skills or "basic" items which could be predictive of spatial sense and serve for students assessment, analysing spatial situations (for example Van den Heuvel-Panhuizen et al., 2015) or geometrical problems (Duval 1999, 2006). On the other hand Berthelot & Salin, in coherence with their support framework, don't attempt to describe finely "the" spatial skills but ask students to solve real spatial problems in which spatial skills are at work.

3) Papadaki (2015) and Swoboda (2015) allow us to realize that gestures can be a powerful help to mentally construct geometrical images and facilitate visualization. Among the gesture the rotary motion (rotation) could play an important role.

4) Visualization is enriched with new entries as gestures and motion; it has gained increasing importance on the spatial skills. But what is meant by this term? Another inquiry to lead...

# Autism and mathematics education

Michiel Klaren, Birgit Pepin and Marieke Thurlings

Eindhoven University of Technology, The Netherlands; [m.j.klaren@tue.nl](mailto:m.j.klaren@tue.nl)

*Inclusive education urges educational research to deepen its understanding of students with special needs. The aim of this theoretical paper is to provide an overview of the didactical aspects in the field of autism and mathematics education. First we review literature on autism spectrum disorders (ASD) from a broad psychological perspective, and second, we focus on three cognitive theories which are used to explain the behavioral symptoms of ASD. Next, we discuss mathematics specific didactical issues that relate to these cognitive theories. Finally, we elaborate on an example of research on mathematics education for ASD students based on the Van Hiele model of thinking in geometry. In the conclusions we bring together the findings and give suggestions for future research.*

**Keywords:** Autism Spectrum Disorder, mathematics, geometry, Van Hiele, secondary education, didactics, inclusion.

## Introduction

Autism is a neurodevelopmental disorder characterized by impairments in social interaction and communication, and by restricted and repetitive patterns of behavior (American Psychiatric Association, 2013). Different combinations of the impairments occur, and together form a continuum, which is called the autism spectrum of disorders (ASD; Wing, 1988). Both the severity of the symptoms and the intellectual capacities of people with ASD vary widely. There is a growing understanding that people with autism can also provide a substantial contribution to society (e.g. Mottron, 2011). In most countries, and also in the Netherlands, inclusion policies require schools to develop support for children with autism. In this article we will focus on ASD students with higher intellectual abilities<sup>1</sup> and who require limited support, and hence can participate in inclusive secondary education.

Mathematics is a school-subject that builds on logic, is well structured, uses symbolic language with well-defined meanings and deals, at least in its purer forms, with unambiguous questions. These characteristics make mathematics a subject that is relatively easy to access for people with ASD. Research shows that autism is found more often amongst mathematics students than those of other disciplines (e.g. Baron-Cohen, Wheelwright, Burtenshaw, & Hobson, 2007). However, other studies showed that the majority of ASD students and higher intelligence have an average mathematical ability compared to the normal population, while only some have mathematical giftedness (e.g. Chiang & Lin, 2007).

In secondary schools that include ASD students, teaching mathematics is not an easy task. Based on research and our own experiences of teaching in inclusive schools, we claim that ASD students learning mathematics require specific subject-didactical support. A review of research on autism

---

<sup>1</sup> In literature on autism this also indicated as High Functioning Autism and Asperger Syndrome or HFA/AS (Whitby & Mancil, 2009).

showed that most studies are about medical or behavioral aspects, and less than 20% targets education (Graff, Berkeley, Evmenova, & Park, 2014). Research on autism in inclusive education is mainly about pedagogic topics concerning the ASD students (Ravet, 2011). However, there is little research on didactical aspects of autism in specific subject fields.

The aim of this theoretical paper is to provide an overview of the didactical aspects in the field of autism and mathematics education. Our research question is the following:

Which didactical issues are related to ASD students learning mathematics?

## **Literature review**

### **Autism spectrum disorders**

After the first case studies by Kanner in 1943, and Asperger in 1944, it took until the end of the 1970's, when Wing and Gould (1979) provided their classic description of the triad of impairments of autism: first, the absence or impairment of social interaction, especially with peers; secondly, the absence or impairment of the development of verbal and nonverbal language; and third, repetitive, stereotyped activities of any kind. Confusion about different subtypes lead Wing (1988) to the conclusion that there must be an autistic continuum, which she coined the Autism Spectrum of Disorders (ASD) with diagnoses such as classic autism, PDD-NOS (Pervasive Developmental Disorder – Not Otherwise Specified) and Asperger's syndrome. With the latest version of the diagnostic manual DSM-5 (American Psychiatric Association, 2013) the diagnosis of ASD is based on persistent deficits in social communication and social interaction, and on restricted, repetitive patterns of behavior, interests or activities. The subtypes of PDD-NOS and Asperger are no longer official diagnoses, and DSM-5 describes three levels of severity for ASD (i.e. requiring very substantial support; requiring substantial support; and requiring support).

The psychological research into autism has been dominated by three cognitive theories (Rajendran & Mitchell, 2007): the Theory of Mind deficit; Executive Dysfunction; and the Weak Central Coherence accounts.

### **The Theory of Mind deficit**

Children with ASD experience their social environment as unpredictable and incomprehensible (Baron-Cohen, Leslie, & Frith, 1985). They seem to treat people and things the same way. Observations showed, strikingly, that children with Down syndrome and a low intelligence developed a normal social competence, whilst children with ASD and higher intelligence did not (Baron-Cohen et al., 1985). To explain this, Baron-Cohen, et al. did research on the *Theory of Mind*: neurotypical children (non-ASD) are able to impute mental states to themselves and others (in other words, they have a "theory of mind"), whilst children with ASD fail to do so. This "mind-blindness" was shown by the false belief test: a story, played out for the child with dolls, where one doll has a belief about the location of an object that is incongruous with its real location. The test subject is then asked where the doll will look for the object. To answer correctly the test subject should infer the mental state of the doll ("I think she thinks"). A large proportion (80%) of children with ASD incorrectly assumed the doll would look on the real location. To explain the 20% of children with ASD who answered correctly, second-order false belief tests ("I think she thinks he thinks") were developed, and based on those results, it was assumed that a Theory of Mind is not always lacking completely but may be

not fully developed in children with ASD. Another problem was that Theory of Mind can be used to explain impairments in play, social interaction and verbal and nonverbal communication, but not for explaining the other characteristics of ASD, such as the restricted interests, obsessive desire to keep things unchanged (rigidity and inflexibility), and so on (Frith & Happé, 1994).

### **Executive dysfunction**

Early in the 1990's, Ozonoff, Pennington and Rogers (1991) suggested that deficits in the executive functions could explain symptoms of autism such as narrow interests, rigidity and inflexibility.

Executive function is defined as the ability to maintain an appropriate problem-solving set for attainment of a future goal; it includes behaviors such as planning, impulse control, inhibition of pre-potent but irrelevant responses, set maintenance, organized search, and flexibility of thought and action (Ozonoff et al., 1991, p. 1083).

The research by Ozonoff et al. (1991) showed that deficits with executive function were found in both children with classic high-functioning autism and those with Asperger's syndrome (who succeeded on the second-order false belief test). This suggested that deficits in executive function form a primary cognitive deficit in ASD.

### **Weak Central Coherence**

In neurotypical children (non-ASD) the development of information processing is oriented towards extracting the overall meaning from the sensory input. This inclination is called 'central coherence'. Frith (1989) described how this development is different in children with ASD, and she proposed the weak central coherence theory to explain the symptoms of autism. Psychological tests later showed that children with ASD have superior performance on local information processing, but were less inclined to global information processing (Happé, 1999). In people with ASD this is also observed as a preoccupation with details and parts and a failure to understand the meaning of the whole.

## **Implications of ASD for mathematics education**

Although the focus of this paper is on mathematics education, we first address some approaches for ASD students that apply to education in general.

### **General education**

A general pedagogic approach for students with ASD is *structured teaching* (Mesibov & Shea, 2010). Structure can be provided in the physical environment (e.g. arrangement of the room and the use of visual clues), the sequence of events during the day (e.g. an understandable schedule), the individual tasks (e.g. provide specific information of the goals and the completion criteria) and the grouping of tasks into a work system. Many of these approaches in autism have not been well researched, and research is now addressing the determination of evidence-based practices (Reichow, Volkmar, & Cicchetti, 2008).

### **Mathematics education**

Based on a review of 18 studies of mathematical abilities of ASD students with AS/HFA, Chiang and Lin (2007) found that the majority of the ASD students have average mathematical capabilities and only some ASD students have a mathematical giftedness. Based on these results, Chiang and Lin

concluded that an age-appropriate mathematical curriculum can be used, but individual adjustments may be needed to support both relative strengths and weaknesses.

In a review of the literature on academic achievement profiles of ASD students, Whitby and Mancil (2009) report that more than half (52%) of individuals diagnosed with ASD have IQs above 70 and for these children, academic goals come within reach. There is a need for appropriate interventions to allow these children to perform up to their potential and obtain meaningful employment. For mathematical abilities, Whitby and Mancil found that computational skills were intact, but applied mathematics capabilities were impaired. Issues with the application of mathematics are possibly due to executive functioning deficits with their organizational and attentional skills that have a negative effect on multi-step problem solving. Deficits in comprehension (both listening and reading) relate to contextual understanding (e.g. word problems) and conceptual understanding (e.g. abstract concepts).

With word problems, ASD students have difficulty choosing the right approach because they have, due to their weak central coherence, difficulty seeing the similarities and the common structure of different examples and exercises. An ASD adjusted didactical approach for solving word problems should address improving reading comprehension, mathematics vocabulary, computation, and everyday mathematical knowledge (Bae, Chiang, & Hickson, 2015, p. 2206).

In solving mathematical problems (“a question that exercises the mind”; Schoenfeld, 1985) ASD students are impaired by executive dysfunction (Ozonoff et al., 1991). In mathematical problem solving ASD students have similar issues as with word problems, but are also expected to face issues with cognitive flexibility, the use of heuristics and the use of meta-cognitive strategies. Positive results have been reported on the effects of cognitive strategy instructions for students with learning disabilities (Montague, Krawec, Enders, & Dietz, 2014), and these results may also be obtainable for ASD students. In classroom practice we see that some ASD students develop problem solving procedures of their own, which may work on the initial (simple) problems but cannot be generalized to later extensions. Upon receiving feedback, the rigidity of these ASD students sometimes inhibits them from accepting the time-proven approaches. Feedback is also known to play an important role in self-regulated learning (Butler & Winne, 1995). Improving feedback seeking strategies of ASD students, can support their self-regulated learning, and help to overcome barriers in problem solving.

Conceptual understanding can be a challenge for ASD students: they have, due to their weak central coherence, difficulty integrating information and generalizing previously learned concepts (Klinger & Dawson, 2001). Minshew and Goldstein (2002) found that individuals with high-functioning autism had impaired concept formation. Furthermore, these individuals had difficulty with cognitive flexibility and showed incomplete understanding of learned concepts. Temple Grandin, diagnosed with ASD, describes (2006) how she memorizes as much facts and experiences as possible, and uses an internal search engine to retrieve visual images of prototypes to understand a concept. In general, ASD-students benefit from visualization of abstract concepts, and with their strong root memory, they remember the visualizations as prototypes of the concept.

### **An example: A research study on learning geometry by ASD students**

To illustrate research on subject-specific didactic problems for ASD students, we describe an example from geometry and the cognitive theory of weak central coherence. This example is based on a master thesis of the first author (Klaren, 2012). The theoretical/ analytical framework is concerned with Van

Hiele's theory, which defines five levels of the learning process that learners are said go through when learning geometry. The five levels are described by Hoffer (1981) as:

- Level 1, Recognition: the student learns some vocabulary and recognizes the shape as a whole;
- Level 2, Analysis: the student analyzes properties of the figures;
- Level 3, Ordering: the student logically orders figures and understands interrelationships between figures and the importance of accurate definitions;
- Level 4, Deduction: the student understands the significance of deduction and the role of postulates, theorems, and proof;
- Level 5, Rigor: the student understands the importance of precision in dealing with foundations and interrelationships between structures

**Figure 1: Example of question on level 1 (recognition)**

Van Hiele posited that learners master the levels in a stepwise manner and always in the same sequence. In other words: the difficulty of questions specific to the successive levels, will rise. Usiskin (1982) confirmed the ability of the Van Hiele theory to describe and predict the performance of students in secondary education on geometry. The fifth level was not well operationalized by Van Hiele, and left out of further analyses.

Students with weak central coherence (operationalized as students with ASD), are hypothesized to have an inversion of the difficulty of level 1 and 2. In other words: they are expected to find questions at level 1 ("shape as a *whole*"; see Figure 1) more difficult than questions at level 2 (analyses of properties).

To test the hypothesis, 81 children with ASD and higher intellectual abilities, age 12 to 17 years, were tested with the geometry test of Usiskin (with the texts translated in Dutch and the original diagrams). Rasch analyses was used to estimate the average difficulty (on a logit scale) of questions at each level.

The results were compared with results found for non-ASD students by Wilson (1990) in a reanalysis of the data of Usiskin. The combined results (Figure 2) show that the estimated average item-difficulty of questions on level 1 and 2 were indeed shifted for ASD students (level 1 more difficult and level 2 easier) compared to non-ASD students. However, level 1 was not found to be more difficult than level 2 for ASD students. Based on these findings, the (strong) hypothesis of inversion must be rejected, but the test gives some support for the anticipated differences between ASD and non-ASD students

**Figure 2: Average item-difficulty per level**

regarding the difficulty of the first two levels of Van Hiele. In the didactical practice of geometry teaching, this should raise awareness that visual recognition by ASD students is to be linked to explicit analyses of properties in order to support concept formation.

A peculiar observation was that some students who performed well on questions on higher levels, made unexpected errors in questions on level 1: on questions where the squares were to be pointed out (e.g. Figure 1), they included the rectangles. A possible explanation of this type of errors is the ambiguity of the mathematical language: in Dutch the translation of square is “vierkant” (literal translation: “four sides”). In interviews after the test, students explained their answers by stating that the rectangles had four sides. Possibly these students were not relying on the shape as a whole, but applied rule-based logic in combination with literal understanding of the mathematical concept.

## Conclusions

The three cognitive theories described in this paper represent theoretical frameworks that can guide research in autism and mathematics education.

As described by the (lack of) Theory of Mind account, ASD students experience their social environment as unpredictable and incomprehensible. Research on ASD and general education will address the development of evidence-based practices that support ASD students in their social interactions. Research on mathematics education can develop interventions that aim for using (understanding) and seeking feedback with respect to learning mathematical concepts and skills.

Related to feedback is the use of self-regulated learning. Students with ASD, with their typical weak executive functioning, can be supported by interventions that improve their metacognition and use of strategies and heuristics, especially in the field of mathematical problem solving.

Recent research on perception by people with autism (e.g. Pellicano & Burr, 2012; Hohwy, 2013) is deepening the neurocognitive understanding of the weak central coherence account. Research on mathematics education may benefit from these results, and improve the understanding of concept learning by ASD students.

To summarize, students with ASD have deficits in their social interaction, their contextual and conceptual understanding, and the self-regulation of their executive functioning. In order to allow successful inclusion of ASD students in education, teachers have to apply effective instruction methods to overcome the “mind-blindness” of these students. Research can help define design guidelines for instructional methods in mathematics, which are attuned to the specific needs of ASD students and allow them to see the beauty of mathematics.

# Learning sine and cosine in French secondary schools

Ratha Loeng

Paris Diderot-Paris 7 University, France; [loengratha@hotmail.com](mailto:loengratha@hotmail.com)

*The purpose of this paper is to present a questionnaire devoted to trigonometry and its results. More specifically, the study focuses on curriculum and cognitive aspects of learning and teaching sine and cosine over the final five years in French secondary schools, from grade 8 to grade 12. We ask: what are the difficulties of students in learning sine and cosine concepts and making the transition from the geometric setting to the functional setting. We identify four major types of error committed by students. This raises the question of how to make students effectively assimilate the concepts of sine and cosine.*

*Keywords: Trigonometry, sine and cosine, secondary school, available knowledge.*

## Introduction

In secondary schools in France, trigonometry notions are introduced progressively from grade 8 to grade 11 (science option), and end with sine and cosine functions in grade 12 (science option). We ask the key questions: How to articulate the passage from trigonometry in right triangles to the trigonometric circle and to sine and cosine functions? And, how to make the students assimilate these notions? To answer these questions, we investigate the status of the educational system: curriculum and learned knowledge.

In connection with our analysis of institutional texts and manuals for the study of the mathematical organization (Anthropological Theory of the Didactic, Chevallard, 1999; Bosch & Gascón, 2014), we elaborated a questionnaire for grade 12 students. The purpose of this questionnaire is to test the knowledge acquired by students in the final five years of study on trigonometry and specifically the sine and cosine functions in grade 12 (science option), to identify implicit notions in learning and teaching of trigonometry, to clarify the set of issues in our research work on what the students have learned, and to generate further research questions.

The questionnaire consists of six exercises, mainly concerning the cosine and sine of an acute angle in a right triangle, the cosine and sine of an oriented angle in the trigonometric circle, and some properties of the cosine or sine function like periodicity. In this paper, we analyze *the first three exercises of the questionnaire* and describe its results.

## Methodology

For the curriculum study, we use the Anthropological Theory of the Didactic (Chevallard, 1999; Bosch & Gascón, 2014) as a theoretical framework in order to identify the mathematical organization (MO) of the French institutions that is developed in French mathematics textbooks. It is rather an exploratory analysis of French textbooks which gives us an overview of the teaching of trigonometry and of trigonometric functions in secondary schools.

We do not present in details the curriculum study but the identified MO allowed us to construct a questionnaire. It is grounded in the most used types of tasks and techniques in the French teaching institutions, from grade 8 to grade 12 related to trigonometry in right triangles (Exercise I, grades 8-

9), trigonometric circle (Exercise II, grades 10-11) and trigonometric functions (Exercise III, grade 12).

To analyze the tasks in the questionnaire, we choose tools from the Theory of Double didactic and ergonomic Approach (Robert, 2008; Robert & Hache, 2013) which provides us with fine cognitive tools to analyze students' knowledge. The questionnaire is a test given to grade 12 students outside the context of any particular chapter in order to avoid any didactical contract influence. We study the knowledge adaptation in these tasks (see the following section) and especially, in this paper, the available level of knowledge application. This will allow us to have an idea of the cognitive complexity of the questionnaire and what students have learned (particularly in terms of available knowledge).

When tasks require adaptations of knowledge that are at least partly indicated, we speak of the level of knowledge application that can be mobilized. Students' work is not effectively analogous, depending on whether they must look for the knowledge to use (questions of why or what), or apply and adapt the indicated knowledge (question of how). If it is up to the student to recognize the knowledge to use, we speak of the available level of knowledge application. [...] We also distinguish combinations, links, or changes among elements such as frameworks, and work further on different types of intellectual activities that are specific to mathematics. (Robert & Hache 2013, p.37)

The questionnaire was given in two versions in order to avoid any influence of neighbor students. Variations between them were cognitively irrelevant to our study: different lengths in Exercise I, different coordinates in Exercise II, and cosine vs. sine functions in Exercise III.

## Presentation of the questionnaire, a priori analysis

In this section we specify the aims of each question (of each exercise), the available knowledge (AK), the correct methods<sup>1</sup>, possible erroneous methods and possible errors made by students. Most of the tasks are not "simple and isolated tasks" in the following sense:

We first distinguish simple and isolated tasks, or immediate applications of piece of knowledge without adaptation or combination. A single piece of knowledge is used, potentially with simple replacement of general inputs by the given information in the context of the exercise. (Robert & Hache 2013, p.36)

### Exercise I: Trigonometry in a triangle

**Figure 1: Exercise I – Trigonometry in a triangle**

Exercise I (see Figure 1) asks for the values of sine and cosine of the angles of the given triangle.

<sup>1</sup> We focus on the knowledge effectively used by students, for example, we do not discuss methods using scalar product of vectors (seen in grade 11).

Note that in this figure, there is no coding denoting that  $\beta$  is a right angle. We want to know the available knowledge of students, and particularly if the generalized Pythagorean theorem effectively is mobilized by students.

The **first Method, M-I.1**, relies on the definitions of the cosine and sine of an acute angle in a right triangle (seen in grades 8 and 9) which require first the reciprocal of Pythagorean theorem (AK, seen in grade 8) or the visual recognition of the right angle of the given triangle without proof.

Note that trigonometry in a right triangle only allows to calculate the cosine and sine of an *acute angle* whose measure is strictly between  $0^\circ$  and  $90^\circ$  but does not give  $\cos\beta$  nor  $\sin\beta$ , which require another knowledge (AK).

There are three steps in M-I.1, where steps a and b form a non-simple task, and step c reinforces the complexity:

- a. Recognition of a right triangle with the reciprocal of Pythagorean theorem (AK) or by visual inspection.
- b. Definitions of the cosine and sine of an acute angle of the right triangle to find independently  $\cos\alpha$ ,  $\sin\alpha$ ,  $\cos\gamma$  and  $\sin\gamma$ .
- c. Property of the cosine and sine of the right angle to find  $\cos\beta$  and  $\sin\beta$ .

Note that there are two other possible pieces of knowledge that could be used: finding, for example,  $\cos\alpha$  with  $\sin\alpha$  via the formula  $\cos^2 + \sin^2 = 1$  (AK, seen in grade 9) or using a right triangle property (AK, seen in grade 9) that ensures the equalities  $\cos\alpha = \sin\gamma$  and  $\sin\alpha = \cos\gamma$ .

Possible errors of the student are confusion between cosine and sine or an error in formulas.

The **second method, M-I.2**, relies on the generalized Pythagorean theorem (or Al-Kashi's formula, *it allows to calculate the cosine of an angle whose measure is strictly between  $0^\circ$  and  $180^\circ$  or between 0 and  $\pi$  radians*, seen in grade 11) to find the cosine of an angle of any triangle. In this case, what is the reaction of the student when finding  $\cos\beta = 0$ ? Does he/she conclude that  $\beta$  is a right angle? Noticing that the given triangle is in fact a right triangle, will he/she change the strategy to M-I.1 method to determine the remaining values?

There are two related tasks, consisting in finding straightaway cosine, then sine. Apply the generalized Pythagorean theorem (AK) to independently find the three cosines and then, with the results obtained, use the fundamental relation  $\cos^2 + \sin^2 = 1$  (AK, seen in grade 11) to find the three sines. It is a non-simple task to find the cosine of an angle of a triangle. And, it is a non-simple and non-isolated task to find the sine of angle: there is the introduction of steps and also a combination of settings (numerical and algebraic) - transformation into an equation of the type  $x^2 = a$ , determining the sign of the sine of the angle and deducing its value.

Possible errors of the student are in the application of the formulas, in algebraic transformation, and in numerical calculations.

## Exercise II: Trigonometry in the trigonometric circle

**Figure 2: Exercise II – Trigonometric circle**

From Exercise II, we only discuss here the question 1 (see Figure 2) which consists in asking for the cosine and sine of  $\alpha$  (an acute angle) and of  $\beta$  (an obtuse angle). In the context, we gave the coordinates of the points  $M(4/5; 3/5)$  and  $N(-24/25; 7/25)$ . We want to know the available knowledge of students such as definitions of the cosine and sine of an oriented angle (seen in grade 11). It is asked similarly to the Exercise I for the cosine and sine values but in another setting, and moreover, with different notions of angles.

Note that in textbooks corresponding to the 2010 program in grade 11 (science option), one begins by defining measures of an oriented angle, then the cosine and sine of an oriented angle in this way: *The cosine and the sine of an oriented angle are the cosine and the sine of any of its measures.*

The **first method, M-II.1**, relies on the expression of the Cartesian coordinates of a point of the trigonometric circle with the cosine and sine. As  $M(a;b)$  is a point of the trigonometric circle in a direct orthonormal frame  $(O;I,J)$  of the plane and as  $\alpha$  designates the oriented angle  $(\overrightarrow{OI}, \overrightarrow{OM})$ , so we have  $\cos \alpha = a$  and  $\sin \alpha = b$  (AK). It is a non-simple task. As  $\alpha$  does not designate a measure of the oriented angle  $(\overrightarrow{OI}, \overrightarrow{OM})$ , do students use the M-II.1 method, namely that the coordinates of the point M are  $(\cos \alpha; \sin \alpha)$ ? If not, with the graph, will they think of using other methods, for example, like M-II.2 in the following?

The **second method, M-II.2**, relies on the relations between algebraic writing of a complex number and its trigonometric writing (AK) and on the characterization of equality of two complex numbers via equality of real and imaginary parts (AK, seen in grade 12). It is a non-simple task - introduction of steps: mark, in the given graph, the angles  $\alpha$ ,  $\beta$  - consider the points M and N as respective image points of complex numbers of module 1, then write the two complex numbers in two forms: algebraic writing and trigonometric writing - deduce the exact values of the cosine and sine of  $\alpha$

and of  $\beta$ . Compared to M-II.1 method, M-II.2 method requires the change of settings, of registers and of point of view in the reasoning (Duval, 2006).

Possible errors of the student are the confusion of sine and cosine in the expression of Cartesian coordinates of a point of the trigonometric circle with cosine and sine, error in the application of formulas and in numerical calculations.

### Exercise III: Graph of trigonometric functions

**Figure 3: Exercise III – Graph of cosine function**

From Exercise III, we only present here the question 1.c. We want to know the available knowledge of students like the existence and the nonexistence of a point on the curve of a trigonometric function (cosine or sine) and the possibility of placing a point on the curve in the given graph, and particularly the property of periodicity.

The **third method, M-III.1**: Placing the point C of abscissa  $\frac{11 + 6 \times 2016}{6}\pi$  on the curve  $\mathcal{C}$  *within* the graphic is an impossible task: recognize the existence of a point on a curve justifying it using the domain of a function and the given graph. It is a non-simple and non-isolated task - combination of graphical and functional settings.

Comparing the coordinates of A and of C relies on the property of a point on a curve and that of the cosine of a real number (AK) (or rather that of periodicity of the cosine function). It is a non-simple task. Besides, one could use the geometric property of periodicity of a function (AK, using graph of the function with translation).

Note that for comparing the coordinates of A and of C, there is another possible method based on the property of a point on a curve and the calculator in radian mode (an incomplete method with an erroneous conclusion starting from the numerical results from the calculator).

Possible errors of the student are a numerical error in the calculation; the periodicity of cosine function might not be an available knowledge.

## A posteriori analysis of the three exercises shown and their results

The questionnaire was given to 40 students in March 2016 in two grade 12 classes of two different high schools.

**Exercise I:** 37 students used M-I.1 method (22 by reciprocal Pythagorean theorem (see Figure 4) and 15 by visual inspection), only 1 student used M-I.2 method, and 2 students did not answer this exercise.

We identify three major types of error committed by students, denoted TE1 (5 students), TE2 (9 students), TE3 (18 students). TE1 and TE2 are two types of more general errors, and TE3 consists in attempting to give different values of the *cosine and sine of the right angle of the right triangle* in the geometric setting.

TE1: “*Confusion of the values of the cosine and sine of an angle with the value of the angle*”.

For instance,  $\cos \alpha = 5/13 = 67.4$  (with or without the sign “°” designating the measure of the angle  $\alpha$  obtained in degree; here, the second “=” sign would designate “it gives”). We did not meet the error committed like  $\alpha = 5/13$  signifying that the angle  $\alpha$  was the value of the cosine of  $\alpha$ .

TE2: “*Confusion of the value of the cosine (or sine) of an angle with the value of the cosine (or sine) of a real number*”. Students mobilize correctly, for example, the definition of the cosine of an acute angle of the right triangle but they do not stop there, they continue putting the sign “=” and conclude with an approximate value of the cosine of the real number which designates the value of the cosine of the acute angle obtained using the calculator either in degree mode or in radian mode. In this case, their result would be an approximate value of the “cosine of the *cosine of the angle*”. For instance,  $\cos \alpha = 5/13 = 0.99$  with the calculator in degree mode, and in radian mode,  $\cos \alpha = 5/13 = 0.93$  (see Figure 4).

TE3: “*Inventing values of the cosine and sine of the right angle of the right triangle*”. It seems that students do not remember the values of the cosine and sine of the right angle which are the respective particular values 0 and 1. Thus, they invent these values in the right triangle committing TE3 (see Figure 4).

**Figure 4: Exercise I – TE2 and TE3**

We can conclude that the cosine and sine of an acute angle ( $\alpha$  or  $\gamma$ ) of the right triangle are available knowledge only for half of the students while those of the right angle ( $\beta$ ) are not available knowledge because only about a quarter of students correctly gave the values 0 and 1.

**Exercise II:** 11 students out of 40 did not do this exercise. 17 students out of 29 correctly gave the values of the cosine and sine of the angle  $\alpha$ : 11 students recognized the cosine and sine of the angle  $\alpha$  as the  $x$  and  $y$  coordinates of the point M (M-II.1); 2 students exploited the properties of complex numbers (M-II.2); 4 students used previous knowledge seen in the 8<sup>th</sup> and 9<sup>th</sup> grades (M-I.1). 13 of these 17 students also correctly gave those of cosine and sine of the angle  $\beta$  (11 used M-II.1 & 2 used M-II.2) while 4 other students who used M-I.1 method to give the cosine and sine of the angle  $\alpha$  (*acute angle*) had any difficulties to calculate the cosine and sine of the angle  $\beta$  (*obtuse angle*). 3 students out of 12 who incorrectly gave the values of the cosine and sine of the angles  $\alpha$  and  $\beta$  committed TE2, and 5 students did not calculate those of  $\beta$ . Thus, cosine and sine of an oriented angle are not available knowledge because only about a quarter of students effectively mobilized this knowledge.

**Exercise III:** Among 36 students who did this exercise, 11 committed TE4 (see below) and 14 did not answer question 1.c. And, 6 students out of 22 who answered question 1.c committed TE4 (see Figure 5) and they placed inside of the graphic the point C on the curve either at the point A or elsewhere.

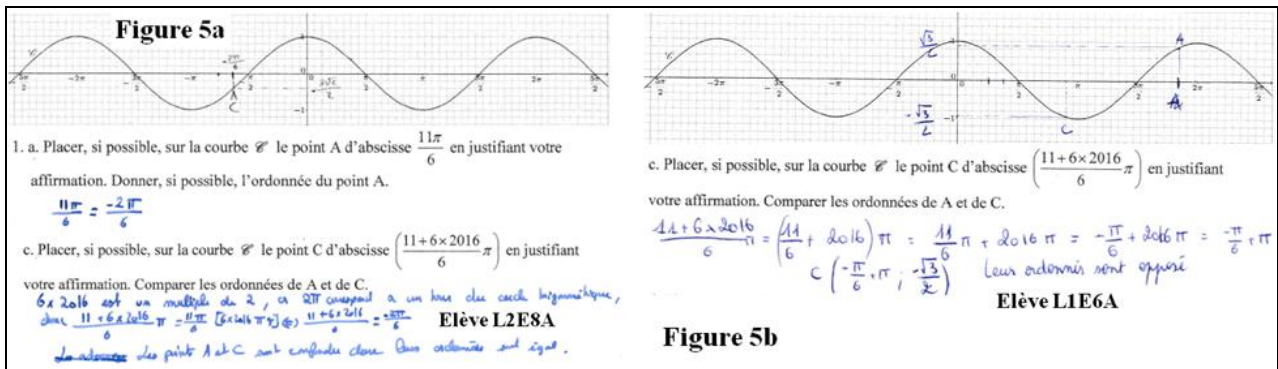

Figure 5: Exercise III-1.c – TE4

TE4: “Confusion between the position of the two points on the trigonometric circle, images of two real numbers of the difference  $2k\pi$  ( $k$  is an integer) and that of the points on the cosine/sine curve with abscissas these two real numbers”. The TE4 is an error amounting to say, for instance, that the points A and C might have the same abscissa while the two points have in fact the same ordinate by the periodicity of the cosine function (see Figure 5a).

## Conclusion

Through our analysis of this questionnaire, we clearly see the difficulties of students in using their knowledge on cosine and sine of an angle (seen in grades 8, 9, 11) and on those of a real number (seen in grades 10, 12) in the geometric and functional settings. Considering French institutional texts and manuals, and the work produced by students in answering the questionnaire, we identify the implicit notions related to the learning and teaching of trigonometry as follows.

In the case of **trigonometry in right triangles** (grades 8, 9), the notion of cosine and sine of an acute angle is an available knowledge for students while that of cosine and sine of the right angle in right triangles is not an available knowledge. To give the values of the cosine and sine of the right

angle, about half of the students tried to use the ratio of two lengths of the right triangle but it is not adapted to the case of the right angle, and other knowledge is required (seen in grades 10, 11).

In the case of **trigonometry in the trigonometric circle** (grade 11, science option), a remarkable number of students have difficulties seeing the link between the coordinates of a point on the trigonometric circle and the cosine and sine of the oriented angle that is defined in this circle. This knowledge is an available knowledge for only about a quarter of the students.

In the case of **sine and cosine functions** (grade 12, science option), some students have difficulties distinguishing between two real numbers of difference  $2k\pi$  ( $k$  is an integer) denoting two measurements in radian of the same oriented angle.

Overall, there is available knowledge for students to solve mathematical tasks on the trigonometry and on trigonometric functions, yet there is a blur or confusion in using their learned knowledge: between the value of cosine (or sine) and the angle or a measure of the angle, between an angle and its measurements, between a measure of an angle and a real number.

We can undoubtedly find epistemological, didactic, and curricular reasons; and this constitutes our research questions.

*This paper refers to the Pythagorean theorem and the use of physical artifacts (called mathematical machines), which are related to one of the proofs of the theorem. It aims to discuss the didactical use of these kinds of artifact, paying attention to students' work with them and the role of the teacher. It presents a laboratory approach to this theorem developed within the Theory of Semiotic Mediation in mathematics education for 13-year-old students in Italy. The analysis shows that manipulation of the machine only does not imply the emergence of the mathematical meanings embedded in the machine. It also pays attention to the different graphical representations of the artifact and their role in the learning process.*

**Keywords:** Artifacts, geometry, laboratory, lower secondary school education, Pythagoras.

## Introduction

The Pythagorean theorem is a traditional content in the mathematics curriculum of the secondary school, not only in Italian school (Moutsios-Rentzos, Spyrou & Peteinara, 2014). This theorem is often proposed in the geometrical domain at the beginning, and it is soon converted into formulas and related to algebraic calculations. There exist several proofs of this theorem<sup>1</sup>, some of them are proposed as visual proofs. On this topic, Bardelle (2010) analyses how university students in approaching a visual proof of that theorem try to look for the algebraic relation among sides starting from their knowledge of the theorem rather than getting the relationships between the components of the given figure. On the other hand, different exhibits are constructed basing on this kind of proofs, and they are also associated with and spread as gadgets (Eaves, 1954). In our work, we ask if and how it is possible to approach the Pythagorean theorem starting from artifacts which embed one of its proofs (Rufus, 1975), taking into account the role of manipulation, with 7-grade students (*13-year old students*). At the same time, we are interested in reinforcing the geometrical meaning of equivalent figures, which makes this theorem a particular case.

In this paper, we introduce the theoretical background for the didactical use of physical artifacts (called mathematical machine<sup>2</sup>, Maschietto & Bartolini Bussi, 2011), then we present the teaching experiment.

## Theoretical framework

In this section, we outline the theoretical framework of our work, based on the Theory of Semiotic Mediation (Bartolini Bussi & Mariotti, 2008) and the cognitive processes in geometry fostered by the

task of reproducing artifacts. The teaching experiment is designed according to the methodology of mathematics laboratory (Maschietto & Trouche, 2010) with different kinds of artifacts.

### Mathematics laboratory

The teaching experiment is proposed and analyzed within the Theory of Semiotic Mediation (Bartolini Bussi & Mariotti, 2008, TSM), grounded in the Vygotskian notion of semiotic mediation and role of artifact in cognitive development. Following to the TSM, the teacher chooses the artifacts evoking particular mathematical meanings and uses them to mediate those meanings, proposing tasks to be accomplished by those artifacts. The tasks are organized in terms of didactical cycles with group work, individual work and collective discussions (mathematical discussions) orchestrated by the teacher. The cycle usually starts with the exploration of the chosen artifact, above all in small group work, structured following fundamental questions as: “How is the machine made?”, “What does the machine make?” and “Why does it make it?”. In general, the first two questions try to take in account students’ processes of instrumental genesis (Rabardel & Bourmaud, 2003). In the mathematics laboratory, students’ processes of formulation of conjectures and argumentation are strongly motivated and supported by the third question. The mathematical meanings emerge from the use of the artifacts, the interactions among peers and between peers and the teacher, who has the role of an expert guide. In all the activities, students are involved in a semiotic activity (producing gestures, words, drawings, called artifact signs) that the teacher makes evolving into mathematical signs (i.e., linked to mathematical contents) by the means of pivot signs. In this sense, the teacher uses the artifact as an instrument of mediation for mathematical meanings.

The teaching experiment on the Pythagorean theorem is carried out with the use of two mathematical machines (M1 and M2 in Figure 1)<sup>3</sup>. They were analyzed in terms of their semiotic potential (Bartolini Bussi & Mariotti, 2008), corresponding to a semiotic relationship between an artifact and: on the one hand the personal meanings emerging from its use to accomplish a task; on the other hand, the mathematical meanings evoked by its use.

The analysis of the semiotic potential considers three components: mathematical content, historical references and utilization schemes (Rabardel & Bourmaud, 2003). This kind of analysis is essential for the choice of the artifact and the identification of mathematical meanings evoked by it.

## Semiotic potential of the artifacts

The mathematical machine M1 (Figure 1, on the left) is a wooden artifact, composed of a square frame and four triangular prisms, with right triangles as the base that are congruent each other. The fundamental relationship between the prisms and the square inside the frame (red square in Figure 1) is that the sum of the legs of the right triangles (base of the prism) is equal to the side of the square frame. This artifact shows a proof of the theorem (Rufus, 1975). For making evident the interior squares as figures, we have added a red paper into the frame.

The scheme of use of this mathematical machine is quite simple: shift the prisms into the square frame, without raising them from the base and without superposing them (this condition is evident because of the height of the prisms and the frame). The mathematical meanings involved in this artifact are: geometrical figures as right triangle and square, the area of those figures, and equivalence of area by addition/subtraction of congruent parts. The property of the triangles to be right-angled is obtained by the support of the square frame, and that represents the hypothesis of the theorem embedded in the machine itself. The movement of the prisms is bound by the frame, which ensures the invariance of the sum of the areas of the triangles and the squares or, in other words, the invariance of the area of the squares, whatever it is. Two tasks can be proposed: the first one is to place the prisms for obtaining square hole(s), the second one is to pass to a configuration (M1 in Figure 1, in the center) to the other one (M1 in Figure 1, on the right).

In our experiment, we asked the students to reproduce 1:1 the first mathematical machine on paper (four triangles and square corresponding to the interior of the frame), after its manipulation and description. This choice was due to the fact that we had only one wooden model in the classroom and we wanted to propose the task about the configurations with a model for each small group. In such a way, the students constructed a new artifact. We want to pay attention to the two elements that characterize the semiotic potential of the reproduction of the machine: the negligible thickness for all the components of the machine and the lack of the frame. The first element can force the students to transfer implicit constraints of the manipulation of the wooden machine into a control of the reciprocal position of the right triangles to avoid their superposition (Figure 2, on the right). The second element fosters to make evident the range of the movement of the right triangles on the big square base (Figure 2, on the left). In this way, making explicit the mathematical components of the utilization schemes is supposed to reinforce the link to mathematics evoked by the machine.

**Figure 2: configurations by manipulating the paper machine**

## Drawings and geometrical figures

In the first activities with the artifact, the students are asked to answer the question “how the machine is made”, with the request of representing it. As we have written above, in this case, the students had

to physically reproduce 1:1 the machine (while, in general, they should draw the machine in their homework or worksheet, which often is not squared paper). In the TSM framework, drawing the artifact corresponds to individual production of artifact signs, strictly dependent on student's knowledge and his interpretation of the artifact. However, with respect to the TSM, we aim to pay more attention to our request of drawing. Following Duval (2005), this is a task of geometrical construction involving student's visualization and how geometrical properties are identified (see also Vendeira & Coutat, 2017). Our tasks involve the two kinds of visualizations that Duval distinguishes as iconic and non-iconic:

A visualisation is iconic when, for instance, it represents positions or shape of real-world. It is non-iconic while it is organised to internal constraints and gives access to all cases possible. (Duval, 2008, p.49)

Concerning the role of visualization as an argument in proof, Duval (2005) analyzes the proof of the Pythagorean theorem corresponding to our first mathematical machine (as given by Rufus, 1975). He claims that the visualization is not complete if it only considers the two configurations (see Figure 1), because the relationship between the big square and the hypotenuse of the right triangles on one hand, and the two other squares and the legs of the same right triangles on the other hand are supposed known for the reader. This is grounded on the relationship between a conjecture and a figure. But if an arrow from left to right, for instance, connects the two representations, the transformation from one representation to another is realized. Nevertheless, the comparison of the areas of the squares is not directly possible, but it has to consider a computation (i.e., the difference between the big square and the four triangles) for paying attention to invariant elements in that transformation. In our machines, the transformation of representations corresponds to the movement of the four triangles, nevertheless with the loss of their simultaneous view.

## Research questions

In this paper, we are interested in the didactical use of the mathematical machines for the Pythagorean theorem. Our research questions are:

1. Is it possible, and how, to approach the Pythagorean theorem with the mathematical machines described above?
2. Does the sequence of movements with the machines give a sufficient representation of the theorem for its understanding?
3. Which kinds of visualization are related to the tasks of drawing M1?

## Methodology

According to our theoretical framework, the didactical methodology is the mathematics laboratory with artifacts. The tasks for students are organized in didactic cycles (Bartolini Bussi & Mariotti, 2008), consisting of small group work (GW), individual activities (IW), and collective mathematical discussions (CW). In the classrooms, other technologies are available, such as the Interactive Whiteboard with its software for making animations of the machines, and the simulations of the second machine made with Dynamic Geometry Software from the web. In the specific case of two classes involved in the experiments, the platform Edmodo was used. Therefore, the teaching

experiment proposes a learning environment in which material and digital technologies are present. In general, it is structured in three phases, as follows:

Phase A: 1) GW: Exploration of the first mathematical machine M1 (Figure 1); 2) CW: sharing of the description of the M1; 3) GW: construction of the M1 by paper; 4) GW: study of the possible configurations of the four triangles of M1 (Figure 2); 5) IW: representation of M1 on workbook; 6) CW: identification of relationships (invariants) between the components of M1.

Phase B: 7) History of the Pythagorean theorem and Pythagorean triples; 8) GW: Generalization of the theorem by different puzzles.

Phase C: 9) CW: Exploration of the second mathematical machine M2 and its reproduction with paper; 10) GW: Preparation of posters on the two mathematical machines.

The teaching experiments have started in 2013, and have involved six Italian classes of 13-years old students and two teachers, co-authors of this paper.

The analysis is carried out on students' worksheets, videos, photos and IWB files.

## Findings

In this section, we refer to phases A focusing on the task of drawing the machine M1.

### Steps 1-3. Work with the material model in small group and its reproduction

During the first three steps, the students worked in small group with the task of describing the machine M1 and collecting the elements (for instance, the types of triangles, the length of the sides) useful for its reproduction with colored paper. Before the reproduction, a collective discussion allowed students sharing their explorations and agreeing on a written description of the machine, with the measure of its sides. In particular, the right triangles were described as equivalent and some students recalled the Tangram game. Then, the students obtained the reproduction scale 1:1 by measuring and using tools for drawing (above all, rules and set square).

After this, the students had to fill a worksheet with the properties of the two figures, square and right triangle, constituting the machine. The manipulation of this new paper machine was guided by the task of looking for "square holes". But this task requires being conscious of the two schemes of use: the triangles must remain in the big square and do not overlap each other (Figure 2). During students' work, the configuration with the two square holes (Figure 1, M1 in the center) often appears first with respect to the configuration with the square alone (Figure 1, M1 on the right). This could be because the sides of the square are not parallel to the side of the square frame.

### Individual Work for representing the two configurations in paper and pencil (Step 5)

Although the students had correctly described the congruence of the four right triangles (and constructed those in the previous step) into the square, several representations were not correctly drawn. We summarize some elements of students' drawings:

- 1) Square base is not equal in the two configurations (Figure 3, on the right);
- 2) All the four right triangles are not all congruent: a) in one configuration itself (Figure 3, left, drawing on the left); b) between the two configurations (Figure 4);
- 3) The "square with the hypotenuse as side" is not a square (Figures 3 and 4).

The review of all the representations shows an important invariant of the machine was not taken into account by the students: the side of the square base is equal to the sum of the two legs.

**Figure 3: Students' representations of the two configurations of M1 on their workbooks**

They are squares because you see the shape and the sides seem equal and the base of a triangle can be turned and it is equal to the other sides.

**Figure 4: Student' representations of the two configurations of M1 on his workbook**

### Collective discussion with IWB

The collective discussion had two phases: the teacher paid attention to the wrong representations of the configurations; he took into account the passage from acting on the machine (both wooden and paper) to identify the relationship between the two configurations. First, the teacher used a checklist with the geometrical properties of the components of the machine that had been shared in the previous discussion for comparing the different representations. After, he asked to make new representations on the workbooks.

**Figure 5: Collective work on IWB**

Then the machine is represented on the IWB from a photo (Fig. 5, on the left). The use of the IWB enables a new collective manipulation of the machine, in which the students passed from one configuration to another one by dragging the right triangles as they made with the material machine.

An important part of the discussion focused on the argumentation that the holes were squares (Figure 6, on the left). The collective use of digital machine allows students linking the manipulation of the triangles to the manipulation of Tangram pieces (Figure 6, on the right) and, so, emphasizing the conservation of the areas of the holes. The Pythagorean theorem becomes a particular case in the equivalence of areas.

**Figure 6: Question on proof and conclusion of the collective work on IWB (screenshots)**

## Discussion and concluding remarks

This paper aims to study the approach to the Pythagorean theorem using some physical artifacts that are material representations of that theorem. Students' answers to different task seem to confirm the assumption that the manipulation carried out by the students on the first mathematical machine is not enough for the emergence of mathematical meanings embedded in the machine. About our first research question, the analysis shows that those tasks allow fostering the production of signs, according to the theoretical framework of the TSM, and representations that can be used by the teacher for the mediation of mathematical meanings.

The scheme of use of shifting triangles for obtaining different configurations can support the emergence of personal signs and show the Pythagorean theorem in the context of equivalence of areas. For instance, in the first task of describing M1, some students recall the Tangram. If this meaning is not available for the students, the teacher has to focus on areas through a written, and/or symbolic calculation. With respect to our second research question on the feasibility of approaching the theorem with artifacts, we can argue that the Tangram, or meaning related to it, can be considered a prerequisite. In this case, Tangram means equivalent areas and manipulation of pieces for obtaining equivalent figures.

The comparison between the resolution of the tasks of making M1 by paper and representing M1 on workbook pays attention that the two tasks foster two different visualizations, as we have asked in our third research question. The first task solicits an iconic visualization of the two configurations, in which the shapes are drawn, but not their relationships inside the same configurations and between the two configurations. The second task seems to support a non-iconic visualization, because the students have to choose the measures of the sides of the figures (that are the parameters of M1) and make links between them. This choice has the potential of giving access to generalization to all the right triangles. However, it is not enough to draw twice a square and four triangles but the students have to represent their relationship, that is, an iconic visualization does not support the resolution as the wrong representations on workbooks show. Moreover, the students do not use the previous description of the components of M1.

Within the TSM framework, when the teacher proposes the discussion about those representations, the students' drawings are pivot signs for him. They are signs related to the artifact, but they are used for identifying and representing geometrical properties and invariants of M1. The potential of giving access to generalization is exploited by the teacher.

# The design of a teaching sequence on axial symmetry, involving a duo of artefacts and exploiting the synergy resulting from alternate use of these artefacts

Antonella Montone<sup>1</sup>, Eleonora Faggiano<sup>1</sup> and Maria Alessandra Mariotti<sup>2</sup>

<sup>1</sup>Università di Bari Aldo Moro, Dipartimento di Matematica, Italy; [antonella.montone@uniba.it](mailto:antonella.montone@uniba.it); [eleonora.faggiano@uniba.it](mailto:eleonora.faggiano@uniba.it)

<sup>2</sup>Università di Siena, Dipartimento di Scienze Matematiche e Informatiche, Italy; [mariotti21@unisi.it](mailto:mariotti21@unisi.it)

*This paper presents a teaching sequence conducted with 4<sup>th</sup> grade students, aimed at the construction/conceptualization of axial symmetry and its properties in which a crucial role is played by a duo of artefacts. This consists of a concrete artefact and a virtual artefact which address the same mathematical content. According to the Theory of Semiotic Mediation, both the artefacts have been chosen for their semiotic potential, in terms of meanings that can be evoked by carrying out suitable tasks involving their use. The design of the teaching sequence is developed with the purpose of exploiting the synergy between the artefacts, in such a way that each activity boosts the learning potential of all the others.*

*Keywords: Axial symmetry, duo of artefacts, synergy of artifacts, semiotic mediation.*

## Introduction

The study of geometric transformations originates from the observation of phenomena and regularities present in real life, and takes on a particularly important role in the field of mathematics, both as a mathematical concept in itself and as a tool that can be used to describe geometric figures. For this reasons, it can offer an interesting lens through which investigate and interpret geometric objects, thus contributing to the development of students' reasoning and argumentation skills (Xistouri & Pitta-Pantazi, 2011). However, an effective use of transformational geometry in mathematics education requires a correct mathematization process of real life observations, ending with the mathematical formalization of concepts and properties (Ng & Sinclair, 2015). This process of construction of meanings could be fostered by the use of artefacts. But, the design of the teaching sequences needs to be developed according to a theory that can take into account the key transitions from the personal meanings, emerging from the activities, to the mathematical meanings, that are the aims of the teaching. This paper presents a teaching sequence aimed at the construction/conceptualization of axial symmetry and its properties, in which a crucial role is played by a *duo of artefacts* (Maschietto & Soury-Lavergne, 2013). This is composed of a concrete artefact and a virtual artefact which address the same mathematical content. The design of the teaching sequence is framed by the Theory of Semiotic Mediation and is developed with the purpose of exploiting the synergy between the artefacts. Both the artefacts have been chosen for their semiotic potential, in terms of meanings that can be evoked when carrying out suitable tasks involving their use. The components of the concrete artefact are a sheet of paper and a pin, while the components of the virtual artefact originate from the components of a specific dynamic geometry environment (New Cabri - Cabrilog), in which microworlds focused on particular concepts can be created. The research hypothesis concerns the synergic action expected to develop when alternating the use of the concrete

artefact and the virtual artefact, so that each activity can boost the learning potential of all the others. The aim of the paper is to highlight key moments of the design of a teaching sequence and to underline, in particular, how the meaning emerges not only through the unfolding of the semiotic potential of the two different artefacts, but also strongly through the synergy activated by the alternate experiences gained using the duo.

## **Theoretical framework**

The geometric concept addressed in this research is axial symmetry, in the sense of the isometric transformation of the plane itself, with a line of fixed points (the axis); from the definition it can be deduced that axial symmetry transforms straight lines into other straight lines, segments into other congruent, comparable segments, and it is an involutory function (Coxeter, 1969). Attention will therefore be paid to the symmetrical properties by means of which it is possible to construct the symmetrical point from a given point in regard to a straight line, in other words the perpendicularity of the axis with respect to the line joining the corresponding points, and the equidistance of the two points from the axis. Although geometric transformation is traditionally reserved for high school students, we believe that it becomes crucial already for the primary school students to move from a generic perception of regularity to that of correspondence between figures, and subsequently to the transformation (point by point) of the plane in itself (Sinclair & Bruce, 2015). The design we present is based on the theoretical framework of semiotic mediation. The Theory of Semiotic Mediation (TSM), developed by Bartolini Bussi and Mariotti (2008) in a Vygotskijian perspective, deals with the complex system of semiotic relations among fundamental elements involved in the use of artefacts to construct mathematical meanings: the artifact, the task, the mathematical knowledge that is the object of the activity, and the teaching/learning processes that take place in the class. The aim of the teaching is to guide the evolution of personal meanings toward mathematical meanings, recognized as such by the math culture that the teacher needs to mediate. In a long, complex interweave process the teacher can foster the shared construction of mathematical signs. Some recent researches have drawn on TSM focusing the interplay between static and dynamic reasoning in the teaching and learning of geometry (i.e. Bartolini-Bussi & Baccaglini-Frank, 2015). The main aspect that we focused upon in the design process of the teaching sequence was the semiotic potential. The semiotic potential of an artefact consists of the double relationship that occurs between an artefact and, on the one hand, the personal meanings emerging from its use to accomplish a task (instrumented activity), and on the other hand, the mathematical meanings evoked by its use and recognizable as mathematics by an expert (Bartolini Bussi & Mariotti, 2008). This potential is the basis underlying both the design of the activities and the analyses of both the actions and production of signs and the evolution of meanings.

## **The duo of artefacts involved**

As stated above, a duo of artefacts is employed: concrete and virtual. The concrete artefact consists of a sheet of paper, with a straight line drawn on it marking where to fold it, and a pin to be used to pierce the paper at the right points in order to construct their symmetrical points. This artefact allows an axial symmetry to be created in a direct fashion because the sheet naturally models the plane and the fold allows the production of two symmetrical points using the pin. The virtual artefact has been designed by the Authors to exploit the added value conferred by technology to the use of the chosen concrete artefact. It is embedded in an Interactive Book (IB) created within the authoring environment

of New Cabri, which allows learning activities to be designed and created, including the objects and tools of a dynamic geometry environment. The IB appears as a sequence of pages including the designed tasks, together with some specific tools that correspond to specific elements of the concrete artefacts. In particular, among the tools available in the authoring environment, and in agreement with the general principles of dynamic geometry, the tools chosen are: those that allow the construction of some geometric objects (point, straight line, segment, middle point, perpendicular line, intersection point), the “Symmetry” and “Compass” artefacts and the “Trace” tool. A fundamental role is also played by the drag function, boosted by the “Trace” tool, that allows to observe the invariance of the properties characterizing the figures.

## **Research methodology**

The study reported in this paper is inserted in a larger project that is aimed at validating the hypothesis regarding the possible synergic effect of the use of the two artefacts. The methodology employed is that of the teaching experiment (Steffe and Thompson, 2000). In this context the design of the teaching sequence plays a key role, because it is this sequence, designed in conformity with the chosen theoretical framework and the teaching hypotheses formulated, that constructs the teaching/learning environment where the observations will be made and, in general, the data collected on which to analyze the results of the experiment. In accordance with the TSM, the design of the teaching sequence follows the general scheme of successive “didactic cycles”. The expression didactic cycle refers to the organization of teaching in activities. These consist of using the artefact, individually producing signs and then in the end collectively producing and absorbing signs through Mathematical Discussion activities (Bartolini Bussi, 1998). As regards the design of the activities using the artefact, in accordance with the study hypothesis that the two types of artefacts may be complementary, it was decided to alternate activities involving the use of one or the other artefact, formulating tasks that could exploit the complementarity of their semiotic potentials. The devised sequence was accompanied by an a priori analysis illustrating the semiotic potential expected to emerge during the activities.

## **Developing the sequence**

In this paper we present the design of the sequence, addressed to 4<sup>th</sup> grade students, describing the six didactic cycles that make it up, and the tasks and semiotic potential of the artefacts involved. These are related to the conceptualization of axial symmetry as punctual transformation, and the properties that allow us to construct a symmetrical copy of an object with respect to an axis.

### **The first didactic cycle and the semiotic potential of the concrete artefact**

The first didactic cycle involves three tasks (T1, T2 and T3). Given a figure (convex quadrilateral) drawn (in black) on a sheet, at the moment when handing over the sheet a red line is drawn on it. In T1 the pupils are asked to draw in red a symmetrical figure to the black one, with respect to the red line, by folding the sheet along the line and using the pin to mark the necessary symmetrical points by piercing the paper. After completing this task, on the same paper a blue line is drawn and in T2 they are asked to draw a blue symmetrical figure to the black one, employing the blue line. In T3 the pupils are asked to write an explanation of why and how they drew the red and blue figures and what looks the same and what looks different about them. In these first three tasks, folding the paper along the line evokes the meaning of axial symmetry, while the holes/points created with the pin evoke the

idea of symmetry as punctual correspondence. In addition, joining the points obtained with the pin is the process that yields as product the symmetrical figure, provided that the correspondence between the segments is preserved. This evokes the idea of symmetry as a one-to-one correspondence that transforms segments into other congruent segments. Finally, comparing what changes and what stays the same when drawing two symmetrical figures with respect to two distinct axes evokes the dependence of the symmetrical figure on the axis. The use of the pin can allow the meaning of the punctual correspondence to emerge without necessarily needing to explain the functional dependence between the points. In addition, folding the paper, so as to make one figure coincide with the other, can allow the intuitive meaning of line/axial symmetry to emerge as the element that characterizes the transformation. Finally, T3 makes the pupils reflect on the invariant aspects and the key role of the axis, when creating a symmetrical figure by folding the paper.

### **The second didactic cycle and the semiotic potential of the virtual artefact**

The second cycle involves two tasks (T4 and T5) to be carried out using the virtual artefact: the button/tool “Symmetry” with the dragging function. In T4, the pupil is asked to build the symmetric point of a point A with respect to a given line, using the “Symmetry” tool and call it C. The second step is to activate the “Trace” tool on point A and point C, move A and see what moves and what doesn’t, and explain why. In the next two steps, in the same way the pupils are asked to move the line and the symmetrical point, after having activated the “Trace” tool on A, and to watch what happens during the dragging. In T5 the pupils are asked to write down in a summary table the answers to the questions asked by the interactive book in T4. In T4 and T5 clicking on “Symmetry” evokes the meaning of symmetry as punctual correspondence and once more underlines the key role of the axis as the element that characterizes the application, because in order to obtain the symmetry it is necessary to click not only on the point but also on the axis. Moreover, dragging the point of origin and observing the resulting movement of the symmetrical point evokes the idea of the dependence of the symmetrical point on the point of origin; dragging the axis and observing the resulting movement only of the symmetrical point evokes the idea of dependence of the symmetrical point on the axis; dragging the symmetrical point and observing the resulting rigid movement of the entire configuration evokes the idea of the dual dependence of the symmetrical point both on the point of origin and on the axis: the effect of the various drags is made even more evident by the “Trace” tool and by the observation of the relations among the trajectories. The difference in the movements between the symmetrical point and the point of origin can be compared to the distinction between dependent and independent variable.

### **The synergy resulting from alternate use of the artefacts**

The hypothesis formulated is that the observation the pupils need to do in T4 will cause the concrete experiences they have already had with the concrete artefact to reemerge, in other words, that the images on the screen can be better interpreted in the light of the previous acts of folding and piercing. In this way we expect that the meanings that have already emerged thanks to the use of the concrete artefact may be extended and completed by the specific meanings that should emerge using the virtual artefact. In short, the expected phenomenon is that a reciprocal boosting process will occur, in the form of a synergic process of mediation through the different types of artefacts. For example, after having constructed the symmetrical point using the button, the relation between the two points can be interpreted through the actions of folding, so the two points can be seen as two holes. But the

meaning of the relation, that is symmetrical, can be enhanced by the distinction between the original point and the corresponding point, thus contributing to the development of the mathematical meaning of a functional – asymmetrical – relation between a point (independent) and its symmetrical point (dependent).

### **The third didactic cycle and the semiotic potential of the concrete artefact**

According to our hypothesis, the third didactic cycle involves three tasks (T6, T7 and T8) again using the concrete artefact. In T6 the pupils are guided as they see how correct folding yields the perpendicularity between the segment joining two symmetrical points and the axis, and the equidistance of the symmetrical points from the axis. In T7 they are asked to construct a symmetrical point without using the pin but just by correct folding. In T8, finally, they are asked to explain what two segments joining two distinct pairs of symmetrical points have in common and what is different about them. In the tasks of the third cycle, folding the paper along the line passing through the two corresponding points and then, without opening, along the axis and finally observing the superimposition of four right angles, evokes the properties of perpendicularity between the axis and the segment joining two corresponding points; observing that the two points are superimposed when folding along the joining line and then, without opening, along the axis, in other words that the segment joining the two corresponding points is cut in half by the axis, evokes the property of equidistance of each of the two points from the axis. The complex folding processes required in the accomplishment of these tasks can be compared to the symmetry of the relationship between perpendicular lines and evokes the idea that the perpendicularity and equidistance properties allow a symmetrical copy of points to be constructed with respect to a line without needing to use the pin but just by folding correctly. Comparing the segments to be created in T8 could allow to see the perpendicularity and the equidistance as being characterizing properties. Finally, from the mathematical point of view, the step that leads to the elimination of the pin is fundamental in order to bring about the evolution of the meaning of symmetry from the simple operative level of folding, to the mathematical meaning of geometric transformation identified by a line and the geometric properties that characterize it.

### **The synergy resulting from alternate use of the artefacts**

We expect that, the interpretation of the actions and the configurations with the concrete artefact might be related to the experiences within the virtual environment. In particular, we may expect that two different points, of which to construct the symmetric points, can be interpreted as different positions adopted by a point that has been dragged, thereby contributing to the generalization of the two properties (perpendicularity and equidistance) and to the evolution of the status of these properties from being seen as contingent to being seen as characterizing.

### **The forth didactic cycle and the semiotic potential of the virtual artefact**

The fourth cycle involves two tasks (T9 and T10) to be carried out using the virtual artefact composed by the buttons/tools “Perpendicular line”, “Compass” and the dragging function. In T9 pupils are asked to construct the symmetrical point of a point A with respect to the given line, without using the tool “Symmetry”, and call it C. Then it asks them to check whether the construction they have made is correct, using the tool “Symmetry” and moving point A. In T10 it asks them to explain how they found C and why what they did works. Clicking the button “Perpendicular line” and then on point A

and on the axis, evokes the idea of the perpendicularity between the segment for A on which the symmetrical point lies and the axis; clicking on the button “Compass” and then on the intersection point between the axis and the line through A perpendicular to the axis and on A, evokes the idea that the symmetrical point is obtained from the intersection between the circumference thus created and the perpendicular line, and so is at the same distance as A from the axis; constructing the line through A perpendicular to the axis and the circumference with the center at the intersection point between the axis and the perpendicular line and radius at the distance of A from the axis, evokes the idea that by using the properties characterizing the symmetry, already previously constructed, it is possible to identify the symmetrical point.

### **The synergy resulting from alternate use of the artefacts**

In the same way as occurred for task T7 we expect that so as to construct C, without using the tool “Symmetry”, the pupils will need to rely on the properties of perpendicularity and equidistance, already emerged from folding activities. However, this will bring them to recognize and to reuse these properties to construct the symmetrical point using specific buttons. These are quite complex notions and we do not expect the resolution process to be immediate but rather to be the result of trial and error. We also expect that the recognition of perpendicularity and so the possibility of using the button “Perpendicular line” may act synergically on the construction of the signs built up during the whole process, in terms of both images and words. We then expect a quite different complexity to present when transforming the properties of equidistance using the tool “Compass” (whose use should not be correctly linked to the mathematical meanings embedded into it): the conceptualization of the configuration could consist of the relation between the segment joining the two points and the axis that divides it in half, rather than have been conceptualized in terms of distances and equalities among distances.

### **The fifth and sixth didactic cycles: inverting the order of the artefacts**

In the fifth and sixth cycles the order of use of the two artefacts is inverted and they start with the virtual artefact. Both the cycles consist of the same two tasks (T11 and T12; T13 and T14), the difference is in the artefact. In T11 and T13 there are a pair of points A and C that must be interpreted as symmetrical points with respect to a symmetry where the axis is hidden. They are asked to identify and trace the axis. Finally, they are asked to check, using the button/tool “Symmetry” or with the pin, whether the symmetrical point of A with respect to the line is really C. In T12 and T14 they are asked to write down how the axis was identified and to explain why what they did works. In the tasks of these two last cycles, drawing the segment AC and then using the button “Midpoint”, such as folding along the line through A and C, and then without opening the paper, folding so as to superimpose points A and C, evokes the idea that the middle point is a point that is equidistant between A and C and so must belong to the axis; observing that by folding so as to superimpose A and C you obtain the superimposition of four equal angles, evokes the idea that the line/fold for the middle point that allows the superimposition of A and C is perpendicular to segment AC; clicking on the button “Perpendicular line” and then on the middle point between A and C and then on segment AC, such as folding first along the line through A and C and then without opening, superimposing A and C, and seeing that four right angles are formed, evokes the idea that the axis is perpendicular to the segment joining A and C, as well as that it is perpendicular to the axis, as they had already seen. It should be noted that these tasks have been devised so that the same properties of symmetry used to

construct the symmetrical point with respect to a line (without using the artefacts “Symmetry” and pin) can be used to identify the axis that generates a pair of symmetrical points. But to draw up the construction the pupils need to invert the relation of perpendicularity between the axis and line through A and C. In addition, the property “the middle point of segment AC lies on the axis” must be redefined as “the axis passes through the middle point”. Also in this case it is a form of inversion of the belonging relationship, expressed in two different ways that have the same geometric meaning but that focus attention (by inverting the subject of the sentences) on one or the other element of the relation.

### **The synergy resulting from alternate use of the artefacts**

The use of the same task (T11 and T13) with the two different artefacts, is not accidental but has been designed with the aim to bring out the common elements between the different schemes of use of the artefacts. We expect that this strengthens the idea that the two construction are both based on the use of the characteristic properties and are feasible only using them. In particular, what emerged in the previous activities, related to the double folding and to the properties of axial symmetry needs to be thought over within the collective discussion aiming to bring out the development of the operational meaning of perpendicularity toward the geometric meaning of mutual relationship between lines. This is expected to recognize the geometrical meaning of the word perpendicular and of the configuration composed by two intersected lines so that four right angles are formed. In conclusion, two signs could be shared, a verbal and an iconc, defining the perpendicularity as “a property concerning two lines that by interesction form four equal angles”. It could be also noted that, this can be connected to the common routine to construct the “sample” of a right angle by means of a double folding. In T12 and T14, we expect that the pupils will describe the construction by listing, in the fifth cycle the used button and in the sixth the folding actions carried out and their effects. The relationships between a button and its embedded property such as the ones between the folding and its effects should emerge in the pupils’ descriptions.

### **Final remarks**

The teaching sequence described above has already been experimented in a first pilot study. The analysis of results, based on videotapes and dialog transcriptions, has shown that the use of the duo of artefacts seems to develop a synergy whereby each activity enhances the potential of the others (Faggiano et al., 2016). Our research hypothesis concerning the synergy developed through using the artefacts has been validated. For instance, in the second cycle it was seen that the dynamic representation of the points and the observation of the coordinated movements of the points of origin and its symmetrical point, characteristic of the virtual artefact, recalled the meaning of correspondence between points that had previously emerged when piercing the paper with the pin using the concrete artefact. In this way, the dynamism of the virtual artefact enahnced the understanding of point-to-point correspondence, paving the way to making further considerations about the correspondence between segments and between lines. The study is still in progress but the results obtained encourage us to go ahead and develop a long term teaching experiment to confirm them.

# Hide and think: Limiting the obvious and challenging the mind in geometry

Chrysi Papadaki

University of Bremen, Germany; [chrysi@uni-bremen.de](mailto:chrysi@uni-bremen.de)

*In this paper I will present the implementation and some preliminary results of a teaching experiment conducted in a 9th grade geometry class within the framework of my doctoral studies. For the teaching experiment I designed geometry tasks in a Dynamic Geometry Software (DGS), with specific characteristics: they involve transitions from 2D to 3D geometric objects (and vice versa), they are “Black Box” tasks and they are designed to cause surprise, uncertainty or cognitive conflict to the students. The main foci of the paper are the description of the tasks, examples of strategies that a pair of students followed while dealing with them and the influence that the characteristics of the tasks had on students’ strategies, visualization and argumentation.*

*Keywords: DGS, argumentation, visualization.*

## Introduction

In the lesson of geometry students are often asked to solve a problem, which is usually accompanied by a drawing. In many cases the drawing acts as an obstacle for students’ argumentation, as “since they are able to *see* results on the drawings, since they can work easily on it, mathematical proof seems to be useless” (Mithalal, 2009, p. 796).

The idea behind the study presented in this paper could be expressed by the following question: What would happen if we asked students to solve geometry tasks designed in a DGS, in which the drawing of a geometrical solid that they would have to identify was actually invisible to them? This is something that one couldn’t do with physical objects, hence the designing of the tasks in a DGS. My hypothesis is, that when challenging the students with such a task, they will reach a point at which they will realize that when naive visualization is limited or fails, they have to turn to more efficient strategies in order to prove a conjecture or justify an answer. In this hypothesis the strategies are based on the use of geometrical properties of the figure. The aim of the study is to examine how students’ argumentation can be promoted by using tasks with specific characteristics and how visualization and argumentation are interweaved in 3D-DGS tasks.

I will show how these two parts of the geometrical activity are linked theoretically and then present the teaching experiment that was conducted and some preliminary results.

## Theoretical background

### The interplay between visualization and argumentation in the frame of tasks designed in DGS

The notion of visualization has constituted a topic of research interest both for psychologists and mathematics education researchers. Nevertheless, until today researchers have not yet agreed on one unique definition regarding this notion. In this problem-solving context it is the cognitive part of visualization that will be taken into account, as it is related to argumentation.

Duval (2005) classifies visualization into two categories, *iconic* and *non-iconic visualization*. In *iconic visualization* “the drawing is a true physical object, and its shape is a graphic icon that cannot

be modified. All its properties are related to this shape, and so it seems to be very difficult to work on the constitutive parts of it” (Mithalal, 2009, p. 797). In *non-iconic visualization*

the figure is analysed as a theoretical object represented by the drawing, using three main processes:

**Instrumental deconstruction:** in order to find how to build the representation with given instruments.

**Heuristic breaking down of the shapes:** the shape is split up into subparts, as if it was a puzzle.

**Dimensional deconstruction:** the figure is broken down into *figural units* — lower dimension units that figures are composed of —, and the links between these units are the geometrical properties. It is an axiomatic reconstruction of the figures, based on hypothetico-deductive reasoning (ibid, p. 797)

It follows that argumentation isolated or visualization isolated, is not enough for students to solve a problem or prove a statement. There needs to be a continuous interplay between the two, for students’ geometric reasoning to progress and evolve. And it is through the use of tasks designed in a DGS that the interplay between visualization and argumentation is made stronger.

Several studies that have been conducted show that the use of DGS can promote students’ visualization skills (see for instance Christou et al., 2006). During the last three decades DGS, like GeoGebra and Cabri, are being used more and more in the teaching of mathematics in secondary education. In this paper, the focus regarding DGS will be on their use in geometry teaching.

As Laborde characteristically writes: “DGS contain within them the seeds for a geometry of relations as opposed to the paper and pencil geometry of unrelated facts” (2000, p. 158). Healy and Hoyles (2002) and Jones (2000) argue that DGS could play an important role in supporting students formulating deductive explanations and therefore also in the development of students’ deductive reasoning, as they

appear to have the potential to provide students with direct experience of geometrical theory and thereby break down what can be an unfortunate separation between geometrical construction and deduction (Jones, 2000, p. 81)

Before I proceed to the presentation of the study and the tasks, I would like to give some more insight regarding the theoretical perspectives on which the task-design was based.

### **Theoretical perspectives behind the task design in this study**

The design (the characteristics) of the tasks, aims at challenging the students to produce conjectures and examine their validity using strategies that go beyond iconic visualization and naïve empirical justifications, engaging them naturally in mathematical activity that involves non-conic visualizations and argumentation.

#### **Characteristic No 1 – D-transitional tasks**

According to Markopoulos (2003), understanding the properties of a solid is equivalent to understanding the characteristic parts of a 3D shape, the comparative relations between the same or different structural parts and how the elements of the solid are interrelated. That is an idea which is very close to what Duval (2011) calls “figural units” of a figure. That means that the properties of

the component parts (figural units) of a 3D geometrical object are also properties of the 3D geometrical object itself.

This correlation of properties between shapes and geometric objects of different dimensions is vividly present in tasks that involve both 2-dimensional (2D) and 3-dimensional (3D) geometric objects. This thought generated the idea of what I call *D-transitional tasks*. These are tasks involving transitions from 2D to 3D (and vice versa) geometric objects. Such tasks provide students with the opportunity to think about an object through the manipulation of another, and thus combine their properties and identify the relationships, connections and dependencies between their properties. Furthermore, contrary to other studies which also use 3D DGS geometry tasks (see for instance Hattermann, 2009), the students are not asked to see 2D units in 3D shapes, but to identify 3D shapes by studying 2D sub-figures of them.

Laborde argues that:

If properties of figures are not conceived as dependent, a deductive reasoning has no meaning. The question of the validity of a property conditional on the validity of other properties would not arise in a world of unrelated properties (2000, p. 157)

As Pittalis and Christou explain:

Students should understand that each paradigm of a 3D shape has a number of invariant and variant geometrical properties based on the properties of the isolated component parts and its own properties as a unified structure. The invariant properties constitute the criteria that the 3D shape should meet in order to represent an example of a class of 3D shapes (2010, p. 194)

### **Characteristic No 2 – Cognitive conflict, uncertainty and surprise**

As cited in Hadas et al.:

Goldenberg, Cuoco, and Mark (1998) stated that: “A proof, especially for beginners, might need to be motivated by the uncertainties that remain without the proof, or by a need for an explanation of why a phenomenon occurs. Proof of the too obvious would likely feel ritualistic and empty” (p. 6)

They concluded that DGS may provide opportunities for the creation of uncertainties, leading students to seek for explanations (2000, p.128).

But uncertainty is not the only possible motivation for students to seek for a proof of the validity of their conjecture. According to Healy and Hoyles (2002), and Laborde (2000) students feel the need for explanation when what they observe on the computer screen gives them a feedback that is surprising or is in conflict with what they expected.

### **Characteristic No 3 – Black Box: A way to create uncertainty and surprise**

Black Box activities were designed by Laborde (1998) in the context of geometry teaching. Such activities have also been used by Knipping and Reid (2005) during a research in geometry teaching using Cabri Geometry. In such a task, a construction is already offered to the students but the properties and rules on which this construction is based are hidden. The Black Box activities give to students the opportunity of interesting and productive explorations. “When students’ predictions

turn out to be wrong, this is a good opportunity for asking ‘Why is it so?’ and calling for an explanation or even proof” (Laborde, 2002, p. 311).

## The teaching experiment

The teaching experiment was designed by the researcher and implemented by the participating teacher as part of his geometry lesson. The participants were 24 students of a 9<sup>th</sup> grade class. *Five D-transitional* tasks were designed in the *3D Graphics* environment of GeoGebra 5. Before the implementation of the teaching experiment, a 90’ session was dedicated to introduce the software to the students. During the teaching experiment the students worked in pairs on the computers.

For the purposes of the data collection there were used 3 cameras. Each camera was focused on one pair of students. For the three pairs of students that were video recorded, a screen-recording program was used to record their work in GeoGebra. The analysis of the data is based on the transcribed video of the students’ discussions, the screen recordings and their notes on the worksheet they were provided with for each task.

## Description of the tasks

In each task the GeoGebra window was divided into two sub-windows. On the right sub-window (*3D Graphics*) there was a 3D coordinate system in which a solid was designed, and a blue plane defined by axes  $x$  and  $y$ . On the left sub-window (*Graphics*) there were three sliders (h for height, t for tilt and s for spin), which the students could manipulate in order to move the solid, and a 2D depiction of the cross-section that was created when the solid intersected with the blue plane. The decision for the use of this representation was made, based on the prior knowledge of the students, who had already worked on intersections of solids in previous geometry lessons.

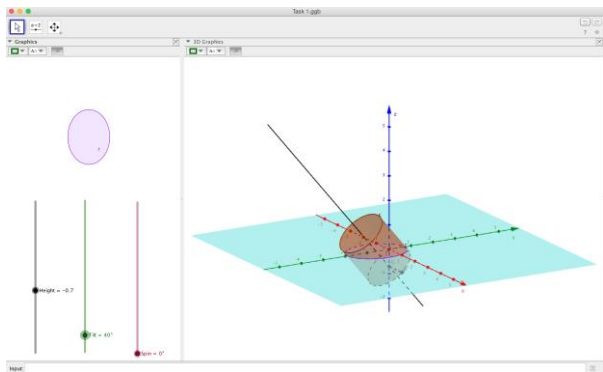

Figure 1: Snapshot of Task 1

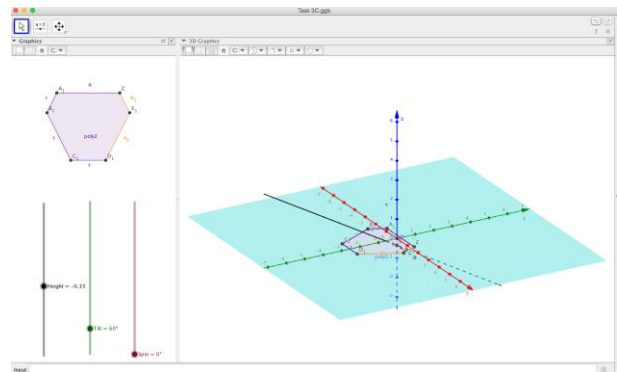

Figure 2: Snapshot of Task 3C

In Task 1 (see Figure 1), the solid (a cylinder) was visible. The students were first asked to experiment with the three sliders and describe what the function of each slider was and how it affected the position of the solid in space. Subsequently, they were asked to examine the shapes of the cross-sections that were created in some different (h, t, s) positions of the sliders.

In Tasks 2, 3A, 3B and 3C (see Figure 2) the solid was hidden. The question set to the students in each of these tasks was “Which solid do you think this could be, judging from its cross-sections?”.

The teaching experiment was conducted in two phases. During each phase the students worked as shown in Table 1 below.

Phases	Steps of the Phases	Duration
<b>1<sup>st</sup> Phase</b> – Students work in pairs (1 <sup>st</sup> day)	Task 1 – Visible Cylinder	22'
	➤ Classroom discussion	18'
	Task 2 – Invisible Sphere	15'
	➤ Classroom discussion	5'
<b>2<sup>nd</sup> Phase</b> – Work in parallel. Students work in pairs (2 <sup>nd</sup> day)	Task 3A - Invisible Cone	50'
	Task 3B - Invisible Pyramid	
	Task 3C - Invisible Cube	
	➤ Classroom discussion	30'

**Table 1: Phases of the teaching experiment**

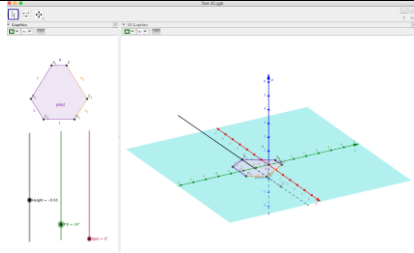

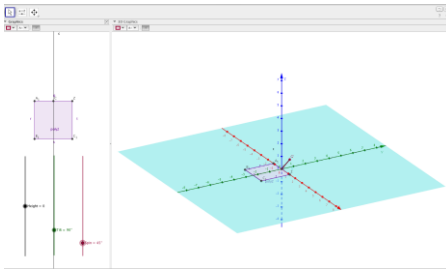

Before each phase, the teacher explained the lesson procedure to the students. He explained to them that the focus of these tasks should be the justification of their answers. That was both linked to the didactical contract and the tasks. The students were asked to be as precise and explicit as possible in their explanations, to use mathematical arguments in order to support their answers to the rest of the classroom, during the classroom discussions that would follow.

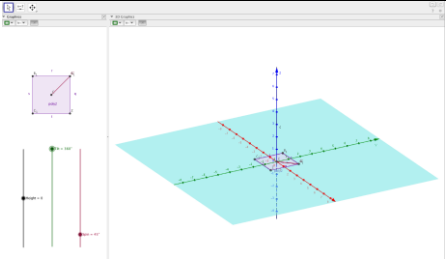

During the time the students worked on the tasks, the teacher and the researcher were only observers of the situation. During the classroom discussions the teacher acted as a facilitator of the discussion.

### Preliminary results

As the analysis of the collected data is still in progress, I will here present an example from the data as part of the preliminary results of this study. I will present the analysis of some excerpts from Gabriel and Elbert's discussion while working together on Task 3C (see Table 2). The students started by exploring freely the situation in the task, without using the worksheet that has been given to them as a helper.

Dialogue	Pictures and Analysis
<p>G: Holy ****! What is this sh**? It should be symmetric!</p> <p>E: It could also be a cube. Change the height again. Make it zero (the tilt) and change the height. (They have set <math>h=0</math> and <math>d=0</math> and they change the tilt)</p> <p>E: Ay ay ay!</p> <p>G: We have here a diagonal cross-section, that is no...</p> <p>E: No cube (he laughs)</p> <p>G: No cube... Right?</p>	<p>The first sign of surprise is seen in the reaction of Gabriel, when he starts exploring the cross-sections performed, by the blue plane, on the solid when moving it with the sliders. The students' first conjecture, based on their visual perception, is that the hidden solid is a cube. Nevertheless, as soon as they find some unexpected cross-sections like pentagons and hexagons, their naïve visualization proves insufficient and they start questioning their initial conjecture.</p>

	
<p>[...]</p> <p>E: Quite...not a cube. But it should be a cube.</p> <p>G: Could be one (cube).</p> <p>E: The other face is definitely square. We have seen that.</p> <p>G: Mhm.. (affirmative)</p> <p>E: The top face is also square. So, it could be a cube, it could –</p> <p>G: Wait, wait, wait. Spin 90, 90. So, 45. So, now is this thing perfectly oriented.</p> <p>E: Or it could be a – what do you want to see?</p> <p>G: More than one, more than one. I have more than one, therefore lets try the tilt. Now it is straight, right? I have simply oriented the thing (the solid) on the coordinate system</p> <p>E: That would work, if it is a cube, but it could also be a, a thingy. How is it called again? Prism?</p> <p>[...]</p> <p>G: That would be a cuboid.</p>	<p>They start following a more organized exploration, by identifying some figural units of the hidden solid. They now start looking at the properties of the cross-sections (the 2D geometrical object), that is of the figural units, of the solid and relate and transfer them to the hidden solid (the 3D geometrical object). At this point, they discuss that according to the characteristics and properties of the cross-sections they have seen until now, they can only argue that the solid is a cuboid and not a cube yet. Although they have moved from iconic visualization to identifying figural units of the solid and some of their properties, they haven't yet reached the level of dimensional deconstruction.</p>
<p>[...]</p> <p>E: We know that the height and the width are equal. We know that it is square. That the faces are square. That means, it must –</p> <p>G: We check that, right? We are here at the smallest –</p> <p>E: No, this is so. Everything else makes no sense. We have a height of 2,35, a width of 2,35 and a length of 2,35.</p> <p>G: Well good.</p> <p>E: That is a square, eeh a cube!</p> <p>[...]</p> <p>G: Yes, as we proved, the face is square. We have proved that. But</p>	<p>The students end up to the conclusion that their initial conjecture was true, basing their justification on deductive arguments linking together and relating the properties and the characteristics of both the visible cross-sections and the invisible solid. This process resulted to the reconstruction of the hidden solid by first achieving the dimensional deconstruction of its cross-sections.</p> 

<p>the length, the width and the height are equal, we have proved, because we changed the tilt and the object was always a square at 90, 180, 270 and 360 and 0. Just turned round the axis.</p>	
--	--

**Table 2: Excerpts from the collaborative work of Gabriel and Elbert on task 3C**

## Conclusion

Gabriel and Elbert wanted to come up with a justification of their conjecture that would be satisfying for them. The nature of the task and the students' initially "unorganized" exploration soon caused them surprise and cognitive conflict. The students started doubting their conjecture and they turned to a deeper exploration moving from iconic visualization to identifying figural units of the solid and their properties. They based their reasoning on the properties of both the cross-sections and the solid and also the dependencies between them. They achieved the reconstruction of a hidden solid, judging by its 2D cross-section and subunits. At the end they correctly identified the hidden 3D shape as a cube by studying its 2D sub-figures. They stopped and accepted their conjecture as true only when they had produced what for them constituted a valid argumentation.

There is still a long way to go until I can present some more general results from my study. Nevertheless, examples like the one presented here show that it is possible to support students' visualization, argumentation and deductive reasoning in geometry, by using tasks whose design is based on the idea of the interplay between visualization, argumentation and which have the characteristics presented in this paper.

# What influences grade 6 to 9 pupils' success in solving conceptual tasks on area and volume

Veronika Tůmová

Charles University, Faculty of Education, Prague, Czech Republic; [veronika.tumova@pedf.cuni.cz](mailto:veronika.tumova@pedf.cuni.cz)

*In this article, I investigate relationship of space structuring and multiplicative thinking with success in solving volume and area problems. The observations are made based on the analysis of written tests completed by 748 Czech pupils from grades 6 to 9. Phenomena observed in solutions of three volume problems are used as indicators of the level of space structuring and multiplicative thinking, which is then related to the pupils' results in the conceptual part of the test. Relatively strong connections were identified for both factors.*

*Keywords: Volume measurement, multiplicative thinking, structuring of space, hypothetical learning trajectory.*

Many Czech teachers mention measure in geometry as one of the critical parts of primary mathematics and Czech pupils scored in TIMSS well below their average in most of the tasks concerning area or volume. Moreover, our previous research (Vondrová, 2015; Tůmová & Janda, 2014) shows that pupils' problem often lies in conceptual understanding. However, the measurement in geometry is problem worldwide – the difficulty seems to be intrinsic to the topic itself (Duval, 2006; Finesilver, 2015; Kamii & Kysch, 2006).

The aim of my research has been to investigate how the conceptions of area and volume are built, what the major pitfalls and problems are, what skills and strategies are helpful for solving problems and what are the frequent unsuccessful strategies and pupils' misconceptions.

## Theoretical framework and review of existing literature

As Sáiz (2003) pointed out, it is helpful to distinguish between the concept of volume, which means a set of encyclopaedia knowledge of volume with its uses in various contexts (theoretical construct, or semantic field of volume) and conception of volume, which is its counterpart in the internal, subjective “universe of human knowing” (Pehkonen & Furinghetti, 2001, as cited in Sáiz, 2003, p.97).

The concept of volume is rather complex compared to area also because there are several ways it can be understood: e.g., as a capacity, a free space inside a closed surface or a space occupied by the solid (Potari & Spiliotopoulou, 1996). I will focus on the second perspective which I also understand like a space that can be filled with cubic units (limiting myself to rectangular prisms).

Further, I presume that pupils' conceptions are built gradually and hierarchically – as described in the hierarchic interactionism theoretical framework presented by Sarama and Clements (2009, pp. 20nn). In order to describe a likely trajectory that pupils may take while getting familiar with the concepts of area and volume, I will use a tool called hypothetical learning trajectory (HLT). A learning trajectory describes a sequence of levels of thinking. It consists of a goal, a developmental progression, or learning path (i.e., ordered sequence of mental ideas and actions), and therefore it has also teaching implications (i.e., what instruction helps pupils to move along that path).

The starting point of my further work has become the HLT for volume as proposed by Battista (2007, p. 903) as it distinguishes two parallel streams: numerical reasoning and non-numerical reasoning

(Table 1). By non-numerical reasoning, I mean reasoning in the geometrical context about conservation, comparison, transformations, geometry motions, etc. The emphasis on non-numerical reasoning when building a conception of area or volume is in line with research (Kospentaris, Spyrou, & Lappas, 2011; Huang, 2011).

Seeing the HLT as two parallel streams, we can see another important feature of geometrical measurement: the importance of building connections between numerical and non-numerical aspects. For example, Huang (2011) showed that both the curriculum which stresses the numerical calculations for area measurement and the geometry motions curriculum aimed at developing the non-numerical reasoning have to be combined to improve pupils' performance.

Non-numerical reasoning	Numerical reasoning
1. Holistic visual comparison of shapes	1. Use of numbers not connected to unit iteration
2. Visual comparison of shapes by decomposing/recomposing	2. Unit iteration and enumeration (coordinated structuring of space into arrays), includes: <ul style="list-style-type: none"><li>• Units properly located only along the edges/sides</li><li>• Units properly located without overlaps or gaps</li><li>• Units organized into composites (layers) – repeated addition; multiplication</li><li>• Operating with other units than cubes</li></ul>
3. Comparison of shapes by property preserving transformations/decompositions	
	
	3. Operating on numerical measurement <ul style="list-style-type: none"><li>• Structuring becomes implicit – multiplication of measures</li></ul>
4. Integrated numerical and non-numerical reasoning	

**Table 1: HLT used for the concept of volume**

I will use this HLT as a roadmap, showing a hypothetical way how the conceptions of volume and area is built. In my work, I will try to find relations between selected elements described in the HLT (e.g. space structuration into arrays) and success in solving conceptual area and volume problems.

Battista (2007) distinguishes pupils' problems with space structuring of the situation and problems in connecting the space structuring with appropriate numerical procedures. The latter is apparently very difficult. Pupils often use a completely different formula (e.g., for the surface or area instead of volume) or substitute wrong measures into the formula (Vondrova & Rendl, 2015; Tan Sisman & Aksu, 2016; studies cited in Battista, 2007, p. 893). These problems can be found not only with pupils, but also with prospective teaches (Dorko & Speer, 2013).

Huang (2014) found a significant relationship between multiplicative thinking and performance at solving a certain type of area measurement problems. In our previous research (Tumova & Janda, 2014), we also identified a relation between multiplicative thinking and success in solving application tasks for volume and area: pupils who were able to calculate the number of tiles needed using division were much more successful than pupils who had to draw the actual tiling and use multiplication.

The structuring of space into arrays is one of the main building blocks in the HLT. Dorko & Speer (2013) hypothesize that the ability to structure space into arrays of cubes is related to the computational success in all their tasks. I wanted to explore these two issues on a larger scale.

## Research questions

The article focuses on the part of my work dealing with volume and grade 6 to 9 pupils. The research questions are: (1) Is the ability to structure space into arrays related to success in conceptual tasks? (2) Can we see any relation between multiplicative thinking and success in conceptual tasks?

## Methodology

### Tasks

I constructed tasks roughly corresponding to the HLT of area and volume. They can be divided into three categories. The first category consists of *non-numerical tasks* that aim to find whether pupils can de-compose and re-compose 2D and 3D objects and manipulate these objects (or their parts) mentally. Results of these tasks are not used for the data analysis in this article.

The second type are *structuration tasks* – i.e., tasks that rely heavily on array structuration of space (manipulation). In 3D, tasks H12, H13 and H14 were used.

*H12.3: The blue cube building has 20 cubes in the first layer. How many cubes do you have to add in order to get the smallest possible completely filled prism (in other words, if the building was in a tightfitting rectangular box, how many cubes you have to add in order to fill that box completely)?*

H12.1. and H12.2. are similar, with different cube buildings with first layers of 9 and 12 cubes, respectively.

**Figure 1: Blue cube building**

The aim of task H12 is to identify, how well the pupil can understand the array structure when the structure is depicted and unit cube is used. It can be solved by enumeration of the missing cubes, no calculation is needed.

*Task H13: You have exactly 59 cubes (with the edge of 1 unit) to build a cube building<sup>1</sup> on a plot of land which is 4 units long and 3 units wide. You have to use all of the cubes but the building has to be as LOW as possible. How many layers will there be? How many cubes will there be in the top layer? [No drawing provided.]*

In H13, two types of solving strategies are possible. The first is calculation-based: divide 59 by the product of 3 and 4 (i.e., the number of cubes in one layer). The resulting whole number means the completely filled layers and the rest is the number of cubes in the last incomplete layer:  $59 : (3 \cdot 4) = 4$  (rem. 11). The other approach is partially manipulative: draw cubes in the bottom layer and see how high we can continue building until all 59 cubes are used (using repeated addition or multiplication). Based on the method the pupil will use and drawings he/she will make (e.g., if he draws just a rectangle, or structure consisting of rows and columns), we can hypothesize what kind

<sup>1</sup> This term was understood intuitively by pupils – it is a building made of unit cubes and a subset of a 3D array structure that can be physically built (all the columns must be built putting one cube on another).

of space structuring the pupil used and relate it to the levels in HLT (Table 1, rows 2 and 3 in the right column).

Task H14: *What is the maximum number of parcels measuring  $2 \times 1 \times 1$  dm that would fit into a cubic box with an edge of 6 dm? Justify your answer. [No drawing provided.]*

H14 also has two types of strategies. One is calculation-based: calculate the volume of the box and the volume of the small parcel and divide the two to get the correct number of fitting parcels. The manipulative strategy: draw or imagine how many parcels are in one layer and multiply it by the number of layers. H14 is more complex because the unit to be used is not a cube, also the volume of the box has to be calculated from the length of the side.

The third category of tasks are *conceptual tasks* (4 for area and 2 for volume) – these are non-routine or novel tasks that require more advanced understanding of the underlying principles and concepts than a simple use of formula (see also the definition of Tan Sisman and Aksu, 2016, p. 1298). After piloting the tasks, only those were selected as conceptual tasks to the main test in which the percentage of pupils that used structuration as their solving strategy was less than 10 %. Task H16 is a typical example.

Task H16. *A cuboid-shaped vase has a base of  $9 \times 12$  cm. If I pour one litre of water inside, how high it will reach? (Hint:  $1 \text{ l} = 1000 \text{ cm}^3$ ).*

### Data collection

After a small scale pilot testing of the tasks and revision based on discussions with experts, the test was distributed to more than 1 300 pupils (grades 4 to 9) from 8 different ordinary primary schools in Prague (it is to be noted that this was a convenience sample). The pupils solved the tasks within the first three weeks of September 2015, after summer holidays to eliminate the influence of the mathematics topic currently taught and test pupils' long-term knowledge. The test was given by mathematics teachers who got instructions from me. The test took 55 minutes and it was completed by 735 pupils in grades 6 to 9.

### Data analysis

Pupils' solutions were coded by the author and two more coders. Based on the above *a priori analysis* of tasks, we had some preliminary codes. The coders first coded for the preliminary codes and while doing so, assigned points for each task and noted other phenomena such as what mistakes appeared, what other calculations appeared in the written solution, etc. Examples of codes are in Findings section. The codes were further grouped and analysed both quantitatively and qualitatively. The bulk of the quantitative analysis consisted of looking for relations between phenomena and the total result in all the conceptual tasks (CONC total).

Note: Whenever I look at the performance of pupils, I always report the result of all conceptual tasks (CONC total) – i.e., for both area and volume problems (tasks H3-H6 and H15-H16). I wanted to assess the conceptual understanding of geometrical measurement therefore I included both concepts into the result. The results are reported in percentages calculated as the number of points actually achieved by the pupil divided by the maximum number of points.

## Findings

Phenomena identified for structuration problems H12, H13 and H14 will be related to CONC total regardless of age of pupils. The findings will be grouped according to research questions.

### Structuration of space and its relation to the success in conceptual tasks

H12 to H14 are hypothesized to form a series of tasks with a growing demand on space structuring abilities. H12 tests pupils' ability to structure space properly in a situation when the structure of cubes is given (shown in a picture) and the unit is a standard unit cube. H13 tests whether pupils are able to calculate the height of a cuboid based on the knowledge of its volume and base in a discreet situation. H14 diagnoses how pupils can structure space using non-cubic units.

**Figure 2: Venn diagram showing the overall test score and a number of pupils successful in H12-14**

The Venn diagram in Figure 2 shows the number of pupils who scored at least 50 % in H12, H13 and H14. The number in brackets is the average CONC result (i.e., of all conceptual tasks) for relevant group of pupils. For example, 252 pupils successfully solved H12 but not H13 or H14, the average CONC result for these pupils is 11%. There were 74 pupils successful in all three tasks (in the centre) and their average result was 51%.

As expected, H14 proved to be the most difficult and the pupils who solved it, also scored the highest in the conceptual part of the test. As we can see, there seems to be a relationship between pupils' ability to structure space into appropriate structure (3D array) and their success in the conceptual tasks in the test. If we calculate correlation between the result of structuration tasks (H2, H12-14) and conceptual tasks (CONC total), we get a relatively high Pearson correlation of 0.66.

Further, in the solutions of H13, we identified almost all the strategies for space structuring mentioned in the HLT (pupils most often drew the first layer only, so the structuring is, in fact, a tiling). The strategies were coded as follows (see Table 2): "Unable to structure" (incorrect number of cubes in a layer, structure only along the edges – perimeter or structures 5x4, etc.), "Individual cubes" (each cube drawn separately), "Rows and columns" (partitioning drawn for whole rows and columns), "3D structure" (3D drawing), "Implicit structure" (no drawing or only the rectangle drawn and number of cubes correct), "Unable to identify" (where the structuring strategy was unclear from the test).

The difference in CONC total result is statistically significant between strategy "Implicit structure" and all other strategies<sup>2</sup>. This means that the pupils who can determine the number of cubes in one

<sup>2</sup> Data are shown in left part of Table 2. The independent sample T-test in SPSS was used for each pair of codes.

layer without having to draw the structure (according to HLT, this means that they have reached the level where the structure became implicit for them), perform significantly better than other pupils. Again, there seems to be a relation between the way the space structuring is depicted and success in the test – the higher level of structuring (according to HLT), the better average result in the conceptual part of the test.

To see connections with space structuration, we look at manipulative strategies in H14 in more detail (about half of the pupils solving this task used manipulative strategy) – see Table 2 right.

Structuring of area in H13	Avg CONC total	No. pupils	Strategy in H14	Avg CONC total	No. pupils
Unable to identify	24%	71	Strategy cannot be determined	16%	31
Unable to structure	11%	43	First layer incorrect	19%	41
Individual cubes	19%	68	No. of layers incorrect	24%	25
Rows and columns	21%	80	Numerical error	34%	5
3D structure	27%	31	Structure correct	47%	43
Implicit structure	38%	93	<b>Manip. strategies total</b>	<b>31%</b>	<b>114</b>
<b>Total H13</b>	<b>25%</b>	<b>386</b>			

**Table 2: Space structuring and strategies vs. success rates in tasks H13 and H14**

First, we look at the manipulative strategies: 43 pupils were able to structure the space inside the box properly and solve the task (Structure correct) – they scored the highest in the conceptual tasks (the average result of 47%). These pupils performed significantly better in the conceptual tasks than pupils who used other strategies. Quite a few pupils (41) were not able to structure even the first layer (their average CONC result is only 19%). If we presume that the strategies represent the level of skill in space structuration, we can say that pupils who cannot fill even the first layer would form the lowest level, those who did one level correctly but did not get the number of layers right would be on the next level, followed by those who drew the correct structure. We can see that pupils who structured space better score higher in CONC total.

### **Multiplicative thinking and its relation to the success in conceptual tasks**

To analyse the use of operation, we look at H13. The codes we used are (Table 3): “No operation mentioned”, “Unable to interpret results of operation” (includes 9 pupils who could not perform the operation of division correctly), “Repeated addition” (calculate the cubes one by one or by layers – i.e.,  $12+12+\dots$ ), “Repeated multiplication” (such as  $3 \cdot 12$ ,  $4 \cdot 12$  until something bigger than 59 is reached), “Division and correct interpretation” (division  $59 : 12 = 4$  (rem. 11) and correctly interpret results). All strategies were present in all grades – around 5% of pupils in all grades were not able to interpret results of the operation they used and 18% of all pupils in grade 9 still used repeated addition strategy to solve this problem.

<b>Strategy_OPERATION</b>	<b>Average result of CONC and Structuration tasks</b>	<b>Average of CONC result</b>	<b>No. of pupils</b>
No operation mentioned (NO)	25%	13%	126
Unable to interpret (UI)	23%	16%	33
Repeated addition (RA)	32%	22%	106
Repeated multiplication (RM)	38%	30%	53
Division and interpretation (DI)	47%	39%	68
<b>Total</b>	<b>33%</b>	<b>18%</b>	<b>386</b>

**Table 3: Use of mathematical operation and success rates in H13**

The independent sample T-test in SPSS showed that the combined result of Structuration tasks and CONC total result for strategy DI is significantly different from all other strategies, except from RM. The same is true for CONC result. This means that the pupils who can use division and correctly interpret results in this task, performed significantly better in all conceptual tasks and in all conceptual and structuration tasks than pupils who used repeated addition or pupils who could not interpret results of their calculations. The difference between RM and DI groups was not significant.

Quite a few pupils (33 in H13) were not able to interpret results of the operation they used. This is apparent in other tasks as well. In H14, there were 41 pupils who used what may seem to the observer like a random mathematical operation on given numbers and their interpretations of results were incorrect.

## Conclusion and discussion

To sum up, the structuring of space seems to be related to the success in our conceptual tasks. We looked at space structuring from two perspectives. First, when pupils are able to apply the correct structuring (i.e., which of H12 to H14 are solved correctly). Second, how pupils depict the structure of a layer which is in a rectangular form with given lengths of sides. In both cases, the pupils who structure space better achieved better results in area and volume conceptual problems. This seems to confirm the hypothesis of Dorko and Speer (2013) above.

The relation between the use of mathematical operation (multiplicative thinking) and success in our conceptual problems seems to manifest itself even on a large sample which confirms our finding from the previous research (Tumova & Janda, 2014). From the observed number of pupils who were not able to interpret results of the operations they used we can see that connecting the appropriate mathematics operation with the geometrical situation is another major problem for Czech pupils as mentioned in (Battista, 2007). Not only how good is their multiplicative thinking, but what operation in which situation they decide to use and with what numbers might be the most important. Investigating this connection in more depth (how it is built, what promotes building it) remains an open question for future research. Also, connections between multiplicative thinking and space structuring seem to be worthwhile to investigate further. The connection seems to be bidirectional: structuring of space guides enumeration but also enumeration can help space structuring (Finesilver, 2015, p. 257).

One of the limitations of my research is the fact that the results cannot be easily generalised as the sample was not representative. Another limitation is in the set-up of research – I did inferences on pupils' thinking based only on what was written in the test. Some of my interpretations of the written solutions might need additional support in interviews with pupils.

# Shapes recognition in early school: How to develop the dimensional deconstruction?

Céline Vendeira<sup>1</sup> and Sylvia Coutat<sup>2</sup>

<sup>1</sup> University of Geneva, Faculty of Education, Geneva, Switzerland; [celine.marechal@unige.ch](mailto:celine.marechal@unige.ch)

<sup>2</sup> University of Geneva, Faculty of Education, Geneva, Switzerland; [Sylvia.coutat@unige.ch](mailto:Sylvia.coutat@unige.ch)

*In primary school there is, in geometry, an important rupture between primary (age 4 to 12) and secondary school. Some activities are already proposed for students from 8 to 12 years old to help to prepare for this rupture. Our research has the same aims, but for students from 4 to 6 years old by developing some pre-geometrical activities around shape recognition using dimensional deconstruction.*

*Keywords: Shape recognition, visualization, dimensional deconstruction, way of thinking.*

## Context

In all French speaking Switzerland we have a common program for all compulsory education. For the geometry curriculum, in the elementary division (from 4 to 8 years old), students use a physical space where «the shape is linked to the visual perception of the object»<sup>1</sup>. Then, from 8 years old, they use a conceptual space where objects are associated with figures as «unchangeable and ideal». These figures are independent of their graphical representation. We consider that there is an important gap between these two divisions, and we need to help students to overcome it.

## Theoretical framework

Some researches like Berthelot and Salin (1993-1994), Houdement and Kuzniak (2000), Parzysz (2003), Braconne-Michoux (2008) show a rupture, in geometry teaching, between primary and secondary school where the focus is put on reasoning and deduction. Without reaching the theoretical level of the geometric objects and therefore of their properties, an intermediate work on the elements which compose the forms is possible and constitutes the heart of this research with students of cycle 1 and beginning of cycle 2. As Duval (1994) says, one of the aims of geometry in primary school is to emerge the operative apprehension of a figure parallel to the one, first and naturel, more perceptive. Therefore, to help, it “presupposes the dimensional deconstruction of the visual representations”<sup>2</sup> (Duval & Godin, 2005, p.11). The first visualization is global; the perception is centered on the closed contours of the shape. This visualization is called two dimensional visualization (2D element), which is referred to by Duval (2005) as the iconic way of seeing. The dimensional deconstruction considers the elements of the shape like the sides and the lines, which are one dimensional elements (1D element) and the vertices and the points, the zero dimensional elements (0D elements). This is what Duval (2005) distinguishes as the non-iconic way of seeing. The decomposition of shapes into figural unities is an essential stage prior to building the non-iconic visualization.

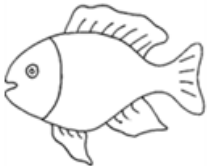

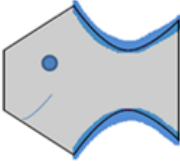

---

1 Our translation from the French speaking Switzerland curriculum « Plan d'études romand » (<https://www.plandetudes.ch/per>) : « la forme est liée à la perception d'ordre visuel d'un objet ».

2 Our translation.

Having as objective to evolve the students' visualization of geometrical shapes, we rely on the work of the Lille group (Duval (1994), Duval, Godin & Perrin-Glorian (2004), Duval & Godin (2005), Keskessa, Perrin-Glorian, Delplace (2007), Godin & Perrin (2009), Perrin-Glorian, Mathé & Leclercq (2013), Perrin-Glorian, Godin (2014), Perrin-Glorian (2015), Bulf & Celi (2016)) which consider the transition between the recognition of a form by global perception and the deduction from its axioms as the "identification of properties that are verified or produced with instruments"<sup>3</sup> (Houdement and Godin, 2014, p.28). Most of those researchers propose tasks of reproduction of figures in particular the reproduction problems called "restoration of figures (define by Perrin-Glorian and Godin (2009)). In our case, we work on tasks of forms recognition. To prepare students to the rupture pointed out between primary and secondary school, we introduce two new levels between the global perception and the non-iconic way of seeing. We call them the "hybrid thinking" and "thinking by characteristics". Below, we associate each thinking according to the ways of seeing of Duval. We give an example based on the following shape:

	Iconic visualization	Towards dimensional deconstruction		Non-iconic visualization
Way of thinking	Perceptive thinking	Hybrid thinking	Thinking by characteristics	
Associated vision				
Associated language <sup>4</sup>	« It looks like a fish »	« It looks like a fish with a flat nose and a curved body »	« It is a shape with holes (the convex character). It as rounds and straights (straight and curved edges) »	

**Table 1: Levels of the different visions of the shapes**

Those levels focus 1) on a global vision of the shape (2D) 2) on a hybrid vision of the shape (using the global vision and some characteristics of the shape (0-1-2D) 3) on the vision of only some localised areas of the global form (as the types of lines (straight or not, etc.)) considering therefore some of the characteristics of the shape (0-1D). This third level corresponds to pre-geometrical work. The last level "non-iconic visualization" relates to the definition of the properties of geometric figures. So, to think by the characteristics is more than a perceptive vision but does not yet correspond to the geometric properties. As for the hybrid thinking, it mobilizes in the same time the global vision of the shape, through its surface, and a more expert vision from its elements.

This table shows a wider process of dimensional deconstruction than usual. Thus, our goal, in this research, is to develop some pre-geometrical activities around shape recognition using these two new levels to provide students with a more harmonious transition in order to overcome the gap between primary and secondary school.

<sup>3</sup> Our translation.

<sup>4</sup> In the next steep of our research we will also consider the "associated action".

## The developed material

In order to help 4 to 6-year-old students to pass from the perception of the shapes as they are worked in primary school to what is expected in secondary school, we propose to work on shapes recognition tasks with a collection of 36 shapes. Very often, the most common use of characteristics concerns the number of sides of the shape. However, students at this age are precisely building the concept of number which is therefore "fragile". Other characteristics of shapes are nevertheless affordable and interesting from Cycle 1. For example, the presence of straight or curved edges, symmetries, parallel opposite sides or the convex or concave character of the shape. Of course, students are not expected to use the correct mathematical terms. What is important is that they identify these characteristics, whatever the vocabulary used. The collection of 36 shapes takes into account the different characteristics cited. Figure 1 presents the collection of the 36 shapes. All the different tasks are built around this collection (tasks of classifications, associations and housing).

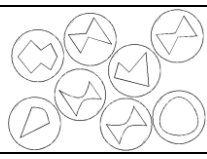

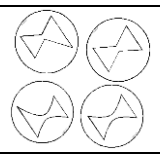

**Figure 1: The collection of the 36 shapes**

The chosen shapes are not nameable, at least not using "classical" shape names such as triangles, squares, rectangles, circles. To identify them, students have to focus on other aspects than their name. Either students recognize, in the shape, a resemblance to a well-known object (for example the fish mentioned above), or they are obliged to refer to its characteristics. This last point promotes dimensional deconstruction with the components of shapes.

Thus, the main objective aimed through the developed activities is that the student constructs a thinking of the objects based on their characteristics. This does not mean that it is necessary to replace the global thinking, but to supplement it. The joint use of the hybrid thinking and the thinking by characteristics is therefore also necessary. For example, in many activities, students can first classify the shape by global perception (we put together shapes perceptually close), and then only need to distinguish them through their characteristics.

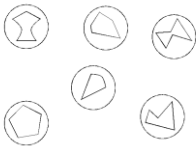

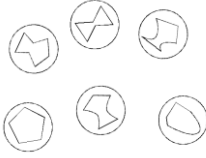

Below is an example of strategy to find a shape in a collection of eight shapes  :

Starting Collection	Reduced collection	Identified shape in the reduced collection
		
I observe and manipulate the assortment of forms	I extract all "bow ties" (or "vases") of the assortment.	I then focus on the characteristics "it is the one that is not regular (=symmetrical) and with rounds (=curved edges)". I select then the corresponding shape.

**Table 2**

The choice of the selected shapes is essential because it can directly influences the way of thinking that the students will mobilize.

Perceptive thinking	Hybrid thinking	Thinking by characteristics
		

**Table 3**

Thus, if the selected shapes are perceptively distant, the overall vision is promoted. Conversely, if the shapes are perceptively close, an entry through the characteristics is necessary. These shapes are cut out from "translucent" Plexiglas. The choice of a circle does not favour any particular orientation. With this material, we can work on the shape using the edging by the exterior or the interior of the shape. Depending on the activity, we may choose to present one or both of these supports (or both). The interest of this material is that it can be embedded providing direct feedback for students.

The inside form

the empty circular part

With this collection of shapes we then create activities working on shape recognition with different kinds of tasks, classifications, associations and housing.

## Methodology

For one school year we have worked with six classes including four classes in a downtown Geneva school, a class in the Geneva countryside and a class in neighbouring France. This diversity makes it possible to confront our material and our activities in different contexts (without pretending any generalization). In total there were 112 students aged from 4 to 6. At the beginning and the end of the year all the students took a test. We do not develop the results of the tests in this article. The students worked in small groups with the researchers from 2 to 4 periods in total. Each period lasts 45 minutes. In every class, except one, we realized, among the proposed periods, a session with big shapes in the “meso-space”.

**Photo 1: Work with big shapes**

In each class we have: 1) One individual pretest at the beginning of our research in which we use the activity « families to build ». This test has been passed by the teachers and was not filmed. 2) Many activities using the developed material. Each session was filmed by one or even two cameras.

3) One activity with big forms. 4) One « concluding activity » at the end of the year. 5) One post-test at the end of the school year (exactly the same as the pretest). 6) One pretest at the beginning of the following year (exactly the same as the previous ones). This test was filmed and students were systematically asked about their production.

We thus have many hours of observations that allow us to verify if students of this age can mobilize the characteristics of the shapes.

### **Presentation of an activity for 4 to 6 year old students: Families to build<sup>5</sup>**

The activity is done in groups of 2 to 5 students. The teacher selects an assortment of 8 to 16 pieces from the collection (the inside form or the empty circular part). Below is an example of an assortment that has been frequently used in classrooms with students.

**Figure 2: An assortment frequently used in classrooms**

In this activity students must build families (with a number of families imposed or not). The pieces are scattered on a table. Students must create families by putting the pieces "that fit well together". Students must agree and be able to explain their choice, possibly giving a name to the families created. Various objectives can be identified for this activity: 1) classification of shapes based on characteristics 2) emergence of a common lexicon that can be reinvested in other activities 3) peer collaboration with the need to agree and to argue. Thus, according to the assortment of selected pieces, students can use global or hybrid thinking or thinking by characteristics. The choice of perceptively close shapes or not is therefore an important didactic variable for this activity as well as the number of families (imposed or free).

In the pooling phase the teacher can introduce new pieces to check the solidity of students' family choices. Either they manage to integrate the new pieces within the existing families, or they need to question their classification criteria and maybe modify them.

<sup>5</sup> For more activities see Coutat & Vendeira (2015).

**Photo 2:** An example of three families built by a group of students: 1) "the mountains" 2) "the pebbles" 3) "the fish" (vision according to the resemblance of the shapes to well-known objects)

## Some results

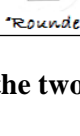

In this section we look at the productions of three students which reveal three different ways of thinking that the students mobilize about the shapes following our interventions in class. These are outcomes from the activity "families to build" carried out during the pretest (done at the beginning of our research) and the same test realized a year later.

Concerning the case of Luce, almost no change is noticeable between the two productions at one year interval. During the first run, it is found that very perceptively similar objects are associated in order to create three families. A year later, the student explained that he had formed a family of *mountains*, *trumpets*, *teapots* and *lamps* and could not say more. It is possible to relate these objects to some of their characteristics as the sharp peaks for the mountains, the symmetry for the lamps or the asymmetrical spout for the teapot. However, this remains implicit and the primarily mobilized vision is, in this case, global.

	Luce					
Activity in 2016						
Activity in 2017						
	Mountains		Lamp	Teapot	Trumpets	

**Table 4:** the two productions of Luce at one year interval

Lea's productions at the same task are identical to those of Luce for the first test. Her vision is essentially global. On the other hand, the two families created the following year are quite distinct. She chose only two families by mobilizing hybrid thinking. Indeed, the global perception is partially used with the second family where Lea recognizes *thunder* thanks to their "peaks in". As for the first family, it only possesses "rounded in" and does not belong to the family of the thunders.

	Léa		
Activity in 2016			
Activity in 2017	  <i>"Rounded in only"</i>		   <i>Thunder with "peaks in"</i>

**Table 5: the two productions of Léa at one year interval**

The first production of David is distinct from those of these two classmates. However, without a trace of his activity, it is difficult to understand how this student proceeded. It is conceivable (1) that devolution has not taken place; (2) that David mobilizes hybrid thinking but it is impossible for us to interpret. This is why we focus directly on the second production made the following year. The first family of David is justified according to two characteristics common to the three forms, namely "rounded and sharp". As for the second family, the forms are "all sharp", but have no rounding. This student thus mobilizes some characteristics of the forms.

	David		
Activity in 2016			
Activity in 2017	   <i>Rounds and sharps</i>		   <i>Sharps only</i>

**Table 6: the two productions of David at one year interval**

## Conclusion

The task "build families" is very interesting for the researcher because it gives a lot of information about the student's perception of the shape such as the visualization to build the families (global or not), the use of characteristics to build the families, the use of a pertinent language for oral interactions.

The various tasks created with the developed material and experimented in classrooms allow a progressive change of the visualization of geometrical shapes. It is important to note that students do not replace their perceptual way of thinking with a new way of thinking by the characteristics of the forms. Indeed, these ways of thinking must coexist and intertwine, sometimes giving rise to a hybrid way. It remains to be defined 1) whether the work undertaken allows all students to change their eyesight and 2) whether they are able to mobilize the appropriate thinking according to the situation.

Currently we are experimenting with new tasks with students from 6 to 8 years old and still analyzing the data collected with students from 4 to 6 years old. In addition, the developed material is currently tested in five schools. We look forward to the feedback from the teachers.

<sup>3</sup> University of Lisbon, Institute of Education, Portugal; [brunamayarabatistarodrigues@gmail.com](mailto:brunamayarabatistarodrigues@gmail.com)

*Keywords: Origami, geometric places, ellipse, investigation.*

This work presents part of the thesis developed in the Professional Master's Degree in Mathematics, at the Pontifical Catholic University of Rio de Janeiro, entitled "The study of Conics through Origami." In the present work, we will focus on the construction and study of the Ellipse, highlighting the definition of its geometric place through the axiomatic geometry of the Origami.

Teaching geometric concepts may present many challenges, because its process requires the study of concepts and relations that are not learned by students in activities which use memorizing and exercise techniques. Therefore, it's necessary to have creativity and reasoning. In this context, it is important that the student is encouraged to see the Geometry study as a practice of investigative and exploratory nature.

According to Ponte, et al. (2006), "The geometric investigations contribute to realize the essential aspects of the mathematic activity, such as the formulation and conjecture tests, the search and demonstration of generalizations." Moreover, to investigate, explore and establish conjectures in activities of geometric nature are not easy tasks. Among various teaching methods that can be explored in order to foster the meaningful learning, we can be highlighted the use of manipulable materials. In this regard, we spotlighted the possibilities of geometric investigation offered by a simple and powerful teaching tool: the paper.

Ancient and modern at the same time, "the art of the paper folding", better known as "Origami", transcends the boundaries of a simple art with its ability of conducting to the mathematic learning, either by its harmonic visual or by the Axiomatic Geometry inherent in the folds. Its description is given by the Huzita-Haroti Axioms, which consists in the seven basic operations capable of align straight lines and pre-existing points in a paper sheet through a single fold.

Some researches have already chosen origami as a resource which improves the learning of maths, such as Monteiro (2008), who used the technique to solve some equations and to demonstrate theorems, as well as Asrlan & Isiksal (2014) who described an experience about preservice teachers training using this japanese tool.

Despite the different themes that can be broached through the axiomatic geometry of folds, allied to an investigative and exploratory practice, we will highlight an activity which the objective is to explore the definition of the geometric place of the Ellipse. In its teaching, it is verified an undue priority for the memorizing of equations, and in many cases, the students only dedicated themselves to the repetition of exercises which solely involved algebraic methods. In order to rescue the

geometric approach of the topic in question, we unite these two elements in the present work, conic curves and Origami, with the aim of developing concepts of the first one from the constructions of the second, emphasizing the investigative practice through the process.

In order to spread the geometry of folding as a resource for activities of geometric investigation, to rescue the approach of the geometric place of the Ellipse and to validate the presented research, a workshop was developed, applied, evaluated and enhanced in a group of 17 Mathematics Licenciade Degree students.

As a basis for the development of the activity, which consisted of the construction of the curve, we used four moments related to the investigation process in mathematics classes mentioned by Ponte, et al (2006): recognition of the situation, its preliminary exploration and the formulation of questions; conjecture formulation process; testing and eventual refinement of the conjectures; argumentation, demonstration and evaluation of the work done.

Thus, we will present in this poster the Huzita-Hatori axioms description, the method of the Ellipse construction, the mathematics concepts related to the folds and finally the results of the activity application with the future mathematics teachers.

Through the application of the construction activity and the study of the Ellipse, we realize that the geometric place concept is underexplored in Mathematics Licenciade Degree courses, which culminates in disfavouring this content in Basic Education. Thus, this work is expected to be a source of motivation to the teachers and professors to valorise the approach of the geometric concepts in an investigative way. Also, we look to find in the folds a possibility to mix various mathematical themes in a meaningful manner.

*Keywords: Visualization, spatial ability, preservice teacher, onto-semiotic approach.*

## **Introduction**

We present a preliminary study focused on a scale on cognitive configurations for tasks requiring visualization and spatial reasoning. The main notion used is that of cognitive configuration from the onto-semiotic approach (Godino, Batanero and Font, 2007). The results show that there may be several configurations at each level and these levels depend on both certain conditions of the task and the visualization skills involved.

## **Theoretical framework**

From the onto-semiotic approach (OSA), the analysis of the mathematical activity, of objects and processes taking part in it, focuses on the practices done by people implied in the solution of certain mathematical problems (Godino, Batanero and Font, 2007). The enforcement of this approach to visualization leads to distinguish between visual practices and non-visual or symbolic/analytic ones (Godino, Cajaraville, Fernández and Gonzato, 2011). In order to make these principles operative, the OSA poses as one of its tools the ‘onto-semiotic configuration’, i.e., the network of objects and processes involved in the fulfillment of a mathematical practice (Font, Godino and Gallardo, 2013). These configurations can be socio-epistemic (networks of institutional objects) or cognitive (networks of personal objects). Here we will focus on the second ones.

## **Research problem and method**

Can we set a scale on cognitive configurations associated to tasks requiring visualization and spatial reasoning (VSR)? To answer this question, three spatial tasks requiring counting, folding/unfolding and composing/decomposing have been selected. These tasks have been proposed to a total of 400 preservice teachers and the answers have been analyzed using the cognitive configurations (CC) proposed by the OSA (Fernández, Godino and Cajaraville, 2012).

## **Results**

A variety of CC associated to each of the tasks has been found. This allows us to describe skill levels in VSR (Table 1) subject to certain conditions directly depending on the characteristics of the task, the visualization skills (Del Grande, 1990) required and the synergy between visual and analytical languages of each configuration (Godino, Blanco, Gonzato and Wilhelmi, 2013).

Task	Levels					Rank	%
Truncated cube	Level 1	Level 2	Level 3	Level 4	Level 5	High: levels 4 and 5	10,25
	CC2	CC1	CC3	CC6	CC5	Intermediate: level 3	11,50
		CC4	CC8	CC7		Low: levels 1 and 2	45
Folding/ unfolding	Level 1		Level 2		Level 3	High: level 3	8,5
	CC1		CC2		CC3	Intermediate: level 2	14
			CC5		CC4	Low: level 1	52,50
Perforated cube	Level 1	Level 2	Level 3	Level 4		High: levels 3 and 4	49,25
	CC2	CC4	CC3	CC1		Intermediate: level 2	0,75
		CC5		CC6		Low: level 1	24,25

Table 1: Scale of configuration levels

## Conclusions

In general the ratio of students expressing high level CC is significantly below than of those exhibiting low level. The analysis shows that students mobilized variety and quantity of visual objects and processes. However, they do not reach the solution successfully. This fact might be due to students are not used to working with these objects and visual processes.

# Diagrams in students' proving activity in secondary school geometry

Keith Jones<sup>1</sup> and Kotaro Komatsu<sup>2</sup>

<sup>1</sup>University of Southampton, UK; [d.k.jones@soton.ac.uk](mailto:d.k.jones@soton.ac.uk)

<sup>2</sup>Shinshu University, Japan / University of Southampton, UK; [kkomatsu@shinshu-u.ac.jp](mailto:kkomatsu@shinshu-u.ac.jp)

*Keywords: Geometry, proof, proving, diagrams, DGS.*

## Introduction

Diagrams appear in many different forms in mathematics and in its teaching and learning. While the use of diagrams is pervasive, research on learners' activity with diagrams is somewhat limited (for partial reviews, see Jones, 2013; Sinclair et al., 2016). In this short paper, our focus is on the question of how secondary school students work with diagrams during proving activity in secondary school geometry. We use data from a project investigating the design of dynamic geometry software (DGS) tasks that facilitate students' proving activity (see Komatsu & Jones, 2017).

## Existing research and theoretical background

Samkoff et al (2012, p. 49) argue that “diagrams are viewed by mathematicians and mathematics educators alike as an integral component of doing and understanding mathematics”. Even so, existing research indicates that, amongst other things, learners' beginning identification and interpretation of diagrams tends to be based on spatio-graphical properties represented in the diagram (Laborde, 2005) and that learners can have difficulties distinguishing within the configurations of a geometric diagram the visual characteristics that are relevant from those that are not (Gal & Linchevski, 2010). How secondary school students work with diagrams during proving activity in secondary school geometry is likely to vary depending on whether the geometrical diagram is ‘static’ (as in physical books and worksheets) or ‘dynamic’ (via digital technologies; for example Yerushalmy & Naftaliev, 2011).

## The study

Data (in the form of transcribed student talk, student written work, and digital files) come from a task-based interview using the tasks in Figure 1 with a triad of 11<sup>th</sup> grade students (16-17 years old), Kakeru, Sakura, and Yuka (pseudonyms), from an upper secondary school in Japan. The students had previously learnt geometric proofs, including using the conditions for congruent and similar triangles. As such, they were familiar with the inscribed angle theorem, the inscribed quadrilateral theorem, and the alternate segment theorem. Prior to the task-based interview, they had four hours using DGS.

For Q1, and only using paper and pencil, the students conjectured that  $\triangle PAB \sim \triangle PDC$  and wrote a suitable proof based on the inscribed angle theorem. For our analysis for this paper, we focus on what happened as the students worked on Q2 after they had used the DGS to construct the figure.

## Findings

Our analysis found that during the time that the students worked on Q2, they moved (‘dragged’) points A, B, C, and D to various places on circle O. In working with this ‘dynamic’ diagram, we found that their discussion settled on various versions of the diagram that we could categorise into the six types of diagram shown in Figure 2.

Q1. (1) As shown in the diagram given, there are four points A, B, C, and D on circle O. Draw lines AC and BD, and let point P be the intersection point of the lines. What relationship holds between  $\triangle PAB$  and  $\triangle PDC$ ? Write your conjecture. (2) Prove your conjecture.

Q2. Construct the diagram shown in Q1 with GeoGebra. Move points A, B, C, and D to various places on circle O to examine the following questions. (1) Is your conjecture in Q1 always true? (2) Is your proof in Q1 always valid?

**Figure 1: Tasks used in the interview**

**Figure 2: Types of diagrams the students produced**

For Figure 2a, which the students created by dragging points so that points A and B (and consequently point P) coincided, they commented that “if (the points) overlap, (our conjecture is) impossible” because “(triangle PAB) disappears”. For Figure 2c, where they considered that line AC was parallel to line BD, they concluded that “(our conjecture is) impossible” because “intersection point (P) disappears when (lines AC and BD are) parallel”. Eventually, they concluded that their conjecture was not true for these two cases (for more on the other types of diagram, see Komatsu & Jones, 2017).

### Concluding comment

The diagrams we found in the students’ proving activity underlines the observation by Samkoff et al. (ibid) that the processes involved in using diagrams in mathematics are “surprisingly complex”, especially the extent to which students are aware of the general result or a specific diagram.

[michel.gagnon@polymtl.ca](mailto:michel.gagnon@polymtl.ca)

*Keywords: Intelligent tutoring system, automated theorem proving, didactical contract, Design in use.*

QED-Tutrix (QEDX) is an intelligent tutoring system which assists students in proof problem solving by providing hints while taking into account the student's cognitive state. QEDX stands out by the fact that it adapts to each user and class reality, not the opposite. However, this model implies recognizing, like a teacher would, proofs that do not necessarily conform to a formal logic. Hence, QEDX can't rely on an automated proof engine (Tessier-Baillargeon, 2016), raising the question of how to expand QEDX's problem database without manually implementing each valid proof. Therefore, our poster at CERME10 doesn't present a traditional research project with its research questions, its methodology and conclusions. It rather aims at presenting the new research questions that stem from the challenges that arise with trying to broaden QEDX's problem bank while staying true to our main goal, which is to create a geometrical workspace (Kuzniak, 2006) according to witnessed student/teacher interactions through a design in use approach (Rabardel, 1995). Here we will focus our attention on the process of problem implementation, starting with how we currently generate a proof problem's solution graph.

### Generating a proof problem's solution graph.

QEDX's **HPDIC** graph (Figure 1) is used to record all the valid proofs to a given problem. It includes **H**ypotheses, **P**roperties, **D**efinitions, **I**ntermediary results and a **C**onclusion. This graph is unique to each problem and is built from the inferences individually identified as true according to the problem to solve and the class context. The HPDIC graph for the *rectangle* problem in Figure 1 is fairly simple since it counts only 13 inferences. However, in the five problems implemented in the current QEDX version, one counts 214 inferences creating a much more complex HPDIC graph.

**Figure 1: HPDIC graph, *rectangle* problem that asks to prove that a quadrilateral with three right angle is a rectangle**

Needless to say, there is a great amount of prerequisite work to be done before a problem can be added to the system. Therefore, in order to expand QEDX's problem database, we need to, at least partially, automatically generate each problem's solution space. A rich problem database will allow the student to navigate a geometrical workspace made up of a sample of problems put together to help him or her overcome difficulties as well as exercise proving skills through personalized problem itineraries. However, since QEDX aims at adapting to every didactical contract (Brousseau, 1998) by expecting and recognizing proofs according to what the teacher of any given classroom would require, manually generating every valid solution becomes almost impossible. How can we take into account teaching traditions while maximizing our proof problem pool? This challenge will define the next steps in QEDX's design and development.

# Children's block-building: How do they express their knowledge of geometrical solids?

Susanne Wöller and Simone Reinhold

University of Leipzig, Germany, [susanne.woeller@uni-leipzig.de](mailto:susanne.woeller@uni-leipzig.de); [simone.reinhold@uni-leipzig.de](mailto:simone.reinhold@uni-leipzig.de)

*Keywords: Building of geometrical concepts, solids, construction activities, primary school.*

## Introduction

The main focus of the study is on primary students' concept knowledge about geometrical solids. In particular, we intend to detect the development of geometrical concept knowledge of Year 3, 4 and 5 students (aged 8 to 11). We investigate young children's knowledge of geometrical solids by providing wooden blocks in construction tasks: 52 third-graders (German and Malaysian children), 30 fourth-graders and 9 fifth-graders were asked to construct cuboids and cubes according to their knowledge and visualization. Results are interpreted according to the Van Hiele framework. In addition, we have a closer look on the variety of cube and cuboid constructions and raise conclusions concerning the development of children's conceptual knowledge.

## Theoretical framework

The customary conception of a *concept* comprises the "ideal representation of a class of objects, based on their common features" (Fischbein, 1993, p. 139). In this sense, *geometrical concepts* refer to common features of a class of geometrical shapes or solids which can be visualized or perceived when encountering concrete representatives. Typical representatives (prototypes) depict specific features of the class of geometrical figures in particular (Mitchelmore & White, 2000). Based on this notion, students' conceptual knowledge of geometrical solids reaches beyond the capability of correctly naming concrete representatives or giving a verbal definition. It rather comprehends the perception, visualization and identification of distinctive properties which refers to individual mental images students have while thinking of a specific solid (Tall & Vinner, 1981). The development of geometrical concept knowledge from primary to secondary has been described by the well-known Van Hiele Model which defines five levels of development (Van Hiele, 1986). Yet, most research which refers to the Van Hiele framework has been concerned about children's geometrical concept knowledge of 2-D shapes, whereas little is known about children's concepts of 3-D solids. Based on this theoretical framework, we assume that analyses of similarities and differences in individual construction processes and products of Year 3, 4 and 5 children provide deeper insights into children's visualization of geometrical solids, regarded to be a core element of geometry and mathematics education in primary schools.

## Research questions, methods and results

The results of the study are expected to contribute to a deeper understanding of the development of children's concept knowledge of geometrical solids at primary level.

- How do Year 3, 4 and 5 children (aged 8 to 11) articulate their conceptual knowledge of geometrical solids via construction activities with wooden blocks (cubes, cuboids, prisms and Froebel's Gift No 6)? Are these constructions in line with their verbal explanations?

- What kind of cuboids and cubes do they construct and which variations occur? Do they possess particular approaches in their activities?
- How can we interrelate these results to the Van Hiele framework and is there a necessity to enrich the *Model of Development of Conceptual Knowledge*?

We analyse the conceptual understanding, strategies and reasoning of Year 3, 4 and 5 children when observing and video-taping their construction activities of 3-D solids (cuboids and cubes) with wooden blocks. In a first step, German and Malaysian children were asked to explain their ideas and knowledge of geometrical solids in a short dialogue with the interviewer. Afterwards, a variety of tasks invited them to express their knowledge of cuboids and cubes via construction activities. During their constructions children were encouraged to describe their strategies. Data was coded with software support by *Atlas.ti*. A coding-guideline was developed mainly according to *Grounded Theory Methods* (Corbin & Strauss, 2015), trying to detect facets of articulating children's conceptual knowledge of geometrical solids and to relate our first results with the Van Hiele framework (Van Hiele, 1986).

Our results show an impressive variety of different types of constructed cuboids and cubes and of individual approaches, which indicate a wide variety in children's geometrical concept knowledge of the selected solids. Relating to cubes, most children focus on a square-base area during their constructions, some German and Malaysian third-graders only built one quadratic layer and name this a *cube*. Furthermore, we detected ambiguous mental images in children's concept knowledge concerning cubes. Relating to cuboids, our results illustrate the existence of prototypical representatives, e.g. convex constructions with various layers, followed by constructions only consisting of one layer. Furthermore, children's constructive activities can be (partly) interrelated to the Van Hiele framework, most children are at level of *Visualization* ("It's a cube because it looks like a cube."), resp. *Analysis* ("It's a cube because all surfaces are the same."). None of the children are in the phase of transition from *Analysis* to *Abstraction*, all children Year 3, 4 and 5 faced difficulties in realizing relationships between a cube and a cuboid.

## TWG05: Probability and statistics education

## **Introduction to the papers of TWG05: Probability and statistics education**

Corinne Hahn, *ESCP Europe* and LDAR-Université Paris Diderot; Daniel Frischemeier, *University of Paderborn*; Sibel Kazak, *Pamukkale University*; Aisling Leavy, *MIC- University of Limerick*; Caterina Primi, *University of Firenze*

### **Overview**

The working group gathered 30 participants from 15 countries. 22 papers and 4 posters were accepted.

The first session started with an ice-breaker activity. Firstly, the participants were asked to introduce themselves to a neighbor they had never met before. In a second time, each participant had to briefly present her/his colleague: her/his name, occupation, country and expectations about the working group. The cross-presentations made it possible to identify 3 main expectations. First researchers who attended TWG5 sought after constructive feedback on their work. Then they hoped to widen their point of view: gather new ideas, get informed of new trends, get to know better research works from other countries. The third main expectation was about networking: meet nice and smart people and develop possible collaborations.

The team of co-leaders had organized papers into 5 groups on 5 different topics. A session was devoted to each group and this session was managed and chaired by one of the co-leaders.

### **Teacher education (Aisling Leavy)**

This session explored a broad spectrum of research in teacher education pertaining to statistics. The presentation by Artego, Diaz-Levicoy and Batanero reported on a study of the competence of 140 Chilean primary school students levels in reading pictograms. Frischemeier and Biehler reported on the development of statistical literacy and thinking in a statistics course for elementary preservice teachers. Negotiating the content and the teaching of statistics during teachers' professional development was the focus of the presentation by Bakogianni. The research reported by Gokce and Kazak examined middle school mathematics teachers' pedagogical content knowledge in relation to statistical reasoning. Afeltra, Mellone, Romano & Tortora reported on the results of a study designed to support teachers' interpretative abilities and use of errors as a didactic resource.

Discussion focused on the following guiding questions: What are the important understandings that teachers/students need to develop? What experiences can we provide to promote and develop teacher understanding? What considerations should we take into account when designing tasks to assess statistical understandings? In what ways might current knowledge frameworks limit/support the identification of teacher knowledge?

When discussing the important understandings and knowledge that teachers need to develop, there was acknowledgement of the limited experiences of pre-service teachers in statistics and the limited space it receives in teacher education courses. The greater recognition in teacher education of the dual role of content knowledge and pedagogical content knowledge was welcomed. In moving forward there was the recommendation of the need to support teachers in developing awareness of

the features of good tasks so they can design and modify their own tasks to ensure maximal learning benefit for children. When discussing the considerations that need to be taken into account when designing tasks to assess understandings/knowledge, there was agreement that it is difficult to assess teacher knowledge when we are not entirely sure what knowledge is important in order to teach statistics. Thus, there is the need for more research that elaborates what it is that teachers need to know in order to teach effectively in their classrooms. Finally, when discussing the ways in which we can promote and develop teacher understanding, there was discussion around the importance of acknowledging what makes statistics unique (from mathematics). Consensus was also reached on the importance of task design is drawing attention to conceptual understanding, on the usefulness of focusing on children's responses (both errors/misconceptions and correct responses) and on the use of collaborative feedback is useful in revising understandings about teaching and learning statistics.

### **Informal statistical inference (Caterina Primi)**

Recently several researches effort are made to understand the informal ideas relating to statistics inference (ISI) as it is seen as having a potential to help build fundamental concepts that underlie formal statistic inference. Indeed, students can show complex ideas regarding statistical concepts (such as distribution, sampling) that can be seen as “precursor notions” of regular statistical concepts.

Four papers were presented on this topic. Leavy explores the informal inferential reasoning of primary students (5-6 years old). In Büscher's paper students' patterns of thought and the processes of their conventionalization are reconstructed in a qualitative study with students of grade 7 (12-14 years old). De Vetten shows the importance of preparing primary school teachers for teaching ISI, identifies learning goals for the teachers, and reports on an intervention study focusing on these learning goals. McLean's paper reports on students' modelling activities involving resampling process of bootstrapping.

In the final discussion emerged the importance of informal inferential reasoning in particularly how it should be promoted at every level (from early years upwards) as it is the beginning of access to a statistical cultural. Additionally, the group agree that Informal inference has an important socio-political contribution and may represent the first exposure to prediction and data-based inference. For this reason, the group has identified the need for national curricula and policy bodies to promote an emphasis on informal inference at the school level. As future directions, the group has identified the critical role of task design, language and technology in accessing understandings of inference, and finally the research of evidence of whether and how informal statistical inference improves the transition to formal statistical inference.

### **Probability and sampling (Sibel Kazak)**

Four papers were presented and discussed in the subtheme of probability and sampling. The paper by Paparistodemou, Meletiou-Mavrotheris and Vasou report on young students' ideas of randomness and expressions of probability of an event when designing their own games with the use of Scratch software. Silvestre and Sanchez examine high school students' reasoning while engaging with the idea of sampling distribution and the estimations of likelihood of outcomes in repeated random sampling by using Fathom software. Elicer and Carrasco explore the use of a

sequence of tasks designed based on the framework of didactical engineering to introduce conditional probability as a decision-making tool. Eichler, Vogel and Böcherer-Linder describe and compare the use of different visualization tools, such as unit square, tree diagram and 2x2 table for visualizing Bayesian situations that involve conditional probability and Bayes' rule. In the general discussion based on these papers the following issues were raised:

- Use of 'uncertainty' term instead of 'probability' to emphasize the link between probability and statistics and informal inferential reasoning.
- Current trend in teaching probability topics in higher grade levels in school mathematics curricula in different countries.
- Mismatch between emergence of probabilistic ideas in young students and how the school mathematics curricula are designed. Lack of focus on subjective probability in school.
- Role of representations in conditional probability situations and in decision-making. It was noted that there is no ultimate representation but variety of choices for different purposes.
- The need for attending to cognitive and non-cognitive components of learning both for teachers and for students of all ages (elementary through to college level).
- How to design tasks or activities in game-based environments like Scratch that will foster the development of statistical/probabilistic reasoning. By over stipulating the environment we may lose the affordances that the environment provides (i.e. openness, creativity).
- Use of technology in task-design and challenges in implementating such tasks in classrooms.
- Research (future directions): More research on ways of thinking about what children can do and more focus on philosophical perspectives in research are needed.

## **Technology (Daniel Frischemeier)**

This session explored in what ways technology can promote and develop statistical reasoning. In detail we got to know about the use of different technology tools like educational software, spreadsheets, online platforms (for distance learning), response tools, and programming tools in statistics education. Overall we have five papers in the session on technology.

Parzys reports on the use of spreadsheets to teach probability and introduces learning environments for French High school students to learn about the binomial distribution with spreadsheet software like Excel and discusses the potential and limitations of using spreadsheets when simulating random experiments and when shifting from discrete to continuous distributions. Serpe and Frassia present teaching examples to enhance the discussion on the meaning and interpretation of probability for higher secondary school students in Italy. In detail Serpe and Frassia show ways to implement programming for simulating chance experiments and introduce specific tasks (e.g., airplane task). In the article of Tacoma, Drijvers and Boon the reader gets to know about the potential of feedback devices and response tools in statistics education. Their research aims how students' models can be used to generate feedback in an online course on statistical sampling. The paper of van Dijke-Droogers, Drijvers and Tolboom describes a study which investigates ways to enhance grade 8 students' statistical literacy through within-class differentiation. The study is framed in a design-based research project and interventions like Digital Mathematics Environments and digital tools are used. Finally, Meletiou-Mavrotheris,

Paparistodemou and Bayes describe an online course about statistical methods for post-graduate education majors and point out prospects and considerations of distance education.

Two fundamental issues have arisen in the discussion at the end of the session regarding the learning and teaching with technology in statistics education: design issues (task design and design of learning environments) and also the role of technology in teacher education. Regarding the first aspect “design issues” two fundamental questions have arisen in the discussion process of the whole TWG5: How to support learners in their use of technology? How to concentrate on the content rather than on technical issues of the tool? Regarding the second aspect “technology in teacher education”, the group agreed that teachers need a solid technological knowledge (technological pedagogical content knowledge, TPCK) to be able to implement and orchestrate technology in statistics classrooms successfully. As future directions in the field of technology in statistics education the group has identified the potential of web-based applications, mobile devices and online learning systems for the learning and teaching of statistics.

### **Varia (Corinne Hahn)**

Five papers were gathered in a “varia” group as they covered issues that were not directly related to other subthemes. Arteaga and colleagues describe a large study carried out in Chile with 6<sup>th</sup> and 7<sup>th</sup> grades students. The aim of this study was to explore students’ competencies in reading pictograms. They report that the highest level they called “critical interpretation” is rarely reached by students. Gea and colleagues analyse correlation and regression problem situation in Spanish textbooks. Amazingly they report that there were very few problems with context. Trakulphadetkrai presents a qualitative study carried out with undergraduate students, with the aim of exploring how students learn statistical concepts through enactive story writing. Gonzales and Chitmun describe a socially open-ended problem in a sport related context and present the results of an exploratory study on the impact of one of these problems. Chiesi and Primi investigate how students’ attitudes changes during an introductory statistics course and discuss educational implications.

The general discussion at the end of this session focussed on the question of task design. We raised many questions, among which the following three have been particularly prominent:

- Can a problem be “real” or simply realistic or meaningful?
- What could be the most appropriate task for the statistic classroom: didactical situation, project work, inquiry-based activity, open problem?
- What is the role and impact of tools?

### **Conclusion**

In this working group, we challenged current frameworks and perspectives on statistics education research and some important issues emerged from the discussions. The participants agreed that we need to know more about:

- uncertainty in IIR,
- theoretical frameworks / philosophical frameworks for research purposes,
- childrens’ naive conceptions and how to build on them.

## Errors or didactic resources:

### A teacher education task in the context of probability

*In this paper we discuss a teacher education task centred on the request to interpret the reasoning of students addressing a ‘throw of the dice’ task. The task for teachers was designed after an analysis of class excerpts, carefully selected by our research group because of the interesting educational reflections to which they gave rise. The goal of the task is to support prospective teachers to develop interpretive ability in order to use errors as a didactic resource and to help students build their mathematical knowledge starting from their reasoning.*

*Keywords: Probability, teacher education, task design.*

### Introduction

In the framework of PISA 2015 the domain “Uncertainty and Data” is put at the core of the mathematical cultural experience. Items about this topic are, by now, present in all the national assessment tests and the bad students’ results to these items, both in national and international tests, put in evidence the need to improve the teaching of Probability and Statistics in school. But this request, as is often the case, is not adequately satisfied, at least in Italy, by a specific plan of teacher education.

Many studies (see, e.g., Batanero, Godino & Roa, 2004) have highlighted that teachers do show interest for this topic but, at the same time, declare to feel a lack of knowledge and experience in it. Indeed, on one side probability was not included in school curricula until a few years ago, and, on the other side, many teachers, even with a Master Degree in Mathematics, did not take the exams of Probability or Statistics in their plan of studies, as in the past it was an optional exam. Nevertheless, it is well known that the success of any educational design aimed at developing students’ knowledge and skills in Probability, as well as for any other topic, depends in great part on teachers’ knowledge and attitude toward the topic itself.

In this study, we refer to Mathematical Knowledge for Teaching (MKT) framework that serves as a resource for specifically addressing the mathematical demands of teaching (Ball, Thames & Phelps, 2008). More and more researches all around the world are demonstrating the effectiveness of this frame for teacher education.

Several studies (Tversky & Kahneman, 1974; Jones, Langrall & Mooney, 2007), starting from the fact that situations of uncertainty are widely present in daily life, show that very often the common sense or the experience linked to gamble can conflict with the mathematical management of the situation. For this reason we think that it is crucial to design practices of teacher education in this topic which take into account students’ answers and look at them as didactic resources (Borasi,

1994), even when these answers seem to be in conflict with the formalization goal of the educational design.

In this paper we discuss a particular teacher education task in teaching Probability. Its design and implementation is rooted in the “modus operandi” of our research team, in which university researchers, in-service school teachers and Master students are involved as a co-learning community throughout an inquire research experience (e.g., Jaworski & Goodchild, 2006). We will explain the rationale that guided us in the choices of some transcripts of classroom discussions, used to design a task for in-service teachers that, in our opinion, should be considered the final product of a long training path and an effective tool to develop their interpretive skills. Finally, we try to answer to the question whether this particular type of task could be used also with perspective teachers, in order to scale up the reflections and the outcomes developed in our co-learning community.

## Theoretical framework

Teacher knowledge and, in a broader sense, teachers’ attitudes and goals, play a key role in any effort of educational innovation. Among the different conceptualizations of teacher knowledge, the MKT effectively describes the particular features of mathematical knowledge needed for teaching (Ball, et al., 2008). In particular, many studies underline that, in order to improve the teaching of Probability, it is crucial to support teachers’ training not only in the Common Content Knowledge (CCK), subdomain of MKT, i.e. the general knowledge of a math topic, but also in terms of the Specialized Content Knowledge (SCK), that is the knowledge about the topic specifically connected with its teaching. However, to develop SCK in the context of Probability, different aspects need to be taken into account (see, e.g., Ponte, 2008): i) epistemological reflections on the meaning of concepts (e.g., different meanings of probability); ii) awareness of the closed connections between probabilistic and statistical issues; iii) students’ learning difficulties, errors, obstacles and counterintuitive ideas in this field; iv) necessity to plan assessment tests and instruments for interpreting students’ responses.

In this study, we focus on the third point of the previous list, looking at errors and non-standard reasoning not as something to avoid but rather as a source to be capitalized, that really shapes the dynamics in mathematics educational process (Borasi, 1996). Indeed, in our perspective, one of the main task for a mathematics teacher is to grasp the “meaning” of students’ answers, in order to develop their mathematical knowledge starting from students’ reasoning.

This aspect is even more crucial in Probability than in other fields, considering that all the typical technical terms (probable, possible, random, event) are widespread common words. The epistemological consequent conflict can be faced only if teachers get aware that, according to Borasi (1996), ambiguities, in particular linguistic ones, can play a useful role in the development of mathematics learning. This peculiarity makes students, and, sometimes also teachers, more susceptible to counterintuitive ideas, which, in addition, arise in Probability already at an early level, more than in other branches of mathematics (Borovcnik & Peard, 1996).

We are firmly convinced that improving students’ mathematical knowledge on the basis of their arguments, even when they seem naïve, requires that teachers activate a real process of interpretation, shifting from an *evaluative listening* to a more flexible *hermeneutic* listening (Davis,

1997). In this peculiar field, the wrong answers of students often arise from well-known misconceptions (Ang & Shahrill, 2014), the same ones that afflict teachers, even in service, as discussed in (Batanero, Godino & Cañizares, 2005). According with this vision, we have proposed a design of tasks to develop teachers' SCK, specifically addressed to support them in making didactic choices fit to develop students' mathematical knowledge, starting from their reasoning (Ribeiro, Mellone Jakobsen, 2016). The tasks we have designed address the difficulties encountered by students in coordinating the classic and frequentist approaches to probability, above all with respect to the representativeness of the sample, and in recognizing the notion of equiprobability as a basic aspect of any probabilistic judgement. These tasks come as a final result of a training path in our research group, with the aim to enhance teachers' professional development. But, after experiencing the task within our community, we also decided to propose a similar task for teachers' learning, because we agree with (Robutti et al., 2016) that it is necessary to scale up the significant experienced practices for teacher professional development.

## Methodology

The particular task we are going to present was developed during the meetings of our research group. In the last two years, our group have been working as a co-learning community, where educators :

(...) create opportunity to work with teachers, to ask questions and to see common purposes in using inquiry approaches that bring both groups closer in thinking about and improving mathematics teaching and learning. (Jaworski & Goodchild, 2006, p. 354)

This group is composed by five university researchers (two in mathematics education and two in physics education), fifteen in-service teachers with a long experience (one kindergarten teacher, five teachers from primary school, two from first order secondary school and 7 from second order secondary school), and some Master students in Mathematics or Education who have been working in their master thesis with us. Most of the teachers have been collaborating with the researchers since 2004, some were also involved in a three-year project (PDTR, Professional Development of Teacher-Researchers, [www.pdtr.eu](http://www.pdtr.eu)), financed by the European Community, aiming at “engaging classroom teachers of mathematics in the process of systematic, research-based transformation of their classroom practice” (Malara & Tortora, 2009 for the Italian contribution). It is worthwhile to say that we have found several similarities with the method of work of the mathematics learning communities in Norway described in (Robutti et al., 2016).

In the last two years, we decided to start a reflection about Probability and we used to meet once a month for three hours at the Department of Mathematics of the University of Naples. The training path was divided into two parts. Firstly, we organized several theoretic seminars on the epistemological bases of Probability, the connections between Probability and Statistics and on the necessity to enhance the study of Probability at school. Secondly, our meetings were devoted to plan didactic activities in Probability, from primary to secondary school. Each teacher had the possibility to adapt the didactic paths to his/her school level according with the national curricula. Successively, the teachers were asked to illustrate the outcomes of the didactic activities in their classrooms, sharing with the community audio and video recordings of class discussions, and samples of students' productions.

In this paper, we focus on some excerpts of the discussions occurred in Piera's (one of the author of this paper, and expert secondary teacher of the group) classroom of 10<sup>th</sup> grade students.

The class discussions were registered and transcribed thanks to the help of Laura (another author of the paper) who have been working to her Master Degree Thesis in Mathematics on the experimental educational activities on Probability, carried out in Piera's classes (Afeltra, 2015). Piera had already involved her two 10<sup>th</sup> level classes in inquiry based activities about descriptive statistics and her students were quite used to discuss each other, in order to deepen their understanding of what they were asked to study. The didactic path had been planned in the learning community with the aim to check if her students would have evidenced the predicted difficulties, also considering that most of them had studied the early elements of Probability in the previous years, often with a formula based approach. Among the others, we selected those class excerpts that gave rise to deep discussions during our meetings, about the possible interpretation of students' answers, as we will illustrate in the following. In order to mobilize teachers' SCK, we focused our attention on the following two frequent students' errors: to view different outcomes of an event as always equally likely (within a classic approach to Probability); and to consider a too small sample as representative to estimate the probability (within a frequentist approach).

These excerpts had a significant impact on the professional development of all in-service teachers, since most teachers, with a master degree in mathematics, seemed not able to act as students, because of a clear prevalence of their CCK on the SCK, necessary to predict students' learning difficulties. In our learning community, Piera's classroom excerpts were considered particularly interesting to be used for a pre service teachers' training activities, as they show, even on a small sample, that these misconceptions are a common way of thinking, so a teacher has to be ready to appreciate the opportunity to transform a wrong answer into a challenging one.

## **A teacher education task**

In the following, we present the teacher education task based on excerpts of a class discussion on the game of tossing two dice, indeed, a very rich and complex context, in spite of its apparent simplicity. In fact, it is one of the typical contexts used to introduce Statistics and Probability, nevertheless several research studies show that both students and teachers can run into counterintuitive ideas about the representativeness of the sample, when rolling one die, and about the item of equiprobability, when playing with two dice (see, e.g. Batanero et al., 2005). Moreover, this context offers many interesting experiences involving the necessity to handle at the same time different approaches to Probability. It is necessary that students become aware of the intrinsic limits of the two approaches: in the classical case, it may be all but easy to identify all the possible equally probable cases, whilst in the frequentist approach it may be not possible to repeat a large number of trials at the same conditions. On the other hand, students who have already studied some elements of Probability in their previous scholar levels can get quite confused about the probability of an event, when they may calculate it in two different ways, for example when playing with dice, but with a small sample. Indeed, the game with dice, as all kinds of gamble, allows to introduce the Law of the Large Numbers in a significant way.

The task is organized as a questionnaire composed of three items, two of them centred on class discussion's excerpts. In the following, we comment on each item, and, in particular, on the class

excerpt, to illustrate the reasons why we consider them meaningful to be interpreted and interesting from the teacher education's point of view.

### Item 1

Read and analyse the following class excerpt.

Teacher: Playing with one die, how can we measure the probability of each side?

Daniele: There is no favourite side, so for each of them the probability is  $1/6$ .

Federica: But rolling the die, we have got five 8 times over a total of 63. So the probability is 8 over 63, that is approximately 0,127.

Daniele: One sixth is 0,167, they are not the same!

Federica: Yes, we can use both definitions... but we have studied that in this case it is certainly one sixth!

- a) For each students' answer discuss if, in your opinion, it is mathematically correct or not;
- b) Plan a suitable didactic action to develop students' learning, starting from their answers.

We consider this excerpt as a good starting point to discuss the link between the classic approach and the frequentist one to Probability. The transcript shows that Federica is firmly convinced that the classical definition of Probability is prevalent over the frequentist approach. On the other hand, the play with one die is a very well known situation, and the "a priori" probability is so simple and evident that Federica's answer is quite "reasonable". In our opinion, the thought-provoking thing is her absolute indifference to the value of the relative frequency obtained as the result of rolling the die several times. Many speculations are possible: Federica's certainty can come from a previous formula-based approach to probability, experienced in previous years, or, instead, from the awareness that the frequentist definition needs a large number of data. In both cases, the item allows to reflect on the necessity that teachers clarify the question with their students. Moreover, it shows the importance to involve students in activities of data collection, which gives the chance to significantly introduce the Law of Large Numbers, also, maybe, with the aid of a digital simulator, to work with large samples.

### Item 2

During a lesson on Probability, a teacher submits to his/her students the following question: "When two dice are simultaneously thrown, what are the chances of obtaining 7 as the sum of the two sides up?"

- a) Answer the question, as you are able to do; b) Which possible answers, correct or not, in your opinion, will be given by students? c) Discuss about the possible difficulties that, in your opinion, a student will encounter when addressing this question.

The first item of the task aims to put teachers at the place of students. The whole task involves teachers in a brainstorming activity, mobilizing their CCK about the topic. In this way, teachers can recognize a didactic obstacle, and, consequently, realize the need to design an educational path to face it. Moreover, in the following item, the teachers can confront their own answers with those given by the students.

### Item 3

In the following excerpt it is reported a discussion between a teacher and his/her students about the previous question.

Teacher: When two dice are simultaneously thrown, what are the chances of obtaining 7 as sum of the two numbers?

Gianluigi: There are 11 possible sums, from 2 to 12, so the probability is  $1/11$ .

Ludovica: No, it would be true if we used a die with 11 sides. We have to consider all the possible couples, such as one and one, one and two and so on.

Teacher: Ok. And then, how many?

Students work in groups for a while until one of them affirms:

Massimo: There are 21 possible couples.

- a) For each students' answer, discuss if, in your opinion, it is mathematically correct or not;
- b) Identify a set of possible questions that you would pose to students to support them their learning process.

According to the classic definition of probability, Gianluigi's answer has to be considered wrong, since the 11 values of the sum are not equally likely. But Gianluigi's answer opens up the reflection about the difference between the sample space and the possible cases. The transcripts were enlightening for most teachers in our community. Even Piera, one of the author, witnessed that, in the previous years, on the basis of her CCK only, she would have rejected this answer, immediately underlining that the eleven possible outcomes are not equally possible. In the light of the reflections previously made in our community, this time she rather decided to give space to the classroom discussion. Moreover, Ludovica smartly refers to another context, where 11 would have been the correct answer, and this seems to us a significant process to support the construction of meaning, above all because it arose from students.

Even Massimo's answer, which is caused by the common belief that, throwing two dices, the order is not relevant (see, e.g., Batanero et al., 2005), is wrong but interesting. Indeed, we have selected this excerpt because, in our meetings, it triggered many discussions about the didactic choice, for example, to use or not dice of different colours, in order to avoid this error. Finally, we agreed on the opportunity to use dice of the same colours in order to open up the possibility that reasoning as Massimo's one emerge.. In this way, a teacher has the possibility to ask students to look for contexts different from the dice game, where the order turns to be relevant. In our meetings, many ideas were proposed: the most popular examples were contexts of sport competitions, while a more sophisticated context could be the Bose–Einstein statistics. Only on the basis of her learning's development, due to the participation in our co-learning community, the teacher was able to guide her students in finding a possible context in which Massimo's answer could be correct, activating in this way an hermeneutic listening (Davis, 1997) Her actions helped students not only to better understand the crucial role of equiprobability, but also to describe mathematical models and formulate hypotheses about them.

## Conclusions

For several years researchers in probability education have been investigating the counterintuitive ideas arising when people formulate judgements in real situations involving uncertainty (Tversky & Kahneman, 1974). These ideas are often in conflict with the mathematical formalization of Probability, so they can cause, if not recognized, paradoxical results. It is widely known that a correct probabilistic reasoning needs a specific instruction (Fischbein, 1975), therefore, it is fundamental that a teacher is able to use students' intuitions, their counterintuitive answers or incorrect reasoning as resources for learning (Borasi, 1994). We think that this work is particularly useful for Probability, even more than for other mathematics topics, since, in this field, widespread counterintuitive ideas arise from many daily situations.

Our research group has been working as a co-learning community (Jaworski & Goodchild, 2006), where the professional development of all the participants was enhanced throughout inquiry activities, in order to improve learning from experience and reflection. In this paper we have focused on the process which led us to design a teacher education task, starting from the analysis of excerpts of classroom activities. We selected the excerpts most challenging to be converted in interpretative tasks for teacher training, with the aim to improve teachers' SCK about some crucial notions of Probability. The deep impact observed on the Math teachers of our community encourages us to redesign a similar path to be used for teacher training on a larger scale, as an attempt to face the issue of dissemination of the significant practices experienced in a co-learning community, as described in (Robutti et al., 2016). In this direction many questions are still open, and need further investigation. However, we are just now exploring the real effectiveness of this types of task with in-service and perspective teachers, their difficulties and limits.

# Negotiating the content and the teaching of statistics: Two complementary processes in teachers' professional development

Dionysia Bakogianni

National and Kapodistrian University of Athens, Greece; [dbakogianni@math.uoa.gr](mailto:dbakogianni@math.uoa.gr)

*This study builds on Wenger's (1998) notion of meaning as the essence of a practice and the process of negotiation of meaning as determinant in the development of a practice. Following an emerging community of 11 secondary mathematics teachers, I aim at exploring the interactions between two dominant processes in teachers' work, the negotiation of the statistical content and the negotiation of the teaching of statistics. The results indicate that the two processes act complementarily in the formation of the practice of the community and consequently in the professional development of the teachers. Evidence of how the one provides feedback and meaning to the other is also illustrated and discussed.*

*Keywords: Community of practice, mathematics teachers, teaching and learning of statistics.*

## Introduction

The development of teacher education programs that aim to support teachers to promote statistical inquiry in their classroom, is gaining an increasing attention the last years in statistics education community. This current discourse emphasizes the importance of offering teachers opportunities to experience as learners statistical investigations (Makar & Fielding-Wells, 2011), and nominates the significance of teachers' engagement with inquiry in the teaching (Shaughnessy, 2014). A further approach suggests combining experiences in teacher education, namely as learners and as teachers, and provide evidence that this combination can help teachers not only to strengthen their statistical content knowledge but also to be able to transfer their understanding to the classroom (Heaton & Mickelson, 2002). Although the complementarity of teachers' experiences as both learners and teachers seems to be crucial in teacher's professional development, we still know very little on how these two types of experience interact and provide feedback to one another.

In this study I explore the interplay between the process of negotiating the content of statistics (NCS) and the process of negotiating the teaching of statistics (NTS) in the professional development of teachers. Particularly, I followed a group of 11 secondary mathematics teachers who worked collaboratively in an emerging Community of Practice (CoP) (Wenger, 1998) to develop the statistics teaching practice. During their work in this community, the teachers had the opportunity to engage in tasks that promote negotiation of meaning in both the content and the teaching of statistics, and so they participated as both teachers and learners. The research question that guides this exploration is the following:

How do negotiation of the content of statistics and negotiation of the teaching of statistics interact and provide meaning to each other in the context of a Community of Practice?

## Theoretical perspectives

In this study, I view the teaching of statistics from a *statistical thinking* point of view (Wild & Pfannkuch, 1999) which sets inquiry at the core of statistical teaching and learning and highlights both the specificities and the complementarity between statistics, probability and mathematics. I focus

on three dimensions related to statistics teaching practice. The first dimension is the *learning potentials* which refer to particular skills, abilities and knowledge that are connected to the statistical activity, e.g. that students are expected to understand and deepen in the fundamental statistical ideas (Burrill & Biehler, 2011) or that they need to be able to use and evaluate appropriate statistical tools and methods in order to analyze data (e.g. Franklin et.al., 2005). The second dimension is the *features*, namely instructional tools and strategies that seem to be crucial in supporting students to achieve the defined *learning potentials*. Examples of features are students' engagement in statistical investigations (MacGillivray & Pereira-Mendoza, 2011) or the use of dynamic software tools that support data explorations (Ben-Zvi, 2006). The third dimension is *resources*. The variety of the resources that are brought into the teaching of statistics constitutes a dynamic ground where teachers can build and form their practice. In my view of resources I adopt Adler's (2000) conceptualization which extends beyond material resources (e.g. software tools, physical objects, media extracts, real data sets) to include human resources (e.g. previous experiences, collaboration with colleagues, knowledge about concepts and procedures) and cultural resources (e.g. time, classroom habits).

In my view to practice, I use the lens of the social theory of learning (Wenger, 1998) which theorizes learning in practice through four components: *meaning* (the way we experience our life and the world as meaningful), *practice* (shared historical and social resources and actions), *community* (social configurations to which we belong) and *identity* (personal histories of becoming). In the social theory of learning, practice is about both action and interpretation of the action, and meaning is the essence of a practice and it is situated in the process of *negotiation of meaning*. In this study, I acknowledge two types of meaning that is negotiated in the CoP, the meaning related to the content of statistics where the teachers participate as learners in the negotiation, and the meaning related to the teaching of statistics where the teachers participate as teachers in the negotiation. The study of the interaction between the process of NCS and the process of NTS aims to get insight on how NCS can provide meaning for NTS and vice versa. Especially in the case of teaching statistics where the mathematics teachers are challenged with a content that they are not familiar with (Hannigan et.al., 2013) and which contains epistemological differences from the mathematics content they teach (Moore & Cobb, 2000), such insights could be rather helpful for the research in statistics teachers' professional development.

## Methodology

To achieve my research goal I followed an exploratory case study methodology (Yin, 2003), where the case was a group of 11 secondary school mathematics teachers, 5 practicing (Akis, Dinos, Kimon, Lidea, Marcos) with 8-30 years of teaching experience and 6 prospective (Athina, Chloe, Eva, Lia, Ria, Sofi). All teachers were mathematics graduates and also graduates or senior students in a Master's program in Mathematics Education with no particular familiarity with the teaching and learning of statistics and with a varied background in statistics. This group was gathered in a voluntary basis and worked collectively for two years (2012-2013 and 2013-2014 academic years) in a regular base (about 2 meetings per month that lasted approximately two and a half hours each). Two researchers were also participants (the author-R1 and the supervisor of the study-R2) encouraging the active participation of the teachers, providing various resources, finalizing each meeting's agenda and challenging teachers to reflect on their experiences. The main agenda of the meetings was formed around a cyclic route of: (a) inquiring the content of statistics, (b) designing for their classroom (c)

implementing the designed tasks in their classroom and (d) reflecting on their practice. I considered this group as an emerging Community of Practice (Wenger, 1998) by encouraging the development of mutual engagement, joint enterprise and shared repertoire. This paper is based on the data of a full cycle (inquire the content, design teaching, teach the planning lesson and reflect on it) which covered 10 of the total of 12 meetings in the first academic year.

All meetings were audio and video recorded and the group discussions were fully transcribed. Semi-structured individual interviews at the beginning and at the end of the study were also conducted. Another source of data was teachers' journals regarding issues they considered as central in each meeting. Although these reports were not a complete source of data, they often constituted a useful source of triangulation in order to corroborate the study's findings.

The analysis of the data was based on a grounded theory perspective using the ATLAS.ti software. During the coding process I used as unit of analysis the task that the teachers were engaged in. In each task I distinguished NCS and NTS parts in which I assigned *features*, *learning potentials* and *resources* that were visible in teachers' discussions. In Table 1 I present an example of the process we followed. Last, in a second level I focused on identifying how the negotiation of each type of meaning was mobilized as well as exploring interactions among the negotiation of the two types.

Negotiating the content (extract from the 2nd meeting)	Features	Learning Potentials	Resources
<p>Akis: Now, I couldn't understand this very well. As Fischbein mentioned in his article it is the concept of proportionality behind this. He said that we still use proportionality in order to make a conclusion instead of using the <b>Low of Large Numbers</b>.</p> <p>Lidea: An what is this Low of Large Numbers?</p> <p>Ria: It is when something is repeated many times, then it approaches the <b>theoretical probability</b>.</p> <p>Marcos: It is what we say to estimate the probability through the <b>relative frequency</b>. We then consider the probability as the number of the favorable cases to the total number of the cases, when we repeat this many times and the number of times tends to infinity etc. So let me explain what we have here. You have a small and a big hospital and you get a <b>sample</b> from each one, I think that this has to do with the <b>variability</b>, I mean practically it is like you have a small and a big sample, which one do you expect to be more accurate? More <b>representative</b> with regard to the theoretical probability. It is the small sample or the big sample? It is the big. This is the case with the big hospital, because in the big hospital the births will be closer to the <b>mean value</b>, while in the small hospital you will have large variability.</p> <p>Lidea: But I still can get why the small one is the right answer in this task?</p> <p>Marcos: Wait a moment. What is the question in this task? It asks in which hospital it is more likely to have more such days.</p> <p>Akis: Is it possible that I may didn't <b>translate</b> it correctly?</p> <p>Lidea: No Akis, it is absolutely correct. I translated it with exactly the same way. But I can't understand why. When he says 'such days'...</p> <p>Dinos: (talking to R1) Do you remember the <b>example</b> you had discussed with us (he means sometime in the past). The one that says that the half of the newborn children are boys. This is very similar and more comprehensible. <b>Maybe you could show us this one.</b></p> <p>(R1 goes to the <b>computer</b> and <b>projects</b> the task mentioned by Dinos, they continued to discuss the <b>task</b> using the <b>projector</b> and the <b>blackboard</b>)</p>	<p>Engagement with an inquiring task</p> <p>Plenary discussions and negotiations (as experienced by the teachers)</p>	<p>Connect to probability ideas</p> <p>Deepen on sampling notions</p> <p>Appreciate variability</p>	<p>Educational research (Fischbein's article)</p> <p>Mathematical tools (proportionality, Law of Large Numbers, theoretical probability)</p> <p>Statistical tools (relative frequency, sample, mean value, variability)</p> <p>Cultural tools (language)</p> <p>Human (collective experiences, difficulties)</p> <p>Material (computer, projector, blackboard)</p>

**Table 1: Example of the data analysis where the teachers were discussing the 5th problem presented on Fischbein & Schnarch's article (Fischbein & Schnarch, 1997)**

## Results

In Figure 1 I present the various tasks that the teachers were engaged in during the 10 meetings. As we can see, there were tasks oriented to encourage negotiations in the content of statistics (e.g. exploration of statistical tasks/situations), tasks that aimed at negotiating the teaching of statistics (e.g. design for the classroom, reflection on the teaching) and tasks that had the potentiality to immobilize negotiations in both types of meaning. However, as we can see in Figure 2 the realized negotiations indicate that the interaction between NCS and NTS was not only a function of the nature

of the task. This is especially obvious in the case of the design for the classroom tasks, where a quite large part of teachers' discussion was related to NCS.

**Figure 1: General description of the meetings agenda**

### How NCS provides meaning to NTS

The analysis of the data showed that NCS was mobilized by the teachers' need to understand better or deepen in a statistical concept or process. In the extract presented in Table 1 above, the teachers were discussing students' false intuitions with regard to the effect of sample size while Akis' intervention mobilized a negotiation of meaning related to sample notions and the Law of Large Numbers. This episode was expanded and lasted for about 10 minutes during which the teachers together with R1 exchanged arguments and utilized various resources that aimed to deepen their understandings around these notions. This discussion helped teachers not only to deepen their content knowledge but also to negotiate new difficulties that they had (making connections with particular knowledge and abilities required to gain meaning, namely the learning potentials) and means that helped them to overcome these difficulties (namely the features that can facilitate these learning potentials). In other words, they had the opportunity to incorporate their NCS experience into their teaching practice. Akis notes in his meeting report are indicative of how NCS provided meaning for the teaching practice: "What I observed is that our beliefs and our attitudes towards probability and statistics are very close to those of students, I mean we are guided by an intuitive way of thinking. If we want our students to adopt a more inquiring stance, we first need to give them appropriate tools to overcome their intuitions. I think that the way we discussed in the meeting, revealing our misconceptions and resolving them could be a good model for our teaching".

**Figure 2: Alternations in the content of negotiation in the various meetings**

Moreover, NCS was also mobilized by teachers' need to gain experiences with data. This was the case for example in the 6th meeting, where the group conducted a pilot study for an experiment that was designed for the students by a team of five teachers. Particularly, in this experiment the students were supposed to investigate if listening to music affects their ability to recall words. The teachers designed the experiment and before they implemented it in the classroom they collected data inside the group, explored the data, made conclusions and thought of possible modifications in the

experiment's design. In this sense the NCS helped teachers to acquire experience and confidence regarding the implementation of the designed activity. The words of Dinos in his final interview are characteristic: "this interaction gives you the impression that this (he means the task) will be considered by many couples of eyes, by many views. I mean especially in statistics where you can never acknowledge all the possible parameters,... it is not that you will learn something new, it is that it helps to illuminate other dimensions that you may have neglected at first".

Furthermore, in many cases the teachers transferred directly their experience as learners to their teaching practice. For instance, in the 6<sup>th</sup> meeting Dinos used an example to help his colleagues to understand the notion of the standard deviation in the estimation of a probability. Later in the discussion, Dinos suggested using the same example in the classroom and the others responded:

Sofi:                So you suggest using the same example with the students. I like it. Actually it helped me to understand so it would be also helpful for students to understand.

Athina/Chloe: Yes, I agree too.

Last, as can be seen in the examples discussed above, it is also the general context of their enterprise, namely the community of statistics teaching practice, that mobilized them to analyze their NCS experience in terms of identifying learning potentials that could be supported in the classroom, features that could support these learning potentials and resources that could facilitate students in the learning process.

### **How NTS provides meaning to NCS**

Apart from the nature of the task, NTS was mainly mobilized due to a question posed by one of the researchers, such as "Would you use such a task in your classroom and if yes how?" or "What do you think a student can gain from the experience of such a task?". Such questions encouraged teachers to extend their experience as learners to start a negotiation of meaning around the teaching and learning. The extract below is from the 3<sup>rd</sup> meeting when teachers discussed a statistical task and illustrates how such NTS was mobilized.

R1:                What difficulties can someone face in the classroom with this task? Would you try to implement such a task? If yes, then how and with what goal?

Kimon:           I could try it with 12<sup>th</sup> Grade students not with younger ones.

Dinos:           I could do this with young students as well, with 8<sup>th</sup> Grade students for example.

Lia:                I agree with Dinos. I think this would be useful in the formation of their attitudes towards probabilistic ideas. In 12<sup>th</sup> Grade level they have already formed quite formal conceptions.

Dinos:           But the point is what modifications we can do.

This discussion for which the starting point was the question posed by R1, continued for about 30 minutes during which the teachers exchanged views and suggestions, referred to specific learning potentials, discussed potential features that could serve their goals and utilized or suggested resources (e.g. use of statistical tools / suggestion to include in their study all the students in the school instead of the students in the classroom) that could facilitate the learning process with regard to the defined learning potentials. In this way, teachers extended their NCS experience to consider aspects of

teaching and learning and to connect the statistical objects they negotiated with features, learning potentials and resources that broaden their view towards these objects.

Another example is the case where, during NTS, the teachers or the researchers asked for clarifications regarding particular teaching decisions or suggestions. In this way teachers reconsidered their choices and developed a deeper understanding on the underlying concepts or possible conceptual connections. The following example, from the 7<sup>th</sup> meeting, is indicative of this case. In this extract Marcos was trying to explain his choice to use mean values instead of median when students study the difference in our ability to recall words and no words.

R1: Marcos, why did you choose to use the mean values here?

Marcos: It actually depends on what you want to see.

Chloe: And what about you? What do you want to see?

Marcos: Look. It is true that with the median is easier to manage the results, I mean it could be easier to find subsets that can give a difference on median that is so big or bigger than the one we get. But on the other hand... What if the difference is small, like here? If I was to choose from a students' perspective, I would choose the median, but not with a very small difference. I mean maybe there are other parameters that result in such a small difference. I am not sure what I would say to students for a very small difference.

This episode continued and lasted for about 4 minutes during which Marcos developed arguments to explain his choice. In this way, Marcos got insight not only in his didactical choice but also in the role of the mean value and the median in the study of differences between two variables. Such an inquiry, although it refers to NTS, was also helpful in illustrating statistical concepts and thus provided meaning to NCS as well. Almost all the teachers of our study, in their final interviews, referred to the positive impact of their inquiry in teaching on their content knowledge. This was either because they were facilitated by their colleagues or the researchers' examples and explanations or because of their attempt to help or convince their colleagues, which guided them to develop appropriate examples or arguments and thus helped them to deepen in their own understandings. In both cases, the context of the CoP which encouraged the collaboration among them played a determinant role on this interaction. Below, we present two characteristic extracts from the final interviews.

I feel I gained a lot, especially as a learner. You see, the concepts we decided to work with in the classroom were blurred for me, too. It was mainly Dinos' examples and explanations that helped me to understand first these concepts and consequently what we were going to do with the students. (Chloe, final interview)

These discussions helped me to develop a deeper awareness of many issues. I mean, when you are trying to take a stand towards an issue or a particular decision, it helps you either to get a more clear position, by developing a deeper understanding or to consider new views or aspects that were out of your attention. (Marcos, final interview)

## Conclusion

This study aimed at getting insight into the interaction of NCS and NTS in the context of a CoP. The results showed that both processes were mobilized either by the nature of the task itself or by reasons that are related to the teachers' needs and the context of their work inside the CoP. Moreover, we saw that NCS process, apart from teachers' content knowledge, helped them to enrich their teaching repertoire (appreciate learning potentials, explore features, get access to new resources) as well as to strengthen their confidence in handling particular statistical concepts inside the classroom. Similarly, NTS process, apart from a space for inquiring teaching and learning, was also a starting point for the teachers to develop deeper understanding on statistical content, to make conceptual connections and to acknowledge different dimensions of the underlying problem. These results go beyond the work of Heaton & Mickelson (2002), which shows the importance of the complementarity of the two processes in the professional development of teachers, to give empirical evidence of how the one process provide feedback and meaning to the other. Moreover, the collaborative context of a CoP acted supportively in the interactions between them. Thus, such a context, that fosters the co-existence of NCS and NTS, seem to help teachers not only to experience statistics as learners, but also to link this experience with classroom reality.

Last, this complementarity and feedback are especially important to the professional development in the case of statistics since the stochastic nature of the content on the one hand, and the unfamiliarity of teachers with the statistical tools on the other hand, constitute factors that, as we saw, reinforce the interactions between NCS and NTS.

## Acknowledgment

This research was supported by the Special Account for Research Grants of the National and Kapodistrian University of Athens (70/3/13297). My special thanks to my supervisor and invaluable discussant in this study Prof. Despina Potari.

# Common patterns of thought and statistics: Accessing variability through the typical

Christian Büscher

TU Dortmund University, Germany; [christian.buescher@math.tu-dortmund.de](mailto:christian.buescher@math.tu-dortmund.de)

*Allowing students to construct meanings of statistical concepts like variability requires building on their individual experiences. The notion of patterns of thought is utilized to conceptualize the difference between formal statistics and learners' initial thinking and to describe a pathway to bridge this gap between individual and mathematical thinking. Students' patterns of thought and the processes of their conventionalization are reconstructed in a qualitative study with  $n = 10$  students of grade 7. An outlook is given on the possibility of connecting students' patterns of thought with formal statistics.*

*Keywords: Informal inferential reasoning, design research, concept development.*

## Introduction

One of the aims of statistics education is to foster informal inferential reasoning (IIR), the ability and disposition to use data in order to reason about some wider universe (Makar, Bakker, & Ben-Zvi, 2011). In IIR, statistical concepts are combined with contextual knowledge under certain statistical norms and habits, such as a “critical stance towards data” (see Makar et al., 2011 for a more thorough overview). While the framework of IIR can explain the *role* of statistical concepts in producing informal statistical inferences (ISI, see Makar & Rubin, 2009), it does not account for the *development* of statistical concepts. Accordingly, there exists a lack of research concerning statistical concept development of students with little experience in statistics. Tracking of the development of concepts, Bakker and Derry (2011) draw on the background theory of inferentialism, linking students' emerging concepts in inferential practices with IIR. Looking at the micro level of students' reasoning processes, Bakker and Derry argue that students can show complex ideas regarding statistical concepts such as center, variation, distribution, and sampling. These ideas are not formally articulated, but can rather be seen as “precursor notions” of regular statistical concepts (Bakker & Derry, 2011, p. 20).

These precursor notions could provide a promising basis for the development of more formal statistical reasoning. The challenge remains however to design tasks that draw on these precursor notions in order to foster students with little prior experience in formal statistics. These tasks need to draw on students' individual ways of reasoning as a resource in order to develop statistical concepts meaningful to the students. This requires paying careful attention to students' learning processes, and to uncover the links between formal statistical concepts and students' everyday thinking. This study aims at reconstructing students' individual ways of thinking on a micro level in order to find ways to connect students' everyday thinking to regular statistical concepts.

## Patterns of thought in everyday thinking

The mathematician and philosopher Wille (1995) argues that in order for mathematics to become learnable and possibly meaningful to non-experts (i.e. the general public), the discipline of mathematics itself has to be restructured in a program he coined *Generalistic Mathematics* (“Allgemeine Mathematik”). Wille calls for mathematicians to reveal the reasons, the aims, the

common patterns of thought, and the boundaries and dangers of mathematical concepts and of whole mathematical theories. This however must not be done in the language of mathematical theory. Opening mathematics to the general public necessitates the use of common language, rather than specialized vocabulary, to describe those reasons, aims, patterns, and boundaries.

This approach to make mathematics open and meaningful resonates well with Lengnink and Peschek (2001), who see the challenge and goal of mathematics education in explicating the connection between *everyday thinking* and *mathematical thinking*. For them, mathematical thinking manifests as conventionalized everyday thinking. In this way, confidence intervals can be seen as a conventionalized form of the generalizations taking place in daily life: being reasonably sure that some observation of daily life can be taken as true, with a certain intuitive degree of variation.

This places a firm emphasis on the importance of common thought patterns and practices, so that a task of mathematics education becomes the identification of these patterns of thought. While Wille (1995) sees this task in the hands of (the philosophy of) mathematics, Prediger (2008) points out that empirical insights into mathematical learning processes form a valuable and even necessary basis for identifying connections between everyday thinking and mathematical thinking. This also means that thought patterns cannot be approached in a general way, but rather are tied to the specific mathematical content of the learning process under investigation. This study adopts the approach outlined by Prediger (2008), in order to reveal patterns of thought and their connection to the statistical concepts of center and spread when comparing distributions.

### **The typical as a common pattern of thought**

One way students' thinking differs from formal statistics is in the use of measures. In statistics, measures such as median or standard deviation function as highly specialized tools for talking about statistical concepts like center or variability. In their intuitive approaches to statistics, students use strategies such as utilizing "modal clumps" instead (Konold et al., 2002) to point out 'the majority' of the data. Since to the students the location and the width of the clump both are important, these modal clumps can simultaneously address the center of a distribution as well as a form of spread. Thus, in their everyday language, learners integrate many different statistical concepts that would formally be strictly distinguished through use of different specialized measures (Makar & Confrey, 2005).

This raises the question on what would be promising patterns of thought to build on. One such candidate would be the practice of identifying 'typical' values or ranges of values within datasets. Some research indicates that 'typical' might be a good way for students to think about the average (Makar, 2014), while other research finds 'typical' or 'normal' to be a term for talking about ideas combining center and spread (Büscher, 2016a; Büscher, 2016b). Thus, the pattern of thought of identifying the 'typical' of a distribution seems a promising candidate as a resource for concept development, although it remains unclear for which concepts exactly.

### **Patterns of thought and concept development**

To address the question of how patterns of thought can support concept development, this study follows a conceptual change approach (Duit & Treagust, 2003). Learning is understood as a restructuring of prior conceptions, occurring when these conceptions no longer satisfactorily explain phenomena. The goal of statistics teaching is then to initiate the development of conceptions into statistical concepts. Since statistical concepts show a high degree of connection to each other, learning

trajectories in statistics however should not address concepts in an isolated way, but rather in a holistic way (Bakker & Derry, 2011). This calls for organizing structures that (a) connect to learners' prior conceptions, (b) holistically address statistical concepts, and (c) lead to regular statistical concepts. Patterns of thought can provide just such a structure, as they encompass different prior conceptions and thus enable the connection of everyday thinking to mathematical thinking.

## Research questions

The theoretical background of this study suggests that designing learning trajectories towards statistical concepts should start from fruitful patterns of thought. It is thus an issue for empirical investigations to find those patterns of thought in students' thinking which can indeed serve this function as starting points in learning trajectories. Looking at what is 'typical' was identified as one potential pattern of thought that could result in such concept development. This study therefore aims to answer the following research question: *What concepts do students address and develop when conventionalizing the vague pattern of thought of 'identifying the typical'?*

## Research design

This study adopts the methodological framework of topic-specific didactical design research (Prediger & Zwetzschler, 2013) with a focus on learning processes (Prediger, Gravemeijer, & Confrey, 2015). This approach aims at providing empirically grounded local theories on topic-specific learning processes as well as design principles and concrete teaching-learning arrangements for the topic. While the framework utilizes iterative cycles of design experiments, this study reports on the third cycle of design experiments.

## Data gathering

Design experiments were conducted with five pairs of grade 7 students (aged 12 – 14) who had only little experience with statistics within the mathematics classroom. Experiments consisted of two sessions of 45 minutes each, with each session having its own arrangements of data and tasks. They were fully videotaped and partially transcribed. The process-focused analysis of the video data from the first session of the design experiments allows to reconstruct the development of students' patterns of thought, in their relation to task design.

## Task Design

For designing the teaching-learning arrangements, various design principles have been implemented throughout the different cycles of design research, two of which play an important part in this study.

*Drawing on 'typical' as pattern of thought.* As outlined above, connecting to the pattern of thought of characterizing what is 'typical' of a certain distribution can potentially provide a starting point for processes of conventionalization that lead to meaningful use of formal statistics. Therefore, 'typical' has to be explicitly addressed in the task design, and the setting of the task has to provide a context in which this pattern of thought can naturally occur.

*Criticizing conventionalizations.* As Lengnink and Peschek (2001) point out, mathematical learning has to explicitly address the relation between everyday thinking and mathematical thinking. Following this, it is not enough for a task to just utilize students' patterns of thought and to encourage conventionalization of those patterns of thought. It is rather these conventionalizations that have to

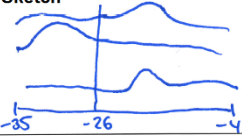

become the object of investigation. Under a Generalistic Mathematics perspective this could mean addressing reasons, aims, and boundaries of these conventionalizations.

These design principles were realized in the design of the *Antarctic weather task*. The initiated activity puts the students into the role of consultants to researchers at the Norwegian Antarctic research station *Troll forskningsstasjon*. In the first phase of the task, the students investigate dot plots of daily temperatures for the month of July 2004 and predict the weather for next July by giving a distribution of ten days. In Phase 2, additional data for July 2002 and 2003 were included (Figure 1). Predicting the weather was chosen as activity because it is rooted in everyday thinking, combining experiences of short-term variability (one can never be too sure about the weather...) with long-term signals (... but there are typical temperatures after all).

**Figure 1: Distributions of the Antarctic weather task (translated from German)**

In order to support conventionalization of patterns of thought, the third phase introduces a design element called *report sheets* (cf. Figure 2 and 3). The report sheets are introduced to serve as a brief summary of the Antarctic weather in July. They combine graphical representations and the use of measures with a brief inference. First, the students are asked to fill out their own report sheet. After that, in the fourth phase, the students receive three different filled-in report sheets by fictitious students (Figure 2). These filled-in report sheets differ in their interpretation of typical. This serves as a basis for discussing and criticizing the different conventionalizations of typical, as the students are asked to evaluate the correct use of typical.

Report sheet: temperatures at Troll Forskningsstasjon		Report sheet: temperatures at Troll Forskningsstasjon	
<b>Sketch</b>	<b>Summary</b>	<b>Sketch</b>	<b>Summary</b>

Maximum: -4	<u>between -18 and -8</u>	Maximum: -4	
Typical: -18 bis -8		Typical: -19	

**Figure 2: Fictitious students' filled-in report sheets (translated from German)**

## Data Analysis

The students' patterns of thought were reconstructed in an interpretative analysis using concepts-in-action and theorems-in-action from Vergnaud's (1996) theory of conceptual fields. Concepts-in-action are "categories (objects, properties, relationships, transformations, processes etc.) that enable the subject to cut the real world into distinct elements and aspects, and pick up the most adequate

selection of information according to the situation and scheme involved” (Vergnaud, 1996, p. 225). Theorems-in-action are statements held to be true by the learner.

Which concepts-in-action and theorems-in-action are activated depends on the pattern of thought utilized by the learners. Thus, patterns of thought are conceptualized as groups of concepts-in-action concurrently occurring in the learners’ activity. Concepts-in-action and theorems-in-action are reconstructed from the students’ point of view, and do not necessarily correspond to regular statistical concepts. In the analysis, the reconstructed concepts-in-action are symbolized by  $\|...\|$ , while theorems-in-action are denoted by  $\langle...\rangle$ .

### Empirical Insights: The case of Maria and Natalie

The first snapshot starts with Phase 2 of the Antarctic weather task. After getting the additional data of the years 2002 and 2003, Maria and Natalie, Grade 7, try to explicate their view on the data.

- 1 Maria: We are pondering what the relationship, like, how to...
- 2 Natalie: Yes, because we want to know what changes in each year. And we said that there [2003] it came apart.
- [...]
- 8 Maria Yes, I think it [2004] is somehow similar to that [2002], but that one [2003] is different.
- 9 Natalie: Like here [points to 2004, around -12 °C] are, like, like the most dots, and here [2002, -12 °C] are almost none. And there [2002, -8 °C] are the most and here [2004, -8 °C] are almost none.

This excerpt serves as an illustration of the starting point in the students’ reasoning. The students are trying to characterize the differences observed in the distributions. At first, the students formulate differences between 2003 and 2002/2004 in terms of  $\|spread\|$ : in 2003, the temperatures “came apart” (#2). Another difference they notice is the difference of the location of the  $\|center\|$  between 2002 and 2004, indicated through modal clumps (“the majority”, #9).

It is important to note that at this stage, the students face difficulties in trying to express their findings. The distributions of 2004 and 2002 are found to be “somewhat similar” (#8) though “different” (#8) to 2003, with further explanation supplied by Natalie through use of gestures and improvised vocabulary (“like, like the most dots”, #9). Few minutes later, the students find a way to deal with the complexity.

- 21 Maria: Well, we first should look at how many degrees it has risen or fallen. Generally. In two years.
- [...]
- 27 Natalie You mean average, like...
- 28 Maria The average, and then we look at how the average changed in two years.

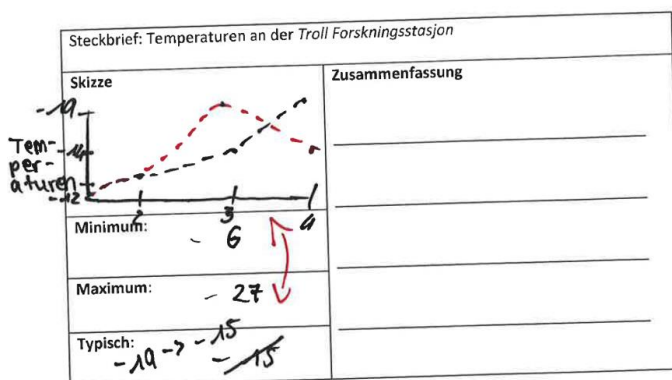

By introducing the notion of reducing the distributions to a  $\|general\ value\|$  (“Generally”, #21), the students are able to handle the complexity of the differences between the distributions. For this general value, they appear to already know an adequate measure: the  $\|average\|$ . To the students,  $\langle the\ average\ represents\ the\ general\ value\ of\ a\ distribution \rangle$ . The average acts as a summary to be used in further procedures, as  $\langle the\ differences\ between\ distributions\ can\ be\ described\ by\ differences\ in\ general\ values \rangle$ .

In the following exchange, after having estimated the averages to be  $-12$  (2002) and  $-14$  (2004), Maria and Natalie try to use their result for a linear extrapolation of the weather in 2015 to be predicted.

- 41 Natalie: Wait. If it gets colder by  $2^{\circ}\text{C}$  in two years, then it gets colder by  $1^{\circ}\text{C}$  each year, so we have to...
- 42 Maria: Nah, eh, yeah okay
- 43 Natalie:  $13^{\circ}\text{C}$  colder average temperature. Right?
- 44 Maria: Yes.
- 45 Natalie: But that's too much, isn't it?

When reflecting on their result however, the students realize that a decline of the average temperature by  $13^{\circ}\text{C}$  is not a realistic proposition (#45). While their knowledge of the real-world context helps them to identify this contradiction, they are not able to find another solution. In the minute following (not shown here), the students stay insistent in using the average and a linear extrapolation of the trend. It is important to note that, at this stage, their ideas concerning *//spread//* as expressed in the first excerpt seem to have disappeared, replaced by the stronger notion of *//general value//* expressed through the more conventionalized form of *//average//*.

The design experiment progresses through the third phase, in which the students create their own report sheet (Figure 3). The analysis picks up at beginning of the fourth phase, with the students comparing the different interpretations of 'typical' in the filled-in report sheets.

Translations:

"Report sheet: temperatures at Troll Forschungsstasjon"

Skizze – Sketch

Typisch – Typical

Zusammenfassung – Summary

Temperaturen – Temperatures

(The black graph was drawn first, labeled a mistake, and immediately replaced by the red graph. Typical was first assigned as  $-15$ , then after the fourth phase changed to  $-19$  to  $-15$ .)

**Figure 3: Maria and Natalie's report sheet**

Comparing the different interpretations of 'typical', Maria and Natalie are intrigued by the possibility to use an interval to characterize 'typical'. This leads them to reflect on their use of the average.

- 61 Natalie: But the average temperature isn't really typical, is it?
- 62 Maria: What, typical? Of course the average temperature is the typical.  
[...]
- 66 Maria: Well, no. Typical is more like where the most... no...
- 67 Maria: The average temperature isn't the typical after all. Because it's only the general, the whole. The typical would be for example for this [2004] here [points to  $-14$  on the 2004 dot plot].
- 68 Natalie: Typical I think simply is what is the most or the most common.

The students utilize Typical to differentiate between two different ideas: The *//general value//* that is expressed through the *//average//* ("the general, the whole", #67), and the *//most common//* part of the

distribution, expressed through the *//Typical//* (“the most common”, #68) – although at this point it is not yet clear if Typical consists of a number or an interval. With the *//most common//* corresponding to the notion of *//center//* expressed earlier (“the most dots”, #9), Typical seems to help the students to express ideas that got swept aside by the more conventionalized average. Both, average and typical, start to act as conventionalized tools for talking about specific aspects of distributions.

Some minutes later, Natalie summarizes her view on the relation between ‘typical’ and average.

- 81 Natalie: And average is pretty imprecise, because it doesn’t say anything about a single day. And with typical, I’d say, that it’s a span between two numbers, because that way you can better overlook how it is most of the time.

In the end, typical and average provide two different applications. Whereas the average acts as a summary, ‘typical’ gives an overview into a distribution. The average can be used in comparing distribution in an efficient way, while ‘typical’ gives an insight into a range of ‘normal’ or ‘expected’ temperatures, to which any single day can be compared. In this way, ‘typical’ combines aspects of *//center//* and *//spread//*.

## Conclusion

The aim of this study was to examine the interaction of concept development and students’ patterns of thought. The students showed two different patterns of thought: Characterizing data through a general value and through a range of typical values. These patterns differed in their degree of conventionalization. While the general-pattern was addressed through use of the average, the students lacked a conventionalization corresponding to the typical-pattern. This resulted in the typical-pattern to be suppressed in favor of the general-pattern, as the ideas addressing spread disappeared. Only when the students were supplied with different conventionalizations of Typical, they were able to reconnect to their typical-pattern. This then allowed them to express ideas combining center and spread.

This identification of thought patterns provides a promising starting point. Work still remains however utilizing these thought patterns to develop regular statistical concepts. This could be achieved by reconceptualizing formal statistics in terms of a typical-pattern. One possible connection could be interpreting the ‘box’ of a box plot as the typical area of a distribution. Additionally, more insight into processes of conventionalization is needed in order to be able to successfully guide students on their way to meaningful statistics (for one example see Büscher, 2016).

# Do attitudes toward statistics change during an introductory statistics course? A study on Italian psychology students

Francesca Chiesi and Caterina Primi

University of Florence, Italy; [francesca.chiesi@unifi.it](mailto:francesca.chiesi@unifi.it), [caterina.primi@unifi.it](mailto:caterina.primi@unifi.it)

*Mixed results have been reported about changes that might occur in students' attitudes as a consequence of attending introductory statistics courses and about male and female students' differences in attitudes. Thus, the aim of the current study was to shed light on attitudes changes in students attending introductory statistics courses taking gender into account. Overall, we observed changes in attitude that resulted in a more positive attitude from the beginning to the middle of the course. Nonetheless, along with a general positive trend, it was possible to highlight that some students get significantly worse attitudes and many of them do not substantially change their initial attitudes. Overall, no significant differences were found between male and female students. Finally, probabilistic competences along with statistics anxiety accounted for individual changes in attitudes toward statistics. Educational implications were discussed.*

*Keywords: Statistics education, attitudes toward statistics, attitude changes, gender differences.*

## Introduction

Attitude toward statistics is a disposition to respond favourably or unfavourably to objects, situations, or people related to statistics learning (Schau, Stevens, Dauphinee & del Vecchio, 1995). It is commonly described as a multi-dimensional concept that consists of affective (students' positive and negative feelings about statistics), cognitive (beliefs about the ability requested to learn statistics and about the discipline), and behavioral (interest and effort) components, which are deemed to have an effect on achievement. Emmioglu and Capa-Aydin (2012) provided a meta-analysis that addressed this relationship suggesting that there is a significant correlation between students' achievement and statistic-related beliefs, motivation, and feelings. Indeed, whereas the reviewed studies employed different research approaches and included different kinds of samples and courses, more positive attitudes were correlated - with different extent, and directly or indirectly- to a better course performance.

For this reason, a basic question of research refers to the changes that might occur in students' attitudes as a consequence of attending introductory statistics courses. Although some studies reported an increase in attitudes as a result of the courses (e.g., Chiesi & Primi, 2010), Schau and Emmioglu (2012) conducted a large-scale investigation reporting that the different attitude dimensions do not substantially change through the courses. Nonetheless, Millar and White (2014) highlighted that the mean changes were around zero but the variability in the individual changes was relatively large, i.e., whereas in some cases the attitudes actually did not change, positive changes (i.e., shifts to a more positive attitude) and negative changes (i.e., shifts to a more negative attitude) were both observed.

Finally, literature on attitudes toward statistics addressed the issue of gender differences. Presumably due to the different sample and course characteristics (engineering students, economic students, psychology students, pre-service teachers), inconsistent results were reported. Some authors found

that men expressed more positive attitudes toward statistics than women (e.g., Chiesi & Primi, 2015; Tempelaar & Nijhuis, 2007), others studies found no gender differences (e.g., Martins, Nascimento & Estrada, 2011), and some others documented more positive attitudes for women (e.g., Rhoads & Hubele, 2000).

These mixed results suggest, in line with the recommendation made by Eichler and Zapata-Cardona (2016), to intensifying research on students' statistics-related attitudes. Thus, the aim of the current study was to shed light on attitudes changes in students attending introductory statistics courses taking into account gender differences. The specific aims can be detailed as follows.

- a. To investigate the possible changes in attitudes as result of the course. Based on previous studies conducted on similar samples (e.g., Chiesi & Primi, 2010), we hypothesized that a positive overall change might occur from the beginning to the middle of the course. To take into account possible gender-related difference in attitudes, we observed the differences from pre- to post-test in male and female students separately. We expected that the course had an effect on both genders.
- b. To provide a more fine-grained investigation we looked at the individual differences in attitude changes, i.e. if the student shifted to a better attitude, or if she/he got worse attitudes as a result of the course, or if the student's attitudes remained unchanged. In defining these typologies we referred to Schau and Emmioglou (2012) and Millar and White (2014). They suggested that, along with the statistical significance of the change in attitude scores, it is important to ascertain if students' attitudes change consistently, i.e., if there is a substantial increase/decrease in the observed scores. As such, following their indications to determine the relevance of the score change, we investigated individual differences in attitude changes controlling for gender. We expected that positive and negative shifts as well as no changes might be observed in both men and women.
- c. Since we expected that students – all attending the same course - might change in positive or negative their attitudes towards statistics or maintain them stable, we explored if some specific factors could accounted for individual differences. In line with previous studies on cognitive and non-cognitive factors related to statistics education, we looked at mathematical and probabilistic competences along with test anxiety and statistics anxiety.

## Method

### Participants

Participants were 136 psychology students enrolled in an introductory statistics course at the University of Florence in Italy (mean age = 20.93 years,  $SD = 3.59$ ; 70% female). They were first year students who did not have previous experience with the discipline at the university level but they might have encountered the discipline before in school-related contexts or in their out-of-school lives. All students participated on a voluntary basis after they were given information about the general aim of the investigation (i.e., collecting data for a research project on students' statistics achievement).

### Description of the course

The course was compulsory. It covered the usual introductory topics of descriptive and inferential statistics (including basic concept of probability theory and calculus), and their application in psychological research. It was scheduled to take place over 10 weeks, and takes 6 hours per week (for

a total amount of 60 hours). During each class some theoretical issues were introduced followed by exercises using either paper-and-pencil procedure or a computer package (*R-commander*). Students were assigned homework for which they were allowed to work in groups. Consultation hours were also offered for one on one help with exercises. The instructor was one of the authors of the current paper.

## Measures

Attitude toward statistics was measured administering the 28-item version of the *Survey of Attitudes toward Statistics* (SATS) (Schau et al., 1995; Italian version: Chiesi & Primi, 2009). The SATS contains Likert-type items using a 7-point scale ranging from *strongly disagree* to *strongly agree*. It assesses four attitudes components: Affect (6 items) measures positive and negative feelings concerning statistics (e.g. “I will feel insecure when I have to do statistics problems” or “I will like statistics”); Cognitive Competence (6 items) measures students’ attitudes about their intellectual knowledge and skills when applied to statistics (e.g. “I can learn statistics” or “I will make a lot of math errors in statistics”); Value (9 items) measures attitudes about the usefulness, relevance, and worth of statistics in personal and professional life (e.g. “Statistics is worthless” or “Statistical skills will make me more employable”); Difficulty (7 items) measures students’ attitudes about the difficulty of statistics as a subject (e.g. “Statistics formulas are easy to understand” or “Statistics is a complicated subject”). Two versions to use at the beginning (pre-SATS) and during or at the end (post-SATS) of the course were developed. For both the pre- and post- versions of the SATS responses to negatively scored items were reversed. Because the subscales were composed of a different number of items, scores were obtained by dividing each component score by the number of items that assess that component. As such all the scores ranged from 1 to 7 and higher scores indicated a more positive attitude. For Difficulty a positive attitude (i.e., high scores) means that students believe that statistics is easy whereas a negative attitude (i.e., low scores) means that it is harder.

The *Mathematics Prerequisites for Psychometrics* (MPP, Galli, Chiesi & Primi, 2011) was employed to measure the mathematical skills needed by students enrolling in introductory statistics courses. The MPP consists of 30 multiple-choice format questions (one correct out of four alternatives) from which a total score (range 0-30) was calculated. Additionally, the *Probabilistic Reasoning Questionnaire* (PRQ; Primi, Morsanyi & Chiesi, 2014), designed to measure proportional reasoning and basic probabilistic reasoning ability, was administered. The scale consisted of 16 multiple-choice questions from which a total score (range 0-16) was calculated.

The *Test Anxiety Inventory* (TAI; Spielberg, 1980) was administered to measure anxiety associated with test-taking situations. The TAI is self-report instrument consisting of 20 items. Respondents are asked to report how frequently they experience specific symptoms of anxiety from 1 (*almost never*) to 4 (*almost always*). A total score was calculated as the sum of all items, with higher scores corresponding to high test anxiety. Along with this general anxiety indicator, the specific anxiety toward statistics was assessed using the *Statistical Anxiety Scale* (SAS; Vigil-Colet, Lorenzo, & Condon, 2008; Italian version: Chiesi, Primi & Carmona, 2011). The SAS is a self-reported measure consisting of 24 items with a five-point rating scale ranging from 1 (*no anxiety*) to 5 (*very much anxiety*). The SAS includes Examination anxiety (8 items, e.g., “Studying for examination in a statistics course”), Asking for help anxiety (8 items, e.g., “Asking the teacher how to use a probability table”), and Interpretation anxiety (8 items, e.g., “Trying to understand a mathematical

demonstration”). A composite score was calculated with higher scores corresponding to high statistics anxiety.

## Procedure

Students were administered the SATS-pre, the MPP, the PRQ, and the TAI at the beginning of the course. At the middle of the course (about four weeks later), the SATS-post was administered along with the SAS. The questionnaires were introduced briefly to the students and instructions for completion were given. Answers were collected in paper-and-pencil format and the time needed to complete them ranged from 20 to 40 minutes.

## Results

To ascertain the possible changes in attitudes toward statistics and the gender related differences, we ran a  $2 \times 2$  mixed ANOVAs with course (pre/post) as a within-subjects factor, and gender as between-subjects factors on each of the four attitude dimensions. It was found a main effect of course - that resulted in an overall increase - on Affect ( $F(1, 134) = 17.34, p < .001, \eta_p^2 = .12$ ; pre:  $M = 3.44, SD = 1.08$ , post:  $M = 3.74, SD = 1.25$ ), Difficulty ( $F(1, 134) = 24.17, p < .001, \eta_p^2 = .15$ ; pre:  $M = 3.23, SD = 0.64$ , post:  $M = 3.51, SD = 0.66$ ), Cognitive Competence ( $F(1, 134) = 59.67, p < .001, \eta_p^2 = .31$ ; pre:  $M = 4.19, SD = 1.01$ , post:  $M = 4.72, SD = 1.07$ ), and Value ( $F(1, 134) = 4.89, p < .05, \eta_p^2 = .04$ ; pre:  $M = 5.03, SD = 0.85$ , post:  $M = 5.20, SD = 0.94$ ). With the exception of Value ( $F(1, 134) = 1.91, p = .17$ ), significant between-subject differences were found for the remaining attitude dimensions (Affect:  $F(1, 134) = 8.36, p < .01, \eta_p^2 = .06$ ; Difficulty:  $F(1, 134) = 4.82, p < .05, \eta_p^2 = .04$ ; Cognitive Competence:  $F(1, 134) = 6.17, p < .05, \eta^2 = .04$ ) with male holding more positive attitudes. Nonetheless, there were not significant course by gender interactions (Affect:  $F(1, 134) = 2.08, p = .15$ ; Difficulty:  $F(1, 134) = 0.26, p = .61$ ; Cognitive Competence:  $F(1, 134) = 1.99, p = .16$ ; Value:  $F(1, 134) = 0.89, p = .35$ ) indicating that attitudes improved regardless gender differences in the attitude degrees. In Figure 1 the descriptives by gender are reported for each attitude dimension.

**Figure 1. Mean scores of the four components of the *Survey of Attitudes toward Statistics* (SATS) at the beginning and at the middle of the course in male and female students.**

Because the rating scale ranged from 1 to 7 and 4 is the midpoint, mean values revealed that male students were around the midpoint at the beginning of the course and later tended to be above it. Female students, whereas they get better across time, remained below it. On average, even taking into

account the positive shift from the beginning to the middle of the course, both men and women were below the midpoint for Difficulty, whereas scores over it were observed for Cognitive Competence and Value.

To look at the individual differences, i.e. if students get better, worse, or unchanged attitudes, we referred to Schau and Emnioglu (2012) and Millar and White (2014) to weigh the relevance of the change. Thus, we considered differences of about .5 point or more in absolute value as important. This means that students' scores would change consistently if they changed, for example, their Likert scale responses by 1 point on half of the items in the component. In the current study, to take into account the direction of change, we classified the score as follows: a negative difference of .5 point or less indicated a substantive decrease, a positive difference of .5 point or more indicated a substantive increase, all the other values indicated no substantive changes. To take into account possible gender-related difference in attitudes, we observed the kind of pre-/post-test differences separately in male and female students (Figure 2).

**Figure 2. Percentages of negative, stable and positive pre-post difference scores of the four components of the *Survey of Attitudes toward Statistics (SATS)* in male and female students.**

Chi-square tests indicated no significant differences between genders (Affect:  $\chi^2(2) = 2.16, p = .34$ ; Difficulty:  $\chi^2(2) = .34, p = .84$ ; Cognitive Competence:  $\chi^2(2) = 2.48, p = .30$ ; Value:  $\chi^2(2) = 3.83, p = .15$ ). Comparing the four components, the highest percentage of negative shifts (more than 15%) was found for the Affect component. A prevalence of stable scores (60% or more) was observed for the Difficulty and Value dimensions. Finally, we registered the highest percentage of positive shifts (about 50%) for the Cognitive Competence component.

To establish the relative impact of mathematical and probabilistic competences, test anxiety, and statistics anxiety on attitude changes, regression analyses were run (Table 1). In order to capture the variability in the changes occurred from the first to the second assessment, the criterion variable was the difference between the pre- and post-test scores. Given the overall absence of gender differences these analyses were conducted on the total sample. Results showed that none of these factors explained changes in Cognitive Competence ( $F(4,130) = 0.71, p = .59$ ) and Value ( $F(4,130) = 0.76, p = .55$ ). On the contrary, the regression models indicated that probabilistic competences and statistics anxiety contributed in explaining changes in Affect ( $F(4,130) = 4.90, p < .01, R^2 = .13$ ) and Difficulty ( $F(4,130) = 5.02, p < .01, R^2 = .14$ ). Specifically, higher competences were associated with higher

positive changes, whereas higher anxiety levels were associated with higher negative changes. Finally, test anxiety predicted changes in Difficulty in the same direction observed for statistics anxiety, i.e., the greater the degree of anxiety, the less the attitude increase (Table 1).

Criterion	Predictors	$\beta$	$t$	$p$
<i>Affect change</i>	<i>Mathematical competence (MMP)</i>	.045	0.41	.66
	<i>Probabilistic competence (PRQ)</i>	.29	2.87	.005
	<i>Test anxiety (TAI)</i>	.04	0.45	.65
	<i>Statistics anxiety (SAS)</i>	-.24	-2.33	.02
<i>Difficulty change</i>	<i>Mathematical competence (MMP)</i>	.15	1.46	.15
	<i>Probabilistic competence (PRQ)</i>	.25	2.47	.015
	<i>Test anxiety (TAI)</i>	-.20	-2.02	.045
	<i>Statistics anxiety (SAS)</i>	-.36	-3.60	<.001

**Table 1. Regression analyses on statistics attitude changes (in brackets the scales employed to measure the predictor variables)**

## Discussion

The current study aimed at investigating in detail attitude changes in male and female Italian psychology students attending introductory statistics courses. In doing that, we took into account some cognitive and non-cognitive variables that might help in shed light on individual differences in attitude changes. Overall, we observed changes in attitude that resulted in a more positive attitude from the beginning to the middle of the course. Except for the Value component, men held more positive attitudes. However, there were not significant course by gender interactions indicating that attitudes improved in both male and female students. On average, and regardless the positive shift from the beginning to the middle of the course, both men and women believed that statistics was difficult, although they had confidence they would be able to learn it. Finally, all students valued statistics somewhat positively.

To provide a more fine-grained investigation we looked at the individual differences in changes as well as to the relevance of the change. Indeed, along with a general positive trend, it is possible to highlight that, although part of the students shifted markedly to better attitudes, some of them got significantly worse attitudes, and many of them did not substantially change their initial ones. Investigating gender-related difference in attitude changes, we observed no significant differences in male and female students. Thus, looking at the general patterns of change, it emerged that about half of the sample remained substantially stable across the four attitude dimensions (with the higher percentage for the Value component), more than one third of the sample shifted to a more positive attitude (with the higher percentage for the Cognitive Competence component), and a small percentage showed a negative shift (with the higher percentage for the Affect component).

When looking at the factors influencing the direction of the shift, we observed that probabilistic competences along with statistics anxiety accounted for changes in Affect and Difficulty components. That is, students with stronger competences were more likely to move to positive feelings about the

discipline and to consider it less hard. At the same time, more anxious students were more resistant to positive changes, i.e., they persistently dislike statistics and consider it hard.

Given these findings, it is interesting to note that the course *per se* promote positive changes in the students' attitudes. That is, arguably when interacting directly with the topics at an introductory level, some students tend to perceive it in a more favorable way. However, many students do not change or even get worst attitudes. Thus, it becomes important to identify methods for promoting better attitudes, for example arranging activities in which students could reinforce their basic competence in probability and providing them the adequate learning strategies to cope with anxiety. As such, they can perceive the subject easier and reduce negative feelings toward the discipline.

The present study has some limitations that we have to take into account when interpreting the results. First of all, it was conducted with Italian psychology students and this may limit their generalizability. Thus, future investigations should be conducted with different student populations to provide further evidence on the changes in attitudes and their determinants. Second, individual differences in changes of the value and cognitive competence components remain basically unexplained. As such, other factors (i.e., self-efficacy, motivation) should be taken into account to understand why some people do not change while others do. Finally, students valued statistics somewhat positively contradicting to some extent previous results on psychology students (e.g., Dempster & McCorry, 2009). This might be a result of social desirability effect that should be controlled in further studies.

*Teachers who engage primary school students in informal statistical inference (ISI) need to have a good content knowledge (CK) and pedagogical content knowledge (PCK) of ISI themselves. However, little is known of how teacher college education for pre-service teachers can contribute to the development of their ISI CK and PCK – a shortcoming we attempt to address in this paper. A class of 21 pre-service primary school teachers participated in an intervention consisting of five lessons. Design research methodology guided the design of the intervention. The preliminary results indicate that most pre-service teachers seemed to be aware of the inferential nature of research questions and the uncertainty inherent to ISI, but not all of them understood the fundamental idea that if a properly selected sample is representative for the population it can be used for an inference. Lacking this understanding might hinder them in teaching ISI.*

*Keywords: Informal statistical inference, informal inferential reasoning, primary education, statistics education, teacher education.*

## Introduction

In daily life, sample data is regularly used to make generalizations that go beyond the data collected; informal statistical inference (ISI) is a form of this phenomenon. The ability to critically evaluate such generalizations is increasingly useful in participation in present and future society. ISI is defined as “a generalized conclusion expressed with uncertainty and evidenced by, yet extending beyond, available data” (Ben-Zvi, Bakker, & Makar, 2015, p. 293). Unlike formal statistical inference, ISI does not make use of formal statistical tests that are based on probability theory (Harradine, Batanero, & Rossman, 2011). In recent years, statistics education researchers have turned their attention to how primary school students can be introduced to ISI. It is hypothesized that if students are familiarized with the concept in primary school, it will help them to understand the processes involved in its reasoning and in statistical reasoning in general (Bakker & Derry, 2011; Makar, Bakker, & Ben-Zvi, 2011). Evidence suggests that meaningful learning environments can render ISI accessible for primary school students (Ben-Zvi et al., 2015; Meletiou-Mavrotheris & Paparistodemou, 2015).

If students are to be introduced to ISI in primary school, future teachers need to be well prepared to conduct this introduction (Batanero & Díaz, 2010). This requires them to have an appropriate content knowledge (CK) of the subject and to have adequate pedagogical knowledge (PCK) (Burgess, 2009). Recent research shows that pre-service teachers have difficulty making generalizations and

understanding sampling representativeness and the logic of sampling (De Vetten, Schoonenboom, Keijzer, & Van Oers, 2016a; De Vetten, Schoonenboom, Keijzer, & Van Oers, 2016b). However, little is known how we can prepare pre-service teachers to teach ISI to primary school students. This paper reports on the design and preliminary results of an intervention at a teacher college for primary education that aimed to foster the development of the ISI content knowledge (CK) and PCK of pre-service primary school teachers.

## Teachers' knowledge of ISI

In his seminal article, Shulman (1986) uses two broad categories to categorize the knowledge teachers need to have to teach a particular subject: pedagogical content knowledge (PCK) and content knowledge (CK) of the subject. Shulman's first category, pedagogical content knowledge, includes knowledge of how to present, illustrate and explain new material (Knowledge of Content and Teaching; KCT for short); and knowledge about the students' conceptions and misconceptions (Knowledge of Content and Students; KCS for short). Concerning content knowledge, teachers need to understand the subject at the level of student (Common Content Knowledge; CCK for short), but also need to have specialized knowledge of the subject that enables them to teach the subject and that is specific for the job of teaching (Specialized Content Knowledge; SCK for short) (Ball, Thames, and Phelps, 2008).

For ISI no categorization of CK and PCK is available. We combine the categorization of Shulman with the ISI framework of Makar & Rubin (2009) to conceptualize the CK and PCK needed for teaching ISI. Makar & Rubin (2009) argue that an ISI consists of the following three components:

1. 'Data as evidence': The inference is based on the data, and not on tradition, personal beliefs or experience.
2. 'Generalization beyond the data' (in short: 'Generalization'): The inference goes beyond a description of the sample data to make a claim about a situation beyond the sample data.
3. 'Uncertainty in inferences' (in short: 'Uncertainty'): The inference includes a discussion of the sample characteristics, such as sample size and sampling method, and a discourse on what these characteristics imply for the representativeness of the sample and the certainty of the inference. Moreover, it requires an understanding of basic logic sampling: the understanding that if a properly selected sample is representative for the population it can be used for an inference, because sample-to-sample variability is low. We have subdivided this component into three subcomponents: sampling method, sample size and uncertainty.

There are a limited number of studies that investigate (pre-service) primary school teachers' CK of ISI. The authors of this paper have investigated all three ISI components in two studies (De Vetten et al., 2016a; De Vetten et al., 2016b). In an exploratory design study, De Vetten et al. (2016a) show that regarding 'Data as evidence' most pre-service teachers indeed use data as evidence when comparing two samples to generalize to the population. In a large scale questionnaire study, De Vetten et al. (2016b) found less positive results when pre-service teachers were asked to evaluate whether data can be used as reliable evidence for a generalization. Concerning 'Generalization', De Vetten et al. (2016b) show that pre-service teachers are well able to discern that probabilistic generalizations are permissible, while deterministic generalizations are not. However, De Vetten et al. (2016a) report that pre-service teachers tend to only describe the samples, and do not generalize beyond the data.

The evidence on the ‘Uncertainty’ component suggests that many pre-service teachers show a limited understanding of sampling methods, sample size, representativeness and the logic of sampling and sampling variability (De Vetten et al, 2016a; De Vetten et al., 2016b; Meletiou-Mavrotheris et al., 2014; Mooney, Duni, VanMeenen, & Langrall, 2014; Watson, 2001).

Research on teachers’ PCK of ISI and ways to prepare to teach ISI is even scarcer than research on teachers’ CK of ISI. Leavy (2010) reports that pre-service teachers tended to focus excessively on procedures, spent too much time on descriptive analyses at the expense of discussion of inferences, and failed to stimulate data-based reasoning. Using the same data, Leavy (2015) shows that it is critical that pre-service teachers learn how to pose questions that invite students to reason about inference. Madden (2011) shows that tasks that are statistically, contextually and/or technologically provocative triggered high school mathematics teachers to reason about ISI.

Since little is known how to prepare pre-service primary school teachers to teach ISI, the aim of the present study is to investigate in what way teacher college education for pre-service teachers can contribute to the development of their ISI CK and PCK. The research question is: To what extent, and how, do the ISI CK and PCK of pre-service school teachers develop during, and as a result of, an intervention at primary education teacher college aiming at developing ISI CK and PCK?

## **Method**

### **Context**

In many countries, including the Netherlands, current statistics education curricula in primary and secondary education do not include ISI. Actual teaching practices focus primarily on statistical procedures and graphing skills, where concepts are learned without reference to the need to collect and analyze data (Ben-Zvi & Sharett-Amir, 2005; Friel, Curcio, & Bright, 2001; Meijerink, 2009). When statistical inference does form part of the secondary education curriculum, the ideas of sample and population are often only dealt with on a technical level. Consequently, many students enter tertiary education with a shallow and isolated understanding of the concepts underlying statistical inference (Chance, DelMas, & Garfield, 2004). In contrast to many other countries, where students can only opt for teacher education after completion of a bachelor’s degree, in the Netherlands, initial teacher education starts immediately after secondary school and leads to the attainment of such a degree. For these students, mathematics teaching is usually not their main motive for becoming teachers.

The intervention was part of a course on mathematics education for grade 3 to 6. The course was the fourth course on mathematics education and the second for mathematics in grade 3 to 6. During the semester the pre-service teachers worked in a grade 3 to 6 class in a work placement school. Since in the Dutch mathematics curriculum for teacher college statistics gets only minor attention and since we wanted to have an intervention that would fit in the normal teacher college curriculum, we decided to restrict the length of the intervention to five lessons, out of the 16 lessons of the total course.

### **Design**

We employed design research methodology to study the development in ISI CK and PCK of the pre-service teachers and to explain this development (Van den Akker, Gravemeijer, McKenney & Nieveen, 2006). Previous research (Ben-Zvi, 2006; De Vetten et al., 2016a&b; Paparistodemou &

Meletiou-Mavrotheris, 2008; Saldanha & Thompson, 2007) and our own ISI teaching experiences with primary school students informed us which learning goals are within reach of pre-service teachers and what PCK is necessary to teach ISI to primary school students (see Table 1). These learning goals were categorized into the three ISI components ‘Data as evidence’, ‘Generalization’ and ‘Uncertainty’.

**Table 1: ISI learning goals for the intervention at primary education teacher college**

ISI component		Knowledge type <sup>a</sup>	Learning goals	Attained? <sup>b</sup>
General		KCT	To reason with students about ISI in a meaningful way, teachers can (1) have students conduct empirical investigations with an inferential research question about a meaningful topic or (2) have students evaluate research (for example as reported in the media) with an inferential research question about a meaningful topic.	0.75
Data as evidence		CCK	Use data as evidence, not other sources	1
		CCK	Sample provides information about likelihood of population parameters	0.5
		KCS	Many students do not use data as evidence	0.5
		KCS	Many students think that every sample distribution is evenly likely	0.25
		KCT	To teach students that data can be used as evidence for answers on inferential questions teachers can (1) have students conduct empirical investigations where sample and population are concretely visible, (2) regularly point at the sample, and (3) ask students on what arguments they or other researchers reached their conclusion.	0.25
Generalization beyond the data		CCK	It is possible to make claims about population, despite individual differences between subjects	0.75
		CCK	It is possible to use sample to make claims about population	1
		CCK	Awareness of inferential nature of research questions	1
		CCK	Claims about a population are often based on a sample	1
		CCK	Correctly articulate answers to inferential questions	0.5
		KCS	Many students answer inferential questions descriptively only	0.5
		KCT	To teach students that it is not necessary to investigate an entire population, but that a sample suffices for a reliable conclusion, teachers can (1) use examples from media where a sample is used, or (2) use resampling activities where different samples yield similar results.	0.25
		KCT	To make students aware of the inferential nature of research questions, teachers can (1) use real empirical investigations where sample and population are concretely visible, and (2) ask questions, such as 'Does our result hold for the sample only, or also for the population?'	0.25
KCT	To help students to correctly articulate answers to inferential questions, teachers can reformulate students' responses.	0.25		
Uncertainty inherent to inferences	Sampling method	CCK	Which of the following sampling methods are (in-)appropriate: convenience sampling, random sampling, quota sampling	0.75
		SCK	Understand why random sampling is appropriate	0.75
		KCS	Many students think random sampling is not an appropriate sampling method	0.5
		KCS	Many students tend to use incorrect matching techniques in sampling	0
		KCT	To teach students that a sample needs to be representativeness of the population, a teacher can (1) ask students to investigate how other researchers have selected their sample and what students think of the representativeness of the sample and (2) let students discuss how they would select a representative sample to answer a specific research question and let the children execute the sampling.	0.75
	Sample size	SCK	Why a larger sample leads to more certainty	0.5
		CCK	Sufficient sample size	0.25
		CCK	Sample size is independent of population size	0.5
		KCS	Many students do not take sample size into account in the certainty of their answers	0.5
		KCS	Many students make very certain inferences, even for small samples	0.5
		KCS	Many students think that sample size is dependent of population size	0.25

	Uncertainty	KCT	To teach students the effect of sample size on the certainty of inferences, teachers can use real empirical investigations where resampling is used, select to two samples of different size and ask which sample provides more certainty.	0.5
		CCK	Acknowledge uncertainty of inferences and impossibility of absolute certain inferences	1
		CCK	The larger the sample, the more certain the inference	1
		CCK	The better the sampling method, the more certain the inference	0.75
		CCK	When a sample is properly selected, the probability is small that another but likewise sample gives an entirely different result	0.5
		CCK	Correctly articulate uncertainty in inferences	0.5
		KCS	Many students express complete (un-)certainty in their inferences	0.5
		KCT	To make students aware of the uncertainty of inferences, teachers can use real empirical investigations where resampling is used, and confront the children that different samples lead to different conclusions.	0.25
		KCT	To help students articulate uncertainty in inferences, teachers can reformulate students' responses or ask how much certainty the students have.	0.25

<sup>a</sup>CCK: common content knowledge; SCK: specialized content knowledge; KCS: knowledge of content and students; KCT: knowledge of content and teaching. <sup>b</sup>Each learning goal received one of the scores 0, ¼, ½, ¾ or 1 (0: not attained; 1: attained by (almost) all pre-service teachers)

For each lesson, a hypothetical learning trajectory was designed, connecting activities with the learning goals for the lesson, while also explaining in what way the activities were hypothesized to help to attain the learning goals. Using example lessons was one type of activity used to foster the CK and PCK of the pre-service teachers. These lessons introduced many CK concepts and provided opportunities to discuss how children would deal with issues involved in these lessons. Each lesson was evaluated to inform the design of the next lesson. Table 2 provides an overview of the intervention. Part of the intervention was that pre-service teachers would give an ISI lesson in their work placement school. The analysis of these lessons is beyond the scope of this paper.

**Table 2: Overview of the ISI intervention at the teacher college**

Week	Activity
1	Informed consent, pre-test and homework instruction
Between 1 and 3	CK: Pre-service teachers make homework assignment: 1. Look up an article in the media that makes a claim about a population based on a sample and that somehow appeals to you. 2. Describe how the researchers came to their conclusions. 3. Write a critical evaluation about the quality of the research: to what extent is in your opinion the conclusion justified based on the research conducted?
3	<b>Lesson 1</b> CK & PCK: Small group and whole class discussion of homework assignment, attention for both CK and PCK aspects of the assignment CK: Explanation of random sampling and appropriate sample size using an ICT demonstration
5	<b>Lesson 2</b> CK & PCK: Teacher educator models an example lesson which the pre-service teachers could give themselves in their work placement schools PCK: Discussion of teacher educator's experiences with teaching the example lesson in primary school
5	<b>Lesson 3</b> CK & KCS: Discussion of equiprobability bias using a task CK Short recap of main ISI concepts PCK: Teacher educator presents learning goals of ISI lesson (KCT), discusses typical responses of students (KCS) and provides instructions for the ISI lesson (KCT)
Between 5 and 12	Half of the pre-service teachers teach an ISI lesson in their placement school.
12	<b>Lesson 4</b> PCK: Discussion of pre-service teachers' experiences with teaching with teaching the ISI lesson PCK: Pre-service teachers provide suggestions for alterations of the ISI lesson and tips for their fellow students.
Between 12 and 16	The other half of the pre-service teachers teach an ISI lesson in their placement school.
16	<b>Lesson 5</b> PCK: Discussion of pre-service teachers' experiences with teaching the ISI lesson
16	Post-test and evaluation of the intervention

## Participants

One class of second year pre-service teachers participated in this study. They studied at a small teacher college for primary education in a large city in the Netherlands. The intervention took place in their second year of study, because statistics is part of the knowledge base that is tested in the third of study. This particular class was chosen, because the pre-service teachers had fewest credits open from their first year of all three second year classes. The class consisted of 23 pre-service teachers. They were asked to provide their informed consent. While all of them were required to participate in the activities and lessons, one pre-service teacher invoked the possibility to have her results excluded from the analysis. The results of another student were also excluded, because of absence during all but one of the lessons. This resulted in a sample of 21 pre-service teachers. The procedure was approved by the ethical board of the Faculty of Behavioural and Movement Sciences of Vrije Universiteit Amsterdam. The average age of the participants was 21 years (SD: 2.19); 6 were male; 10 had a background in secondary vocational education (students attending this type of course are typically aged between 16 and 20), 7 came from senior general secondary education, 2 had been enrolled in university preparatory education, and the educational background of the remaining 2 was either something else entirely or unknown. Their average score on the obligatory first-year mathematics exam for Dutch pre-service teachers was 135 out of 200 possible points (SD: 12.86). A score of 103 equals the 80th percentile of Grade 6 primary school students in the Netherlands. The first author was the teacher educator. He had four years of experience as a mathematics teacher educator, a master degree in economics and experience as a university statistics lecturer. He had taught most of the pre-service teachers during their first year of study.

## Data collection

During the lessons, whole class interactions were recorded on video and audio, while small group interactions were recorded on audio. Furthermore, during most lessons one of the co-authors was present as observer, taking notes. Finally, all written work was collected. A pre-test and post-test were used to measure ISI CK and PCK at the start and at the end of the intervention. The results of these tests will be presented during the CERME presentation.

## Data analysis

The goal of the analysis is to study the development of the ISI CK and PCK and to explain these developments. This paper reports preliminary analyses. After each lesson, the teacher educator's and observer's notes and reflections were used as for estimating to what extent the learning goals relevant for the particular lesson had been attained by the pre-service teachers as a whole. Each learning goal received a score ranging from 0 to 1 (0: not attained; 1: by large attained by (almost) all pre-service teachers). These estimations per lesson were used to make an overall score for each learning goal. Next, average scores were calculated for the various components and types of knowledge. Based on these notes and reflections, these scores were related to the activities used during the intervention. The final results will show in detail the development of ISI CK and PCK at the level of the pre-service teacher and the role of the activities used in the intervention.

**Table 3: Attainment of the learning goals, summarized by ISI component and knowledge type**

Component	Average score <sup>a</sup>		Knowledge type	Average score <sup>a</sup>
General	0.75		Common content knowledge	0.73
Data as evidence	0.5		Specialized content knowledge	0.63
Generalization beyond the data	0.61		Knowledge of content and students	0.39
Sampling method	0.55		Knowledge of content and teaching	0.43
Sample size	0.43			
Uncertainty	0.59			

<sup>a</sup>Each goal received one of the scores 0, ¼, ½, ¾ or 1 (0: not attained; 1: by large attained by (almost) all pre-service teachers)

## Preliminary results

The preliminary results reveal to what extent the learning goals have been attained and shed some light on what activities helped to reach these goals. Table 1 shows to what extent the learning goals are attained. Table 3 shows the average score for the learning goals summarized for components and knowledge type respectively. There are some notable results. First, most pre-service teachers seemed to be aware of the inferential nature of research questions and the uncertainty inherent to the results. The homework assignment at the start of the intervention seemed to have helped to foster this awareness. Second, the modeling of the example lesson seemed to be a good context to reason about sampling methods, because it naturally led to the use and discussion of random and quota sampling methods. Moreover, although average scores on PCK learning goals are lower than on CK learning goals, modeling helped the pre-service teachers to get a better idea how to teach ISI to primary school students. Thirdly, while the presentation of PCK issues by the teacher educator in lesson 8 did not seem to contribute much to the pre-service teachers understanding, the discussion of PCK based on the pre-service teachers' experiences in lesson 12 and 15 did. Finally, an understanding of the fundamental idea that if a properly selected sample is representative for the population it can be used for an inference, might be conditional for understanding other ISI concepts. While part of the pre-service teachers seemed to understanding this idea, part of them did not. Lacking this understanding might hinder them in teaching ISI.

# Chilean primary-school students' levels in reading pictograms

Danilo Díaz-Levicoy, Pedro Arteaga, and Carmen Batanero

University of Granada, Spain; [parteaga@ugr.es](mailto:parteaga@ugr.es)

*In this paper we analyse the competence in reading pictograms by 140 Chilean students (6th and 7th grades). The written responses to two activities taken from textbooks are used to describe the children's reading levels and strategies to interpret pictograms and translate them to a table. Results suggest that students do not find major difficulties in translating the pictogram to a table; however, few of them reach the upper reading level needed for a critical interpretation of the information displayed in the pictogram.*

*Keywords: Pictograms, understanding, primary education.*

## Introduction

A relevant part of the information we face every day is given in statistical graphs, whose interpretation is often needed to make different decisions; therefore there is a need for citizens to achieve enough graphical competence (Ridgway, Nicholson & McCusker, 2008). These reasons led countries like Chile to introduce statistical graphs in the primary education (Díaz-Levicoy, Batanero, Arteaga, & López-Martin, 2015). More specifically, in Chile children are requested to collect and record data to answer statistical questions about themselves and their environment, using bar charts, tables and pictograms, as well as to read and interpret these representations since the 1<sup>st</sup> grade (MINEDUC, 2012). There is however no available empirical studies providing evidence that Chilean children understand these graphs at the end of primary education. The aim of this paper is to analyse the reading level of the pictograms, reached by Chilean children in the last year of primary school (6th grade) and what they remember a year later (7th grade). Since statistical graphs are included in primary education in many countries, this information may be useful in other contexts. Below we describe the foundations, method and results.

Pictograms are statistical graphs that display information using icons, whose size is proportional to the frequency of each attribute. Each icon represent a fix value, and can be repeated, to achieve the attribute frequency; its iconic character has been considered relevant in conveying recommended modes of behavior (Tijus, Barcenilla, De Lavalette, & Meunier, 2007), such as helping sick children understand a treatment that they are undergoing (Hämeen-Anttila, Kemppainen, Enlund, Patricia, & Marja, 2004).

Understanding statistical graphs involve composing individual data values into an aggregate or distribution and perceiving this distribution as a whole; however, some students only perceive graphs as “collections of values” instead (Konold, Higgins, Russell, & Khalil, 2015). In our research we are interested in the children competence in interpreting a distribution represented in a pictogram and in the reading level shown in the children responses when reading pictograms. We use Curcio's (1989) categorization.

- *Level 1. Reading the data.* At this level the student can successfully perform a literal reading of the information presented in the graph, but does not succeed in more sophisticated reading, do not

provide an interpretation, or carry out additional calculations with the information displayed in the graph.

- *Level 2. Reading within the data.* In addition to making a literal reading, the student can obtain information that is not explicitly displayed in the graph, with simple mathematical processes, such as arithmetic operations or comparisons.
- *Level 3. Reading beyond the data.* The student is able to extrapolate or interpolate the data to predict values that are not shown in the graph. He or she is also able to make a critical reading to detect an incorrect interpretation of a graph.

We only found a few investigations related to our study. Cruz (2013) analysed the interpretation of pictograms by 21 children in 3rd year of Primary Education in Lisbon after a teaching process. The responses to a written questionnaire with different types of graphs were analysed: 82% of children properly completed those reading activities that required Level 1 in Curcio's (1989) classification, while 70.5% reached level 2 and 66.5% level 3. One of the activities consisted in reading a pictogram where each icon represents a unit. In his item the author obtained 95% of correct answers to Level 1 questions and 77.3% to the Level 2 questions. There were no questions of Level 3. Regarding other types of graphs, Evangelista (2013) proposed single and double bar graphs and line charts to a sample of 60 students in grade 5th in Brazil. The results show that children correctly answer 51% of the activities; on average, the students correctly answered 59% of the activities in bar graphs and 43% of line charts. Level 1 questions had an achievement of 60% and level 2 between 51% and 41%.

## Method

The sample consisted in 140 Chilean Primary Education students from 6th grade (69 students, 11-12 years old) and 7th grade (71 students, 12-13 years old). Two different schools in the city of Osorno took part with collaboration from the schools' principals and of the teachers responsible of these groups, to all of whom we sincerely thank. Although we used a convenience sample, the socio-economic setting and average mathematical ability of children is varied and represent the situation in Chile.

The questionnaire (Figure 1) included two items taken from Chilean mathematics primary education textbooks. In the pictograms included in the questionnaire each symbol represents a uniform and defined value; therefore, a priori, should be simple for children. In the first adapted from a 3th grade Primary Education textbook (Charles et al., 2014, p. 253) item the student should read the pictogram, where each icon represents 15 statistical units (books). The student has to read two sentences; the first one is false (since there are 30 science fiction books) and the second is true (there are 60 children books). To complete the task the student must recognize the row for each value of the variable *book type* and understand that its frequency is given by the number of icons multiplied 15 (the frequency represented by each icon). Therefore, the student first has to *read within the data* (Level 2 according to Curcio's, 1989 classification), as he or she has to perform calculations with the values in the graph. In addition, the student should reason that each statement is true or false; therefore the student has to make a critical reading of the graph and consequently work at Level 3 (reading beyond the data in Curcio's, 1989 classification).

In the second item, adapted from a 4th grade primary education textbook (Batarce, Cáceres & Kükenshoner, 2013, p. 343), the student has to translate information from a pictogram to a table.

Besides reading the number of icons corresponding to each value of the variable, the student has to perform calculations; in this case, two types of icons are used to represent either 10 or 5 hours of light. The student has to reach level 2, *reading within the data* and complete the table, calculating the total amount of hours the light was turned on.

**Item 1.** The school librarian made an inventory of the library books.

 The image part with relationship ID rId8 was not found in the file.

Decide if each of the following statements is true or false. Explain your answer.

	True	False
1. There are only two science fiction books.		
2. There are 60 children books.		

**Item 2.** Complete the following table with the information displayed in the graph.

 The image part with relationship ID rId8 was not found in the file.

Number of hours per week that the light is turned on	
Place	Number of hours
Exercise room	
Dressing room	
Swimming pool	
Tennis court	
Total	

**Figure 1: Questionnaire**

## Results in item 1

In item 1 we first analyse the percentage of correct responses and then the reading level that the students of our sample reach when providing a justification of their response.

### Percentage of correct answers

In Table 1 we present the percentage of correct answers in the questions regarding the truth or falseness of the two statements given in this item. We observe that less than 50% of the students provided a correct response to these claims. The results are apparently worse than those obtained by Cruz (2013) in reading pictograms, but this author only made questions that involved reading within the data (Level 2) and each icon in his pictograms represented only one unit, while in our item each icon represents 15 units; therefore, our items are comparatively more difficult.

There was a higher level of success in the 6th graders than in the 7th graders, which may be due to the effect of forgetfulness, since pictograms are studied in Chile with more intensity in the first four years of primary education, and in 6th grade some activities related with pictograms are proposed in textbooks (Díaz-Levicoy et al., 2015). On the contrary, pictograms are rarely used in 7th grade. Anyway, the differences were not statistically significant difference in the t-test of difference of proportions (that test the hypothesis of having equal proportion of correct responses in both groups).

Statement	Total (n=140)	6 <sup>th</sup> grade (n=69)	7 <sup>th</sup> grade (n=71)	p- value*
1.It is not true that there are only two science fiction books	47.9	55.1	40.8	0.0904
2. There are 60 childhood books	49.3	55.1	43.7	0.1774
* Test of difference of proportions in independent samples				

**Table 1: Percentage of correct answers according to statements of item 1**

### Reading level

We secondly analyse the reading level that the students achieved to decide the truth and falseness of the statements and to justify their response. Their arguments were classified according to Curcio's (1989) reading levels, which are interpreted as follows:

- *Level 0* is reached if the information requested in the question is not read or the graph reading is incorrect (students do not even read correctly the number of icons).
- The students' justifications are classified in *Level 1* if they simply read the number of icons for the variable values indicated in the question without performing any calculations. The student has identified the graph row corresponding to the variable value, and has counted the number of corresponding icons. However, he or she does not take into account that each icon represents 15 books, and does not perform the necessary calculations to determine the frequency corresponding to each category. Some examples are:

*It is true, because in the inventory two science fictions books appear* (Student 55, first question)

*It is false, there are four children books* (Student 73, second question)

- *Level 2* is reached if the student correctly answers the question and apparently has carried out the calculations required to determine the frequency of a category in multiplying the number of icons by 15. In this case, the student is able to correctly interpret the pictogram but does not sufficiently argue the truth or falseness of the claim posed. We have also considered within *Level 2* those responses in which students perform an incomplete argument, i.e. they do not explicit the arithmetic operations performed. For example:

*It is false; there are 30 science fiction books* (Student 21, first question)

*It is true, one book is 15 and there are 4 books* (Student 66, second question)

- We consider that a student response reaches *Level 3* if the student has performed the calculations required to determine the frequency of the category and interprets correctly the pictogram. In addition, the student reaches a critical reading, because he or she can give an argument that supports the correct or incorrect statement.

*It is false, because as you can see each icon represents 15 books and there are two icons for science fiction books; for this reason if we sum 15+15 the result is 30 books* (Student 38, first question).

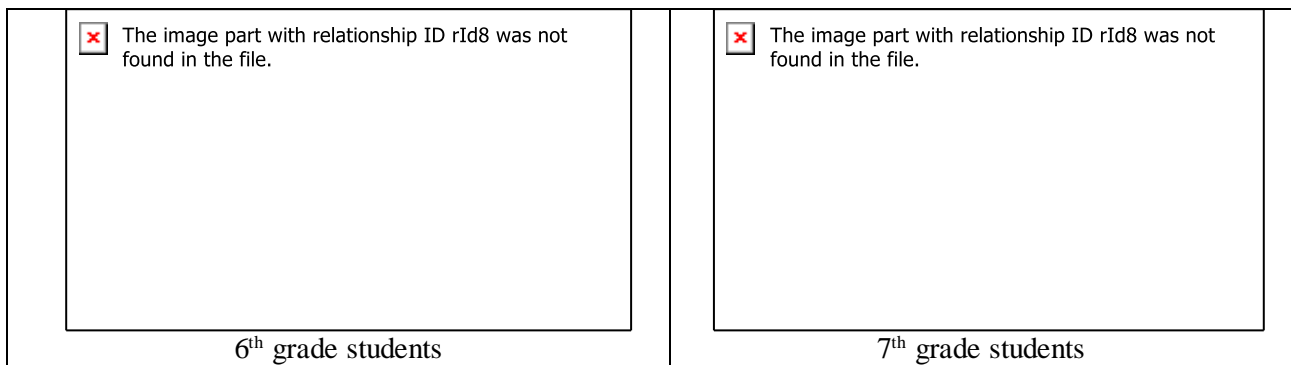

In Table 2 we present the distribution of the reading levels achieved by the whole sample, as inferred from the arguments that children provide to express their agreement or disagreement with both statements.

Statement	Reading Level			
	0	1	2	3
1. There are only two science fiction books	1.6	37.3	55.4	5.6
2. There are 60 childhood books	2.3	33.4	53.2	11.1

**Table 2: Percentage of reading levels achieved by students in their responses to item 1**

Overall the most common reading level in both questions was Level 2, which involves comparisons and data operations. The second most frequent was Level 1, where students read literally the information displayed, and very few students reached Level 3, which involves critical reading (a few more in the second statement).

**Figure 2: Percentage of Reading levels in both parts of the item1 in each group**

When analysing the results by grade and statement (symbolized by S1 and S2) (Figure 2), 7th grade students more frequently provided Level 1 answers in both statements (63.4% in the first statement and 59, 2% in the second) that the 6th grade students (50.7% in the first statement and 43.5% in the second). These, also had higher percentage at Level 2 (42% in the first statement and 40.6% in the second), while the 7th grade student's percentages at level 2 were 26.8% and 21.1%. Level 3 answers were scarce in both grades; at this level, 7th grade students got better results than 6th grade students, due to their better level of reasoning, but the difference is small. Overall the 6th grade students have better results, since they achieved a higher percentage of responses in Levels 2 and 3.

## Results in item 2

In this item we first describe the results achieved in the reading level and then those related to student competence to translate the graph to a table.

### Percentage of correct answers

In this item, students should make a translation of the pictogram to a table. The answers given by students are classified according to the following categories:

- *Correct table.* When the student has successfully translated all data on the pictogram to the table. He or she has also correctly calculated the total of the table.

- *Partially correct table.* The student makes a partially correct translation of the information shown in the pictogram; the table is correct, with some mistake. These errors are: a) taking into account one icon more or less when calculating frequency (12 students); b) wrong calculation of total hours (7 students); c) considering that the icon that represents half bulb is equivalent to 15 hours of consumption, instead of five (1 student); d) considering that one of the icons represents one hour of consumption, while the rest has been translated well for 10 hours (1 student); e) producing some correct rows in the table, but not finishing the table (1 student); f) not calculating the total, although the table is correctly constructed (1 student); g) making two of the above errors (1 student).
- *Incorrect Table.* When all or most of the rows in the table are incorrect, what happens, in particular, to all of the students who only reached the Level 1 when reading the pictogram.
- *Do not complete the table.* When the student does not develop the activity or when students reached Level 1 partially.

Table 3 shows the distribution of the answers given by the students in translating to a table, where most students have completed the task successfully, with a percentage bigger than 76% in each course and globally. The differences were not statistically significant.

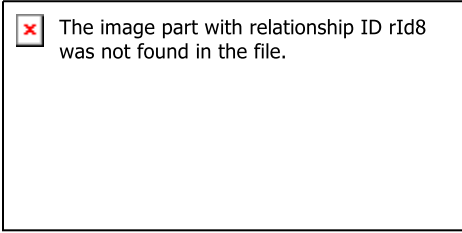

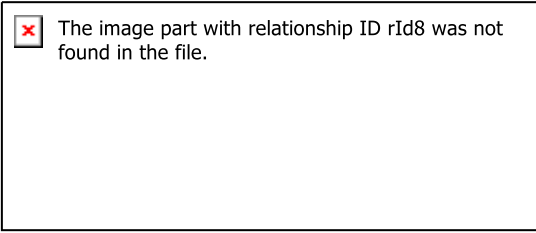

Type of answer	6th grade (n=69)	7th grade (n=71)	Total (n=140)
Correct	76,8	78,9	77,9
Partially correct	18,8	15,5	17,1
Incorrect	0	2,8	1,4
The task is not completed	4,3	2,8	3,6

**Table 3: Percentage of students by table correctness**

## Reading level

In this item these levels are interpreted as follows:

- At *Level 0* are the students who provided no answer or who fail to read the graph.
- At *Level 1* students perform a literal reading of the data (either all or part of the data). For example, some students believe that each bulb represents a unit. An example is given in Figure 3 in which the student considers the bulb as an unit in all the categories, except one.
- At *Level 2* are those students who identify the number of icons corresponding to each variable value and multiply this number by 10 or 5 to obtain the corresponding frequency. An example is given in Figure 4.

	
<b>Figure 3: Level 1 table (Student 29)</b>	<b>Figure 4: Level 2 table (Student 75)</b>

In Table 4 we present the distribution of the reading levels reached by the students in this item, where the highest percentage of responses are located at Level 2 (reading the data) in both courses. Over 90% of students are able to correctly read the pictogram at level 2 and 7th grade students show better performance levels when the translation is done correctly.

Level	6th grade (n=69)	7th grade (n=71)	Total (n=140)
0	0	2.8	1.4
1	8.7	2.8	5.7
2	91.3	94.4	92.9

**Table 4: Percentage of students reaching each reading level by course and in total**

## Discussion and conclusions

This study has provided information about the reading levels reached by the students in the sample when reading pictograms and when translating between pictogram and data table, complementing previous work. In relation to the work of Cruz (2013) we used more complex pictograms, as each icon represents several units, while in those proposed by the author each icon symbolized one unit. In relation to the work of Evangelista (2013) with lines and bar graphs, the results in levels 1 and 2 are somewhat lower than in our work but not too much.

In our first item students can reach up to Level 3 in Curcio's (1989) categorization, while Cruz only considered the first and second level. This explains why our results are apparently lower than those in Cruz. However, the second item proposed in our study has been very easy; both in reading the pictogram where our results were better, as in the translation to a table, a task that was not proposed by Cruz. Part of the errors found in the first item, where students are asked to refute or confirm a statement, are due to their lack of critical reading, and argumentations skills. As suggested by Freedman and Shah (2002), graph comprehension is influenced not only by the display characteristics of a graph, but also a viewer's domain knowledge, graphical literacy skills, and explanatory and other scientific reasoning skills that these children may lack. In the next step in our research we are expanding the sample of children and schools to confirm the results.

# Conditional probability as a decision-making tool: A didactic sequence

Raimundo Elicer<sup>1</sup> and Eduardo Carrasco<sup>2</sup>

<sup>1</sup>Roskilde University, Denmark; [raimundo@ruc.dk](mailto:raimundo@ruc.dk)

<sup>2</sup>Metropolitan University of Education Sciences, Santiago, Chile; [ecarrasc@gmail.com](mailto:ecarrasc@gmail.com)

*Conditional probability arises as a tool for analyzing a strategy for decision-making that molds to new conditions. From that point of view, an introductory sequence which utilizes diachronic games is designed and analyzed under the framework of didactical engineering, bringing conditional probability into play as a decision-making tool. It can be observed that students tend to base their decisions on heuristics and experiential considerations, and do not see the need for a proper calculation of theoretical probabilities. At most, they use experimentation as a tool, not computing probabilities based on relative frequencies, but comparing absolute frequencies.*

*Keywords: Decision-making, conditional probability, didactical engineering.*

## Introduction

UNESCO has dedicated a full chapter about confronting uncertainties on its “Seven complex lessons on education for the future”. It describes uncertainties of reality and knowledge, and proposes ways of taking action despite the unavoidable uncertainty of the world (Morin, 1999). Ignoring or downplaying uncertainty could lead us to make fragile decisions, which can generate a negative impact as soon as the circumstances change (Taleb, 2012). In this matter, probability and statistics emerge as the core mathematical subjects for facing this challenge. Thus, these subjects should play an important role in modern mathematics curricula for general education.

However, in general students have low scores on these fields. PISA 2012 reveals that 76.9% of tested students do not pass the second level of accomplishment in the areas of uncertainty and data (Organisation for Economic Co-operation and Development [OECD], 2014). At the best they can apply suitable calculation basic procedures in familiar contexts such as coin tossing or dice rolling. However, they are not able to reason and make critical reflections in order to make valid contextual or general conclusions.

Probability and statistics have given shape to a field of economics studied since the 40s. It has been dominated essentially by “expected value theory” as a normative model of rational choice, proposing that rational individuals maximize the expected value of their utility functions (Friedman & Savage, 1948). This approach has been criticized lately by behavioral psychology and behavioral economics, pointing out many situations in which the axioms of the theory show themselves inadequate for modelling reality (Kahneman & Tversky, 2007). The authors propose a “prospect theory”, taking into account individuals’ biases towards the probability and impact of each choice.

The research related to this paper is embedded within a broader domain that embraces the relationship between didactics of probabilities and statistics, and decision-making under uncertainty. It involves facing the philosophical debate between the idea of probability and statistics as decision-making tools, against decision-making scenarios as resources for improving the institutionalized techniques within probability and statistics. Moreover, the research relates to critical mathematics education, which emphasizes the empowerment of students as citizens as an argument for mathematics in general education (Skovsmose, 1994).

In this frame, two research questions are addressed. (1) “What kind of probabilistic contents and related didactics could help students make better and more reflexive decisions in their lives?” and (2) “How do we assess the students’ learning of probability theory and methods, and which role can decision-making scenarios play in such assessment?”

In particular, this paper reports the results of an exploratory application of didactical engineering that involves conditional probability in decision-making scenarios. The purpose is to illustrate challenges and difficulties involved in the teaching of probability under this point of view.

## Theoretical framework

From an *enactivist* perspective (Brown, 2015), knowledge is only reflected by and detectible through action by those who know. One learns with an embodied mind, within a process called *enaction*. This notion breaks *representationist* ideas of the mind, considering an incarnated cognition, in which meanings arise as particular states of cooperation in neuronal networks. These states are put into action –enacted– via retroactive co-definitions between the subjects and the contexts they live in. This concept implies that, when faced upon a learning situation, students will enact the knowledge that had let them to act in similar situations, not only their school experience.

Within the scope of this research, students would enact what they have learned from situations of uncertainty and decisions they made before, their previous formal school knowledge, operational aspects such as heuristics and perceptual aspects like feelings that the context evokes in them.

According to mathematical philosophy literature (e. g. Leitgeb & Hartmann, 2014), two types of decision-making scenarios can be defined. Namely, a *situation under uncertainty* is a setting in which one does not know what the relevant probabilities are, and in decision-making *situation under risk*, the probabilities of the various outcomes are in principle. In both cases, decisions are made based on the best available information and building conjectures about likelihood of different results. We will consider the latter one in this paper. Here we will intend to use mathematical objects, such as probability theory and calculations, in the context of mathematics teaching.

Morin proposes “(...) two ways to confront the uncertainty of action. The first is full awareness of the wager involved in the decision. The second is recourse to strategy” (Morin, 1999, p. 47). Strategy must prevail over program, which gets stuck as soon as the outside conditions are modified. A strategy is meant to be adaptable to variations in the context. In this regard, as one acquires new information about the situation in which one requires to make decisions under uncertainty, the notion of conditional probability lets us incorporate changes in the degrees of belief about possible outcomes (Batanero & Díaz, 2007), improving decision-making based on predictions. As a consequence, the rank of experiments to consider in the classroom becomes wider.

The central mathematical object of study is, therefore, conditional probability. The learning goal is, as stated on the study program at 11<sup>th</sup> grade in Chile, to “solve problems that involve computation of conditional probabilities within simple situations” (Ministerio de Educación [MINEDUC], 2004). The choice of situations and means of representation (tree diagram, 2x2 tables) are left open for the teachers, but the given established notions involved are:

- Meaning of “probability of event A, given event B”, using the notation  $P(A|B)$ .
- If A and B are independent events, then  $P(A|B) = P(A)$ .

- If A and B are not independent events, then  $P(A|B) = P(A \text{ and } B)/P(B)$ , with  $P(B)$  not equal to 0.

As an example, let's say that an experiment consists of tossing a fair coin twice. Let A be the event of obtaining two successive heads, and B be the event of obtaining a head in the first toss. According to previous contents, students should be able to calculate theoretically that  $P(B) = \frac{1}{2}$  and  $P(A \text{ and } B) = \frac{1}{4}$ . Given the context, students should be able to interpret and calculate that  $P(A|B) = \frac{1}{2}$ , because now that we know that B happened, then for A to happen, a second head should be obtained. Also, it may be obtained that  $P(A|B) = P(A \text{ and } B)/P(B) = \frac{1}{4} / \frac{1}{2} = \frac{1}{2}$ .

## Methodology

Didactic engineering is assumed as a research and design method, and includes four phases: preliminary analysis, *a priori* analysis, execution, and contrast and redesign (Artigue, 1988).

For the preliminary analysis, historic-epistemological elements are obtained by selected authors, in particular, Pascal and Huygens, and their significant work on the development of probability (Pascal, 1983; Basulto, Camuñez, Ortega, & Pérez, 2004). The analysis is made from a chronological construction of the concepts by the authors and their sociocultural contexts. Practices that build the necessity and give meaning to gambling and decision-making are documented. For the cognitive analysis (Elicer & Carrasco, 2014), exploratory tests are taken to gather productions of students about their probability notions and their strategies to make decisions in the Monty Hall game (Batanero, Fernandes, & Contreras, 2009). The didactic analysis is made from the 11<sup>th</sup> grade study program and textbook delivered by the Chilean government to public and subsidized schools, which represent 91.1% of the total enrolled students in 2015 (MINEDUC, 2015).

The didactic sequence is then designed taking into account key notions resulting from preliminary analysis and an increasing level of complexity. Students should start making specific calculations and end making justified decisions. For the *a priori* analysis, conjectures emerge from the authors, according to the cognitive analysis. It is fair to anticipate similar outcomes from the students and, therefore, to add questions that help them have a critical insight about them.

The execution stage consists in the application of the didactic sequence to a group of students and the contrasting between initial conjectures and the students' actions and productions. The experimental group is one upper secondary class of 19 students aged 15-17 years old. They have already been introduced to probability calculations using Laplace's law, tree diagrams and basic combinatorial techniques. Students have not yet studied the concept of conditional probability.

Finally, transcriptions of students' written outcomes are tabulated according to defined categories in the preliminary analysis (Elicer & Carrasco, 2014). Those which are unexpected and do not match these categories are highlighted and mentioned in the results. Suggestions for redesign resulting from the discussions with the teachers are mentioned for each activity.

## Results and discussion

The designed sequence is fully exposed on the Appendix of this paper. It is meant to be executed as an introduction to the mathematical object of conditional probability. This means no new institutional contents would be presented, they should use their previous knowledge. The first session includes Activities 1 and 2, and the second session concludes with Activities 3 and 4.

For a full revision of relevant elements of the preliminary analysis see Elicer & Carrasco (2016). Those considered for the design are as follows, given in parentheses the questions implemented.

**Historic-epistemological.** In Pascal-Fermat correspondence, probability analysis arises from projective decision-making, in the effort of setting a fair share (1.1, 1.4, 2.1 and 3.4), in particular when a gambling game stops (2.5, 2.8 and 2.9). After this notion comes the idea of betting with some kind of advantage. Studying the ratio between favorable and all cases comes from getting to know every possible case. Huygens brothers association between forecasting situations, such as life expectancy, and gambling, allows us to give a new meaning to the idea of probability in a game, as an a posteriori calculated probability. From this point of view, possible outcomes of a game are described in statistical data (1.2, 1.4, 2.4, 2.7 and 3.3).

**Cognitive.** Students conceive that different realizations are all possible cases, without weighing them, and draw upon non-mathematical arguments to make a choice (3.1). They also recognize that they would make different decisions if they played the actual game, where they had to make a choice in situ and not a priori (4.1 and 4.2).

**Didactic.** The main activity proposed in the textbook is theoretical probability calculation (1.3, 2.2, 2.3, 2.6, 3.2 and 3.5), without decision-making or searching for an advantage in gambling. This is implemented on Activity 3, where the Monty Hall problem involves an actual decision.

Activity 1 goes as expected. Students unanimously recognize this is a fair game because both players have the same probability of winning (1.1), which is well calculated using the Laplace law (1.3). Usually, the distraction of doing eleven repetitions is recognized by them, saying there are too few repetitions, that it is an odd number (1.2), and that results depend on chance or luck (1.2 and 1.4). One particular comment we didn't expect was that "the game is not fair, because the results depend on chance and not on personal abilities" (1.1). Considering a future design, the meaning of fairness should not be trivialized. Might be defined or discussed.

Activity 2 throws similar responses about the basics (2.1 and 2.4), which is the intention. Some students still confuse the concept of "possibility" and "probability" (2.2) when giving their answer, which could be revised before. They do not use their previous combinatorial reasoning. Instead, they count different scenarios than come up to their minds (HTT, HHT, ...), which not always lead to counting four possibilities for each player (2.2). For this reason, they might answer that each player has the same probability of winning (2.3), based on their intuition and the scheme made in question 2.2. The same schemes lead some of them to wrong answers.

For the second part of Activity 2, most students recognize that one player has an advantage after the first toss. Just a few could actually compute the theoretical probability (2.6), so most of them base their answers on interpreting experimentation results (2.7). Here the probability of success arises as an estimation of compared absolute or relative frequencies, giving use to fractions. Our observation is that an exact calculation of these probabilities does not seem to be necessary for answering the question, so the intention must be revised.

As for the repartition when the game is interrupted, (2.5, 2.8 and 2.9), there are two main types of reasoning among the students. One big group defends an equal repartition of 50% and 50%, arguing that "even when one of us has more possibilities of winning, randomness says that any of us could win", giving

randomness a mean for equality. Others recognize fair to split it according to probabilities, using fractions constructed on their ratio phase (Fandiño, 2015) as an operator to multiply the poll to be shared.

In Activity 3, most of students believe each of the remaining doors give an equal chance of winning (3.1), falling into an isolation effect (Tversky, 1972). Since there is a choice to make, they use personal experience-based explanations, repeating many of the answers obtained on the preliminary analysis. This is expected to change after the experimentation, finding the need for a proper probability calculation. Most of them change their position (3.3 and 3.4), based only on experience. This means the frequentist meaning of probability is stronger than a classic or theoretical one, as a decision-making tool. Questions 3.2 and 3.5 are too confusing for them and most of answers are left blank. We recognize there is no need for analyzing the sample space in an introductory session.

## Conclusion

In the context of primary and secondary compulsory education, probability and statistics usually arise as mathematical concepts that represent tools for description of uncertainties. In order to move forward, the authors participate on the idea of having them as elements for decision and action. Didactical sequences should involve escalating decision-making scenarios and questions. According to the historical development of probabilities, it is convenient to ask if a game is fair or not (Hernández, Yumi & de Oliveira, 2010), followed by building a strategy to make it favorable.

Researchers and teachers should anticipate that heuristics and personal experiences are frequently more powerful considerations than calculations about probability and risk, when students are faced with decision-making scenarios. This has been documented not only in the didactics of mathematics research (e.g. Serrano, Batanero, Ortíz & Cañizares, 1998), but also (even previously) in psychology and economics literature. In particular, teaching and learning the conditional probability object could involve decisions within diachronic games. These are subjected to the isolation effect (Tversky, 1972; Kahneman & Tversky, 2007), among other difficulties, such as perceptions of independence and sample space, and interpretations of convergence (Batanero et al., 2009).

We recommend creating new sequences for other probabilistic concepts. Natural extensions are total probabilities and Bayes' theorem. Given information about medical research, students may decide whether approving or not a certain pharmaceutical product; or deciding about changes on their habits according to the relationship between cancer and processed meat or smoking.

## Acknowledgments

The authors thank teachers Michelle Godoy and Victoria Núñez for their initiative into applying and commenting feedback from the sequence proposed in this paper, in their school Liceo Bicentenario Italia from Santiago, Chile.

This work was funded by the doctoral scholarship CONICYT BCH/DOCTORADO 72170530.

## Appendix: Proposed sequence for execution

### Activity 1: Single coin toss

Two players choose heads or tails. They toss a coin and whoever guesses wins.

1.1 Do you think this is a fair game? Why?

1.2 Repeat this game eleven times and register who wins each time. Do you keep your answer for question 1?

1.3 What's the probability of winning for each player?

1.4 [Teachers compile the results on the board]. Do you still keep your answer for question 1?

### Activity 2: Best out of three

The game consists in two players choosing heads or tails, betting 60 each. They toss a coin successively three times and whoever obtains the most guesses wins.

2.1 Do you think this is a fair game? Why?

2.2 How many options does each player have of winning?

2.3 What's the probability of winning for each player?

2.4 Repeat this game ten times and register who wins each time. Do both players have the same amount of victories? Why do you think this happens?

Now suppose the first coin toss results on heads and the game is interrupted. You must decide what to do with the poll.

2.5 Would it be fair to split the poll by 60 each? Why?

2.6 Could you calculate the probability of winning for each player starting from that point?

2.7 Still assuming the first toss resulted in heads, simulate ten times the two remaining tosses, and register who wins the best out of three each time.

2.8 Given this scenario, would it be fair to split the poll giving 80 to the player who betted heads, and 40 for the one for tails?

2.9 Propose a repartition coherent with each one's probability of winning.

### Activity 3: Monty Hall game

You are faced against three doors. Behind two of them there are goats and the other has a new car. Your goal is to guess the door where the car is hidden. The sequence is as follows: (1) The host offers you to pick a door. (2) After your choice, the host opens another door, different from the one you have chosen and shows there's a goat. (3) Now he offers a second chance: will you keep your first choice or change it to the other closed door?

3.1 What would you decide; would you keep your first choice or change it? Explain what is relevant for you to make this decision.

3.2 Which events have the same probability of occurring?

3.3 In pairs, play the game with your cups and car toy. One of the players will always change his or first choice, and the other will never change it. Repeat this ten times and compile the results for the whole class. Is there any difference between both types of players?

3.4 Is, therefore, any way of betting with an advantage?

3.5 Reconsider your answer from question 3.2. Given that the game has two stages of choice, which events have the same probability of occurring?

## Activity 4: Plenary

Each pair of students responds the following questions in front of the class.

4.1 How would you face the Monty Hall game if you had to be there?

4.2 What recommendations would you give to someone who is about to play?

# Stepwise development of statistical literacy and thinking in a statistics course for elementary preservice teachers

Daniel Frischemeier & Rolf Biehler

Paderborn University, Institute of Mathematics, Germany; [dafr@math.upb.de](mailto:dafr@math.upb.de)

*In this paper we describe the design, realization and evaluation of a course for elementary preservice teachers, applying the PPDAC-cycle (Wild & Pfannkuch, 1999), using innovative methods and digital tools like TinkerPlots (Konold & Miller, 2011). We will refer to design principles of the course and show in which way a stepwise development of statistical literacy and thinking with TinkerPlots works in cooperative learning environments.*

*Keywords: Elementary preservice teachers, design based research, cooperative learning, statistical literacy and thinking, TinkerPlots.*

## Introduction

Since the implementation of the leading idea “Data, Frequency and Chance” (Hasemann & Mirwald, 2012) in mathematics classrooms in primary schools in Germany, statistics has become a central topic in primary school. This has set requirements not only for schools and teachers, but also for universities who have to educate preservice teachers in statistics for their upcoming school career. Requirements for teacher education in statistics can be found on German national level (e.g. AK Stochastik, 2012), and on international level (e.g. Batanero, Burrill & Reading, 2011). Two important aspects appear at both levels: applying a whole data analysis cycle (like PPDAC, see Wild & Pfannkuch, 1999) and analyzing data with digital tools (see Biehler, Ben-Zvi, Bakker & Makar, 2013). We decided to use TinkerPlots (Konold & Miller, 2011) for our purposes, since it is easy to learn, no formulas are needed, and it enables learners to create multiple representations of data. In our sense, TinkerPlots can serve as educational software for pupils from grade 4, as software for teachers for analyzing data, and as medium for demonstration purposes in classroom. This was our motivation to design, realize and evaluate a statistics course for elementary preservice teachers with TinkerPlots on the basis of the Design Based Research paradigm (Cobb, Confrey, diSessa, Lehrer & Schauble, 2003).

## Our course to develop statistical literacy and thinking with TinkerPlots

The main goal of this course is to develop statistical literacy and thinking components (for a definition see Garfield & Ben-Zvi, 2008, pp. 34) and the technological knowledge of our participants. At Paderborn University in Germany elementary preservice teachers for mathematics attend an obligatory course “Elementary Statistics”, which is about data analysis, combinatorics and probability theory. Due to limits of time, there is no space for going through a whole data analysis cycle like PPDAC or to do further data explorations in multivariate datasets. For that reason our course was designed taking into account the principles of the “Statistical Reasoning Learning Environment” (Garfield & Ben-Zvi, 2008), to expand preservice teachers’ knowledge in data analysis and to introduce a new tool to them, which better fits to primary and lower secondary school. Fundamental ideas realized in our new designed course are to “focus on developing central statistical ideas”, to “use real and motivating data sets”, to “use classroom activities to support the development of students’ reasoning”, the integration of “appropriate technological tools”, to “promote classroom discourse that includes statistical arguments and sustained exchanges that focus on

significant statistical ideas” and the “use of formative assessment” (see Garfield & Ben-Zvi, 2008, p. 48). On the paradigm of the PPDAC-Cycle (Wild & Pfannkuch, 1999), the course has the aim to encourage participants to define a statistical problem and to pose statistical questions (First “P” in PPDAC), to plan and to prepare a data collection (Second “P” in PPDAC), to collect data (with regard to data management and cleaning – “D” in PPDAC), to analyze data (“A” in PPDAC) and to make conclusions of the data explorations (interpretation – “C” in PPDAC). We implemented cooperative learning environments like the “Think-pair-share” method to develop the statistical literacy and thinking components of our participants (see Roseth, Garfield & Ben-Zvi, 2008) and to support peer-learning, peer-feedback and expert-feedback. In this respect, in a “Think-pair-share” setting, students first deal with the task on their own (“think phase”), discuss about their findings in peers (“pair phase”) in a second step and finally discuss their findings in class with the teacher (“share phase”). All in all, the course consists of four modules: The first module deals with the generation of statistical questions, the preparation of data collection and the collection of data. Here the participants get to know the “PPD” elements of the PPDAC cycle with a special emphasis on the generation of adequate statistical questions (see Biehler, 2001). The second module has the intention to introduce the participants into data analysis with TinkerPlots. Here the participants can learn first steps in data analysis using data cards and hands-on-activities and then use TinkerPlots for first explorations in small datasets. Because the focus is on the “AC” (Analysis & Conclusion) elements of the PPDAC cycle, the datasets are given to the students in an already prepared form. Furthermore the students learn to describe and interpret distributions of categorical and numerical variables with special emphasis to the elements and characteristics of distributions like center, variation, etc. as it is proposed in Rossman, Chance & Lock (2001) and Biehler (2007a, 2007b). Module three builds on module two and covers advanced data analysis with TinkerPlots in large multivariate datasets. Here the learners are introduced into comparison of groups (Pfannkuch, 2007). A major aspect in module two and three is to enable the participants to explore datasets and make their own statistical investigations with their own statistical questions (for a typical task for a statistical investigation in this respect see Figure 1). Module four has the intention to introduce the participants into inferential statistics, especially into randomization tests with TinkerPlots (Frischemeier & Biehler, 2014). Further details on the course design and the lesson plans can be read in Frischemeier (2017).

## **Accompanying research of the course: Stepwise development of statistical literacy and thinking**

The course was taught by the first and second author and consisted of 14 sessions, each session lasted 90 minutes. One major goal of the course was to develop the elementary preservice teachers’ statistical literacy and thinking components with TinkerPlots. Since statistical investigations of complex datasets are new to our participants, we want to evaluate the statistical investigations in the introductory stage (module 2) and see in which way the quality will improve over time in cooperative learning environments. Two major research questions arise: How is the quality of the statistical investigations in the intermediate steps in module two? How does the quality of the statistical investigations develop in process of module two?

### **Participants, task and data collection**

All in all 22 elementary preservice teachers participated in the course. All of them attended the course “Elementary Statistics” as described in the introduction. As a typical task a multivariate dataset with an exercise sheet consisting of four subtasks was given. As example you can see the “KinderUni”-task in Figure 1, where the dataset “KinderUni” had to be explored. The KinderUni dataset, is a (non-random

sampled) dataset with 28 variables containing information about leisure time and school activities of 39 pupils in the area of Kassel, Germany. In the introductory phase of module two the idea was, that learners at first explore small multivariate datasets to get used to data explorations with TinkerPlots and then to explore larger datasets in module three. So when working on the “KinderUni” task, the participants are at first (subtask (i)) asked for a short description of the dataset to get familiar with it. The second part (ii) of the task was to generate an appropriate statistical question. This statistical question of subtask (ii) is the starting point for subtasks (iii) and (iv). In subtask (iii), the participants are asked to create suitable graphs with TinkerPlots, which allow answering the statistical question arisen in part (ii). In subtask (iv) the participants are supposed to describe and interpret the TinkerPlots graphs of (iii) and finally to answer the statistical question posed in (ii).

### **„KinderUni“ task**

- (i) Explore the dataset “KinderUni”. Which variables are taken into account?
- (ii) Generate an appropriate statistical question!
- (iii) Create suitable graphs in TinkerPlots, which help you to answer the statistical question posed in (ii). Take also further explorations into consideration.
- (iv) Describe your TinkerPlots graphs created in (iii). Interpret them and summarize your findings in a statistical report.

**Figure 1: Task “KinderUni” as typical statistical investigation task in module two**

The participants worked in pairs of two on the “KinderUni” task. So all in all, we had 11 pairs, who remained constant all over the course. When working on the task “KinderUni”, the participants were asked to document the procedure of their statistical investigations in written form in Microsoft Word with the TinkerPlots graphs implemented. We collected all word documents from the “KinderUni” task. As mentioned above, one major idea of the course was to improve the quality of the statistical investigations by peer-feedback and expert-feedback. This happened with cooperative learning activities like “think-pair-share”. First, in the “think” phase, all pairs worked on the task on their own and produced the preliminary version of the task (preliminary version: V1). Then two pairs came together and discussed the products of their statistical investigations (not necessarily with the same questions) in peers in the “pair” phase with the goal to find improvements for the TinkerPlots Graphs, for the descriptions of the TinkerPlots Graphs, etc.. Finally after revising the documents after the “pair” phase (version after peer feedback: V2), as a last step, the revised documents were discussed in plenum with the first and second author. After this phase the participants were again asked to revise their products for a final version (version after peer- and expert-feedback: V3). So for our data analysis we have the documentations on the statistical investigations of the participants as preliminary version (V1, n=11 documents), as version after peer feedback (V2, n=11 documents) and finally as version after expert-feedback (V3, n=10 documents).

### **Methodology for data analysis and coding**

Our main goal was to rate the quality of the statistical investigations by points. Due to the huge amount of data, we used qualitative content analysis (Mayring, 2010) for rating the quality of the subtasks. We decided to weigh the subtasks (ii), (iii) and (iv) with equally two points maximum since these tasks are fundamental for the statistical investigation. In subtask (i) only one point is given, since this is an introductory task and easier than subtasks (ii), (iii) and (iv).

For subtask (i) we expected a description of the dataset (number of cases and variables, description of variables). In our course we have set the norm to begin every statistical investigation with an introduction. So two codes are given: “subtask (i) done correctly” and “subtask (i) not done correctly”. If subtask (i) is done correctly, one point is given, if it is not done correctly no point is given for this subtask. Details given with examples can be found in Frischemeier (2017, p. 350).

To distinguish the quality of statistical questions posed in subtask (ii), we took into account the classification of Biehler (2001) in “one-variable-” and “two-variable-” questions from a deductive point of view. So we distinguished whether the questions take into account one variable (example: “What is the distribution of the variable height?” - variable: height) or two variables (example: “In which way do boys and girls differ in respect to the variable height?” - variables: gender and height). For questions taking into account only one variable one point is given as maximum, because the exploration coming out of questions containing one variable is easier than for questions taking into account two variables. For “two-variable-questions” a maximum of two points are given. In between we inductively identified different qualities of statistical questions: So there can be “one-variable-questions”, which have just “yes” or “no” as answer (example: “Do 60% of the pupils have a mobile phone?”) – rated with 0.5 points, whereas “one-variable-questions” in regard to a characteristic of a distribution (example: “How many pupils have a personal computer?”) – rated with 1 point - are a little bit more sophisticated. Also in the set of “two-variable-questions” we find different types: There are questions leading just to a “yes”/“no” – answer (example: “Is there a difference between boys and girls in their time spending on computer use?”), whereas other types of questions lead to working out differences between the distributions (example: “In which regard does the computer use differ between boys and girls?”). Questions of the first type are rated with one point, questions of the second type are rated with two points. There is also another type of “two-variable questions”, which we call “open and complex”-questions like “which differences exist between boys and girls in regard to their leisure time activities?” This type of “two-variable-question” is also rated with two points. In this course we have set the norm to try to pose statistical questions which aim at two variables. As an example for our rating in regard to subtask (ii) we take the question “How many kids have a way to school of 30 or more minutes?” of the pair Anne and Alice. We rated the question with one of two points, since it only covers one variable (“way to school”) and it is aimed at one characteristic of a distribution (“how many ...?”). Further details for the categorization of questions are given in Frischemeier (2017, p. 350).

For subtask (iii) an adequate TinkerPlots graph has to be created, which enables participants to answer the statistical question posed in (ii). Since we want our participants to focus on the distribution of the investigative variable and on the influence in regard to further variables, we have set the norm in our course that the icons should be stacked in TinkerPlots and further explorations (taking into account other variables) have to be made. If all three requirements (informative TinkerPlots graph, stacked dots and further explorations) are fulfilled, subtask (iii) is rated with the maximum of two points. Table 1 shows the several ratings for subtask (iii).

Informative TinkerPlots graph, stacked and further explorations	2 points
Informative TinkerPlots graph, stacked and no further explorations	1.5 points
Informative TinkerPlots graph, not stacked and further explorations	1.5 points
Informative TinkerPlots graph, not stacked and no further explorations	1 point
Non informative TinkerPlots graph/missing TinkerPlots graph	0 point

**Table 1: Overview of ratings and their definitions of subtask (iii)**

As an example for our rating with regard to subtask (iii) we take the pictogram (with stacked icons) of Anne and Alice in Figure 2. With this TinkerPlots graph they are able to answer their question (“How many kids have a way to school of 30 or more minutes?”) posed in subtask (ii). Since icons are stacked, but no

further explorations are made, this graph is rated with 1.5 of 2 points. Further details and examples on the ratings of subtask (iii) can be read in Frischemeier (2017, pp. 354).

**Figure 2: TinkerPlots graph for “KinderUni” task of Anne and Alice**

In subtask (iv) the TinkerPlots graph (see Figure 2) has to be described adequately in at least one aspect and the question arisen in subtask (ii) has to be answered correctly. A maximum of two points are given, if both conditions are fulfilled. As adequate descriptions of the TinkerPlots graph we see elements like center, variation, shape, peaks, clusters and outliers (see Rossman et al. 2001, p. 48) but also absolute and relative frequencies of bins. For adequate elements to be carved out in group comparisons, see Frischemeier (2017, p. 42). In Table 2 we see the ratings for subtask (iv).

Component of TinkerPlots graph described and question (ii) answered correctly	2 points
Component of TinkerPlots graph described and question (ii) not answered correctly	1 point
Component of TinkerPlots graph not described and question (ii) answered correctly	1 point
Component of TinkerPlots graph not described and question (ii) not answered correctly	0 points

**Table 2: Overview of ratings and their definitions of subtask (iv)**

As an example for our rating in regard to subtask (iv) we have a look at the conclusion of Anne and Alice in subtask (iv): „We can see that 12+3 pupils have a way to school of 30 minutes or more.“ This was rated with the maximum of two points, since one component (absolute frequency of pupils in bins 30-59.9 and 60-90) of the graph is described and the question posed in (ii) is answered correctly. Further details on the ratings of subtask (iv) can be read in Frischemeier (2017, pp. 362).

## Results

Let us have a look at the quality of the statistical investigations for the “KinderUni” task in module two in the different stages V1, V2, V3. For each team we rated the subtasks and calculated the success rate “points gained in all subtasks divided by the maximum points in all subtasks” for the “KinderUni” task in each stage (V1, V2, V3). In Figure 3 we see the distributions of the success rates in stages V1, V2 and V3.

**Figure 3: Success rates of the statistical investigations in stages V1, V2 and V3**

Regarding to our research questions we can say that the median and also the mean (see blue triangles in Figure 3) of success rates of the different teams increase in the process of the several stages: In preliminary version (V1), where the pairs were on their own, 10 of 11 statistical investigations have a rate below 0.50, the median of the rates is 0.40, the mean of the rates is 0.3636. After the peer feedback phase (“pair”), there is a big positive shift in quality from V1 to V2. Exemplarily one peer feedback component which has often occurred was the advice to stack the dots in the plot to get a better view on the distribution of the data. The quality of the statistical investigations in V2 has increased a lot (mean=0.5236; median=0.56), since in this version only 3 of 11 statistical investigations are below the 0.50 rate. After the expert feedback (“share”) in stage V3 all reports are over the 0.50 rate, the median of the rates is 0.65 and the mean of the rates is 0.6520. The expert feedback concentrated most notably on prompts which suggest a better description of the TinkerPlots graph and a more adequate answer to the statistical question posed in subtask (ii). Finally we can identify a positive development of the quality from V1 to V3. We can also see that the distributions in Figure 3 are heterogeneous at the beginning (stage V1) and become more homogeneous in V2 and V3. For a more detailed look we will have a look at Table 3, which identifies the changes within the development of quality in between the four subtasks (i), (ii), (iii) and (iv) in the stages V1, V2, V3. We see that there is an improvement of quality in all subtasks, but the amount of the improvements differ on the kind of subtask. In subtask (i) there is a high quality (0.73) even in the beginning at the preliminary version (V1). This quality improves over time in the different stages V2 (0.91) and V3 (1.00). In V3, the rate is 1.00, which means that every pair began their report at this stage with an introduction of the dataset. In subtask (ii) we see the smallest development of quality: for the questions in the preliminary stage (V1) the rate is 0.47 on average, there is no improvement in V2 (0.47) and only a small improvement in V3 (0.50). Even at the stage V3, in subtask (ii) all questions were only rated with one point, since none of the questions went beyond single characteristics of a distribution or beyond “yes”/“no” answers. One reason might be that the peer and also the expert feedback concentrated too much on the improvement of subtasks (iii) and (iv) but not enough on the development of the quality of the statistical questions.

	V1	V2	V3
Average success rate in subtask (i) of all pairs	0.73	0.91	1.00
Average success rate in subtask (ii) of all teams	0.47	0.47	0.50
Average success rate in subtask (iii) of all teams	0.39	0.51	0.68
Average success rate in subtask (iv) of all teams	0.19	0.55	0.74

**Table 3: Development of quality (average of rates) between the subtasks**

In subtask (iii) the tasks were rated 0.39 on average at the preliminary stage and improved over time (0.51 at V2 and 0.68 at V3). In subtask (iv) the performance was very poor at the beginning (0.19), but improved in progress: In V2 the rate was 0.55 on average and in V3 the rate was 0.74 on average. So in summary we can say that peer feedback and expert feedback in a think-pair-share environment enhances a stepwise development of statistical literacy and thinking components with TinkerPlots. Especially with regard to subtask (iii) und (iv) the creation of TinkerPlots graphs and their description seem to improve after peer and expert feedback. Only in subtask (ii) problems with the generation of statistical questions occur and there was no “big” improvement of quality.

## Discussion and implications

The quality of statistical investigations depends on the statistical question raised for the investigation. As we could see, some questions only lead to a short exploration because the answer to that question is just “yes” or “no”, whereas there can be also other questions which are aiming at carving out many differences between two or more variables. The analysis of the reports on the “KinderUni” task shows, that especially the creation of informative TinkerPlots graphs and also their description and interpretation with regard to the statistical question succeeds and the peer- and expert-feedback can improve the TinkerPlots graphs (subtask (iii)) and the descriptions and interpretations of the TinkerPlots graphs (subtask (iv)). The key point is the generation of adequate statistical questions aiming at more than only one variable. Although this was taught in our course, too many statistical questions lacked quality. For the re-design and the upcoming cycle of the course it would be important that there will be feedback on the statistical questions to improve their quality as well. Here it could be helpful to discuss adequate and non-adequate statistical questions in class to help learners to differentiate between adequate and non-adequate statistical questions.

# Variables characterizing correlation and regression problems in the Spanish high school textbooks

María M. Gea, Carmen Batanero, Pedro Arteaga and J. Miguel Contreras

University of Granada, Spain

[mmgea@ugr.es](mailto:mmgea@ugr.es), [batanero@ugr.es](mailto:batanero@ugr.es), [parteaga@ugr.es](mailto:parteaga@ugr.es), [jmcontreras@ugr.es](mailto:jmcontreras@ugr.es)

*The aim of this paper is to analyse the problem situations within the topic of correlation and regression in the Spanish high school textbooks for Mathematics Applied to Social Sciences. In a sample of eight textbooks we firstly characterize the main problem situation used to contextualize correlation and regression, starting from the historical analysis of the topic. We then study the distribution of the following variables characterizing these problem situations: strength, sign, type of relationship and data contexts. Results show predominance of high and direct correlations, scarce examples of nonlinear regression and an excess of problem without context.*

*Keywords: Correlation and regression, textbooks, problem-situations.*

## Introduction

New curricular reforms emphasize statistical reasoning and its role in decision making and professional work (e.g., NCTM, 2000, CCSSI, 2010). Main content in these curricula for high school in Spain (MEC, 2007; MECD, 2015) and other countries are correlation and regression, which are fundamental statistical ideas that expand the previous knowledge about univariate distributions and mathematical functions. They also extend functional dependence to random situations and can be applied in a variety of other school subjects (Engel & Sedlmeier, 2011).

Previous research is mainly focused on students understanding of correlation (Estepa & Batanero 1995; Estepa, 2008; Zieffler & Garfield, 2009) with little attention to teaching materials, and, in particular, to the way the topic is taught or presented in the textbooks, in spite of their role as educational tools. From the official curricular guidelines until the teaching implemented in the classroom, an important step is the written curriculum reflected in the textbooks (Herbel, 2007). The selected textbook is an important part of teaching and learning mathematics, since it provides the main basis why the topic is taught (Shield & Dole, 2013). Moreover, mathematical textbooks receive increasing attention from the international community; see for example Fan and Zhu (2007).

The aim of this research was to analyse the tasks characterizing the problems used to present correlation and regression in high school Spanish textbooks directed to Social Sciences students. It is part of a wider project, where the way in which correlation and regression are presented in the textbooks in Spain is analysed. Complementary results were published in Gea et al. (2015).

## Theoretical framework

We base on the Onto-semiotic approach to teaching and learning mathematics (Drijvers, Godino, Font & Trouche, 2013; Godino, Batanero & Font, 2007), where mathematical knowledge has a socio-epistemic dimension, since it is linked to the person's activity and depends on the institutional and social context in which it is embedded. In this framework, the meaning of mathematical objects

is linked to the mathematical practices carried out by somebody (a person or an institution) to solve specific mathematical problems. Around the mathematical practices linked to these specific problems, different rules (concepts, propositions, procedures) emerge (Godino et al., 2007) supported by mathematics language (terms and expressions, symbols, graphs, etc.), which, in turn, is regulated by the rules. All these objects are linked to arguments that serve to communicate the problem solutions, and to validate and generalize them to other contexts and problems.

The authors conceive different types of institutional meanings for a mathematical object (in this case correlation and regression): a) *reference meaning* (the system of practices used as reference in a particular research); b) *intended meaning* (the part of the meaning that is planned for teaching; for example, that proposed in the curricular guidelines); c) *implemented meaning* (what was finally taught to the students); and d) *assessed meaning* (content of assessment) (Godino et al., 2007). In our research we try to identify the implemented meaning of correlation and regression, as defined by the problems proposed in the textbooks, and to compare it with the intended institutional meaning for these students, as defined in the curricular guidelines (MEC, 2007; MECD, 2015).

## Background

In spite of the relevance of these topics, previous research suggests poor results in people's understanding of correlation and regression. For example, Erlick and Mills (1967) found that negative correlation is commonly estimated as close to zero. Other authors studied the influence of previous theories about the context of the problem on the accuracy in estimating correlation. In this respect, Chapman and Chapman (1967, p. 194) described "illusory correlation" as "the report by an observer of a correlation between two classes of events which in reality (a) are not correlated, or (b) are correlated to a lesser extent than reported, or (c) are correlated in the opposite direction than that which is reported". The estimates are more accurate if people have no theories about the type of association in the data. If the subject's previous theories agree with the type of association reflected by the empirical data, there is a tendency to overestimate the association coefficient. But when the data do not reflect the results expected by these theories, the subjects are often guided by their theories, rather than by data (Jennings, Amabile & Ross, 1982).

According to Barbanchó (1992), the correlation between variables may be explained by the existence of a unilateral cause - effect relationship (one variable produces the other), but also to interdependence (each variable affects the other), indirect dependence (there is a third variable affecting both variables), concordance (matching in preference by two judges in the same data set) and spurious correlation (or coincidental covariation). In addition to the estimate accuracy, understanding correlation involve the discrimination of these types of relationships between variables.

Estepa (1994) studied the understanding of correlation in a sample of 213 Spanish high school students. The author defined the *causal conception* according to which the subject only considers correlation between variables, when it can be explained by the presence of a cause - effect relationship. He also described the *unidirectional conception*, where the student does not accept an inverse association, considering the strength of the association, but not its sign, and assuming independence where there is an inverse association.

As regards research on textbooks, Sánchez Cobo (1999) classified the definitions of concepts

presented in 11 textbooks published in the period 1977-1990 as procedural, structural or a mixture of them. Lavallo, Micheli and Rubio (2006) analysed the concepts and procedures included in 7 high school textbooks from Argentina. The current paper complements these publications and our previous paper (Gea et al., 2015), where we analyse the presentation of concepts, properties and procedures in the same textbooks that we are analysing here.

## Method and results

The sample was made of eight mathematics high school textbooks (H1 to H8), directed to Spanish Social Sciences students that are listed in the Appendix. They still are used in the schools, and were published by editorials of prestige and wide diffusion in Spain just after the past curricular guidelines were introduced (MEC, 2007). We performed a content analysis (Neuendorf, 2002) of the chapters devoted to correlation and regression with an inductive and cyclic procedure, and classified all the problems, exercises and examples used in the chapter according the variables described below. The total number of problems analysed were 2166, distributed according Table 1.

	Textbook							
	H1	H2	H3	H4	H5	H6	H7	H8
Number of problems analysed in the book	268	221	258	225	318	176	403	297

**Table 1: Sample of problems analysed**

## Main types of problem fields

Anthony and Walshaw (2009) reported on the different types of tasks that have been analysed in mathematics education research, which include problems centred on specific mathematical content; problems that promote mathematical modelling; tasks requiring students to interpret and critique data and those that prompt sense making and justification of thinking. The problems analysed belong to the first category and were classified according the main types of problems identified by Gea, Batanero, Cañadas and Contreras (2013) in the study of correlation and regression:

$P_0$ : *Organising and summarising bivariate data*, which include graphical representation and computation of summaries statistics.

$P_1$ : *Determining the existence of a relationship between the variables*, which can be subdivided in four types of problems: ( $P_{11}$ ) Defining the univariate variables that constitute the bivariate data; ( $P_{12}$ ) Determining the type of dependence (functional, random or independence); ( $P_{13}$ ) Determining the strength of the relationship; and ( $P_{14}$ ) Determining the direction (direct, inverse or nonlinear).

$P_2$ : *Predicting a variable from the other*, which can be subdivided in the following types: ( $P_{21}$ ) Fitting a model to the data (usually, the linear model); and ( $P_{22}$ ) Making estimations from the model, where we also include assessing the goodness of fit.

All these types of problems appear in the books, with different frequency, as shown in Table 2, with the following distribution: 11%  $P_1$ , 61%  $P_2$  and 28%  $P_3$ . The most frequent field of problems consisted in identifying the strength of correlation ( $P_{13}$ ), (with percentages ranging from 19% in H3 to 24% in H2). The textbooks paid less attention to the problem field  $P_0$ , with the exception of H3, H4 and H7, despite the organisation of data is an important step prior to analysing a relationship

between the variables. We also observe that H4 is more balanced as regards the different types of problems, although the percentage in P<sub>22</sub> problems is still a little low.

Problem field		H1	H2	H3	H4	H5	H6	H7	H8
P <sub>0</sub>		6.7	10.9	17.4	16.9	8.8	4.5	17.4	7.7
P <sub>1</sub>	P <sub>11</sub>	10.1	11.8	6.2	20.0	6.6	15.3	8.4	12.8
	P <sub>12</sub>	14.6	14.0	19.8	11.6	13.8	13.6	11.2	14.8
	P <sub>13</sub>	20.9	24.0	19.0	20.0	23.9	22.2	22.8	20.5
	P <sub>14</sub>	19.4	9.5	14.0	12.0	16.0	9.1	13.4	13.5
P <sub>2</sub>	P <sub>21</sub>	16.4	11.8	10.1	11.6	15.7	15.9	14.6	20.2
	P <sub>22</sub>	11.9	18.1	13.6	8.0	15.1	19.3	12.2	10.4

**Table 2: Classification of activities in the textbooks by problem field**

### Strength, sign and shape of association

For each problem analysed, we computed the Pearson's correlation coefficient when the data suggested linear relationship and the square root of the determination coefficient when the dependence was non-linear. We then classified the problems according to the strength of association in the following way: a) independence, if the value of the coefficient was very close to zero; b) low dependence if these coefficients ranged in the interval [0.1; 0.5); c) medium for the interval [0.5; 0.8), d) high for the interval [0.8; 1), and e) functional where there was a perfect fit of the data to a model and  $r = \pm 1$  or  $D = 1$ . In Table 3 we classify the problems according the strength of the dependence in the data suggested by these coefficients.

Strength of association	H1	H2	H3	H4	H5	H6	H7	H8
Independence	0.7	2.3	9.3	5.3	1.6	3.4	7.4	7.1
Low	9.3	8.6	7.8	23.1	9.7	8.5	22.1	9.1
Medium	19.8	10.4	13.2	20.0	17.3	11.9	16.1	16.8
High	47.4	76.0	48.1	39.1	53.1	60.8	28.3	49.2
Functional	5.6	1.8	8.6	6.2	2.2	1.7	8.7	8.1
No data provided	17.2	0.9	13.2	6.2	16.0	13.6	17.4	9.8

**Table 3: Percentage of problems, according strength of relationship**

Most commonly the data showed a high association or medium association; there were scarce problems with independent data or corresponding to functional relationships, in agreement with previous results from Sánchez Cobo (1999). We remark that most statistical studies in Social Sciences (the speciality that these students intend to follow) deal with moderate correlation, so that we recommend to include more problems with moderate association and a more balanced distribution of this variable in future textbooks.

We also studied the sign of correlation (direct or inverse) in case of linear relationship and found about 60% of problems that used direct correlation, as shown in Table 4. The scarce presence of inverse correlation problems (20% on average), also noticed by Sánchez Cobo (1999), may contribute to the unidirectional conception of correlation (Estepa, 1994) where students wrongly identify negative correlation with independence.

	H1	H2	H3	H4	H5	H6	H7	H8
Independence	0.7	2.3	9.3	5.3	1.6	3.4	7.4	7.1
Direct	59.7	85.1	47.7	68.0	46.2	61.9	51.6	56.9
Inverse	22.4	11.8	28.3	20.4	36.2	21.0	22.8	26.3
Others	0	0	1.6	0	0	0	0.7	0
No data provided	17.2	0.9	13.2	6.2	16.0	13.6	17.4	9.8

**Table 4: Percentage of problems, according sign of correlation**

A third variable analysed, not considered in previous research, was the type of function that fits the data. In order to determine this model, in each problem, we fitted different types of functions to the data and selected the function providing the best fit. Most situations corresponded to linear relationship, as shown Table 5, because this type of function is easier for the students for an introduction for the topic. However, we recommend incorporating some examples of functions well known by the students, for example, quadratic, polynomial or exponential functions to develop their statistical thinking, while avoiding the deterministic conception (Estepa, 1994). We remark that all the books include the least square line, as well as its use for prediction, while only one (H8) includes the Tukey line (2% of problems proposed in the book).

		H1	H2	H3	H4	H5	H6	H7	H8
	Independence	0.7	2.3	9.3	5.3	1.6	3.4	7.4	7.1
Functional	Linear	4.5	1.8	6.6	6.2	1.9	1.7	7.7	6.1
	Non-linear	1.1	0	2.0	0	0.3	0	1.0	2.0
Random	Lineal	76.5	57.9	62.0	66.2	76.1	80.1	63.8	62.3
	Non-linear	0	37.1	7.0	16.0	4.1	1.1	2.7	10.8
	No data provided	17.2	0.9	13.2	6.2	16.0	13.6	17.4	9.8

**Table 5: Percentage of problems, according type of function defining the line of best fit**

### Data context

The relevance of context in the teaching of statistics has been extensively discussed by different researchers. We analysed the context of the situations proposed to the students in these textbooks and classified them (see Table 6) in the following categories: a) Biology (e.g., parents and children heights); b) Science (e.g., speed and distance); c) Sport (e.g., distance and time spent in a competition); d) Economy (e.g., energy consumption and gross national product); e) Education

(e.g., score in two exams in a group of students); f) Sociology (e.g., birth rate and percentage of women at work). Results show a high percentage of problems with no context (students cannot relate their results to a meaningful context) and a similar distribution of other contexts.

Context	H1	H2	H3	H4	H5	H6	H7	H8
Biology	8.2	10.9	7.0	4.4	13.8	17.6	6.9	12.5
Science	13.1	33.0	14.7	13.3	13.2	16.5	9.4	9.1
Sports	4.5	0	5.4	2.2	2.2	0	0	0
Economy	14.2	8.1	13.6	5.3	6.9	14.8	3.5	10.1
Education	10.4	4.5	1.9	14.2	17.0	15.3	5.7	11.8
Sociology	6.3	17.2	10.9	14.2	9.1	12.5	9.9	9.8
No context	43.3	26.2	46.5	46.2	37.7	23.3	64.5	46.8

**Table 6: Percentage of problems according to context**

## Discussion and didactic implications

The study suggests important differences in the problems proposed by the different textbooks; for example, H2 and H6 include a lower proportion of problems with no context, although H2 has the highest proportion of high correlation problems and H6 the lowest percentage of problems  $P_0$ . We also found some biases in the distribution of the variables analysed, in particular there is a tendency towards direct, strong and linear relationship. It is important that teachers complement these types of problems with a wider variety of strength, sign and type of association, as well as with contexts that are interesting for the students, as it is suggested in the curricular guidelines (MECD, 2015): “The teaching of this subject should not be dissociated from its application to social phenomena”.

Our results suggest that the institutional intended meanings for correlation and regression and the implemented meaning in the textbooks analysed do not fit appropriately according to the variables analysed. In this sense, these problems should also be complemented with statistical projects in which the students experiment a complete cycle of statistical enquiry and get experience in the different modes of statistical thinking in Wild and Pfannkuch (1999)’s model (need for data, transnumeration, variation, reasoning with models, integration of statistical and contextual knowledge). Today there are plenty of data available on Internet that can be used to introduce ideas of correlation and regression via projects, as suggested in Batanero, Gea, Díaz and Cañadas (2014).

# Middle school mathematics teachers' pedagogical content knowledge in relation to statistical reasoning

Rukiye Gökce and Sibel Kazak

Pamukkale University, Faculty of Education, Denizli, Turkey; [skazak@pau.edu.tr](mailto:skazak@pau.edu.tr)

*To investigate middle school mathematics teachers' pedagogical content knowledge (PCK) with regard to statistical reasoning, an interview protocol was developed and used with nine teachers. This paper focuses on one of the problems in this interview protocol (Basketball problem) to illustrate teachers PCK in relation to four components: big ideas, student responses, student difficulties, and instructional intervention. Our analyses showed that levels of teachers' PCK varied in each component. Teachers had difficulties mostly in explaining student difficulties, developing instruction intervention strategies and distinguishing appropriate and inappropriate student reasoning.*

*Keywords: Statistical reasoning, pedagogical content knowledge, middle school teachers.*

## Introduction

The reliability and persuasiveness of advertisements or arguments that people encounter in daily life were ensured by the statistical information (Ben-Zvi & Garfield, 2004). For being informed citizens, it is crucial to analyze and interpret such statistical information and to make inferences from them. These problem solving, inquiry, analysis, justification and interpretation skills in statistics are all related to statistical reasoning. Garfield, delMas and Chance (2003) define statistical reasoning as “the way people reason with statistical ideas and make sense of statistical information” (p. 8). In statistics education, teachers have a critical role in helping learners develop deep conceptual understanding of statistical ideas. Shulman (1987) notes the importance of the capacity of a teacher to transform their content knowledge into pedagogically more powerful forms. Shulman (1986) states that the teacher content knowledge is not sufficient by itself for teaching a subject and points out the teacher pedagogical content knowledge (PCK) referring to the combination of content knowledge and pedagogical knowledge. More specifically, PCK is described as “the blending of content and pedagogy into an understanding of how particular topics, problems, or issues are organized, represented and adapted to the diverse interests and abilities of learners, and presented for instruction” (Shulman, 1987, p. 8). In statistics education literature, the studies by Watson and her colleagues (Watson, Callingham & Donne, 2008; Callingham & Watson, 2011) on examining levels of teachers' statistical PCK suggest that teacher knowledge needs to be investigated more systematically and note the need for uncovering the current state to advance the statistics education. However, there is little research on teacher knowledge particularly with regard to statistical reasoning (e.g., Mickelson & Heaton, 2004; Makar & Confrey, 2004). Thus, the aim of this study is to investigate middle school mathematics teachers' PCK related to statistical reasoning. Our research question is: In a distribution comparison task, to what extent do mathematics teachers consider the big ideas in statistics in their reasoning, how students might reason and how they would intervene to promote appropriate statistical reasoning?

## Theoretical framework

The notion of PCK, as noted by Shulman (1986), entails teachers' knowledge about both the understanding/misconceptions of students and pedagogical strategies for instruction. According to An, Kulm and Wu (2004) there is an interaction between PCK and content knowledge and between knowledge of curriculum and knowledge of teaching, and the knowledge of student thinking is in the center. Moreover, teachers' competence of making instructional interventions is considered as part of 'enacting mathematics for teaching and learning' which is one of the components in the model of PCK developed by the Teacher Education and Development Study in Mathematics (Tatto et al., 2008). Accordingly, responding to unexpected mathematical issues, evaluating student solutions, identifying student misconceptions, providing appropriate feedback, explaining and representing mathematical concepts are amongst the essential criteria for teacher competency to achieve the goals of learning-teaching process and increase its quality. This study focuses on the knowledge of student and knowledge of instructional interventions as the two components of PCK.

The study by Watson, Callingham and Nathan (2009) focused on teachers' PCK with regard to statistical knowledge at the middle school level. The researchers identified four non-hierarchical components of PCK. The first two components, "Recognizing Big Ideas" and "Anticipating Student Answers", reflect the link between teachers' knowledge of content and knowledge of understanding students. The other two components, "Employing Content-Specific Strategies" and "Constructing Shift to General", involve elements of pedagogical practices that the teachers used by foreseeing the progress of student understanding. In another study by Watson and Nathan (2010), teachers' PCK was investigated using three different problems. Teachers were asked about the big statistical ideas in each problem, possible appropriate and inappropriate student responses and opportunities provided by the problem for teaching. Teachers' responses were analyzed based on the four components of PCK developed previously by Watson et al. (2009). In our study we utilized these two studies for developing interview questions and coding teacher responses.

## Method

This exploratory study focuses on one-on-one interviews with nine middle school mathematics teachers (two females and seven males). The participants were selected on voluntary basis and from two different middle schools in Denizli. Their teaching experience changes from 2 to 30 years. The national curriculum of school mathematics includes data analysis strand since 2005 but according to our classroom observations, the participants tend to teach mainly computations and procedures in a traditional way rather than to focus on developing students' statistical reasoning.

## Data collection and task

Interviews with each teacher were conducted by the first author and video-recorded. These video recordings were transcribed for analysis. An interview protocol was developed to study teachers' PCK with regard to statistical reasoning. In the larger study, the interview tasks involved three different scenarios, in which teachers were asked to determine possible student reasoning and difficulties. In order to develop teacher-student dialogues in these scenarios, these problems initially were administered to a classroom of 6<sup>th</sup> graders. Students' responses provided a basis for constructing the dialogues given to teachers during the interview (see Figure 3). Motivated by the design of statistical reasoning tasks used in Cobb and his colleagues' study (Cobb, 1999) each problem involves

comparing two or three data distributions from equal and small sample sizes to unequal and larger sample sizes. And four kinds of statistical reasoning were addressed in these problems: reasoning about distribution, reasoning about center, reasoning about spread, and informal statistical inferential reasoning. This paper focuses on one of these problems, called Basketball Problem. In the interview, each teacher was initially asked to decide and explain which of the players they would choose to the school basketball team looking at the given data in Figure 1.

Players	Players' scores									
Arda	8	14	11	13	15	12	10	10	9	13
Baris	4	15	8	17	18	9	19	6	18	5
Cem	-	-	-	13	14	10	7	13	11	9

Graph 1: Arda's scores in the last 10 matches

Graph 2: Baris's scores in the last 10 matches

Graph 3: Cem's scores in the last 7 matches

**Figure 1: Data given in the Basketball problem in the interview protocol**

Next, in order to explore teachers' PCK in relation to students' statistical reasoning and instructional interventions, participants were asked to come up with examples of appropriate and inappropriate student reasoning in the context of given problem (see questions 1-5 in Figure 2).

- Q1:** In the context of this problem with appropriate reasoning, how might students answer?  
**Q2:** Why do you think that reasoning is appropriate?  
**Q3:** In the context of this problem with inappropriate reasoning, how might students answer?  
**Q4:** Why do you think that reasoning is inappropriate?  
**Q5:** How would you guide those students who reasoned inappropriately to correct reasoning?  
**Q6:** In this page, there is a dialogue between students and teacher about basketball problem (see Figure 3). Firstly I want you to read this (dialogue sheet).
- Here, could you identify which students make appropriate reasoning? Why?
  - Could you identify which students make inappropriate reasoning? Why?
  - What is the difficulty that prevents the student from reasoning in an appropriate way?
  - When you encounter such a situation in the class, what kind of questions would you ask to your students to make them reason appropriately? What kind of intervention would you consider?

**Figure 2: Interview questions to elicit teachers' PCK in the context of Basketball problem**

After these questions, teachers were given a dialogue between students and teacher about the problem (see Figure 3) to examine their PCK further by the questions 6 a-d in Figure 2.

**Simge:** Well, there is also the probability that Cem will score more or less than that you say he would make. So you also took risk in a way. In my opinion we can do this: Arda made 15 points the most, 8 the least score. So if I sum up these two numbers and divide by 2, I will find the number 11,5 as the middle point. Baris made 19 the most and 4 the least. The middle point of these two numbers is 11,5. Cem made 14 the most and 7 the least. The middle point of these two numbers is 10,5. So I would eliminate Cem.

**Teacher:** Well Simge, how would you choose between Arda and Baris?

**Simge:** I would look at the highest score for both of them. Since Arda made 15 points and Baris 18 points, I would choose Baris.

**Kagan:** As there is a difference between the numbers of matches played so far, we should look at the mean. As the mean of Arda's score is 11,5; Baris's is 11,9 and Cem's is 11, I would choose Baris.

**Duygu:** Baris's mean score can be high. But he performed very well in one match and very poor in another match. He has a varying performance in the range of 4 and 19 points. He is not consistent.

**Teacher:** What do you mean by 'not consistent'? How do you conclude that he is not consistent?

**Duygu:** When we look at the graphs we see that these scores that Baris made seem far and dispersed from each other. Arda's scores seem closer together. Arda has a varying performance between 8 and 15 points. He is more consistent than Baris. There is not much difference between Arda's average score and Baris's average score. I would choose Arda.

**Figure 3: Part of a dialogue between students and teacher about basketball problem**

### Data analysis

Qualitative analysis of data was done by two researchers. Initially a number of codes were adapted from Watson and Nathan's (2010) study to examine interview transcripts for PCK in relation to statistical reasoning and codes were assigned. During the content analysis phase new codes were created from the data. The categorizations of teacher responses were discussed and agreed on by two researchers. As a result, four components of PCK were formed as seen in Table 1: Big ideas, student responses, student difficulties, and instructional intervention.

Aspects of PCK	Codes/Levels	f
<b>Big Ideas</b>	0- Response confused and /or incorrect	-
	1- Response implied and/or understanding revealed beyond initial question	4
	2- <i>Statistical reasoning</i>	5
<b>Student Responses</b>	0- Response irrelevant	1
	1- Appropriate or inappropriate but not both, or unclear	1
	2- Distinguishes both appropriate and inappropriate, <i>but no reason/explanation</i>	1
	3- Demonstrates understanding of students' reasoning <i>with reason/explanation</i>	6
<b>Student Difficulties</b>	0- <i>Response irrelevant</i>	5
	1- <i>Unclear (General statements, lack of knowledge)</i>	1
	2- <i>Correct reason/explanation</i>	3
<b>Instructional Intervention</b>	0- <i>Response irrelevant / personal view</i>	1
	1- <i>Noticing content without given data (common beliefs)</i>	5
	2- <i>Promoting the appropriate use of percents, numbers, measures of center and spread for statistical reasoning</i>	3
	3- <i>Promoting generalization beyond data</i>	-

**Table 1: Codes for PCK (new codes were indicated in italics) and their occurrences**

Differently from Watson and Nathan's study, a new component called "student difficulties" was considered in the current study. In addition, "instructional intervention" was used as a more general component that covers the two components in Watson and Nathan's study, namely "Employs Content-specific Strategies" and "Constructs Shift to General". "Big ideas" aspect of PCK was formed to uncover teachers' statistical reasoning by using big ideas in statistics with the addition of "code 2-statistical reasoning" to the codes in Watson and Nathan's study. Moreover, "no reason or explanation for the appropriateness of student reasoning" and "explaining the reasons for the appropriateness of student reasoning" criteria were added to code 2 and code 3, respectively, in "student responses" component. The codes in "student difficulties" component were formed as a

result of the content analysis. The codes in “instructional intervention” component were formulated as a result of the content analysis and aspects of statistical reasoning skills.

## Findings

### Teachers’ PCK level with regard to big ideas

Five of the teachers were able to reason with the big ideas in statistics (code 2 level). These teachers took into account both variability and central tendency in their comparisons of distributions as it can be seen in Semih’s reasoning: “First we should compute their means. Arda’s is 11,5; Baris’ is 11,9; Cem’s is 11. Baris scored the most. I would choose Arda because of his stability. His scores are placed between 8 and 15 in the graphs. Baris’ scores are placed between 4 and 19. Baris’ average is not much higher than the others.” Another teacher, Ebru, made her decision based on somehow a middle range in addition to the stability criteria. Her reasoning was: “I would transfer Arda. I chose a lower and an upper limit [*between 8 and 15*]. Even though Baris scored more points than this upper limit, from stability point of view Arda is more consistent.” Other four teachers’ responses were yet considered partially correct (code 1 level) because they focused on either the mean or the spread. The following two quotes illustrate code 1 level responses.

I would transfer Baris. He scored in every game, no points less than 4. By just looking at the average, it does not look bad. (Eren)

Their means are close. Arda’s performance is better. These data aren’t adequate. I would prefer Cem. His scores are closer. I am hesitant but I don’t have any reason. I said that I would choose Cem, but I wouldn’t choose Baris. He scored once 4 and the other time 19. There is no consistency. Arda scored 10 twice, 13 twice, these numbers are closer, so more stable. I can take Arda. (Suat)

### Teachers’ PCK level with regard to student responses

Responses of six teachers showed an understanding of students’ reasoning with appropriate explanation (the code 3 level) as seen in the answer below:

A student who reasons appropriately will firstly look at the mean. Arda’s is 11,5; Baris’ is 11,9; Cem’s is 11. Student would look at the place where the cluster is more. Not only the cluster but also between which numbers the cluster is [*pointing to the range*]. His mean is high and the cluster is above a certain number, so he would choose Arda. Moreover their means are close to each other [*pointing to Arda and Baris*]. A student who reasons inappropriately would choose Baris scoring the highest number 19. Student reasoned inappropriately because there is only one match in which Baris scored 19, he scored 4 as well. Student should look at the whole. (Semih)

The other three teachers’ responses were identified at the other levels. For example, Eren’s response was considered at the code 0 level because his answer was related to the use of representations given in the problem rather than using statistical ideas/measures for his reasoning: “Student reasoning appropriately would look at both the graph and the table, evaluate them together and choose Baris. Student who doesn’t reason appropriately would only look at the graph and choose Arda.” In the following quotes, Suat was uncertain about the appropriate student reasoning due to the mistrust in

his own reasoning (the code 1 level) while Sema could distinguish appropriate and inappropriate student response but with inadequate explanation response (the code 2 level).

Since I had a difficulty in answering the question in this problem, I am not able to guess how students could respond. I don't even think that my answer was sound, but a student who reasons appropriately might choose Arda because of the two modes and their being close to each other. A student who reasons inappropriately chooses Baris because he makes the high score. (Suat)

Student reasoning appropriately would interpret the data looking at the table. By computation, he would choose Baris with the highest mean. Because we have only numbers, there is nothing else.

Student who reason inappropriately would choose Baris since he scored the highest point. (Sema)

### **Teachers' PCK with regard to student difficulties**

When asked to explain student difficulties in their reasoning, the teacher responses mostly were inadequate and had irrelevant details (the code 0 level) as seen in Ismail's response: "A student saying 'I'd choose Baris because he scores the most number' thinks in a shallow way." At the code 1 level Okan linked student difficulty to a wider context of school practice while at the code 2 level Suat made an evaluation based on what is expected statistically.

The difficulty in a student who would choose Baris because of his highest mean could be the following. Students have computed the mean since primary school and so always mean stays in mind. The others [*other measures of center*] are introduced in the middle school. For students, the first thing they have learned seems more accurate. That is a student who chooses the extreme values maybe do not know measures of center and spread. (Okan)

A student who chooses Baris according to highest score is looking at the players' best result. In fact the student should look at all of the results. (Suat)

### **Teachers' PCK with regard to instructional intervention**

When teachers were asked about the kind of questions they would ask and interventions they would consider in the classroom to guide students to reason appropriately, most teachers responded at the code 0, code 1 and code 2 levels and none at the code 3 level. Since Suat's example of what he would ask to students was far from the context and irrelevant to the problem, his response was at the code 0 level. When Ismail gave the following answer: "I would ask the following question to the students who choose Baris scoring the highest: 'Guys, if you made a critique about the performances of Arda and Baris, which of them would you find successful? Why?'. If it is the final match, student may say Baris or for league matches Arda. This is important.", it was considered at the code 1 level because his response involved a use of context but not based on data. However, in the following response (the code 2 level) teacher's approach tended to involve having a discussion about the measures of center and spread within the problem context:

I'd ask the student who chooses Baris due to his highest score: 'Who scored the lowest?'. Scoring the least is Baris as well. I would also ask Arda's highest and lowest scores. I would have the student find the range. Arda's range is 7, Baris' is 15. I would show that the scores Baris has made are in a wider interval. I would ask student: 'Would you choose the player who scores 4 in one match and 19 in the other or the player who scores 8 in one match and 15 in the other?' (Semih)

### Identifying appropriate and inappropriate student reasoning in a given dialogue

In the given dialogue between teacher and students within the basketball problem context, only one of the teachers was able to distinguish appropriate and inappropriate student reasoning properly. This teacher (Göksel) argued that since consistency is important in this context, both mean and spread should be used in making the decision. The other eight teachers' responses were partially correct. For instance, one of these eight teachers (Suat) correctly identified student responses using both the mean and range with attention to consistency and yet he also considered the student responses using only the mean or the increases/decreases in the scores as appropriate reasoning.

### Discussion and conclusion

In this study, teachers overall seem to do better in using big ideas in their reasoning and considering possible student responses on the Basketball problem. Yet, some teachers still had slight difficulties consistent with those that students might have in comparing distributions (Cobb, 1999) and in using big ideas for solving statistical problems (Watson & Nathan, 2010). Similar to the previous findings (Watson & Nathan, 2010; Watson, et al., 2008) some challenges also exist for these teachers when considering how students might reason in their decisions. In contribution to the previous research results, this study shows other challenges that most of the teachers tend to have: (1) somewhat incomplete understanding of potential student difficulties, (2) inadequacy for suggesting instructional intervention strategies that could help students make generalizations beyond data and (3) distinguishing appropriate and inappropriate student reasoning in the given classroom dialogue. These findings related to teachers' knowledge about student responses may not be unique to statistics teaching since they show consistencies with previous research with mathematics teachers in other mathematical topics, such as functions and undefined mathematical operations (e.g., Even & Trosh, 1995). The insufficiencies in teacher PCK both in our findings in relation to statistical reasoning and other studies by Watson and her colleagues suggest that there is a need for in-service teacher training on PCK in statistics. More specifically, teachers need to be able to anticipate possible student difficulties in statistical reasoning and develop ways to respond to them.

# Using sport-related socially open-ended problems to coordinate decision-making, variability modeling and value awareness

Orlando González <sup>1</sup> and Somchai Chitmun<sup>2</sup>

<sup>1</sup>Assumption University, Grad. School of Human Sciences, Bangkok, Thailand; [ogonzalez@au.edu](mailto:ogonzalez@au.edu)

<sup>2</sup>Tepleela School, Bangkok, Thailand; [schitmun@hotmail.com](mailto:schitmun@hotmail.com)

*The purpose of this article is to describe the features, as well as the instructional potential and advantages, of socially open-ended problems set in a sport-related context, through which students could be challenged to model variability in order to assess performance and develop data-driven decision-making skills. These arguments will be illustrated by using as an example the “Darts game” task, a problem from a study conducted by González and Chitmun (2015) on Japanese and Thai secondary school mathematics teachers’ professional knowledge of data-driven decision-making.*

*Keywords: Decision-making, socially open-ended problems, variability modeling, value awareness, statistical investigations.*

## Introduction

The importance of using, handling and interpreting data to inform decision-making is fundamental to participate competently in today’s society. Such importance has been acknowledged by recent reforms to the mathematics curriculum in many countries, in which having the attitude and ability to purposely process and grasp features of daily-life data, and making informed decisions in real-life situations, are instructional goals explicitly stated in the statistics-related strands of the mathematics curriculum (e.g., MEXT, 2008, 2009; MOE, 2008). Thus, it is necessary for teachers to be able to choose the most appropriate tasks to take students further in the achievement of such goals.

Although important, being able to grasp features of daily-life data is not enough to make informed decisions. Today’s society is a value-pluralistic one, in which it is natural for people to hold multiple values which, due to life experiences and interactions, will be prioritized, accommodated, negotiated, compromised and traded-off. Moreover, value awareness has been regarded as fundamental for engaging in effective decision-making, since values are principles used to evaluate actual or potential consequences of action or inaction, of proposed alternatives and of decisions (Keeney, 1992).

Under this scenario, socially open-ended problems (Shimada & Baba, 2015) emerge as an appealing and plausible way of providing students with the possibility of using, handling and interpreting data to inform decision-making, as well as with the opportunity to develop the skill of value awareness. The purpose of the present article is to clarify the instructional potential and advantages of socially open-ended problems set in a sport-related context by analyzing the features of a problem of this kind from a previous study (González & Chitmun, 2015). Moreover, in light of the aforementioned analysis, it is our purpose to propose this kind of problem as an instructional way to challenge students to structure variation among repeated observations of the “same” event, to model variability, and to make data-driven decisions. A lesson implementation of the aforementioned socially open-ended problem will be discussed and analyzed, and some conclusions will be given based on the results of the lesson implementation.

## Decision-making process: Definition and related skills

A decision is the process within which a choice among specific options will be made, regarded here as having six phases: Definition, planning, data, evaluation, weighing impact, and making and justifying a decision (e.g., Arvai, Campbell, Baird, & Rivers, 2004; González, 2015). Some related skills are ability to identify, design, and choose optimal ways to make a decision; ability to seek, collect and process data relevant to a decision; and ability to give an informed justification for a decision made. Factors such as values held by the decision-maker, communication and interpersonal interaction all influence the development of each phase of the decision-making process (Keeney, 1992).

## Statistical investigation: Definition and type of problems to engage students in it

A statistical investigation is one of the four central aspects of statistical thinking used in statistical inquiry of authentic problems (Makar & Fielding-Wells, 2011). It is a process, comprised of the following five phases: Problem, Plan, Data, Analysis, and Conclusion (PPDAC). Since each phase of this process can be tied to a particular phase of the decision-making one, in the present article, the process of statistical investigation will be considered as being included under the most general process of decision-making (González, 2015; Keeney, 1992).

Teachers need to be able to plan and conduct statistical investigations that develop rich statistical understandings in their students, and one key issue to achieve this is using problems worthy of investigation, or to guide students to do so (Makar & Fielding-Wells, 2011). Such problems should have the following characteristics (Makar & Fielding-Wells, 2011, pp. 349-350):

*Interesting, challenging, and relevant:* Topics of interest include sport, weather, music charts, movies, and more serious topics of social issues relevant to teenagers (González & Chitmun, 2016). Challenging questions are those calling for a thorough analysis of the given data.

*Statistical in nature:* Problems posing questions calling for students to gather and interpret data and to justify their choices based on such interpretation. Appropriate interpretation of evidence requires simultaneous consideration both of one's knowledge about the domain and of the discernible patterns in the data (Lehrer & Schauble, 2004). The data related to the problem at hand must also offer enough complexity to generate interesting results.

*Ill-structured and ambiguous:* Questions such as “who is the best player?” or “which one is the best team?” raise the issue of what the meaning of “best” is, which enables negotiation and data-driven argumentation and discussion by students.

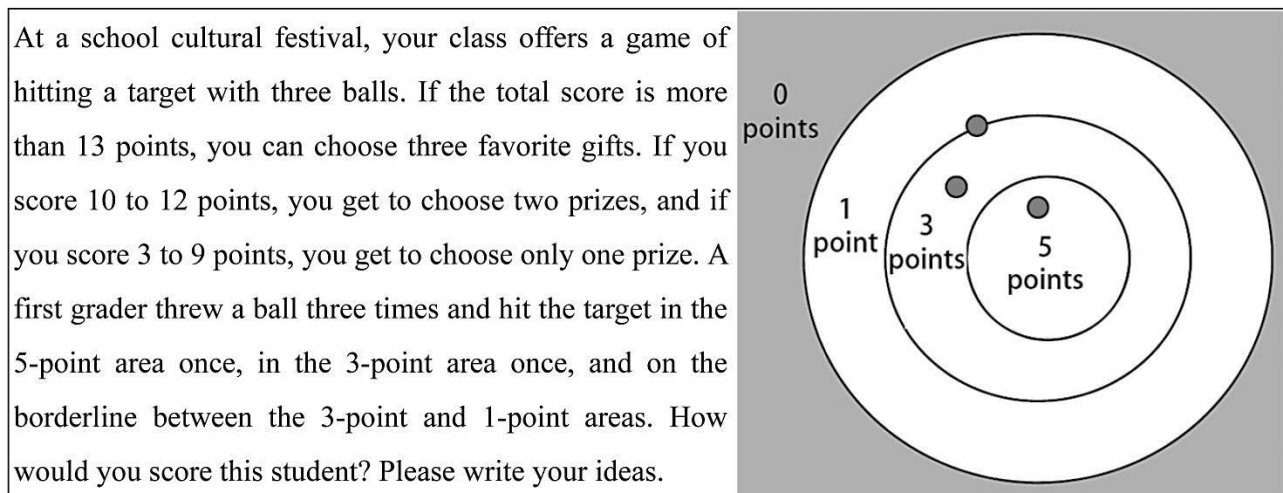

## Socially open-ended problems

Socially open-ended problems (Shimada & Baba, 2015) are problems that are embedded in a real-life context, are familiar to the students and, by extending the traditional open-ended approach (Becker & Shimada, 1997), have been developed to elicit and address students' mathematical values (e.g., visual appeal, parsimony, efficiency, elegance and sophistication), social values (e.g., social responsibility, compliance with the law, human rights, fairness, compassion and equity), and personal values (e.g., persistence, integrity and friendliness) through modeling and argumentation. According to Shimada (2015, p. 11), this ability to address multiple values is one of the competencies expected to be developed in students by using socially open-ended problems in the mathematics classroom. Such ability requires the following skill-set: (1) The ability to build mathematical models—such as a formula, equation or system of equations describing how underlying factors are interrelated—based

on values, which is usually manifested in the first-half of the mathematics lesson; (2) the ability to appreciate the diversity of mathematical models based on values, which is usually manifested in the middle stage of the mathematics lesson; and (3) the ability to critically examine mathematical models based on values, which is usually manifested in the last-half of the mathematics lesson.

**An example of socially open-ended problems: The “Hitting the target” task.**

Shimada and Baba (2015) carried out a problem-solving lesson using the socially open-ended problem “Hitting the target” (see Figure 1).

**Figure 1: The “Hitting the target” task (Shimada & Baba, 2015)**

“Hitting the target”, which is a very popular game among children in Japan, is basically a darts game, but instead of throwing pointed darts at a concentric circles dartboard, small tennis-like balls covered with magnetized foam are used as a safety measure. Through engagement with the “Hitting the target” problem, it is expected from students to create rules in the form of mathematical models, in order to assign a score to the game performance of a participant after completing a set of three throws. The lesson planned by Shimada and Baba (2015) was deployed as follows: Provision of the problem; individual solutions by the students; whole-class presentation and discussion of students’ mathematical models and reasons, and individual selection of one model with its reason at the end of the lesson. Each of these steps can be matched to a phase of a statistical investigation, and the problem itself seems to meet the criteria to be considered a problem worthy of investigation, or to guide students to do so (Makar & Fielding-Wells, 2011). Through the analysis of classroom interaction and students’ data, Shimada and Baba (2015) identified four characteristics: (1) Diverse mathematical models with the same values; (2) Implicit values became apparent through comparison with other values; (3) Some students who transformed their initial values and those who did not; (4) Some students who changed their initial mathematical models under the same values.

Shimada (2015) and Shimada and Baba (2015) concluded that the decision of adopting a mathematical model for this particular problem was made based not just on the ball position on the target board, but also on the values (mathematical, social or personal) held by the students. This is in line with Keeney (1992), who stated that values are the primitive for considering any decision, since the first step in an effective decision-making process is for decision-makers to carefully consider their own values by clearly defining what it is they want to achieve in the decision context.

## **The “Darts game” task: Socially open-ended problems as potential tools for engaging students in decision-making and statistical investigations**

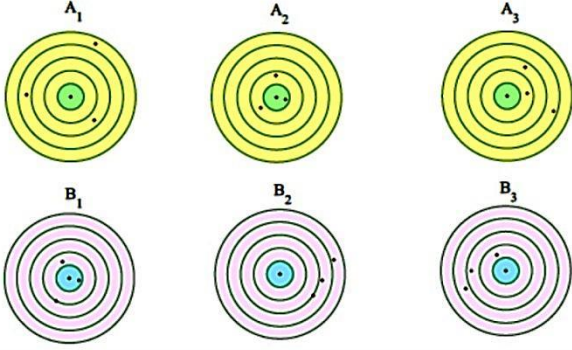

Assessing sport outcomes (such as in the case of the “Hitting the target” task) has been discussed as potential way to build students’ data-driven decision-making skills through statistical investigations (González & Chitmun, 2016). A similar (but more complex) problem to the one posed by the “Hitting the target” task is the “Darts game” task (González & Chitmun, 2015, 2016). This problem was the only one with a sport-related context posed by a Thai teacher—hereafter T1—from a sample of 15 secondary school mathematics teachers in the study conducted by González and Chitmun (2015) on professional knowledge of data-driven decision-making. In the present article, we will use the lesson plan designed by T1 (see Figure 2) as an example of a potential way of instructional design linking understanding of variability, modeling, statistical investigations and value awareness, all under the umbrella of the decision-making process.

The “Darts game” task—which can be considered a socially open-ended problem—represents an enhanced version of the “Hitting the target” task, with a more robust statistical nature. For example, the problem posed by the “Darts game” task will allow students to actively engage in the processes of generation, testing, and revision of real-life models of the world, which are at the very heart of what it means to think statistically (Lehrer & Schauble, 2004, p. 636). Furthermore, this problem focuses on the role of inventing measures of variability as a means for structuring variability. Inventing measures (statistics) of variability affords opportunities for coming to see differences among cases in new ways (Lehrer & Kim, 2009). As in the discipline of statistics, inventing statistics is not a solitary act: The meaning of a statistic for “team performance score” could be discussed and negotiated amongst students in a classroom community (Keeney, 1992; Lehrer & Kim, 2009; Petrosino, Lehrer & Schauble, 2003). Moreover, the formulation of a mathematical model—and scoring functions are mathematical models—can present an interesting challenge to the students.

In the “Darts game” task, unlike the “Hitting the target” problem, landing a dart on any region of the dartboard was not assigned a pre-established score (adding so ill-definition and ambiguity to the problem). So, by interpreting the patterns of the thrown darts to determine which team is the best one, students will engage in data modeling. Characteristics of distribution, like center and spread, could be made accessible and meaningful to students by displaying and structuring variation among observations of the “same” event, instead of considering such observations simply as a collection of differences among measurements (Lehrer & Schauble, 2004; Petrosino et al., 2003). In the “Darts Game” task, students will be required to structure variation among observations of the “same” event. The outcome of that process will be a mathematical model for scoring each team’s performance, in order to make a decision regarding which team is the best one. Such models will be a source of information on students’ structural behavior, observations, in situ measurements, and values.

According to Kazak (2006), engaging students in scoring a dart game will provide them with opportunities to engage in analysis concerning scores assigned around the target point, as well as in a discussion about what to do to get the highest score.

• <b>Intended grade :</b> Grade 9		
• <b>Main topic :</b> Measures of central tendency (this class would be the final one on this topic)

Conclusion	<ol style="list-style-type: none"> <li>1. Teacher and students together try to find conclusions of this lesson.</li> </ol>	<ol style="list-style-type: none"> <li>1. The students will write down the conclusions to their notebooks.</li> </ol>

**Figure 2: Lesson plan designed by T1 to engage students with the “Darts game” task**

T1 did not mention explicitly the role of values in her lesson; however, as a socially open-ended problem, the “Darts game” provides an opportunity to develop students’ ability to address multiple values through the implementation of the ability to address multiple values (Shimada, 2015).

## Research methodology overview: Implementing the “Darts game” task

### Study sample and research methodology: Overview

On November 16, 2016, the second author carried out a problem-solving lesson using the “Darts game” task with Grade 12 students in a public high school in Bangkok. The sample consisted of 34 students, with 18 boys and 16 girls. The second author is a teacher specialized in mathematics education, with 13 years of teaching experience. In this study, almost the same lesson design depicted in Figure 2 was implemented, with two main modifications: Firstly, before lesson implementation, students were asked to find out as many answers as possible to the task as a homework; and secondly, during the presentation and discussion of the individual solutions and reasons, students were not organized in groups, following the lesson design presented by Shimada and Baba (2015).

### Findings and discussion of results

In average, about two answers were provided per student, being the mode one solution (21 students, 61.8%), and the number of given solutions ranging from one to seven. Among those answers, 10 different decision models were identified (see Table 1). Since students were allowed to provide more than one decision model, the total will be more than 100 per cent.

	Model description	Frequency (%)
Decision model	<i>M</i> <sub>1</sub> : Tallying the number of darts landing in each concentric circle. The winner team will be the one with more darts landed closer to the innermost circle.	9 (26.5)
	<i>M</i> <sub>2</sub> : Tallying the number of darts landing on the outermost circle.	1 (2.9)
	<i>M</i> <sub>3</sub> : Determining how clustered the three thrown darts are.	5 (14.7)
	<i>M</i> <sub>4</sub> : Tallying the number of darts landing on a line.	10 (29.4)
	<i>M</i> <sub>5</sub> : Measuring the distance of the farther shot to the bullseye.	3 (8.8)
	<i>M</i> <sub>6</sub> : Developing a scoring function	21 (61.8)
	<i>M</i> <sub>7</sub> : Tallying the number of times a dart hit the bullseye.	3 (8.8)
	<i>M</i> <sub>8</sub> : Counting the times a player landed the darts inside the same concentric circle.	1 (2.9)
	<i>M</i> <sub>9</sub> : Tallying the number of darts landing on the innermost circle.	7 (20.6)
	<i>M</i> <sub>10</sub> : Measuring the total distance to the bullseye	1 (2.9)

**Table 1: Different decision models posed by the students in this study**

The reasons given by students during the phase of individual solutions revealed a diversity of considerations to decide the winner team: taking into account all the members of a team (21 students, 61.8%) vs. only considering a team representative (7 students, 20.6%), or posing decision models considering both perspectives (6 students, 17.6%). Among the reasons for choosing particular models in the phase of individual solutions are the following: difficulty in landing the shot in a particular area of the dartboard (e.g., on a line or on the innermost circle); precision (i.e., how tightly clustered, or spaced apart, the thrown darts are among each other in a particular trial, regardless of their position relative to the bullseye); accuracy (i.e., how close the thrown darts are to the bullseye); fairness and consideration to the whole team; and maximizing the likelihood of winning by selecting the best team player under a particular condition. Students mainly used tables while tallying, and calculated frequencies and modes. As expected, multiple scoring functions emerged from the students’ answers. Although different scores were assigned to landing a dart on a particular circle region, most of the scoring functions assigned the highest score to the innermost circle, and the lowest score to the outermost one. Landing a dart on any line was also scored in multiple ways: averaging the score of

adjacent circle regions; assigning either the highest or the lowest score of adjacent circle regions; a fixed score (e.g., 10 points); no points; or invalidating the trial results for the player.

After engaging in the stage of whole-class presentation and discussion of the mathematical models and reasons, some students changed the decision model from the initial self-resolution stage in the final selection stage (7 students, 20.6%), while most of the students kept one decision model within those posed by them during the self-resolution stage (27 students, 79.4%). Five out of seven students who changed their initially-posed model somehow modified it, introducing aspects that emerged during the whole-class discussion (e.g., scoring by team instead of considering a team representative, and vice versa; considering landing a dart on the line as disqualification). The reasons to make a final decision were also varied: acknowledgement of the effort by all team members; fairness; establishing equal winning opportunities for both teams; easiness to either score or explain the final decision to the team members; and keeping the nature of the game (i.e., the shot closer to the bullseye wins).

## Conclusions

All in all, students engagement with the socially open-ended problem “Darts game”, set in a sport-related context and involving measurement of different observations of the “same” event, seemed to be an appealing and plausible way to, among other things, (1) make accessible and meaningful to students characteristics of distribution such as center and spread; (2) provide students with opportunities to structure variation and coordinate variability and chance by engaging actively in modeling challenges; (3) develop an aggregate view of data; (4) provide students with an opportunity to discuss, argue and negotiate the meaning of a statistic for “team performance score” as members of a classroom community; (5) actively engage students in the processes of generation, testing, and revision of real-life models of the world; and (6) develop students’ value awareness in a climate of open discussion, by implementing the threefold ability to address multiple values. So, in a society in which the role of values, data and decision-making is fundamental for both education and active engagement in critical citizenship (Ernest, 2001), implementing sport-related socially open-ended problems in the mathematics classroom to address statistical contents seems to be a plausible way to help teachers achieve the aims of the mathematics curriculum regarding statistics education.

# Insights into the approaches of young children when making informal inferences about data

Aisling M. Leavy

Mary Immaculate College, University of Limerick, Ireland; [Aisling.Leavy@mic.ul.ie](mailto:Aisling.Leavy@mic.ul.ie)

*There is growing awareness of the statistical reasoning abilities of young children. In this study the informal inferential reasoning skills of a class of 5-6 year old children are examined as they reason about data in the context of a week-long data investigation unit. The strategies young children use to make predictions about data are identified. A discussion ensues around what these strategies communicate about early understandings of statistical inference. The findings suggest that making inferences from data can be challenging for younger students primarily due to the powerful influence of their developing understandings of number. However, there is evidence that children possess some of the building blocks of informal inference most notably in the approaches that point to a pre-aggregate view of data. Situating data investigations within interesting and relevant contexts, alongside good teacher questioning and opportunities to listen to the reasoning of their peers, contributes to the creation of statistical environments that support and develop early understandings of inference.*

*Keywords: Informal inferential reasoning (IIR), early childhood, data modelling.*

## Theoretical perspective

Informal ideas relating to inference are those understandings that are foundational to the development of inferential reasoning. While many different definitions of informal inference have been posited, a useful definition of informal inference is “the way in which students use their informal statistical knowledge to make arguments to support inferences about unknown populations based on observed samples” (Zieffler, Garfield, delMas & Reading, 2008, p. 44). Zieffler et al. (2008) identify three components of an IIR framework as: making judgments or predictions, using or integrating prior knowledge, and articulating evidence-based arguments. Arising from research with primary students, Makar & Rubin (2009, p. 85) propose three principles that are considered essential for informal statistical inference as ‘(1) *generalization*, including predictions, parameter estimates, and conclusions, that extend *beyond describing the given data*; (2) the use of data *as evidence* for those generalizations; and (3) employment of probabilistic language in describing the generalization, including informal reference to levels of certainty about the conclusions drawn.’

One statistical perspective identified as a necessary building block to form a basis for IIR is the ability to *view data as an aggregate* (Rubin, Hammerman & Konold, 2006). Statistical properties of aggregates such as their centers, variability and shapes emerge from attending to features of distributions rather than features of individuals. Thinking about aggregates, while possible, has been shown to be challenging for children (Cobb 1999; Hancock, Kaput & Goldsmith, 1982). Recent work by Konold, Higgins, Russel & Khalil (2015) has resulted in the identification of four perspectives that students use when working with data. The use of these perspectives as a way to analyse an individual’s particular interpretation of data may provide valuable insights into their statistical reasoning and in turn the extent to which they possess the

necessary building blocks for informal inference. These perspectives include *data as pointer* (focus on the event rather than the data), *data as case value* (focus on individual data values or cases), *data as classifier* (identifying subsets of data values that may be the same or similar) and *data as aggregate* (view all the data values in aggregate as an “object” or a distribution).

A study of first-grade student’s data modelling approaches carried out by English (2012) categorised children’s predictions and approaches when working with data using the lenses identified by Konold et al. (2015). Using this framework to guide categorization, 6-year olds in English’s study viewed data in a variety of different ways. Many children focused on the values of particular cases (*case value lens*) and others demonstrated the ability to consider the frequency of cases with a particular value (*classifier lens*). There was also evidence of what English (2012) terms a *pre-aggregate lens* which included approaches that considered all the data, compared the frequencies and had some attention to overall trends. While not as sophisticated as an *aggregate lens*, which involves consideration of the entire distribution as an entity in itself, the presence of this pre-aggregate lens is a strong indicator of the nascent potential of young children to engage in informal inferential reasoning.

A number of studies have explored the reasoning abilities of young children when engaged in data modeling activities in environments supported by the use of picture books (English 2010, 2012; Kinnear 2013, 2016) and data-visualization tools and technologies (Ben-Zvi, 2006; Paparistodemou & Meletiou-Mavrotheris, 2008). This study continues this line of research by exploring the informal inferences young children make about the data presented in a data modelling environment and examining what these inferences tell us about children’s perspective on data.

## Method

A multitiered teaching experiment (Lesh & Kelly, 2000) was carried out with twenty-five 5-6 year olds as they engaged in a weeklong data modeling activity. Statistical activity was motivated by a driving question (Hourigan & Leavy, 2016) and the context was the ‘design of a zoo’ as it was familiar to children and incorporated opportunities to work with data, encourage exploration of variation and make predictions about the data. The Ertle, Chokshi, & Fernandez (2001) lesson note format, developed for use as part of Japanese Lesson Study, guided lesson design considerations. This framework promoted a focus on expected student reactions, concomitant teacher responses and evaluation strategies. These foci supported examination of students’ ability to engage in IIR. This study examines the final lesson which focused on making informal inferences about data.

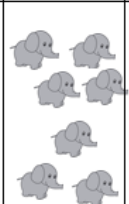

The inquiry was stimulated by playing a video excerpt that we produced:

Hi, I am James the zoo keeper. The elephant’s home in the zoo is getting a little bit crowded. I think we need to make it a bit bigger. But, I don’t know how many elephants will be in the zoo next year which makes it difficult to plan ahead. I was hoping you could look at the numbers of elephants in the zoo for the last four years, and predict how many will be there next year?

Children were then shown live video feed of the elephant enclosure in Dublin zoo and presented with a table of data illustrating the number of elephants born in the first year (3 elephants), second year (4 elephants), the third year (7 elephants) and fourth year (5 elephants) (see figure 1). Children worked in

groups of 5 to reason and make predictions about the number of animals born the following year (year 5). Following the predictions, other data relating to the birth rates of wolves [5, 6, 2, 3], giraffes [8, 8, 5, 5] and monkeys [3, 5, 0, 2] across four years were presented. Children worked in groups and predicted the number of respective animals born in the fifth year. The design of these tasks was informed by the Zieffler et al. (2008) framework to support IIR by challenging students to make predictions and judgments about data and by incorporating opportunities to capture students' informal inferential reasoning.

	The first year	The second year	The third year	The fourth year	The fifth year
					
How many baby elephants were born? 					

**Figure 1: The ‘elephant birth task’**

Conversations in 4 of the groups were audio recorded and one group was video recorded. Our primary focus when analyzing the data was on identifying the ways in which young children make informal inferences in a context rich data modelling environment.

Recordings of group conversations were transcribed. Transcripts were coded according to whether they embodied Makar & Rubin’s (2009) principles of IIR. Thus each transcript was coded at least three times in an effort to identify children’s ability to generalize beyond the data, to use data as evidence and to use probabilistic language. All predictions were further categorized as representing data as pointer, case value, classifier or aggregate perspectives on data (Konold et al., 2015).

## Findings

Children understood the task and were enthusiastic when making predictions about animal births in Year 5. However, making data informed predictions was challenging for some. Initially there was some evidence of idiosyncratic reasoning that was distanced from the context and from the data presented, however, this soon disappeared once the data and context were discussed further. Many children based their predictions on their knowledge of the context and modified their prediction based on discussion with peers. The findings are structured using the three principles of IIR that are considered essential for informal statistical inference (Makar & Rubin, 2009).

### Principle 1: Generalizations beyond the data

While all children made predictions regarding the number of births, not all of the predicted values indicated an ability to generalize beyond the data. Rather, they reflected the influence and power of counting in the mathematical development of the young child. For these children, there was an awareness of frequencies and this was demonstrated in the tendency to list the numbers, order them and then compare the outcome

to the counting numbers. This focus on the frequencies resulted in two approaches to predicting births. The first approach was to *fill in the gaps*. Children compared the frequencies to the sequence of counting numbers usually leading to the identification of a ‘gap’ in the list of numbers. Children were eager to fill this gap i.e. identify a count/frequency that hadn’t occurred in the presented data and avoid presenting a value that had already occurred. Thus, they believed that this missing number would likely be the number of animals born the next year (see discussion between Sheena and Ayesha below around wolf birth rate [5, 6, 2, 3]). The second approach was to *extend the number sequence*. In these situations children were not overly perturbed by an identified gap in the counting sequence and chose instead to extend the numbers beyond the range of the presented data (see Kate below). Generally, the next highest counting number above the upper value of the range was their prediction for the number of births in year 5. Both these strategies indicate a focus on pattern in the sense of ordinal counting numbers and thus the ‘power of counting’. However, from a statistical sense the reasoning was located and justified within the world of counting numbers thus indicating a lack of focus on pattern and trends in the data.

Teacher: How many wolves will be born this year (pointing to year 5)?

Sheena: We say maybe 4 cause 5, 6, 2, 3. And there’s no 4.

Ayesha: We’ve got our reason. 2, 3, 4, 5, 6. It’s 4 cause 2, 3, 4, 5, 6.

Teacher: What would happen if there was a year 6? How many animals might be born then?

Kate: 1. Cause it would start 1, 2, 3, 4, 5, 6.

## **Principle II: Using data as evidence**

Analysis of the transcripts revealed an abundance of situations when children *used data as evidence* to support their predictions and conclusions about data. The explanations provided by children were categorized as falling within one of the four perspectives on data posited by Konold et al. (2015).

### **Observation 1: The prevalence of a case value lens**

The focus on individual data values indicated the presence of a *case value lens*. In particular, children were attuned to the appearance of zero births for year 3 in the monkey data [3, 5, 0, 2] and commented ‘there were none that year’ and ‘there are zero there’. While this case value lens indicates a lack of focus on the aggregate, the individual data values were considered within the greater data context. For example, Eva drew on her knowledge of the context in her efforts to explain why no monkeys were born in year 3 when she stated ‘because if they had too many babies there [pointing to the 5 born in year 2], the mommy babies would have to rest all day’.

Young children’s approaches involving summing data values and calculating totals have been used as indicators of a case value lens (English, 2012). Similarly, in this study, several predictions of the births in year 5 also indicated a case value lens as they were based on summing all or some of the values and presenting this total as the prediction for year 5. Matthew predicted ‘I decided there will be 10 monkeys altogether born’ based on summing the births in years 1–4, and Kornelia predicted that 16 wolves would be born in year 5 ‘because I counted all of them’. This difficulty in attending to the variation in the data was also evident in another child’s response that 10 giraffes [8, 8, 5, 5] would be born because ‘5+5 makes 10’.

However for many of these same children, while there was a focus on counting and the application of a *case value lens*, there was an awareness of pattern in magnitude of numbers. When large numbers were presented as predictions, children rejected these numbers as too big and drew on contextual information to justify their reasoning. In the following segment, children are predicting the number of giraffes [pattern: 8, 8, 5, 5] that will be born in year 5.

Thomas: I think 85. Because there is an 8 there and a 5 there.

Polina: They wouldn't fit into the box. They are definitely not going to fit into the zoo also.

Teacher: Really? Why do you think that?

Polina: Because they [giraffes] are very big.

### **Observation 2: Awareness of trends in the data and evidence of a *pre-aggregate lens***

The responses of 20% of children suggest an awareness of overall patterns and trends in the data. This was termed a *pre-aggregate lens* by English (2012) and may point to some emerging sense of distribution. The awareness of pattern was evident in Mia's response to the wolf births which she described as 'going up and going down'. Similarly the recognition and subsequent extension of a repeating pattern in the giraffe data set [8, 8, 5, 5] was evident when Melios predicted '8. It's 8, 8, 5, 5, 8. Cause it's a pattern: 8, 8, 5, 5, 8'. During a whole class discussion about the number of monkeys that would be born in year 5, awareness of patterns was evident in the comments from Otille and Kate below:

Teacher: How many monkeys did you think were born in year 5? [3, 5, 0, 2]

Otille: I think 1 because it goes down, up, down, up, down.

Kate: 5. Cause 5 here [points to 5] and then low [points to 0 and 2] so it would go back to high.

As can be seen from the transcripts above, children's justifications did not explicitly refer to the context of the data (in this case birth rates) and hence there is the possibility that this awareness of trends stemmed more from an algebraic rather than statistical perspective. However, the greatest indication of the presence of a *pre aggregate lens* was in the reasoning of those children who married an awareness of trends in the data with their understandings of the context in constructing their predictions. In the discussion of the trends in elephant births [3, 4, 7, 6] Polina imagined that animals born in year 1 would have grown up by year 5 and be giving birth to elephants in year 5.

Polina: We put 8 elephants (born in year 5)

Teacher: Why did you put 8 in?

Polina: Because I think these are going to grow up [pointing to the 3 elephants born in year 1] and these ones will be in their tummies [pointing to her prediction for year 5]. It is always going to get bigger.

Teacher: So do you think it will always get bigger?

Polina: Yes, I think so, I think there will be babies born from these ones. These ones are going to be all grown up, they will be adults.

Thus her understanding of the variation in the data influenced her predictions and ensured she always predicted beyond the upper range of the presented data. Another child, Anna, demonstrated her ability to view the trends across the years and used this trend to inform her initial prediction. However, she

subsequently used her knowledge of the context and adjusted her prediction downwards. Here, Anna is discussing her prediction for the number of giraffes born [8, 8, 5, 5] and her initial prediction of '3' may indicate some developing notion of center. However her attention to the context makes her mindful of how her prediction (if it were correct and acted upon) would affect the other animals in the zoo and she adjusts her predict to 'protect' other animals from the negative outcomes arising from her prediction.

Anna: It was different on different years sometimes 5 [pointing to the values for year 3 and 4] but here and here it was 8 [pointing to the year 1 and 2]. So I think 3.

Teacher: Why 3?

Anna: Cause it is like the others. Not too many (baby giraffes) but not none (baby giraffes).

No. No. I think 2. Because if there are too many, all of the branches and the leaves would be gone and there would be no place for a monkey.

### **Principle III: Use of probabilistic language**

Makar & Rubin (2009) emphasize the importance of expressing uncertainty when making inferences – this can be identified in efforts to avoid deterministic claims and in the use of probabilistic language. Analysis of the transcripts reveal that children drew conclusions based on the data presented to them (birth rates over time) and used this data to make predictions beyond the data. All the while they were articulating uncertainty as demonstrated in their use of terms such as 'I think' (see Thomas, Otille, Polina and Anna above), 'probably' 'maybe' (see Sheena above) and 'I'm not too sure'. It is particularly interesting to note that children were comfortable with uncertainty and with the different predictions of others. This openness was evident when Eva pointed out 'we don't know' in relation to how many elephants the mother elephant would have. Her partner Paul continued the reasoning and stated that 'maybe there would be six elephants born because there are 6 elephants there and they could have 6 babies'.

### **Conclusions**

Young children in this study demonstrated the seeds of informal inference in their ability to 'look beyond the data' and engage in data-based argumentation to support their predictions. However, making data-based predictions was a challenging task for some children. Case value perspectives were most prevalent. The lack of repeating data values in the presented data may account for the low incidence of classifier perspectives as compared to the study by English (2012). Similar to English's study there was evidence of the presence of a pre-aggregate lens in the approaches taken by children. A large proportion of children scanned the data for patterns, sought 'missing numbers' and many made predictions based on patterns in the ordered lists of data rather than thinking from a statistical perspective. This reliance on number and algebraic reasoning is not surprising given the curricular emphases in early years mathematics curricula. It is interesting to note the influence of zero on children's deliberations about data was also a factor in the work of Kinnear (2013) and Kinnear & Clarke (2016) when engaging young children in data modeling activities.

The success that some children experienced in making informal inferences was due to a number of factors. The role played by the data and task context is particularly evident. The use of an interesting and relevant context provided a 'crutch' for the children when making predictions. Their personal experiences and high task interest ensured that rather than reasoning about decontextualized data, children were reasoning about and making sense of the situation at hand – this supported their inferences. Secondly, the development of skills in making data-informed predictions was due in large part to the use of good questioning on the part

of teachers and due to their efforts in drawing children's attention to aspects of the data and clarifying misunderstandings as they occurred. Similarly, the work of Paparistodemou & Meletiou-Mavrotheris (2008) highlighted the important role that prompting by the researcher played in supporting children in speculating about larger data sets. The third factor was the importance of peer interactions. Children built on the ideas of others as they reasoned and made prediction within their groups thus providing evidence for the power of co-constructing meaning in small groups and demonstrated 'building on the ideas of others' (Whitin & Whitin, 2008, p.93). This importance of peer interaction in promoting inference and deriving conclusions from data was also evident in the work of third grade students when engaging in inference (Paparistodemou & Meletiou-Mavrotheris, 2008).

*In this study, we examined the models of resampling that a group of students constructed in order to use one sample to make informal inferences about a population of data. Students participated in a model eliciting activity which aimed to elicit the resampling process of bootstrapping. We will discuss the model of resampling and inference constructed by one group of students, the factors which led to the group constructing a model of resampling with replacement, and how these students' conceptions of the sample related to their model. We suggest that the students' conception of the relationship between the sample and population was a key factor in constructing a model of resampling and inference similar to the method of bootstrapping.*

*Keywords: Statistics education, modeling, informal inferential reasoning.*

## Introduction

Bootstrapping is one method of simulating data through resampling that has become an important tool for statisticians, who suggest that it is intuitive to novice statistics students (Lock, Lock, Lock-Morgan, Lock, & Lock, 2013). The term bootstrap is used in the idiom to pull oneself up by one's bootstraps, which means to accomplish a goal with the resources on hand. Rather than take many samples to estimate a sampling distribution, the bootstrap method uses the one sample on hand to accomplish the same goal. Bootstrapping is a process of simulating data beginning by drawing one sample from a population. Resamples are constructed by choosing elements from the original sample, one at a time with replacement, until as many elements are drawn as in the original sample. This new sample is called the bootstrap sample. The process is repeated many times to create a collection of such bootstrap samples. A statistic from each of these bootstrap samples is aggregated to form an empirical bootstrap sampling distribution, which can then be used to make inferential claims about the population from which the original sample was drawn.

Bootstrapping was introduced by Efron (1979) as an alternative to earlier resampling methods. He asserted that the bootstrap was more widely applicable and dependable than earlier resampling methods, while also using a simpler procedure. New curricula for introductory statistics courses at the secondary and tertiary levels have been created which focus on simulation and resampling methods such as bootstrapping (Garfield, delMas, & Zieffler, 2012; Pfannkuch, Forbes, Harraway, Budgett, & Wild, 2013; Tittle, VanderStoep, Holmes, Quisenberry, & Swanson, 2011). Pfannkuch et al. (2013, p. 2) asserted that "the bootstrapping and randomisation methods using dynamic visualisations especially designed to enhance conceptual understanding have the potential to transform the learning of statistical inference." Lock et al. (2013) claimed that bootstrapping capitalizes on students' visual learning skills and helps to build students' conceptual understanding of key statistics ideas. While these curricula and subsequent research have examined students' understandings of the use of method of bootstrapping, studies have not examined how students construct and develop these understandings. We suggest that this lack of research on student

understandings of eliciting the concept of bootstrapping is a gap in the research literature. In this study we examine aspects of the model of resampling and bootstrapping that one group of students constructed in order to make informal inferences about a population of data and these students' conception of the sample's relation to the population. The research question driving this study was what factors led students to construct models of resampling with replacement.

## Review of literature

The current research literature has viewed the bootstrapping method through the lens of formal inferential reasoning, such as using the method as a means to estimate standard errors and construct confidence intervals (Garfield, delMas, & Zieffler, 2012; Pfannkuch, Forbes, Harraway, Budgett, & Wild, 2013). In this study, rather than focus on students' understandings of how this method could be used for formal inference, we focused on how students constructed and developed methods similar to bootstrapping and made informal inferential claims from the resulting empirical bootstrap distributions. Key to eliciting students' models of resampling and inference in this study was understanding the use of students' informal inferential reasoning to make claims about a population. Informal inferential reasoning is the drawing of conclusions from data that extend beyond the data, from viewing, comparing, and reasoning with distributions of data (Makar & Rubin, 2009; Pfannkuch, 2007).

In order to make informal inferential claims in this study, groups of students first needed to determine a method of simulating data. Saldanha and Thompson (2002) explored students' conceptions of a sample in relation to the population while the students participated in an activity which constructed an empirical sampling distribution by collecting repeated samples from a population. Students' conceptions of a sample in relation to the population and sampling distributions were categorized as either additive or multiplicative. Those with an additive conception of the sample only viewed the part-whole relationship between the sample and the populations, with multiple samples representing multiple parts of this whole. The resemblance and relationship between the sample and population distributions was not a factor for those with this conception. Those with a multiplicative conception of the sample viewed the sample as a "quasi-proportional, mini version" (p. 266) of the population. The sample can be used to approximate the distribution of the population, with an understanding that various samples' distributions may bear more or less resemblance to the distribution of the population. We posit that this multiplicative view may be critical to understanding the use of bootstrapping for informal inferential reasoning, since the proportion of each element in a sample is assumed to represent the proportion of those elements in the population.

The focus of analysis for this study was the model of resampling and bootstrapping which participants constructed and developed while engaged in a model eliciting activity (Lesh, Cramer, Doerr, Post, & Zawojewski, 2003). Models are "conceptual systems ... that are expressed using external notation systems, and that are used to construct, describe, or explain the behaviors of other system(s)" (Lesh & Doerr, 2003, p. 10). Model-eliciting activities encourage students to generate descriptions, explanations, and constructions in order to reveal how they were interpreting situations. Model eliciting activities are designed in order for students to:

- Make sense of the situation drawing on both their school mathematics real-life sense-making abilities;

- Recognize the need to construct a model to complete the activity, rather than produce only an answer.
- Create documentation that shows solution paths, patterns, and irregularities that the students considered while constructing their model;
- Assess when their responses need to be improved, refined, or extended,
- Create models that can be extended to use in a broader range of situations (Lesh, Hoover, Hole, Kelly, & Post, 2000).

By using a modeling approach to examine student reasoning, we viewed reasoning as dynamic and developing over the course of instruction. Observing students as they participated in a model eliciting activity allowed us to view the construction and development of their thinking of resampling and inference.

## Design and methodology

This study is a qualitative case study and part of a larger study (McLean & Doerr, 2016) that consisted of an eight-class-session teaching experiment that was enacted in four introductory statistics classes at the high school and community college levels ( $n=68$ ) in the United States. This study focuses on the student reasoning that developed during one class-session as a group of four students from a community college participated in a model eliciting activity that aimed to elicit the method of bootstrapping. During the model eliciting activity, we collected written classwork from all participants and videotaped the group of students in order to document the group's model construction and development. We analyzed the videos and written classwork for evidence of informal inferential reasoning, quantities used and the relationships between these quantities, and the representations and explanations used in their arguments in order to reconstruct the development of the reasoning that were created by the participants.

The group of students participated in a model eliciting activity, using hands-on manipulatives, where they were given one sample from a population and constructed a model of resampling and inference in order to make claims about a population. The activity was designed to elicit a model that could be used to resample from a sample, with replacement, in order to construct a bootstrap sample of the same size as the original sample and use the distribution of these bootstrap samples to determine which outcomes are most likely to occur. The model eliciting activity asked groups of students to help a manager in a grocery store predict the percentage of peanuts in a certain brand of mixed nuts. The students were given a sample of mixed nuts in the form of seven craft sticks marked with a 'P' for peanut and 18 not marked to represent other kinds of nuts. The model eliciting activity prompt and manipulatives are shown below (Figure 1).

[Grocery store] carries many types of nuts, dried fruits and candies in their bulk food section. The manager of bulk food is always interested in bringing new types of food for her customers to try. She recently ordered a sample of a new brand's mixed nuts. From past experiences, she has determined that customers prefer mixed nuts with fewer peanuts. She plans to order a large shipment of mixed nuts and is considering this new brand. Before she orders, the manager wants to know more information about the percentage of peanuts in this new brand. From this one sample of mixed nuts, the manager has asked that you determine a likely range for the percentage of peanuts in the entire brand of mixed nuts. She would also like to know the methods that you

develop to come to your conclusion. Your methods may of use for future bulk food purchases. The bag of sticks is the sample of mixed nuts. Sticks marked with a 'P' are peanuts. Those not marked are other types of nuts.

**Figure 1: Model eliciting activity manipulatives**

Prior to the model eliciting activity, the group of students participated in a model development sequence which elicited and developed models of repeatedly sampling from a population, constructing an empirical sampling distribution, and making informal inferential claims regarding the population. In this model eliciting activity, students could no longer repeatedly sample from a population in order to construct an empirical sampling distribution and needed to construct a new model of resampling and inference that could use only one sample from the population to make informal inferential claims.

## Results

In the larger study from which this data was gathered (McLean & Doerr, 2016), groups of three or four students constructed two categories of models for making inferential claims of a population from one sample. The first category of model ( $n=16$  groups of students) treated the sample of 25 nuts in a manner similar to a population and collected resamples without replacement, from the 25 nuts. The second category of model ( $n=4$  groups of students) discussed or collected resamples from the sample of mixed nuts in a manner which preserved the makeup of the sample while resampling. We will report findings from one of the four groups who constructed this second category of model. This group constructed a model of resampling with replacement similar to the method of bootstrapping. We will discuss two findings of student understanding that were key to constructing these models: the representativeness of the sample to the population; and a method of resampling that preserved this representativeness. Findings like these were unique to the groups of students who constructed the second category of model of resampling and inference, which preserved the make-up of the sample while resampling.

## Representativeness of the sample

Before discussing methods of resampling, the group of students first discussed how they believed that one sample could be used to make inferential claims and how their sample of mixed nuts related to other possible samples of mixed nuts taken from the sample population

- Susan: I would say from this sample, that a little over a quarter of the peanuts, of the nuts are peanuts, from our random sample.
- Randy: But it's only one sample.
- Ted: But this is the only sample we have.
- Brenda: So if you pick another random sample what's going to happen?
- Ted: It's most likely going to change.
- Susan: It's going to change, but I feel like it will probably be still about the same.

Susan made an assertion about the percentage of peanuts in the population under the condition that she was basing her assertion on the random sample, which Randy stressed is only one random sample. Susan emphasized that although other samples of nuts will be different from their one sample, they will probably be "still about the same". Susan demonstrated an understanding that the percentage of peanuts in the sample likely represents the percentage of peanuts in the population. This is a key aspect of inferential statistics. When making inferential claims you take for granted that the sample likely represents the population because as Ted stated, "this is the only sample we have" and as Susan asserted, "it will probably still be about the same" as other samples.

## Preserving the representativeness of the sample when resampling

The group initially decided to take a resample of 14 mixed nuts by drawing one at a time from the bag of mixed nuts, without replacement. The group only took one sample with this method, which yielded five peanuts out of 14 nuts. The instructor then came back over to the group to discuss how the group had collected the sample of 14 nuts.

- Instructor: So how are you choosing those?
- Susan: He [Randy] randomly puts them together, and then I randomly without looking draw them out.
- Instructor: Okay. So you're drawing out one at a time?
- Susan: Uh-uh.
- Instructor: Okay, and you're setting it on the table?
- Ted: Yes.
- Instructor: Then you're going back in and you're drawing another one?
- Susan: Yes.
- Instructor: Okay, so ...

Ted: Ohh! Wait, you said that you're putting them on the table. Was that like, do you think that we should put them back in the bag after we draw it out? Like for probability simulators?

From this exchange Ted considered how the sampling would change if they resampled with replacement instead of resampling without replacement. By using the term "probability simulators" he was approaching the idea that if you do not replace the stick after choosing each one, the probabilities of choosing a peanut or another nut will change. This term was not used previously in the coursework for this class, but likely came from his earlier experience in a mathematics or statistics classroom. Ted was combining the idea of the representativeness of the sample to the population, that the group discussed earlier, with the idea of the probabilities staying constant for each choice of nut, the key concepts of bootstrapping. The group continued to discuss how this process of replacement was different than their initial approach without replacement.

Randy: What are we going to do now?

Susan: Now I'm going to hand you back the Popsicle stick and you're going to mix it back in.

Randy: So you're going to draw ...

Susan: From the 25, not from, you know how before, like when I drew [sic] and set it down, it went less and less and less and less and less?

Ted: So we're going to do it again, we're still going to draw 14, we're just going to put them in.

Susan: So each time we're drawing from 25, instead of a reduced ...

Ted: 'Cause as we would draw, in this one we would draw and there were 10, that meant that there were only 15 left in the bag, which doesn't account for the sample, right? 'Cause you're reducing it.

They asserted that when not using replacement, the nuts that they were drawing from the bag no longer represented the sample after some nuts were drawn and not returned. The group followed this procedure of resampling with replacement to collect a sample of 14 nuts. This was the only sample that they had time to gather before the class was reconvened to discuss each group's approach to determine the likely range of peanuts in this new brand. The group did not use this one sample to draw a conclusion since time ran out for developing their model.

## Discussion and conclusions

We assert that a key difference between this study and previous research addressing data simulation and bootstrapping (Garfield, delMas, & Zieffler, 2012; Pfannkuch, Forbes, Harraway, Budgett, & Wild, 2013), is the *elicitation* of bootstrapping methods by groups of students rather than the instruction of students on how to use the method. By eliciting the method, we were able to view students' statistical reasoning which led students to construct a process similar to bootstrapping: the representativeness of the sample to the population; and a method of resampling that preserved this representativeness. We assert that these students exhibited a multiplicative conception of the sample (Saldanha & Thompson, 2002). These students claimed that the distribution of the sample likely

represented the population and constructed a model of resampling with replacement that simulated resamples which upheld the quasi-proportional relationship of the sample to the population. These findings have implications for future curricula design by examining the key understandings that students may need before instruction on methods of resampling, such as bootstrapping. The findings also suggested that the use of model eliciting activities are useful design for instruction in introductory statistics classrooms in order to analyze students' developing thinking of resampling and inference.

Two limitations of this study were that: although this group of students constructed a model of resampling similar to bootstrapping, they did not collect resamples that were equal in size to the original sample of mixed nuts; and the time needed to sample by replacement with manipulatives did not allow the students to collect a distribution of samples from which to draw informal inferences. Collecting resamples of the same size is key in order to observe the variability in a statistic for samples like the original. While designing the model eliciting activity, we did not foresee issues with how the context of the activity encouraged students to make claims about the populations of mixed nuts, rather than the proportion of peanuts in future samples from the population of mixed nuts. Within this context, rather than use a bulk supply of mixed nuts in which samples of many sizes could be taken, the model eliciting activity may have been better designed to focus on the small packages of mixed nuts with consistent sample sizes. The time demanding nature of resampling could have been alleviating by using smaller original samples or with transitioning to the use of technology. A different context from mixed nuts where smaller samples felt natural, rather than merely a simplification may have allowed more resamples to be simulated. We made the choice to initially explore resampling with manipulatives and in later activities use technology to simplify the resampling process.

*This article focuses on how information and communication tools made available online could be effectively exploited to help improve the quality and efficiency of college-level, at-distance statistics training. The paper first provides an overview of the content, structure, and pedagogical and didactical approach underlying Quantitative Educational Research Methods, an online course targeting post-graduate education majors that has been built based on contemporary visions of web-based statistics instruction and computer-mediated communication. It then presents some of the insights gained from a case study of a group of students (n=49) participating in a recent offering of the course. The article concludes with some instructional and research implications.*

*Keywords: Statistics education, distance education, statistical inference, model-eliciting activities.*

## Introduction

The affordances offered by modern Internet technologies provide new opportunities for statistics instruction, making it possible to overcome restrictions of shrinking resources and geographical locations, and to offer, in a cost-effective and non-disruptive way, high-quality learning experiences to geographically dispersed students. In recent years, we have witnessed an exponential growth of distance education worldwide. Online course delivery has become common in a wide variety of disciplines, including statistics. This expansion is likely to continue, given the expanding access to the Internet and the greater emphasis to lifelong learning. Several advantages associated with distance education have been identified in the literature. In addition to the flexibility and convenience it offers, the distance option may also allow students the opportunity to take courses from established experts in their field of study that might not be available locally. From the viewpoint of statistics, it creates some unique opportunities for enhancing instruction, including the provision of a vast array of technological tools and resources for better understanding of statistical methods and concepts (e.g. interactive applets, virtual laboratory experiments, etc.). Several successful examples of successful programs of teaching statistics via distance have been documented in the literature (e.g., Evans et al., 2007; Everson & Garfield, 2008; Meletiou-Mavrotheris, Mavrotheris, & Paparistodemou, 2011).

Despite its proliferation and the unique opportunities for enhancing statistics teaching and learning that it offers, online statistics course delivery also presents several unique challenges. There are several pedagogical and technical issues that need to be incorporated into the design of an online statistics course for it to provide an effective learning environment. Review of the existing research literature alerts us to the fact that the quality and effectiveness of online statistics training currently offered is variable and inconsistent (Evans et al., 2007). While most of the conducted studies indicate that students taking courses with an online component have similar achievement and satisfaction levels compared to students in traditional, face-to-face classrooms (Mathieson, 2010), there is

growing evidence of many web-based distance learning courses failing to meet the expectations raised. For example, while it is well-documented in statistics education research that the incorporation of discussion and active learning in the classroom can help learners to think and reason about statistical concepts, bringing these important learning approaches to an online course has proved very challenging (Gould, 2005; Meletiou-Mavrotheris & Serrado, 2012).

Early attempts at web-based instruction assumed that setting up an attractive website with interesting multimedia applications was adequate for learning to occur. However, it has now been recognized that the level of success of distance education is determined by multiple factors, including underlying theory, technologies, teaching strategies, and learner support. Elements in the design of an online course such as its content and structure, the tools and cognitive technologies employed, and the amount of interaction between instructors and learners as well among learners, are important factors affecting students' learning and attitudes (Tudor, 2006). A particularly important criterion for the level of success of at-distance statistical training is also the extent to which instruction allows learners to experience the practice of statistics and to apply statistical tools in order to tackle real-life problems.

This article provides an overview of a post-graduate quantitative research methods course that has adopted a non-conventional approach, which promotes online participation and collaboration of students using contemporary technological and educational tools and resources. After describing the course pedagogical approach, and content and structure, the paper presents some of the insights gained from a case study of a group of students participating in a recent offering of the course.

### **Nature of the Quantitative Educational Research Methods course**

“Quantitative Educational Research Methods” is a graduate-level course targeting students enrolled in the M.A. in Educational Studies program offered at European University Cyprus. Although originally developed for a face-to-face setting, the course was in 2013 redesigned as an online course to make it accessible to students enrolled in this program through distance education. In designing the e-learning course, efforts were made to preserve the pedagogical approach, and content and structure of the classroom-based course.

Contemporary visions of web-based instruction and computer-mediated communication underpin the course design. Concurring with Roseth, Garfield, and Ben-Zvi (2008), the online learning environment has been built upon the premise that instruction of statistical methods ought to resemble statistical practice, an inherently cooperative problem-solving enterprise. Students enrolled in the course are provided with ample opportunities for interactive and collaborative learning. They are actively involved in constructing their own knowledge, through participation in authentic educational activities encouraging enculturation such as projects, experiments, computer explorations with real and simulated data, group work and discussions. Statistical thinking is presented as a synthesis of statistical knowledge, context knowledge, and the information in the data in order to produce implications and insights, and to test and refine conjectures. There is a focus on modeling and simulation—along with inference – which is being facilitated by having students use the dynamical statistical software package TinkerPlots2 (Konold & Miller, 2011) for all modeling and analysis. This software was selected because it is designed explicitly to support integration of exploratory data analysis approaches and probabilistic models, and to allow for generation of data (e.g., drawing samples from a model) and experimentation (e.g., improving models, conducting simulations).

The course lasts 15 weeks. It is made up of 7 modules, that are concept driven and focused on enriching students' knowledge of quantitative research methods (mainly inferential) by exposing them to innovative learning situations, technologies, and curricula. Each module involves a range of activities, readings, contributions to discussion, and the completion of group and/or individual assignments. The activities and assignments mirror those completed in the classroom-based course.

Throughout the course, students use TinkerPlots2 to work on a set of carefully designed open-ended Model-Eliciting Activities (MEAs) (Lesh et al., 2000) in which they create and test statistical models in order to solve real world problems of statistics (Garfield, delMas & Zieffler, 2012). The activities are carefully designed to support but, at the same time, also explore students' evolving understandings of fundamental ideas related to statistical inference. Some of the MEAs are completed individually, and others collaboratively in groups of 3-4 students. The MEA "How many tickets to sell?" (adapted from <http://new.censusatschool.org.nz/resource/using-tinkerplots-for-probability-modelling/>) is a typical example of these activities. It is based on the following fictitious scenario: "*Air Zland has found that on average 2.9% of the passengers that have booked tickets on its main domestic routes fail to show up for departure. It responds by overbooking flights. The Airbus A230, used on these routes, has 171 seats. How many extra tickets can Air Zland sell without upsetting passengers who do show up at the terminal too often?*" In this MEA, students use Tinkerplots2 to model the Air Zland flight (e.g. model the scenario in which AirZland sells five extra tickets, i.e. books 176 tickets). They repeat the experiment a large number of trials using the "Collect Statistic" feature of Tinkerplots2 to keep track of the number of passengers not showing up, and draw the resulting distribution of collected sample statistics. Students then decide whether their model should be adjusted or not and, based on that, make recommendations to the airline as to how many extra tickets it should issue. Finally, they use the properties of the binomial distribution to determine theoretical probabilities when booking a certain number of seats (e.g. 176 seats) and compare the results with those they get through the Tinkerplots simulation. (see Meletiou-Mavrotheris et al. 2015 for more details).

A progressive formalization approach is being employed in the course. The first part focuses on building a teaching pathway towards formal inference by helping students experience and develop the 'big ideas' of informal inference. Through their engagement with the open-ended MEA activities, students learn where these ideas apply and how. Later in the course, students are introduced to confirmatory or formal inference methods, and begin comparing empirical probabilities with the theoretical ones. They learn the formal procedures for building sampling distributions, constructing confidence intervals, and conducting hypothesis testing using different statistical tests. The similarities and differences between ideal, mathematical models of reality, and statistical models based on experimental data are being emphasized throughout the course. From informal uses of models early in the course to formal uses as part of significance tests at the later part, instruction encourages explicit discussion of how every model is essentially an oversimplification of reality which involves loss of information, and of how the success of probability models depends on their practicality and potential to give useful answers to our research questions.

The course is delivered completely online using the instructional content and services of the project platform (on the LMS Blackboard system). In addition to the course content (video lectures, PowerPoint presentations, video tutorials, links to statistics resources available on the internet, etc.) the site offers access to various tools for professional dialogue and support (email, videoconferencing,

chat rooms, discussion forums, wikis, etc.). The course instructor acts as a facilitator of a deeper learning experience through guiding discussions, encouraging full, thoughtful involvement of all participants, and providing feedback, in both asynchronous and synchronous activities.

## Methodology

The case studied was a group of students taking the online version of the Quantitative Research Methods course during the Fall 2014 semester. The first author was the course instructor. There were forty-nine ( $n=49$ ) students enrolled in the course, residing in Greece ( $n=38$ ) or Cyprus ( $n=11$ ). Course participants were characterized by a wide diversity in a number of parameters including age, and professional and academic background. Their age ranged from 23 to 55. Some had an academic background in primary education ( $n=18$ ), while the rest were secondary school teachers in different domains (languages, humanities, natural sciences, physical sciences etc.). While the majority were experienced educators with several years of teaching experience, a sizeable proportion were either unemployed or employed in non-education related occupations. Students also had a varied background in statistics. Most of the older participants had very limited prior exposure to statistics, while the younger ones had typically completed a statistics course while at college. Even students who had formally studied statistics had attended traditional lecture-based courses that made minimal use of technology. Thus, upon entering the course, almost all students had very weak statistical reasoning and/or a tendency to focus on the procedural aspects of statistics.

Documenting online student activity and collaborative knowledge construction is a multifaceted phenomenon that requires complementary methods of data collection and analysis in order to understand how learning is accomplished through interaction, how learners engage in knowledge building, and how designed media support this accomplishment (Hmelo-Silver, 2003). Consequently, to increase understanding of the research setting, the current study employed a variety of both qualitative and quantitative data collection techniques, including: (i) The contents of the online discussion boards, chats, and wikis, in which students had been participating during the course; (ii) Bi-weekly collaborative assignments, in the form of Model Eliciting Activities (MEAs); (iii) videotaped synchronous sessions taking place weekly throughout the semester using Blackboard Collaborate as a communication tool; (iv) final course examination administered to both students enrolled in the course under study, and students enrolled in a face-to-face version of the same course again taught by the same instructor; (v) an open-ended survey administered at the course completion, aimed at determining students' perceptions, opinions, and feelings regarding the course; (vi) Quantitative statistics automatically collected by the system (e.g. number of students participating in a discussion forum or successfully completing group assignments, etc.).

The text-based and video-based data collected during the course (MEAs, discussion forums, videotaped synchronous sessions, open-ended survey at course completion) were eventually analysed in order to examine how students' engagement with Tinkerplots2, with MEAs and with each other impacted their motivation and participation levels, and how it scaffolded and extended their understanding of the big statistical ideas encountered during the course. We did not use an analytical framework with predetermined categories. What we instead did was a content analysis aimed at identifying, through careful reviewing of the transcripts, the recurring themes or patterns in the data. Quantitative data (system statistics, performance on final examination) were analysed using descriptive and inferential statistics. Linking the depth of qualitative data with quantitative breadth

provided a more holistic picture of the course impact on students' attitudes and learning of statistics.

## Results

Analysis of the data obtained during the case study, indicates that the online Quantitative Educational Research Methods course provided students with experiences parallel to those provided in its face-to-face version. The course was characterized by high levels of student engagement in online discussions and participation in videoconferencing sessions, and by successful collaborations for the completion of group assignments. Findings also suggest that the adoption of a pedagogical approach focused on modeling, using a dynamic statistics software like Tinkerplots2 for the conduct of statistical investigations, and of technological tools for facilitation of communication and collaboration among learners, is a viable option for online statistics instruction. The informal approach to statistical inference espoused by the course, using TinkerPlots2 as a tool for investigating authentic, open-ended model-eliciting activities (MEAs), fostered students' ability to reason about the stochastic, while also developing their appreciation for the practical value of statistics. Through their engagement in MEAs in which they collaboratively built models and used them to evaluate research claims and hypotheses, the graduate students in our study developed relatively coherent understandings of fundamental concepts related to statistical inference.

The affordances offered by Tinkerplots2 for building and experimenting with data models to make sense of the situation at hand, proved instrumental in supporting student understanding of both informal and formal inferential statistical ideas. Of course, similarly to other researchers we also witnessed a number of challenges associated with the adoption of a modelling approach (Konold, Harradine, & Kazak, 2007), and different levels of student reasoning and understanding of the role of models and modelling, and of the key assumptions underlying the models simulated by the computer (for more details, interested readers could refer to Meletiou-Mavrotheris, Paparistodemou & Serrado, 2015). Nonetheless, use of Tinkerplots2 enabled students to build and modify their own models of real world phenomena, and to use them to informally test hypotheses and draw inferences. Their engagement with data-driven inferences helped them to develop sound informal understanding of the logic of hypothesis testing and its related statistical ideas (significance level, p-value, null and alternative hypothesis etc.), and served as a foundation for the formal study of inferential statistics.

Student performance on assignments and assessments was comparable to what was observed in the face-to-face version of the course concurrently taught by the first author. When the end of the semester, both groups of students were administered an identical assessment instrument (as a final exam) with several open-ended tasks aimed at investigating their understanding of the main ideas and concepts related to statistical inference covered in the course, both groups obtained very similar results (*Mean Score: At distance=76.1, Face-to-face=77.06*). A two-sample unequal variance t-test (conducted after checking all assumptions) indicated that there was no significant difference in mean scores ( $p=0.73$ ) between the two groups of students (see Table 1).

Course	No. of students	Mean Score	Standard deviation	t test for equality of means	
<i>At-distance</i>	49	76.10	14.68	t	Two-tail Sig.
<i>Face-to-face</i>	34	77.06	10.49	-0.3463	0.73

**Table 1: Two-tailed t-test Comparison of Mean Differences in final exam scores**

In the survey administered at the end of the course, students were asked to indicate what they liked

most about the course. The overall feedback regarding the course content, services, and didactical approaches was generally very positive. The flexibility and convenience associated with distance education was an aspect appreciated by all course participants, since it made it possible for them to determine their own place, pace and time of study. Another aspect also much appreciated by the majority of the participants was the fact that both the discussions and the assignments were carefully designed to be learner-centered, and to make explicit ties between theory and practice by utilizing students' own experiences as learning resources. The promotion of communication and collaboration was also considered to be an important strength of the course by most learners. Students, in general, enjoyed the interaction and the sharing of experiences and ideas, although there were a few who expressed a preference for individual assignments, arguing that *"group assignments are less flexible since you have to regularly meet online with your group"*, or that *"in group tasks, some members do minimal work while the rest work very hard, but the end they all get the same score... this is unfair."*

In a previous study conducted by the authors in the context of a transnational online teacher professional development course in statistics education, the biggest difficulty experienced was the limited success in establishing a functional online community of practice (Meletiou-Mavrotheris and Serrado, 2012). Similarly to other statistics education researchers (e.g. Gould and Peck, 2005), there was a much lower than anticipated level of learner-to-learner interaction in the course. Although community building was a main objective, and while at the course outset there was big enthusiasm and very high participation in discussion forums, interaction dropped off over time. The vast majority of messages (around 80%) had been sent during the first half of the course, while in the second half only a handful of learners actively participated in the discussion forums, while the rest had made minimal or no contributions. In the current study, by contrast, students' level of engagement in the discussion forum was consistently high throughout the semester. All discussion forums created during the course were characterized by vibrant interaction and rich dialog.

We consider the active participation of students in the discussion forums witnessed throughout the semester to be an important success of this course since, as the literature indicates, leading a discussion of substance on a "discussion board" is much more challenging and difficult to achieve than in a real classroom (Gould & Peck, 2005). We believe that, in the current study, the adoption of the following strategies led to more successful community building compared to our prior research: (i) Making participation in group activities a compulsory element of the course that counts towards learners' grade; (ii) Establishing a clear set of criteria in the course syllabus to help learners better understand the academic expectations and increase the intellectual depth of their contributions; (iii) Providing sufficient time for group members to make meaningful interpersonal connections before the assignment of the first cognitive task; (iv) Increasing the duration of each discussion forum to allow adequate time for learners to formulate and articulate their contributions; (v) Providing more prompt and effective moderation of online interactions.

Despite the overall success of the course, analysis of the collected data has allowed us to identify a number of issues and student concerns that adversely affected the online participation of course participants. The biggest shortcoming identified was the course overload. When requested, in the end-of course survey, to indicate what they liked the least about the course, most participants mentioned the course workload that made it extremely difficult for them to keep up with the course requirements due to their overburdened schedules. Also, participation in videoconferencing and other activities that

required synchronous communication (e.g. chat sessions) proved very difficult to schedule, as it was almost impossible for all of the students to be available at the same time.

The Quantitative Educational Research Methods course team has adopted a continuous improvement iterative model. Insights from the current study informed the revision of the course, so as to further improve its quality and effectiveness. The heavy workload was corrected in subsequent offerings, and more realistic work expectations were set so as not to overburden students. There has also been more careful scheduling of course activities to offer students more flexibility.

## Discussion

Teaching online courses is a new, unexplored territory for most statistics instructors. Distance education is similar yet different from classroom-based instruction, and requires new teaching skills and strategies. Several pedagogical and technical issues should be taken into account in the course design to provide an effective online learning environment. Using the case study of a distance-based approach to a quantitative educational research methods course as an example, the paper has provided some suggestions on how to best exploit the affordances offered by modern e-learning technologies to improve the quality and attractiveness of the online learning experience through the promotion of hands-on and collaborative knowledge construction. In accord with contemporary visions of web-based instruction that support collaborative and participatory models of online learning, the article has offered some insights on how to build an online learning environment in ways that resemble statistical practice, an inherently cooperative, problem-solving enterprise involving participation in projects, modelling and experimentation with real and simulated data, group work, and discussions.

Statistics education research in distance education settings is still at a developmental stage. More research is needed to advance our understanding of how to best take advantage of computer-mediated communication tools to support the development of effective virtual learning environments. By exploring the forms of collaboration and shared knowledge building undertaken by the group of students participating in our online course, the current case study has contributed some useful insights into the factors that may facilitate or impede the successful implementation of distance education. These insights have helped to further improve the quality and effectiveness of the course, and sketch a road map for our future research work, and for other similar endeavours.

*Making modeling, generalization and justification an explicit focus of instruction can help to make big ideas available to all students at all ages (Carpenter & Romberg, 2004). Because mathematical models focus on structural characteristics of phenomena (e.g. patterns, interactions, and relationships among elements) rather than surface features (e.g. biological, physical, or artistic attributes), they are powerful tools in predicting the behavior of complex systems (Lesh & Harel, 2003). Based on this assumption, we attempted to enhance students' (aged between 8 to 13 years old) reasoning about probability by asking them to design a computer game for modeling probabilistic ideas. Students were introduced to the block-based programming language Scratch 2.0, and used it to create their own games. The findings show that the idea of chance had an important role in their games and that they expressed many probabilistic ideas while they were designing and playing their game.*

*Keywords: Statistics education, randomness, educational game, game design, Scratch.*

## Background of the study

Although probability is increasingly being integrated into the school mathematics curriculum, students face difficulties in understanding a variety of probabilistic concepts. Probability is difficult to teach because of the gap between intuition and conceptual development, even as regards elementary concepts (Batanero & Diaz, 2012). The current article contributes to the emerging literature on game-enhanced statistics learning by exploring the capabilities of a learning environment that uses programming logic in a game setting, as a tool for facilitating the emergence of young learners' informal reasoning about randomness and other key probabilistic concepts. Based on a case study of a group of students (aged 8-13) who developed their own games through use of the visual block-based programming language Scratch 2.0 (Massachusetts Institute of Technology, 2013), the following question was explored: How do students use elements of reasoning about probability when they design their own games?

The research literature suggests that digital educational games have many potential benefits for mathematics and statistics teaching and learning. One of their foremost qualities is the capacity to motivate, engage, and immerse players. It has been shown that educational games captivate students' attention, contributing to their increased motivation and engagement with mathematics and statistics (Ke, 2008). Studies have also demonstrated that, in addition to providing an incentive for young people to engage in learning, games also have the potential to yield an increase in students' learning outcomes (Kolovou, van den Heuvel-Panhuizen, & Köller, 2013). Although much of the research on the effectiveness of gaming on learning is inconclusive at this point, there are strong indications in the literature that appropriately designed and constructively used games can support experimentation with mathematical and statistical ideas in authentic contexts, and can

be used as the machinery for engaging students in problem solving activities, and for promoting the attainment of important competencies essential in modern society (Lowrie & Jorgensen, 2015).

While digital educational games can provide a range of potential benefits for statistics teaching and learning, high quality, developmentally meaningful, digital games for students are less common than hoped. There is a wide variability in content, scope, design, and appropriateness of pedagogical features, with many educational games including mediocre or even inappropriate content, being drill-and-practice, and focusing on basic academic skills rather than on high-level thinking. Nonetheless, some exceptional exemplars that can help create constructive, meaningful, and valuable learning experiences do exist. One promising type is coding gaming software, which teaches students the concepts behind programming in a playful context. With an increasing focus on programming and coding finding its way onto the curriculum in many different countries across the world, some innovative, educationally sound game-based learning environments that support the development of computer programming skills from a young age have begun to appear. Several educational applications are currently available for helping students with no coding background or expertise to grasp the basics of programming through the exploration and/or creation of interactive games (e.g. Scratch, ScratchJr, HopScotch, Bee-Bot). Often, coding game applications enable students to share their games with others, and to play or edit games programmed by others.

Having taken their inspiration from Logo (Papert, 1980), educational programming environments promote a constructionist approach to technology use, with the emphasis being on students using technological tools to become creators instead of consumers of computer games. In addition to the provision of a highly motivational and practical approach for introducing students to computer programming and developing their computational thinking, coding software provide rich opportunities for the reinforcement of problem-solving, critical thinking, and logical thinking skills (e.g. sequencing, estimation, prediction, metacognition) that can be applied across domains.

## **Methodology**

### **Participants and context**

A total of four workshops were organized and each one lasted for 2 hours. Twenty-six students (N=26, 16 male, 10 female), aged between 8 and 13, participated in all four workshops during July 2016 (summer school vacations) on a volunteer basis. An invitation to parents was placed in social media and the students were selected from a priority list based on registration date. All participants had the right to pause or stop their participation entirely at any given moment. Additionally, all parents provided their written consent regarding the use and publication of their students' work for research purposes. In this paper, all names used are pseudonyms in order to preserve participants' anonymity.

To serve the role of the gaming platform, our research team chose Scratch, a visual programming language developed at the MIT Media Lab that consists of reusable pieces of code, which can easily be combined, shared, and adapted. Scratch can be used to program interactive stories, games, and animations, art and music and share all of these creations with others in an online community (<http://scratch.mit.edu/>). It was created to help students think more creatively, reason systematically, and work collaboratively, all of which are essential skills required for the 21st century (Resnick, 2007). The software was first released in 2007 while Scratch 2.0, which is its second current major version, came out in 2013. In this study, we deemed Scratch 2.0 as the most appropriate option to

adopt, due to the fact that there is very little research on how coding learning environments could be used as a tool for developing concepts related to the stochastic.

For each workshop, a different set of extra-curricular activities were closely designed based on constructionism (Papert, 1980), and each meeting was structured in such a way as to promote an unhurried and creative process. The first workshop aimed to a general introduction to the software and in the second workshop students worked on activities based on the movement of a sprite around the screen. In the second workshop the x and y axis were discussed based on the position of a sprite. In the third workshop, students worked on variables and the idea of randomness through experimentation with a flipping coin game, and ways to pick random block. Finally, students were asked to create their own game based on what they had learned. In the last session, students continued their games from their previous meeting, changed them if they wished, and asked a friend to play their game so to identify any bugs and fix them.

### **Data collection**

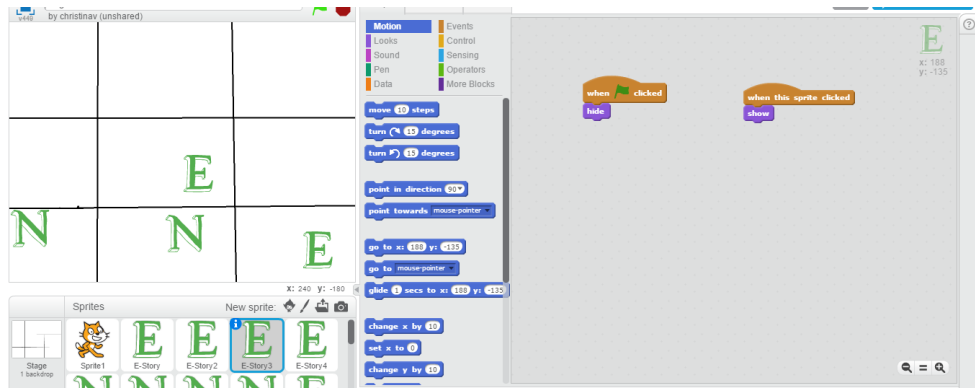

For the purposes of collecting our data, we used a variety of methods, including live video recording of the workshop and screen capturing of the participants' interactions with the software. Other sources of data also included field notes and classroom observations. In six cases, we also conducted individual mini-interviews of selected students (interviewed while engaging in game design) that expressed some exceptional ideas regarding the element of randomness, in an attempt to study further their contributions to this project. For the purpose of analysis, we did not use an analytical framework with predetermined categories. What we instead did was, through careful reading of the transcripts and field notes and examining of the various interactions for similarities and differences, to identify recurring themes or patterns in the data. To increase the reliability of the findings, the activities were analyzed and categorized by all three researchers and any inter-rater discrepancies were resolved through discussion.

### **Insights from students' reasoning about probability in their Scratch games**

In the following paragraphs, we present two main categories of students' reasoning about probability in the context of creating their Scratch games. First of all, we describe how students used the idea of chance and randomness in their games and secondly how they used spatial representations for expressing probabilistic ideas. The students' games we present here were from the last workshop.

#### **The role of randomness in designing games**

In our sessions, students experimented with different mathematical and statistical ideas while designing their games. One of the ideas brought up during the class discussion was that of randomness. The 'pick random' block, which allows users to bring randomness into Scratch projects, was casually explained to students, in a similar way to how the rest of the blocks were introduced. It was interesting to find out that the students ended up using randomness in their games.

**Figure 1: Eric's and Nicole's random game with letters**

Eric (a ten-year-old boy) and Nicole (a twelve-year-old girl) designed a game where the first letter of their name appears randomly when you click on the board. It is like a tic-tac-toe, but the player is not sure where the letter goes.

Eric: I like the fact that the letters appear in a random position. This makes our game more *interesting*.

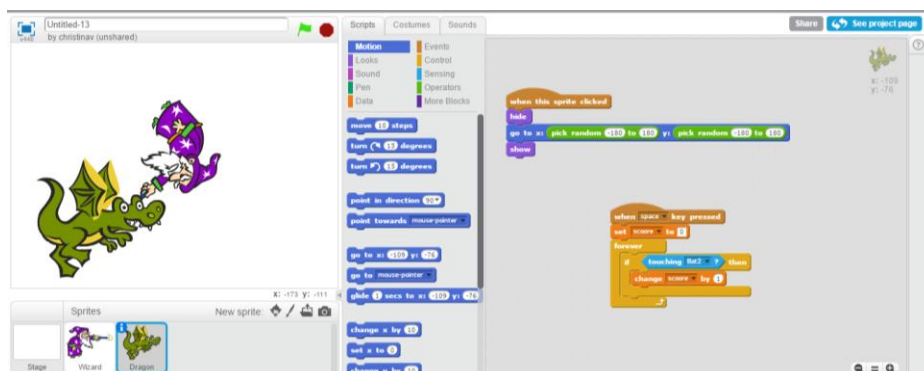

Researcher: Why is that?

Nicole: You have to see the probability, where it might go [the letter], and then select the letter.

Eric: You don't know at the beginning... You need to make a guess. If you don't look at the results and just play, then you are more likely to lose...but nothing is for sure.

Eric and Maria used the random rule in their game in order to make it more interesting. Randomness and uncertainty made their game to have action. Nicole referred to the concept of probability in order to make a correct guess based on the results of the game. So, students were playing the game and trying to guess where the next letter would appear based on the idea that the probability of each letter to appear somewhere is equal-according to their design.

Charis, a nine year old boy, also made a game by using randomness.

**Figure 2: Charis' dragon random game**

The aim of Charis' game is to click on the dragon. When the dragon is clicked, it appears in a random position. The magician then follows the dragon to its new position.

Charis: You know, I made it just for fun! It is nice to see the dragon moving around without *knowing*...But I will develop it. I made the dragon to move all over the place.

Researcher: So, will it appear again in this position we see now?

Charis: Of course! I will make something to count where it goes, so we will see which position it takes...May be to touch something...Let me see what I can do...

Charis realizes that randomness is something that you don't know in advance. It is interesting that he designed a dragon with a random move and then he tried to predict its movements by counting the dragon's position each time. He admits that this is how the game begins to have fun! The idea of using the x and y variables in a random way, and of trying to predict the next position prompted Charis to use the idea that the dragon will move on the pre-designed space and after a long time (law of large numbers) the dragon will pass from every point (based on x and y).

### Spatial representations for expressing probability

Chris, a 13 year-old boy, was one of the students who really liked using randomness in his games. Chris designed a game of a dog crossing the street. The aim of the game is to help the dog to cross safely (without touching any of the cars).

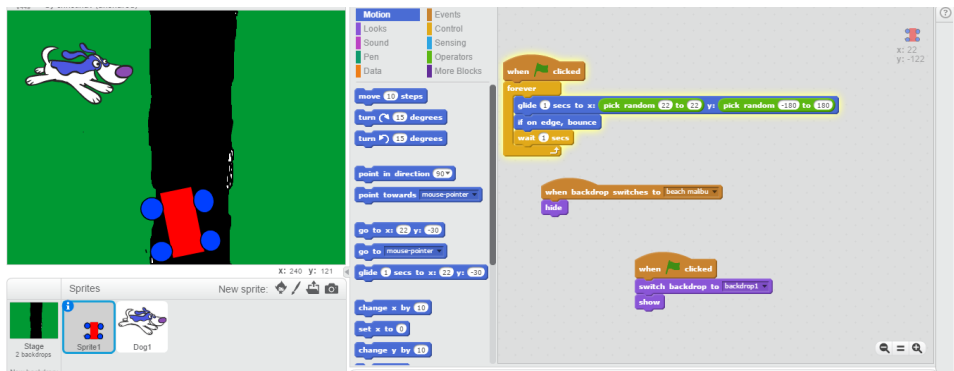

Figure 3: Chris' first version of random game

Researcher (R): So, what is the game here?

Chris (C): Try and see...

R: Interesting... [While R is playing the game.]

C: Yes, you don't know where the car goes. You should be careful!

R: Why? The car will move and cross the road.

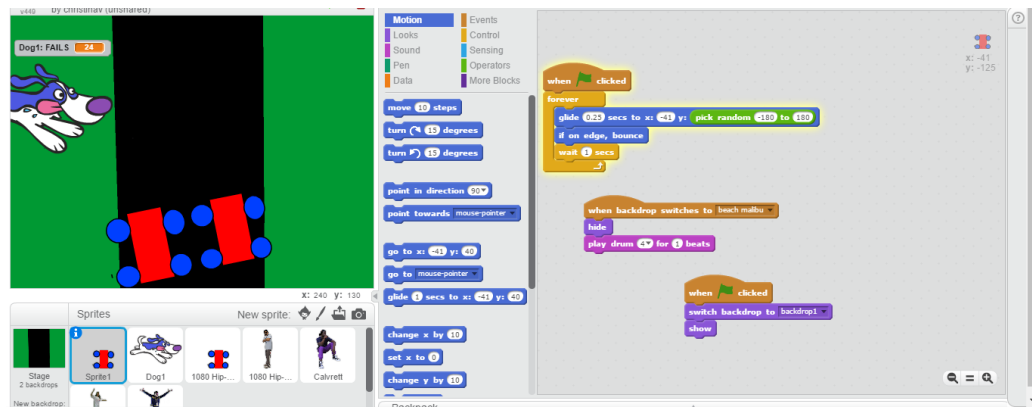

C: Not only...It [the car] moves randomly on this road I design. That's the interesting part...So, you don't know where it goes. And when you touch it! You see! *The dog touched the car*. Do you like it?

We have also here the existence of randomness in games as a factor of making a game interesting. It is important how Chris refers to the dog's movement - the one that the player controls - and not to the car's movement. This also shows a realization that randomness in his game is something 'uncontrolled' and this was made on purpose for making the game interesting.

R: Why didn't you just make the car to move forward?

C: This is boring...just seeing the cars and move around. Now you don't know...Of course it is easy with one car. ...*Chris is making different things on his game.*

We found it interesting that Chris' game was a non-deterministic model of crossing a road. His idea of moving the cars in the road randomly is what makes his game appealing. Chris designed a car that moved in a random way. Although a random movement of the car might have sufficed for the aim of the game, he also used the road as a spatial sample space and tried to increase the difficulty of the game by increasing the number of cars.

**Figure 4: Chris' second version of random game**

R: What have you done?

C: I just put two cars, a counter, made a bigger road and I changed the dog. I changed the code of the cars.

R: Why?

C: It is better this way. I made the road bigger and I asked the cars to move randomly all over the road. This makes it more difficult for the dog to cross.

*[The researcher plays the game. The dog cannot cross the road. The counter keeps track of her failed attempts.]*

R: It is very difficult that way.

C: Yes [he laughs]. This is something that reduces the probability of the dog safely crossing the road to less than fifty-fifty. Actually, it makes it go to zero.

R: Would you like to play it?

C: Actually, that way is not interesting...it's not fair. You know...I can make some change to the design. I will make the dog smaller. That will make it fair...Let's see.

further analyse our collected data and to continue with further research on how students express probabilistic conceptions like the law of large numbers and how students use and elaborate their codes.

# Using spreadsheets to teach probability in French high school

Bernard Parzysz

Université d'Orléans & L.D.A.R. (université Paris-Diderot)

[parzysz.bernard@wanadoo.fr](mailto:parzysz.bernard@wanadoo.fr)

*Including a 'frequentist' point of view has resulted in experimentation becoming an important issue in the teaching of probability in high school. Spreadsheets are now widely used, but the status of the results produced and how to use them are not always clear for the students, since two domains are at play in turn: statistics and probability. Through the French example – but this can also be applied to the teaching of probability in other countries – this paper reviews some questions about spreadsheets, namely simulating random experiments and shifting from discrete to continuous distributions.*

*Keywords. Probability, simulation, continuous distribution, spreadsheet.*

In France as in many other countries, probability has become a prominent subject in the teaching of mathematics, in link with the growing importance of numerical data in everyday and professional life and the development of technologies allowing to process them. Conversely, the point of view on probability has evolved, taking into account a 'frequentist' point of view implying students making experiments. Among the technological tools spreadsheet has become much used in the teaching of probability, the main reason being that it makes getting a large number of tries of a random experiment very easy and fast. This paper is based on the French current situation, but it certainly can apply to many other countries all over the world. Its aim is to give some insights on how new didactic questions have occurred and have now to be tackled by teachers in their classes. As it has already been noticed, "it is not good enough to only consider which technology to use, but (...), in order for effective learning to take place, it is how the technology is integrated into the curriculum and learning process and how the teacher uses it that are vital" (Pratt, Davies & Connor, 2008, p. 98), the more so that "most teachers have little experience with probability and share with their students a variety of probabilistic misconceptions" (Batanero et al., 2005, p.1). I shall discuss some questions about the use of spreadsheet in high school, namely:

- the nature of simulation, implying using a model of the random experiment and making in turn intervene probabilistic and statistical paradigms;
- possible purposes of a simulation: visualize the law of large numbers, make conjectures, bring out the notion of stochastic model, help solving probability problems...
- the suitability of spreadsheet for introducing continuous distributions (exponential, Gaussian...).

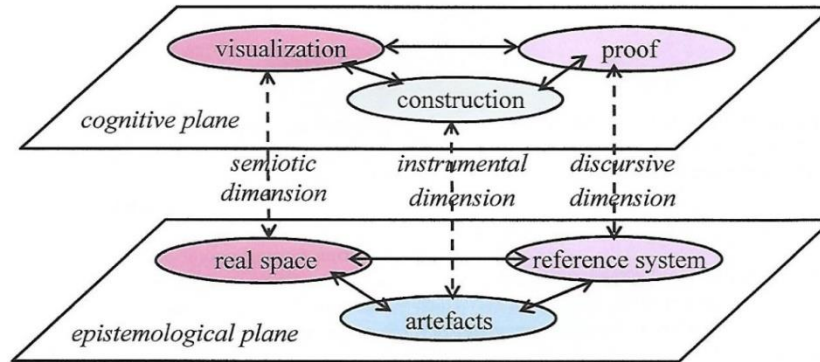

For this, I shall use a theoretical framework including Kuzniak's Mathematical Working Space (MWS), Kuhn's paradigms and Duval's semiotic registers.

## Theoretical framework

In order to get a holistic view of the work undertaken by somebody solving a mathematical problem, one has to take into account not only the domains at play but also the cognitive processes involved. The Mathematical Working Spaces, or MWS, framework (Kuzniak, 2011) considers two "planes" –epistemological and cognitive–, each one having three components:

- in the epistemological plane: a set of representations ('real space'), a set of artefacts (instruments) and a theoretical reference system;
- in the cognitive plane, three processes: visualization, construction and proof

An important feature of the model is the interaction between these two planes according three dimensions, semiotic, instrumental and discursive, linking each component of one plane to a corresponding component of the other (Figure 1). The model also assumes that efficient mathematic work results from involving the 3 dimensions together with interactions between them.

**Figure 1: The MWS model (after Kuzniak, 2011)**

Kuzniak distinguishes 3 main MWSs:

- reference MWS, defined by the syllabus,
- suitable MWS, planned by the teacher to be implemented in his/her class,
- personal MWS of the student.

Kuhn (Kuhn, 1962) defined scientific paradigms as "universally recognized scientific achievements that, for a time, provide model problems and solutions for a community of researchers," (page X of the 1996 edition). This notion was adapted by Kuzniak to taught mathematics, regarding the epistemological plane. In the case of probability several paradigms can be distinguished (Parzysz, 2011):

- a realistic paradigm (R), i.e. the real ('concrete') random experiment itself;
- a paradigm (P1) resulting from a first ("light") modelling of the real experiment by establishing a precise protocol, a list of issues and assigning a probability to each of them;
- a paradigm (P2), in which notions of random experiment and probability are defined, together with properties of probability which can be used for solving problems.
- a paradigm (P3) of the axiomatic type, taught in university.

N.B. In France, at secondary level, only P1 and P2 paradigms are considered, the latter being possibly extended with some elements of calculus at the end of high school (P2+) for the study of continuous distributions.

Regarding the semiotic dimension I shall refer to the notion of 'semiotic register', i.e. a coherent semiotic system allowing 3 cognitive activities: produce identifiable elements (representations), transform an element into another of the same register, convert an element into an element of another register (Duval, 1995). For Duval, a better knowledge is obtained through the use of several registers interacting one with another. He also indicates that the shift from one representation to another one

is more efficient when there is a ‘semantic congruence’ between them, i.e. when there is a one-to-one correspondence between signifying elements of the two representations.

## Simulation

In the beginning of its being studied in high school, probability was taught as an application of combinatorics, through Laplace’s formula (probability = number of favorable issues / number of total issues). This ‘cardinalist’ point of view implies that all the issues have the same chance to appear, and then other random phenomena had to be left aside. For instance this is the case for drawing pins: when tossed, they may come down in two ways, like coins, but no argument of symmetry can help and one cannot assign a plausible *a priori* probability to each of them. In such a case you have to observe the relative frequencies of the issues, assuming that they will ‘converge’ toward their probability when the number of tries grows ‘to infinity’. This is the ‘frequentist’ point of view, theorized by the law of large numbers. This point of view was introduced in French high school 20 years ago. Anyway, whatever is the point of view on probability, one has to decide which probability will be allocated to each issue of the experiment, the difference being that the decision is made:

- either on *a priori* ground (e.g. ‘symmetry’ of the issues) in a cardinalist approach;
- or on *a posteriori* ground (frequencies of the issues) in a frequentist approach.

In past days, teachers were reluctant to let their students perform sequences of a random experiment, mostly because it was noisy and requested too much time, but the coming of computers in classrooms, namely spreadsheet including a so-called ‘random’ generator (see for instance Kroese et al., 2011), provided them with an alternative path (although starting with real experimentation remains necessary to materialize the link with reality). Spreadsheet is now widely used to simulate random experiments, with various purposes.

1) Spreadsheet can be used to visualize the compatibility of the cardinalist and frequentist points of view, and finally get the students confident in the generator. For this purpose one has to introduce into the machine a probability for each issue. Then the evolution of the relative frequencies on fairly large numbers of tries can be observed (Figure 2), this process being in fact a visualization of the ‘law’ of large number (belonging to the P3 paradigm).

**Figure 2: Relative frequencies of heads in 1000, 2000, ...50000 tries of heads and tails**

Thus performing a simulation implies constructing at least a simple probabilistic model (within the P1 paradigm), in order to implement it in the machine. Hence simulation is a ternary process: what is implemented in the software is *not* the real experiment but a theoretical *model* of it (Figure 3).

**Figure 3: The ternary process of simulation**

In such a task several registers are appealed to in turn: natural language, symbolic language (software) and Cartesian graphs. The semiotic-instrumental plane of the MWS is at play, involving the initial P1 paradigm (finding a model of the experiment), then shifting to another paradigm: descriptive statistic (DS) (results of the simulation). It is only when a conjecture about the experiment is asked that the discursive dimension appears (within P2 paradigm).

Both as teacher and teacher trainer, I could observe that some students find it difficult to distinguish between statistical and probabilistic paradigms (the more so than some notions are similar), somewhat analogous with geometrical paradigms. Here, like with GDS, the dynamic feature of spreadsheet, allowing an easy and fast observation of many samples –and consequently many different results (Figure 4)–, can help distinguishing the P2 paradigm (theoretical value) from SD (observed value). But French textbooks do not put the stress on the distinction between the two domains, in particular using the notions in a very loose way (e.g. confusion average / expectation), this probably reflecting actual teaching in classrooms. Similarly, about the instrumental dimension a tendency of textbooks to ‘overguide’ the students, in order to help them deal with the software, must also be noticed.

**Figure 4: Relative frequencies of heads in 50 samples of 100 tries of heads and tails**

2) Simulation can also be used to estimate the value of a probability. For instance, if various models of a same experiment give different probabilities for a given event, a simulation mimicking the concrete experiment can tell which model(s) can be discarded. This is the case with the following problem, which was the basis of an action research with high school students introducing the frequentist approach (Parzysz, 2007):

Toss a well-balanced coin; if head (H) happens you win and if tail (T) happens you toss the coin again; then if H happens you win and if T happens you lose. What is your probability of winning?

In 1754, Jean Le Rond d'Alembert thought that one has 2 chances against 1 to win, at variance with “all authors” claiming that one has 3 chances against 1; Mimicking the process with spreadsheet leads to some difficulty, since one has to distinguish between the two possible results of the first toss. For an easier implementation in the computer the teacher may decide that the coin would be tossed in every case. From a probabilistic point of view the two processes are equivalent but all students are not convinced. (Historically, a similar argument opposed Blaise Pascal with Gilles Roberval in 1654).

The reason for such a reluctance is that the second process is not semantically congruent with the real experiment.

Table 1 shows the corresponding spreadsheets.

Try n°	1st toss	Again?	2nd toss	Result
1	H	no		won
2	T	yes	H	won
3	T	yes	T	lost
4	T	yes	T	lost
5	T	yes	H	won
6	H	no		won
7	H	no		won

Try n°	A coin	B coin	Result
1	H	T	won
2	T	H	won
3	H	T	won
4	T	T	lost
5	H	T	won
6	T	T	lost
7	T	H	won

**Table 1: Spreadsheets of the two simulations**

When comparing the sheets, one can see that putting anything (H or T) in the empty boxes of the left sheet has no influence on the final result. After that one can forget the “Again?” column and have a second toss in all cases, i.e. replace the initial procedure by the second one without any inconvenience (Figure 5).

**Figure 5: From experiments to model**

Thus a visual comparison within the register of double entry tables, in the semiotic-discursive plane, can be a means for deciding if two models are equivalent. And for younger students this can be a possible path towards the notion of stochastic model.

3) A most widespread type of activity in French 10<sup>th</sup> and 11<sup>th</sup> grades describes a random experiment and then asks the student to simulate it a number of times with the spreadsheet, observe the results and formulate a conjecture about the probability of one of the issues or the possible value of a parameter. Then he/she is asked to solve the problem using the probability theory and compare the theoretical results with the initial conjecture.

In this process several paradigms are at play. As seen above, starting from reality (R), the student shifts to probability (generally P1), then moves to descriptive statistic (DS) to extract information from the spreadsheet (frequency, mean, etc.) and back to P1 to formulate a conjecture; solving the problem within P2 will imply the discursive dimension (Figure 6).

N.B. In such activities the spreadsheet is used as a multi-purpose tool: it intervenes in turn as logical tool (instructions for software), random generator (simulation), copying machine (results of tries), calculator (statistical parameters) and plotter (diagram).

Figure 6: The paradigms and processes involved in the activity

## Continuous distributions

N.B. This point is based on a recent research (Derouet & Parzysz, 2016).

The French syllabus for 12<sup>th</sup> grade includes an introduction to continuous probability laws, and the official resource document for that level suggests starting with a statistical continuous variable, in order to approximate the histogram of a sample by a continuous curve “which fits the histogram, the area under the curve being equal to 1”. The general idea is to link a random variable  $X$ , not with a set of isolated probability values as was previously the case, but with a function  $f$  (density) verifying :  $P(a \leq X \leq b) = \int_a^b f(x)dx$  for any  $a$  and  $b$  with  $a \leq b$ . This modelling process, which seems quite sensible, implies also a shift from statistics (DS paradigm) to probability (here P2+) and an essential, though transitional, point is histogram. This rises a difficulty, since spreadsheet *cannot* produce histograms, or rather what it calls histogram is in fact a bar chart. In order to overcome this problem one may widen the bars till they become contiguous (Figure 7), but this trick is restricted to cases in which all intervals have the same width. But the notion of density gets sense only with unequal intervals, since in a histogram the basic notion is area, not height. Thus in this case spreadsheet appears to be of no help if the software does not permit producing *real* histograms.

Figure 7: From bar chart to pseudo histogram

This same syllabus includes the study of normal law and recommends introducing the standard law  $\mathcal{U}(0, 1)$  from the observation of the distribution of  $Z_n = \frac{X_n - np}{\sqrt{np(1-p)}}$ , where  $X_n$  follows the binomial law  $\mathcal{B}(n, p)$ . Then the bar chart for  $Z_n$  is approximated by the curve of a function of the  $x \rightarrow \lambda \cdot \exp(-ax^2)$  type. As above a shift from discrete to continuous law occurs, but this time spreadsheet can help since, contrary to the general case, the values of  $Z_n$  are equidistant (the distance being  $1/\sqrt{np(1-p)}$ ) and then a pseudo histogram is suitable.

All textbooks follow this scheme, in which three types of diagrams are at play in turn: first bar chart (for  $Z_n$ ), then pseudo histogram, then bell curve. Spreadsheet is necessary at every stage of the process, first to get the values of  $P(X_n = k)$  for  $0 \leq k \leq n$  and various values of  $n$  and  $p$ , then the corresponding

bar charts of  $Z_n$ , then its pseudo-histogram and finally the (pseudo-)curve of the standard normal law (in fact a polygon). The main difficulty comes from the histogram and the curve looking proportional but *not equal* (Figure 8) because the distance between the values of  $Z_n$  is different from 1 (see above).

**Figure 8: Pseudo-histogram and pseudo-curve**

This problem of scale is tackled rather awkwardly in textbooks, as is the standardization of the binomial variable. However, the question appears when one wants to compare the shapes of the bar charts for several binomial distributions (Figure 9); one may then think of a ‘calibration’, i.e. changing the units on the axes, in order to get diagrams with the same average and height.

**Figure 9: Comparison of binomial distributions ( $\mathcal{B}(100, .1)$  and  $\mathcal{B}(50, .4)$ )**

In the process the semiotic and instrumental dimensions of MWS are much appealed to, but the discursive dimension is not much present, due to the students’ lack of knowledge.

## Conclusion

The current French high school curriculum starts with descriptive statistics (from 6<sup>th</sup> grade on) and later goes on with probability (at 9<sup>th</sup> grade), introduced through a dual, frequentist and cardinalist, point of view involving several mathematical paradigms (DS, P1, P2, P2+). Experimentation has become a central issue in teaching probability and in this process spreadsheet extends real tries, for the reason that it is incomparably faster once its use (language, gestures) is mastered. It is now included in the semiotic-instrumental plane of the MWS and can play an important role in many ways and for multiple purposes. Some points are of importance for teaching with simulation, namely pay attention to the model subjacent to the ‘real’ random experiment (even when it does not clearly appear), help students distinguish between the statistical and probabilistic paradigms, bring out the idea of stochastic model... When coming to continuous probability a sensible way to introduce it consists of approximating a histogram by a continuous curve. Unfortunately usual spreadsheet cannot produce general histograms –i.e. with unequal classes– but only bar charts, becoming possibly ‘pseudo histograms’, and histograms should have to be produced with another software. However class experimentation showed that a pseudo histogram may prove useful as a transitory artefact in the particular case of shifting from binomial to normal law.

On the whole, although spreadsheet was not conceived for educational but for professional purposes, it has now become a quite appreciable, if not indispensable, tool for the teaching of probability in high school.

# Technology will solve student's probability misconceptions: Integrating simulation, algorithms and programming

Annarosa Serpe<sup>1</sup> and Maria Giovanna Frassia<sup>1</sup>

<sup>1</sup>University of Calabria, Department of Mathematics and Computer Science, Italy  
[annarosa.serpe@unical.it](mailto:annarosa.serpe@unical.it); [frassia@mat.unical.it](mailto:frassia@mat.unical.it)

*The paper presents a proposal of a teaching practice aimed at higher secondary school students, which intends to enhance discussion on the meaning and interpretation of probability, a topic which is often neglected in Italian schools. The authors are convinced that turning the traditional teaching method upside down - that is, proceeding directly to a problem solving approach with the aid of computers as programming tools - better develops in the students the ability to analyse and address uncertain situations correctly, and consolidates a probabilistic mentality. The chosen method was a phenomenon-inductive approach with the help of simulations, which encouraged the formulation of hypotheses and speculation concerning random phenomena.*

*Keywords: Computer-based simulations, problem posing and solving, programming environment, random phenomena, secondary high school.*

## Introduction

Probability is a formidable tool for investigating the world around us, so it definitely ought to be part of the education of informed citizens. The importance of the calculus of probability in the higher secondary school curriculum in Italy had already been acknowledged by the ministerial experimental curricula<sup>1</sup>. That is because the topic of probability lends itself well to mathematical and formal elaboration processes of sensible reality, as well as numerous applications which project a dynamic vision of Mathematics open to the real world. Other European countries have also contributed to the debate on the meaning and interpretation of probability, alongside the development of mathematical theory, by including it in the school curriculum (Ahlgren & Garfield, 1991; Shaughnessy, 1992). However, efforts in this direction in most cases have not produced significant results, that is to say the topic has not received adequate attention for a number of reasons, among which the teachers' insufficient education and training stand out (Stohl, 2005). The fact that in Italy the teaching of probability in higher secondary schools has been relegated to a secondary and often marginal level has led with time to a number of misconceptions, which can have dangerous consequences, especially when one takes into consideration the strong growth of gambling. Learning about probability helps to understand the structure of gambling, but probability has much more important applications<sup>2</sup>. The difficulties in the classic approach have so far represented a real obstacle to classroom teaching and learning of the topic, not only in Italy but also in other countries (Batanero, et al., 2005). However, in recent years the growing interest for statistical methods and the use of information technology have contributed to the study of probability as a limit of stabilized frequency (Biehler, 1991). The

---

<sup>1</sup> PNI (Piano Nazionale Informatica) in the second half of the 80s and Brocca at the start of the 90s.

<sup>2</sup> One only has to think of modern Physics, Biology, Economics, telecommunications, etc.

modelling point of view was adopted in recent years, linking probability teaching with statistical thinking. The introduction of efficient computers in secondary education allows us to simulate models resulting from statistical observations and to introduce students to the large field of statistical inference. The advantage of using simulations is that we can overcome much of the difficulty encountered when using the formal rules. The present paper fits this framework, and proposes an example of teaching practice - aimed at higher secondary school students - which intends to enhance discussion on the meaning and interpretation of probability.

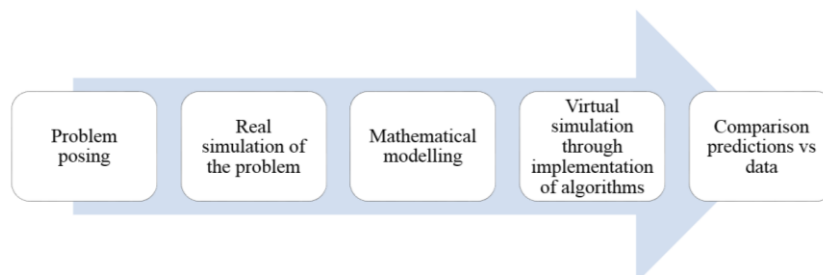

## Theoretical framework

In the Italian Secondary school the approach to probability is either classic or frequentist. In particular, the classic approach has long been dominant; but in recent years the frequentist approach has also been used. The classic approach, based on combinatory calculus, is very hard for the majority of students because of the calculations involved in solving the formulae. This perspective introduces an *a priori* approach to probability in which probabilities can be calculated before any physical experiment is performed (Prodromou, 2014). The frequentist approach is based on observations of relative frequencies of an event associated with a random experiment that is repeated a sufficiently large number of times under the same conditions. In this view, experimental probability is estimated as a limit towards which the relative frequencies tend when stabilizing (Von Mises, 1928). The idea of stabilization is based on the empirical laws of large numbers. However, the frequentist approach does not provide the exact value of the probability for an event and we cannot find an estimate of the same when it is impossible to repeat an experience a very large number of times. It is also difficult to decide how many trials are needed to get a good estimation for the probability of an event (Batanero & Díaz, 2012). To adopt one or the other approach does not help the students to understand the meaning and conceptual scope of the calculus of probability; it is even detrimental because it widens the gap between formal education and actual practice (Pfannkuch & Ziedins, 2014). So we need to look for a synthesis of the two approaches focused on problem-based learning, which also stresses connections with inductive applications and reasoning. Today all this is possible thanks to technology, which both supports training activities effectively, and can itself be the object of the training, and deal with the related problems. The use of appropriate didactic software, for example, while drawing attention to conceptual aspects of the methods, also familiarises the students with the handling of data. The programming environments - already familiar to the learners - which are used as mathematic tools to simulate and analyse casual experiments, are very productive. Computer simulation in fact allows to reproduce a model of a real or imaginary system; from a learning point of view, it facilitates learning 'through discovery' and 'programmed learning'. Moreover, when teaching probability it is fundamental to make effective and efficient representations which help to clarify and explain why some resolving approaches work and aid generalisation. The practice of programming is an important resource in teaching because it is at all effects an infrastructure for the representation of mathematical objects; in this case, simulation through the realisation of algorithms and their implementation helps the student to understand the importance of using models to describe reality and at the same time to formulate clearly and in detail the theory at the basis of the phenomenon to be represented. This paper presents a teaching proposal which emphasises the value of information technology to support probabilistic reasoning, and at the same time moves beyond pre-packaged didactic software which imply the rigid application of 'recipes' in limited contexts and cannot be easily applied to models in

real situations. Specifically, the proposal harmonically combines the classic and frequentist approach to probability into a pedagogic perspective which sees the computer as a programming tool in the MatCos<sup>3</sup> environment. The authors aim to study and experiment new curves in the field of teaching-learning of the calculus of probability taking full advantage of computers, whose potential has already been well illustrated by William Feller in his book (New York: Wiley, 1950).

## Methodology

The psychology of conceptual learning has shown how concepts and judgment are formed along a lengthy pathway which starts from often confused or even distorted intuitions. These however become progressively clearer as new cases either confirm or disprove the initial assumptions, thanks to the reflections triggered by the new experiences. This is also true for probability, one of the concepts which is most likely to be misunderstood or distorted. From the didactic point of view, computer programming plays a crucial role in the creation of social interactions which can assist students in the difficult transition from an empiric and objective interpretation of numbers to a relational and functional one. Based on these premises, the choice of methodology has privileged a phenomenological-inductive approach, which encourages the formulation of hypotheses and conjectures on random phenomena. In Figure 1 we can see the synoptic outline of the process:

**Figure 1: Model of the didactic procedure**

The model in Figure 1 consists of five phases, with appropriate intermediate steps, which lead to the next phase. In practice, starting from reality, first we investigate it; then, after mathematisation, we derive rules of behaviour to be applied to reality itself. The process is carried out encouraging inductive reasoning, in an effort to blend the topics and solution methods while leaving plenty of opportunity for discovery. The simulations allow the students to take stock of the situation and start again from what they already know, to make appropriate considerations and understand why phenomena occur, and their implications. In particular, computer simulation through programming represents a constructive and cognitive activity because it enables the student to acquire skills, strategies and techniques for the solution of problems through the concepts of variable, procedure, repetition and reoccurrence; concepts which are also cross-curricular.

## Design of the teaching procedure

Here we provide details of all the phases of the didactic model described previously.

---

<sup>3</sup> Designed and developed by the Interdepartmental Centre for Didactical Research of the University of Calabria, and widely tested as part of MIUR projects (Ministry for Education, University and Research).

## Problem posing

The teacher proposes to the students the following problem situation:

*For a tour in Sicily, a well-known airline company provides a small plane with 23 seats laid out in the following way: the first row has 2 seats while the others have 3. Those wishing to travel must book on-line through a dedicated platform, which allocates seats in a completely random way. Luisa is the first to access the booking platform; how probable is it that the system allocates her a seat in the first row? If Luisa also books for her husband, does the probability that the system allocates at least one seat in the first row remain the same?*

A careful reading of the text is followed by a discussion guided by the teacher. Such a process of verbalisation is important from the cognitive point of view, and represents a first step towards the formalisation of the problem; at the same time, from the constructive viewpoint it becomes a bridge towards the next phase, to be carried out in groups, which implies the real simulation of the problem (Frassia, 2016).

## Real simulation

The teacher divides the class into groups giving each group a non-see through plastic urn containing 23 spheres, numbered from 1 to 23, identical in shape and material. The task for all the groups is to simulate the previous problem situation and register the results obtained on a chart. The following is the specific task set for the real simulation:

*"From the urn containing 23 spheres numbered from 1 to 23, one is taken out. Calculate the probability of getting a number lower than 3".*

The students simulate for  $n$  consecutive times (for example  $n=25$ ) the casual choice of seat by drawing a numbered sphere, recording the results on a two-way chart. When comparing the results obtained by the different groups, the learners realise they are different, and this motivates them to make a sufficiently high number of trials in a limited time. The need for a tool which can aid the learning experience, an instrument able to simulate a high number of repeated trials within a reasonable time, thus becomes evident.

## Mathematical modelling

The actual simulation of the proposed problem constitutes an important occasion to highlight the ability to switch from the plane of reality to that of mathematics; but in order for the teaching to contribute to a real understanding of the concepts and a solid acquisition of them, the use of computers as programming tools acquires great importance because it is a method, "a mental place" where students have a real chance to explore mathematical concepts, to formulate conjectures to be validated or refuted, and then to continue the experience of problem solving (Frassia, 2015). Mathematical modelling requires the students to reproduce some aspects of sensible reality in order to analyse and study them. Moving from the experience to the construction of the meaning requires the construction of a simple algorithm representing the simulation of the event. Being able to work within a representation register and going from one to the other - that is what Duval (1993) calls 'competences of dealing with and converting' - is fundamental because the meaning of mathematical objects is accessible only through their representations. The probabilistic model is made explicit and reviewed in a logical sequence thanks to the algorithm; furthermore, the use of a programming environment

like MatCos adds value because it helps the students to reinforce their skills in handling mathematical language (Costabile & Serpe, 2009, 2013). The construction of the algorithm is an important and delicate phase because the students have to design the 'finite sequence of steps' that allows the computer to get to the solution. The steps of the algorithm are:

- Step 0 Assignment:  $n$  (Simulation number).
- Step 1 Initialization:  $cf = 0$  (counter for the number of favorable cases).
- Step 2 Cycle (simulation of  $n$  prove consecutive)
  - Creating one variable  $a$ ;
  - Control action: if ( $a = 1$  o  $a = 2$ ) then do
    - Increase counter  $cf$ .
- Step 3 Calculation:  $p = cf/n$ .
- Step 4 Print action:  $cf$ .
- Step 5 Graphic representation: histogram of the absolute and relative frequencies.

### Virtual simulation

The previous algorithm is easily implementable in MatCos.

#### Code MCS1

```
n=readnumber; cf=0;
for(i from 1 to n) do;
  a=int(random(1,23.99));
  if((a=1)o(a=2)) then do;
    cf=cf+1;
  end;
end;
print("In ", n, " extractions, a number lower
3 is taken out ", cf, " times ");
v=Array(2); v(1)=cf; v(2)=n-cf; histogram(v);
w=array(2); w(1)=cf/n; w(2)=1-cf/n;
histogram(w);
```

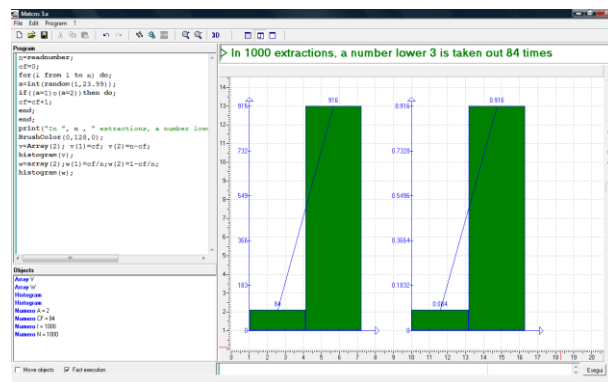

Figure 3: Output of simulation for  $n = 1000$

The students now proceed to the algebraic solution of the set problem and compare the results with the numerical values of the relative frequencies obtained in *output*. Summing up, considering the event:

$A = \text{"Draw a number lower than 3, drawing a sphere from a pool of 23 spheres numbered from 1 to 23"}$

The number of favourable cases and the number of possible cases related to the event  $A$  are:

$$cf = 2$$

$$cp = 23$$

So, the probability of the event  $A$  is:

$$p(A) = \frac{2}{23} \approx 0,087.$$

From a comparison of the results obtained in *output* with the theoretical ones, the students realize that when the number of repeated trials increases, the value of the relative frequencies gets closer to the real value of the probability.

## A question still standing...

The first question has now been answered, but the second is still standing:

*If Luisa books also for her husband, does the probability that the system assigns at least one seat in the front row remain the same?*

The corresponding question is made explicit in the following task:

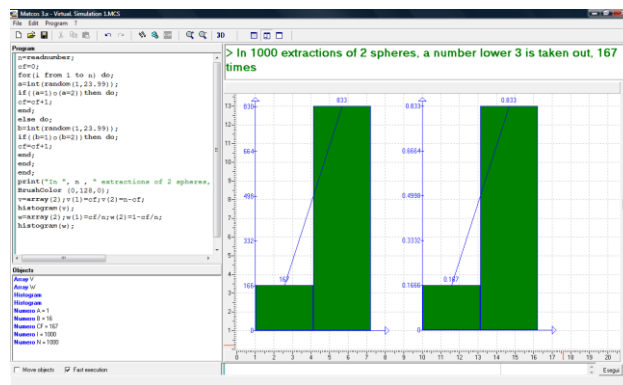

*“From an urn containing 23 spheres numbered from 1 to 23 we pull out two spheres. Calculate the probability that at least one is lower than 3”.*

Supported by the experience so far, the students decide to start directly from the virtual simulation and so make some changes to the previous algorithm. They are convinced that the two questions must have the same solution, and that the teacher just wants to trick them.

Revisiting the previous algorithm implies further steps.

Here we report the steps of the algorithm and one *output*.

- Step 0 Assignment:  $n$  (Simulation number).
- Step 1 Initialization:  $cf = 0$  (counter for the number of favorable cases).
- Step 2 Cycle (simulation of  $n$  prove consecutive)
  - Creating one variable  $a$ ;
  - Control action: if ( $a = 1$  o  $a = 2$ ) then do
    - Increase counter  $cf$ .
  - Else do
  - Creating one variable  $a$ ;
  - Control action: if ( $b = 1$  o  $b = 2$ ) then do
    - Increase counter  $cf$ .
- Step 3 Calculation:  $p = cf/n$ .
- Step 4 Print action:  $cf$ .
- Step 5 Graphic representation: histogram of the absolute and relative frequencies.

**Figure 4: Output of simulation for  $n = 1000$**

The students now proceed to the algebraic solution of the set problem and compare the results with the numerical values of the relative frequencies obtained in *output*. In the drawing of 2 spheres from a pool of 23 spheres numbered from 1 to 23, the students consider the event:

$E = \text{“Obtain at least a number lower than 3”}$

The event complementing event  $E$ :

$E^C = \text{“From the drawing of 2 spheres from a pool of 23 spheres numbered from 1 to 23, both are lowered than 3”}$

So:

$$p(E) = 1 - p(E^c) = 1 - \frac{21}{23} \cdot \frac{20}{22} = \frac{19}{55} \approx 0,170$$

The students by now have all the necessary information to answer the second question in the problem, which requires a comparison of the probability of the two events: event  $A$  and event  $E$ . From such comparison it becomes apparent that the probability of the two events does not coincide. So the students' prior conviction that the two questions of the problem - albeit expressed in formally different terms - share the same solution is proven wrong. The probability of event  $E$  is indeed bigger than the probability of event  $A$ .

## Conclusions

The teaching proposal increases students' confidence on the effectiveness of statistical methods, and at the same time raises awareness of random events. The difficulties encountered during the learning phases of the mathematics of uncertainty can thus be overcome. Virtual simulation, through the practice of programming, plays an essential role because it helps the student to develop good *problem solving* skills. In particular, simulation aids the understanding of the concept of probability of an event, assigning to it a 'degree of reliability' in the prediction of random phenomena. The novelty of this proposal is the setting up of an environment for the learning of probability, showing the close link between probability and statistics thanks to a very specific task (problem posing). The objective is to insist on the role of intuition because, in the majority of cases, students' probabilistic intuitions lead to erroneous convictions and answers. The use of computer programming enables the students to take explorative steps which can lead to the solution of a problem and trains their ability to 'anticipate' and "being able to see" in mathematics. The learner through the programme breaks down complex concepts into simple ones, thinks of and adopts new solution strategies, and compares with previous results. In so doing learners expand their mental processes and consolidate constructive knowledge. After all, education that promotes informed and solid learning cannot fail to redress wrong perceptions on the notions of probability and encourage reflection on its conceptual implications, but this had already been pointed out by Bruno De Finetti in 1967.

# High school students' first experiences with the sampling distribution: Toward a distributive perspective of sampling and inference

Eleazar Silvestre and Ernesto Sanchez

CINVESTAV-IPN, México; [eleazar.silvestre@gmail.com](mailto:eleazar.silvestre@gmail.com), [esanchez@cinvestav.mx](mailto:esanchez@cinvestav.mx)

*We report some initial results of an ongoing investigation about Mexican high school students' (17-18 years) reasoning when working with the sampling distribution (SD) for the first time in a regular classroom setting. Learning activities involve the usage of simulations and are part of a hypothetical learning trajectory (HLT) aimed at fostering a distributional and stochastic perspective of sampling and inference. We describe some appropriate strategies and limitations that students exhibited as evidenced by their a priori reasoning.*

*Keywords: Sampling distribution, statistical reasoning, high school, inference.*

## Introduction

Several errors and limitations have been reported on statistical and probability education in the past decades (Batanero, Godino, Vallecillos, Green & Holmes; 1994). In recent years, the development and availability of educational software in these areas have allowed some researchers to explore the idea that notions or informal versions of different objects and processes embedded in such disciplines, such as statistical inference, can be introduced before tertiary educational levels (Zieffler, Garfield, delMas & Reading; 2008). In particular, we point out that a number of proposals use empirical SD's and random simulations as key resources for developing appropriate conceptions and reasoning of fundamental statistical ideas, such as sampling, estimation and inference (e.g. Rossman, 2008; Batanero & Diaz, 2015; Garcia & Sanchez, 2015). Hence, we consider SD's to be a strong candidate and a starting point for instruction and teaching, with assistance of technology, when introducing statistical inference. We report on some preliminary results of an ongoing investigation that uses an HLT (Simon & Tzur, 2004) aimed to develop and foster a distributive and stochastic concept of sampling based on the SD. We focus on the initial learning activity that explores students' notions of probability, classification of most and least probable sample values, and the use of average as a measure for representation and summary of the SD. Related literature, method of inquiry, analysis of students' performance and some final reflections and discussions are described.

## Some related literature

There are a variety of interrelated elements that intervene in the process of construction, applicability and interpretation of statistical inference such as sample and population, statistic and parameter, distribution and variability, probability and significance, etc. Some researchers suggest that several conflicts and limitations of students, teachers and even professionals regarding their capacity to draw inferences from sample data are strongly related to a lack of or poor formation of concepts such as variability, sampling variability and SD's. For example, a review by Herradine, Batanero & Rossman (2011) points out that people in general hold deep misconceptions about sampling and inference (e.g. representativeness heuristics, law of small numbers, incapacity to reason about many samples) that traditional teaching does not help to overcome, as it tends to focus on calculus and computations instead. Chance, delMas & Garfield (2004), and Liu & Thompson

(2007) also indicate that a deficient or limited understanding of concepts such as the SD and probability could inhibit an appropriate reasoning of statistical inference.

On the other hand, Fathom is a specialized software developed to assist teaching and learning in statistics and probability. It offers the possibility to, among other capabilities, generate random simulations that can cause the emergence of abstract and complex mathematical objects such as the SD. It also allows access to analyze how this concept behaves through the manipulation of its parameters (sample size, population parameters, number of samples); this opens the possibility for didactic treatment substantially different from the traditional one that parts from a theoretical posture. These are key resources that can potentially promote and foster students' statistical thinking (Chance, Ben-Zvi, Garfield & Medina, 2007; Biehler, Ben-Zvi, Bakker & Makar, 2013) and, particularly, can introduce ideas of the logic behind statistical inference (Rossman, 2008).

However, only a few of the aforementioned studies target high school students, with practically none having been conducted in Mexico. The actual curricula incorporate very few, if any at all, statistical and probabilistic content for elementary and secondary education; it is only for some high school programs that introductory courses of statistics and probability are included. In addition, traditional practices use no technology to assist teaching and focus heavily on computations. This makes us believe that students' lack of experience with sampling and statistical inference within schools' practices make them become highly dependent on wrong or inappropriate intuitions and misconceptions when making inferences. The presence of this conflictive situation, and the availability of research results that propose alternative ways to overcome such difficulties, have motivated us to set our initial phase of this investigation: to explore and gain insight as to how these students reason when working with the SD, and with the assistance of Fathom (simulations of random samples), in order to better understand the extent of their reasoning and potential learning.

## Method

A regular high school classroom of 44 students participated in the study (28 female and 16 male); they had previously taken an introductory course (*traditional* style) to Statistics and Probability containing descriptive graphics, measures of center and variability, introduction to classical and frequentist approach to probability, calculations of probabilities for simple events, probabilities for conditional and independent events. Students didn't have any previous experience with Fathom.

This particular learning activity is divided in two stages and was applied in two class sessions of two hours each (one stage per session). The problem was posed/introduced to students (described below) during the first stage and, in the second, they were allowed to work freely in pairs to respond some questions using the software. Data for analysis consist of students' responses (using digital worksheets), observations of two teachers/researchers who also attended the sessions and some brief interviews. We are using principles and initial techniques of the Grounded Theory methodology (Glaser & Strauss, 1967; Birks & Mills, 2011) to analyze students' responses; specifically, we are using: initial purposive sampling, initial (and open) coding, and concurrent data generation and analysis. These techniques have oriented our methodological approach by: (1) selecting appropriate participants to study the phenomena of interest (students' reasoning); (2) depart from a pre-established theoretical framework and apply an open codification and categorization of data (based on incidents-patterns in procedures and arguments students exhibit

when resolving the activities); (3) comparison between incidents-patterns and codes for a greater refinement. At this point, the initial codes provide a general description and evidence of students' reasoning; our ongoing analysis focuses on identifying core categories, something at this time beyond the scope of this communication.

## **The HLT and the unfolding of the learning activity**

The main goal of the HLT is to encourage and provide students with an image of sampling and inference grounded on the study and exploration of the SD from a stochastic and distributional perspective; a conception set apart from the one that usually consists of an image that just reflects a “mini version” of the population. This HLT includes eight learning activities organized in three phases: 1. Introduction to the SD (to obtain estimations of probabilities for samples' outcomes; to generate an unambiguous method to identify usual or typical sample results and; to relate the average of the SD with the population's parameters); 2. Analysis of the SD when sample size is modified (changes in form, sampling variability, estimations of probabilities and typical sample results); 3. Estimation of an unknown population's parameters (assessing estimations based on sample size). In addition, after the three phases are completed, students must face a situation that requires the usage of (informal) hypothesis testing; a key aspect of interest in our research is to analyze students' performance in order to evaluate how much they draw on their knowledge about the SD and aforementioned concepts to do so.

The selected learning activity for this communication is the very initial one of the HLT and the core's first phase. It is based on Saldanha & Thompson's (2007) exploration of students' thinking of sampling and inference, with the distinction of being focused on specific sample outcomes. Due to space restrictions, we do not include explicitly all the components for this activity (learning objectives and hypothesis about the learning process) but briefly describe the unfolding of the mathematical task and its procedure of application.

The first stage of the activity follows a dynamic of an open class discussion guided by the teacher/researcher. It begins by presenting Mr. B to students: a small-medium size container composed of 7,000 beans, of which 50% are black beans and the rest 50% are pinto beans (Figure 1); Mr. B represents a physical dichotomous population whose composition is initially unknown to students. The main interest at first is to estimate the total percentage of pinto beans based on a small sample outcome. After one student draws by hand a random sample of 10 beans from the jar, the starting question that opens discussion is: “is this result (sample's %) enough evidence to assure that Mr. B has X% of pinto beans?” Some students are expected to intuitively detect sampling variability and ask to obtain more samples; the teacher encourage students to explore their argument by allowing them to draw as much samples as they consider necessary to propose a parameter.

We have observed that students don't pay much attention to high levels of variability and tend to hand-draw only a small collection of samples (less than 15), and then roughly conjecture a population percentage out of it using the frequencies, mode or average. After making this proposal (most likely different from 50%), the parameter is revealed to students and their “failed” estimation produces an engagement that is used to explore what parts of the process can be refined. Once the parameter is known to students, the exploration starts by the teacher proposing the classification of the obtained sample values as “favorable” (such as 40% - 60%) or “unfavorable” (replacing

Saldanha and Thompson's "usual/unusual" to highlight the tension between the presence of sampling variability and the expectation of obtaining sample outcomes that match or are very close to the parameter); the next step is to investigate how is it possible to quantify how expectable these results might be and how much for those considered the opposite. That is, we land and focus on obtaining probabilities of sample outcomes through the SD.

Then the teacher guides discussion to the proposal of generating many samples by posing the questions "What if we repeat this experiment a lot of times? Could the generation of many samples help us to calculate a probability or identify which are the most and least likely values?". The second stage of the task begins and Fathom is used to simulate a random collection of 300 sample outcomes and to generate a graph/distribution out of them (an empirical binomial SD emerges, with  $n = 10$  and  $P = .1$ , that students can generate repeatedly instantly using the software). Then the students are organized in pairs to freely respond a series of questions using the software and digital worksheets, which aim to explore key aspects of the SD such as estimations for probabilities, most frequent/probabilistic values and the identification of center. We extract for this report the analysis of the following items:

- Express a number from 0% to 100%, which represents how likely you consider it that you'll get a value of 70% of pinto beans in the sample #301 ( $n = 10$ ). Write down your procedure and any calculations you made.
- Which of all possible sample percentages do you think are the most likely to obtain in sample #301? Which are the ones you consider to be the least likely? Describe the method you used to select those values.
- Express a particular value that summarizes and represents all 300 percentages obtained in a particular simulation. Explain your procedure and include any computations you made.

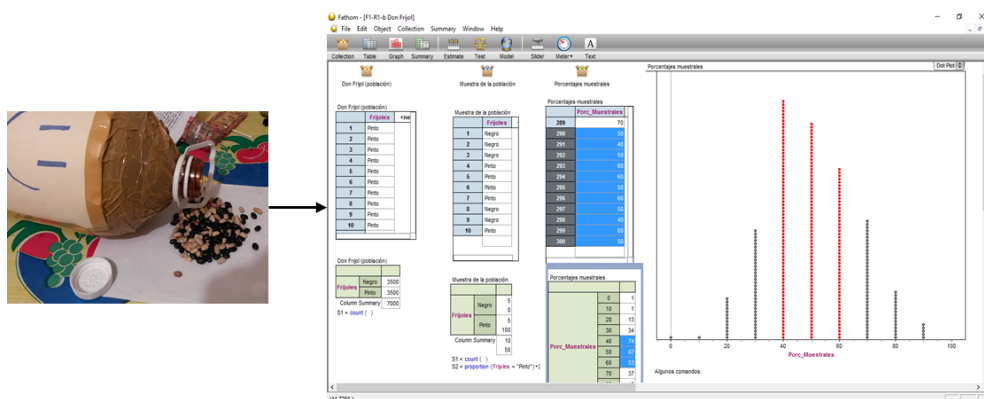

Figure 1: Mr. B (left) and display of an empirical SD using Fathom (right)

## Results: Students' responses

Codes for summarizing students' responses in question (a) are:

	<i>Codes: Procedures and arguments</i>
<i>Makes computations: 6 pairs</i>	Computes correctly an estimation for the probability: provides intervals or particular values – (6)
<i>Makes no computations: 16 pairs</i>	<p>Assigns a probability of 30% or 40% and points out one or two of the following features: the sample value (70%) is less likely to obtain due to its low frequency; considers that the values of 40%, 50% and 60% are the ones that present the highest frequencies (most likely values); specifies the sample's value frequencies – (6)</p> <p>Makes no numerical assignment and only points out one or two of the previous features – (3)</p> <p>Assigns a probability of 35% or 0% because they consider that sample values have those tendencies – (2)</p> <p>Others: Assumes the maximum frequency of the sample value as the probability; assigns 10% because it's one of 10 possible options (of the random variable); assigns 35% as the probability, incoherent argument – (5)</p>

**Table 1: Students' quantification of probability of a particular sample value (numbers in parenthesis indicate frequencies/number of pairs with the same type of answer)**

Two main groups of responses appear; the first one consists of six pairs of students that made an appropriate estimation for the probability of obtaining a specific sample value; five of these gave a particular value for the probability regardless of the number of simulations they made of the sampling distribution, while only one of them expressed it in a form of an interval. For example, pair 16 (P16) mentioned:

“We estimate that sample #301 has a probability of 10%-13% of obtaining 70% of pinto beans because we observe that, when generating different samples, the sample value of 70% appeared in a range of 30 to 40 times, which equals to 10% -13%”

It seems that the other group of students was not able to quantify correctly their expectation of obtaining the value of 70% and, instead, they assigned (six pairs) a value of 30% or 40% as the probability with no computations but most likely based on the frequency of the sample value. Nine of these 16 pairs also mentioned some features they observed in the SD, such as values of very low or high frequencies that they considered were related to a high or low expectation (probability) of obtaining the sample value. For example, P9 answered: “40% because when running the simulation, the value of 70% was not one that appeared constantly or continuously more than the previous values.”. Codes for students' responses in question (b) are:

	<i>Codes: Procedures and arguments</i>
<i>Arguments based on frequencies: 14 pairs</i>	<p>Sample values of 40%-60% because they present the highest frequencies (specifies a particular value for the frequency) – (1)</p> <p>Sample values of 40%-60% because they present the highest frequencies (points out some sample values or the interval) – (13)</p>
<i>Includes or based entirely</i>	Sample values of 40%-60% because they present the highest frequencies and because the population's parameter equals 50% – (1)

<i>on the proximity criteria: 6 pairs</i>	Sample values of 40%-60% because they are the closest to the population's parameter (points out some sample values or the interval) – (4)
	Sample values of 40%-60% because the population's parameter equals 50% – (1)
<i>Others: 2 pairs</i>	Sample values of 40%-60%, redundant answer or incoherent argument – (2)

**Table 2: Students' selection of the most likely/probable sample values (numbers in parenthesis indicate frequencies/number of pairs)**

Fifteen pairs of students used the highest frequencies to determine which sample values they considered to be more likely, but only one of them specified a value for the frequency as a main reference to compare the rest. These two types of responses are shown by P2: "40%, 50% and 60% because their frequency is higher to 55"; and P22: "The values of 40%, 50% and 60% because the Fathom graph shows us that these percentages appeared the most". Six pairs argued that these percentages are the most likely since the population's parameter equals 50% (five pairs' responses are based entirely on this), which is what we call the "proximity criteria" (note that this type of thinking is devoid of reasoning with the main objects at hand, such as frequencies, image of distribution or sampling variability embedded in the SD). To exemplify this, P15 answered:

"40%, 50% and 60% because the quantity of pinto and black beans is the same (50-50) but it's not likely that we will get 50% pinto beans in every sample, so the closest percentages are 40% and 60%."

Due to space restrictions, we do not include responses for the selection of the less likely values; however, we mention that the obtained responses match closely with those previously described. In this case 21 pairs referred to the values of 20% or less and 80% or more (special emphasis on 10% and 90%) as the least likely percentages; only one pair mentioned the values of 30% and 70%. Codes for students' responses in question (c) are:

	<i><b>Codes: Procedures and arguments</b></i>
<i>Uses (or proposes to) the average: 10 pairs</i>	Computes correctly the average of the sampling distribution – (3) Computes incorrectly the average (applies another method to high frequencies of sample values) – (2) Computes incorrectly the average (applies the "rule of three" based on a single sample value of high frequency) – (1) Computes incorrectly the average, does not specify method – (1) Only proposes to use the average, makes no computations – (3)
<i>Uses the mode: 10 pairs</i>	Uses the mode (50%) as a representative for the sampling distribution – (6) Uses a biased-mode (values greater than 50% that are not in the set of the random variable values) – (3) Uses a biased-mode (less than 50%) – (1)
<i>Others: 2 pairs</i>	Values of 50% or 60%, does not justify or explain the reasoning – (2)

**Table 3: Students' numerical representation of the sampling distribution (numbers in parenthesis indicate frequencies/number of pairs)**

The first 10 pairs of students decided to use the average to represent the sample values but only three did so correctly. Three out of four pairs that incorrectly computed the average mistook sample

values for their frequencies, didn't include all values and applied a different method; three more pairs only proposed to use the average but seemed incapable to compute it. For example, P11 mentioned (considers some high frequencies and calculates a percentage):

“We made an average out of the percentages that repeated the most and we came to the conclusion that this percentage value is at least of 68% of the 300 percentages. The calculations were to obtain a percentage of the percentages that presented the highest frequencies: 40 with 60 times, 50 with 82 times and 60 with 62 times. Computations:  $60 + 82 + 62 = 204 / 300 = 0.68 * 100 = 68\%$ ”

The next 10 pairs decided to use the mode but four of these failed to do so correctly; four of them used a biased mode, where three selected values greater than 50% that are not included in the random variable. As an example of this, P21 responded: “Of the 300 simulated percentages, we estimate that the value that repeats the most is 54% because no sample is equal to the previous one and most of the time we get something greater than 50%”.

## Conclusions and discussion

The procedures and arguments showed above are evidence of an a-priori reasoning since we consider our students have not been previously instructed on this type of activities (despite their introductory course). In this study, we identify some appropriate reasoning such as students relating high and low frequencies of sample values to high and low probabilities of obtaining them (even a few calculated correctly this estimation); and the use of the average and mode to summarize and represent the sample outcomes of the SD. Also, we identify limited or biased reasoning such as an incapability to calculate reasonable estimations for probabilities of sample outcomes; an ambiguous method to classify the most or least probable sample values (there's no definition for “the highest/lowest frequencies”; sample values of 30% and 70% are missing for classification); the use of the “proximity criteria” as a resource that avoids reasoning with the available data and is based in distance or proximity to the population's parameter; and limitations to calculate an average (despite “having all data at hand”). We believe these kinds of learning activities helped us significantly to expose students' conceptions about sampling and probability when working for the first time with the SD. The evidence suggests that students are capable of grasping and displaying important statistical-probabilistic notions, as well as resources, when placed in a rich-exploration and problem based environment. These constitute a starting point for researchers (and teachers) to assess and target more efficiently the different learning objectives of statistics education from a more constructivist point of view; it is the focus on the limitations founded in their strategies what can potentially and progressively re-orientate their reasoning to a more appropriate one. Overall, we strongly feel that more studies that can exhibit and foster students' reasoning are still needed in order to better understand and influence more efficiently students' learning of the complex (and necessary) discipline that is statistical inference.

# Using student models to generate feedback in a university course on statistical sampling

Sietske Tacoma, Paul Drijvers and Peter Boon

Utrecht University, Faculty of Science, Utrecht, The Netherlands; [s.g.tacoma@uu.nl](mailto:s.g.tacoma@uu.nl)

*Due to the complexity of the topic and a lack of individual guidance, introductory statistics courses at university are often challenging. Automated feedback might help to address this issue. In this study, we explore the use of student models to provide feedback. The research question is how student models can be used to generate feedback to university freshman in an online course on statistical sampling. An online activity was designed and delivered to 40 Biology freshmen. Instruments for generating student models were designed and student models were generated. Four students were interviewed about the generated models, and about the differences with their own estimation of their understanding. Results show that it is possible to generate individual feedback from student work in an online learning activity and suggest that discussing differences between own estimations and generated student models can be a fruitful teaching strategy.*

*Keywords: Statistics, feedback, educational technology, higher education, student model.*

## Introduction

Many bachelor programs offer introductory courses in statistics. Success rates for these courses are often low, which makes them an obstacle for students in obtaining a bachelor's degree (Murtonen & Lehtinen, 2003; Tishkovskaya & Lancaster, 2012). One challenge is that such courses are often taught to large groups of students, making it difficult for teachers to provide individual guidance. The main challenge concerns the complex topics in these courses. One of these topics is statistical sampling, which involves concepts such as sampling distributions and sampling variability. Understanding statistical sampling does not only require students to understand these concepts, but also the connections between them (Castro Sotos, Vanhoof, Van den Noortgate, & Onghena, 2007).

To address both the problem of individual guidance and the complexity of the subject matter, an approach using automated individual feedback can be promising. If appropriately designed and timed, feedback has the potential to increase student learning (Hattie & Timperley, 2007; van der Kleij, Feskens, & Eggen, 2015). Especially for large groups of students, automated feedback can add individual support that would otherwise be unattainable. For the case of statistical sampling, such automated feedback should aim at student understanding of the complex concepts involved. This asks for feedback on a global level, aggregated per concept, rather than on a local, task level. To gather input for such an overview, a specific digital assessment activity might be set up, but this would take valuable instruction time. A less time-consuming option may be to use student work in an online learning activity. Although such an activity is primarily designed for learning rather than assessing, it might still be possible to track the students' evolving understanding (VanLehn, 2008).

The question now is: how can we use students' solutions to tasks in an online learning activity to generate feedback on their knowledge of statistical sampling? This paper makes a start in answering this question by describing a prototypical approach through the use of student models.

## Theoretical background

The theoretical background of this study includes two main elements: an analysis of the difficulties in the domain of statistical sampling, and the notion of student model.

### Difficulties in the domain of statistical sampling

Samples are the key instruments to make inferences about a population. An important idea in making these inferences is that samples provide useful, but not complete, information about the population. This idea relates to two concepts: sample representativeness and variability. Sample representativeness means that for properly selected samples, sample characteristics will likely resemble those of the population. Sample variability means that not all samples are equal, and that sample characteristics do not necessarily meet population characteristics, and may not even be close. Making inferences from a sample involves a trade-off between these two concepts; a balance that is influenced by factors such as sample size and population variability (Batanero, Godino, Vallecillos, Green, & Holmes, 1994).

Castro Sotos et al. (2007) identify three main misconceptions that students may have about samples and sampling distributions. The first concerns the effect of sample size on the variance of the sample mean: as sample size increases, sample characteristics are likely to approach the population characteristics more and more. Many students misinterpret this so-called law of large numbers and use the sample representativeness heuristic to conclude that any sample's characteristics should be very similar to those of the population. The second misconception concerns the different distributions involved. Students often confuse the distribution of one sample of data with the distribution of sample means for several samples (Chance, del Mas, & Garfield, 2004). This can, for example, result in confusion between the standard deviation in a sample, the mean of the standard deviation over many samples, and the standard error of the sample mean. The third misconception concerns the central limit theorem, which states that for sufficiently large sample sizes, the sampling distribution of the sample mean can be approximated by a normal distribution. Students tend to wrongly extrapolate this theorem and believe that the larger the sample size, the closer the distribution of any statistic in the population will approximate a normal distribution (Bower, 2003).

### Automated feedback through student models

In many online learning environments, automated feedback is offered at a task level or even at a step level. However, as we are interested in the students' conceptual understanding of sampling, it seems more relevant to provide the students with an overview of their knowledge of the entire domain, which, of course, is still based on the scores on single tasks. Such an overview for an entire domain is often called a student model (Brusilovsky & Millán, 2007; Bull, 2004). Student models can be used to adapt the educational intervention (i.e. the series of tasks) to the specific needs of the individual learner (Bull, 2004) and are in this role often invisible to the student. However, opening up the student model can promote learner reflection on his knowledge and understanding, and may help learners to monitor and plan their learning (Bull & Kay, 2007; Sosnovsky & Brusilovsky, 2015).

A student model contains a domain model and an overlay. The domain model consists of knowledge components (KC's) that each describe a piece of knowledge in the domain. All tasks in the learning activity are connected to one or more KC's in the domain model. The overlay contains a score for each KC, based on the student's performance on connected tasks, which describes the student's current understanding. The KC's in a domain model can be more or less coarse grained. An advantage of a fine-

grained domain model is that it enables a very sophisticated and precise diagnose of the student's current understanding. However, when using a course-grained domain model, connections between tasks and the domain model are much easier to manage, while still a reasonable diagnosis can be accomplished (Sosnovsky & Brusilovsky, 2015).

In the light of this theoretical framework, the research question addressed here is: How can student models be used to generate feedback to university freshman in an online course on statistical sampling?

## Methods

To address the research question, a prototypical environment to generate feedback on the understanding of statistical sampling through the use of student models was set up. In this explorative design research, 40 freshmen Biology participated. The design included an online activity on statistical sampling, and a domain model and Q-matrix for generating student models. Data collection included digital student work, a questionnaire and interviews with students. Analysis aimed at choices in generating overlays and describing the students' reactions to their student model.

### Design of an online activity on statistical sampling

**Gemiddelde en standaardafwijking van de steekproef**

Hiernaast zie je weer zes steekproeven uit de populatie van lentetemperaturen. Op deze pagina bekijk je of de gemiddeldes en standaardafwijkingen van die steekproeven goede schattingen geven voor de gemiddelde dagtemperatuur en de standaardafwijking van de populatie.

Vul de tabel met gemiddeldes en standaardafwijkingen verder in. Rond af op één decimaal.

steekproef	gemiddelde (°C)	standaardafwijking (°C)
1	8,7	4,4
2	10,1	4,3
3	...	...
4	10,0	...
5	...	4,2
6	9,1	5,3

Je hebt hiervoor gezien dat het populatiegemiddelde is  $\mu = 9,4$  °C en dat de standaardafwijking van de populatie is  $\sigma = 4,5$  °C. Bij welke steekproeven is het steekproefgemiddelde  $m$  groter dan het populatiegemiddelde  $\mu$ ? En bij welke is de steekproefstandaardafwijking  $s$  groter dan de populatiestandaardafwijking  $\sigma$ ?

**Figure 1: Example page of the DME-activity on statistical sampling**

The online activity on statistical sampling was designed in the frame of the Utrecht University project “Innovative remedial digital learning modules for statistics”, by an educational designer and the researcher (first author), in close collaboration with the teacher of the statistics course for biology students. For the design, the Freudenthal Institute’s Digital Mathematics Environment (DME, see Drijvers, Boon, Doorman, Bokhove, & Tacoma, 2013) was used. Aim of the designed activities was to deepen the students’ understanding of statistical sampling and sample variability. The activities contained theory, a simulation on sampling and questions about the students’ intuitions, the simulation, and the theory. The difficulties described in the theory section were addressed extensively. Students were able to enter answers to all

questions and receive immediate feedback on the correctness of their response. For many tasks, hints and feedback on incorrect responses were designed. For an example page of the activity, see Figure 1.

### **Development of a domain model and Q-matrix**

Through studying theory on statistical sampling<sup>1</sup>, a set of knowledge components (KC's) for the domain of sampling was identified by the researcher. As the intended use of the domain model was to present it to students, a rather coarse-grained approach was chosen and too detailed KC's were avoided. Moreover, for a clear presentation to students, complete descriptions of the KC's were formulated, as opposed to one or two words per KC. Four main KC's were identified: Taking samples (procedure), Estimations based on a sample, Distribution of the sample mean, and Standard error. For each main KC, four detailed KC's were identified.

After the domain model was designed, all tasks in the module were linked to the corresponding KC's by the researcher. This resulted in a Q-matrix, in which entry (i, j) is 1 if task j is related to KC i, and 0 otherwise. The module contained 45 (sub-)tasks in total. For twelve tasks, the researcher judged that no KC's were relevant. In Figure 1, for example, the students are asked to read off values from a table. This activity helps students understand the table-tool they will be working with in this module, but how well students read off the values does not involve their knowledge of any of the KC's. For four subtasks, more than one KC was judged to be relevant. All other subtasks were connected to one KC.

### **Data collection: Student work, questionnaire and interviews**

The participants in this study were 40 biology students, who participated in the first year introductory course Experiment & Statistics at Utrecht University. The students first attended a lecture on sampling and worked on the designed online module in the week following the lecture. Three sources of data were collected in this small-scale explorative study:

- Student work: the DME stores all student work, including all attempts that students do before reaching a final answer. Student work was collected for all 40 students;
- A questionnaire, in which the KC's from the domain model were presented to students. Students were asked to give their own estimation of their understanding of each KC. The questionnaire was completed by seven students.
- Interviews, in which students were questioned about the appropriateness of the domain model and generated overlay, and about differences between their estimated and generated overlay. Out of the seven students who completed the questionnaire, four were interviewed.

### **Data analysis**

In the analysis, the students' attempts were extracted from the DME, exported to Excel and prepared for generating overlays. For each student, an overlay was generated. Next, the generated overlays for the four students who would be interviewed were studied and remarkably high and low scores were recorded.

---

<sup>1</sup> Sources used are two text books on introductory statistics: Whitlock, M., & Schluter, D. (2009). *The analysis of biological data*. Greenwood Village, Colo: Roberts and Co. Publishers, and Field, A. P. (2009). *Discovering statistics using SPSS: (and sex and drugs and rock 'n' roll)*. Los Angeles [i.e. Thousand Oaks], Calif.: SAGE Publications.

Explanations were sought by studying tasks connected to the remarkable KC's and by analysing student explanations in the interviews.

The interviews were transcribed and the students' answers were aggregated by topic. Next, summaries for each topic were written to create a general image of the students' reactions to the overview, and to identify issues in the current calculation of the overlays.

## Results

In addition to the domain model and the Q-matrix, which are described in the Methods section, the results of this study include the generation of overlays, and the students' reactions to their student model.

### Generating overlays

To generate overlays, the students' interactions with the DME had to be translated into scores for each KC. Student interactions with the DME are stored as attempts. Three attempt types are possible: correct attempts, half-correct attempts (for example when a student still needs to round off an answer) and incorrect attempts. To generate an overlay, correct attempts were counted as 1, half correct attempts as 0.5 and incorrect attempts as 0. For each task, the mean attempt score was calculated by dividing the sum of the attempts by the number of attempts. For each KC, the overlay score was calculated as the mean attempt score of all tasks that were connected to this KC in the Q-matrix. See Figure 2 for an example.

KC	P1	P2	P3	P4	E1	E2	E3	E4	D1	D2	D3	D4	S1	S2	S3	S4
Generated overlay	1,00	1,00	0,88	—	0,89	0,50	0,61	0,75	0,83	0,67	0,75	0,67	0,80	0,50	0,57	0,83
Student's estimation	0,80	0,80	0,70	0,70	0,70	0,80	0,80	0,70	0,70	0,80	0,70	0,60	0,70	0,70	0,80	0,80

**Figure 2: One student's generated overlay and his own estimation**

The method used is not the only possible calculation method. Another option that was considered is taking only the student's first attempt for each task into account. The student's subsequent attempts are guided by the DME's immediate feedback and therefore do not directly reflect the student's knowledge, but rather a combination of this knowledge and the student's reaction to the immediate feedback. However, this method neglects the fact that students are likely to learn from the immediate feedback, and therefore this approach is left out of the analysis.

The generated overlays are different for different students, which confirms that they provide individual feedback indeed. Moreover, the scores for each individual student were more or less spread out, so students did score different for different KC's. This shows that our way of calculating discriminates between KC's, and hence can inform students on their understanding of the different KC's.

### Students' reactions to their student model

The domain model was first presented to students in the questionnaire, in which students were asked to estimate their own overlay. In the interviews, the domain model was presented again, this time with the generated overlay. All four students said that they understood the domain model well and thought it formed a useful summary of the domain of statistical sampling. One student explicitly mentioned that he would use the domain model in his exam preparation.

The comparison between the generated overlays and the students' own estimations resulted in fruitful exchanges. Most students seemed to adopt the generated overlay as a true representation of their knowledge. Three students seemed to adjust their own estimation to the generated overlay. For example,

when seeing the generated overview, one student concluded: “Apparently I can give myself higher grades than I did.” The fourth student, however, thought that the activities in the DME were easier than other activities in the course, and therefore thought her knowledge of the topic was not as good as her work on the DME-activity suggested.

When asked about differences between their generated and estimated overviews, students came up with some meaningful explanations:

- One student made some initial mistakes on a certain KC, because he did not understand it correctly yet. Therefore, his generated score was low. But with the help of the DME’s immediate feedback, he realized what he had understood wrongly, and therefore learned from these mistakes and the feedback. In his own overlay, he rated his knowledge in this KC as high.
- Some students were tempted to guess answers to see what immediate feedback the DME would provide. As in the previous explanation, such trial-and-error-behavior results in lower generated scores, but it is likely that students learn from the immediate feedback they obtain.
- Initial confusion about what students were required to do in the DME also resulted in low scores for some tasks. Here, a low score indicates difficulties with DME-interaction, rather than little knowledge or skills.

These explanations for difficulties show two things. First, these are exactly the difficulties that arise when learning material as opposed to assessment material is used for generating feedback. The tasks are above all designed to make students learn, and it is sometimes difficult to determine whether that learning has taken place before or after the student has answered a task. Second, the discussions with the students seemed to help them get a clearer picture of which KC’s they understood and which they did not. So using student work to generate an overlay, confronting that with the student’s own estimation and discussing differences seems to be a fruitful teaching strategy.

## Conclusion and discussion

In this explorative study, we have shown an example of the use of student models for providing individual feedback in a university statistics course. We developed an online activity on statistical sampling, a domain model for the domain of statistical sampling and a Q-matrix connecting the tasks from the online activity to the domain model. Next, we used the students’ work to generate overlays and presented the generated student models to the students, to give them more insight in their understanding of the different concepts involved in statistical sampling.

The generated student models were different for different students, which indicates that they indeed provided individual feedback. Students regarded the domain model as a useful summary of the domain of statistical sampling. As such, the domain model seems a useful instrument to confront students once again with difficult aspects of the domain of statistical sampling. Moreover, students regarded the generated overlay as a more or less true representation of their knowledge of the domain.

Asking students to compare their generated student model with their own estimations resulted in fruitful exchanges and therefore seemed a promising teaching strategy. Students tended to adjust their own estimation according to the generated model, but were also able to explain remarkable differences between their estimation and the generated model. These explanations often involved the immediate feedback provided by the DME, or, more general, the fact that the feedback is based on student interaction with an

activity that is designed to learn from. Calculation methods that account more for this fact are available (VanLehn, 2008) and can be taken into account in future experiments.

Another lesson we have learned is that some tasks are important for the learning activity, but are not useful for the generation of overlays. This concerns, for example, tasks that serve to explain a tool or simulation to be used. Therefore, careful considerations should be made whether or not to include specific tasks in the Q-matrix.

In this study, with its explorative nature, we have shown that it is possible to generate useful student models, based on student work in an online learning activity. A next step is to investigate how these models can best be embedded in education to help students monitor and plan their learning.

### Acknowledgments

We would like to thank Rutger Hermesen, teacher of the course, and Henk Hietbrink, co-designer of the course, for their engagement and all fruitful discussions on statistical sampling. We would also like to thank Johan Jeuring for his comments on previous versions of this paper.

# Undergraduate students' perceptions of learning introductory statistics through producing a statistical picture book

Natthapoj Vincent Trakulphadetkrai

University of Reading, Institute of Education, Reading, UK; [n.trakulphadetkrai@reading.ac.uk](mailto:n.trakulphadetkrai@reading.ac.uk)

*This qualitative exploratory study examined non-statistics specialist students' perceived benefits and limitations of learning statistical concepts through creative story writing. Stories can be a powerful tool as it provides an opportunity for statistics learners to refine their statistical understanding in different contexts – ones that are relevant to their personal experience and interest. The added benefit of learning through creating stories is how it can shift the focus from dealing with numerical data and formulae exclusively to the meaningful application of statistical concepts. Interview and observation data involving seven social sciences undergraduate students at an English university revealed a range of perceived cognitive and affective benefits as well as some limitations of this innovative statistics learning approach.*

*Keywords: Introductory statistics, statistical anxiety, creative story writing, picture book.*

## Introduction

A deficit in quantitative skills among UK university graduates has recently been highlighted as a major cause for concern. In its position statement titled *Society Counts*, the British Academy (2012) – the UK's national academy for the social sciences and the humanities – expresses its deep concern in the UK's weakness in the quantitative skills, particularly within the social sciences and humanities (SSH) disciplines, and highlights how such deficit can have serious implications not only for the future of the UK as a world leader in research and higher education, but also for its graduates' employability and its economy's competitiveness. While the focus of SSH disciplines is not mathematical per se, the recent drive for research-based teaching in higher education (e.g. Jenkins & Healey, 2005) implicitly requires SSH students to be confident in using their quantitative, particularly statistical, skills, to help critically interpret statistical data (as reported in some articles within their field of study) and, where applicable, to help them quantitatively analyse data for their own research-based dissertation project. However, statistics teaching is not often delivered to students in a relevant and exciting way (British Academy, 2012). It is hardly surprising then that statistical anxiety among university students, particularly those within the SSH disciplines, has been widely reported (Lalayants, 2012). The current study proposes an innovative statistics teaching whereby students produce a creative story where statistical knowledge and understanding are required to construct the storyline. More specifically, the study intends to examine the students' perceived benefits of the approach.

## Literature review

### Statistics education

The research field of statistics education is primarily concerned with studies that aim to explore different ways to make statistics learning and teaching more effective, and in some cases, even more enjoyable. In relation to the current study, two key strands of relevant studies include those that focus

on transferability, and those that focus on associating statistics learning with something lighthearted and enjoyable. Concerning the former strand, Groth and Bergner's (2005) study in the USA, for example, investigated the role of metaphors in providing insights into students' statistical thinking. Whilst the focus of Groth and Bergner's (2005) study is on using metaphors to reveal pre-service elementary school teachers' understanding of statistical sample (e.g. "a sample is one toy off a toy shelf" (p. 34)), it can be argued that the underlying principle of using metaphors is deep-rooted in the concept of transferability which can be applied to any group of students and any statistical topic. Concerning the second strand, Friedman, Friedman and Amoo (2002) argue for the use of humour in statistics teaching and learning. Specifically, they argue that humour can be used to build relationships and enhance communication between students and instructor, as well as can be used as a stress-reducing tool in statistics classes. In Neumann, Hood and Neumann's (2009) study, use of humour was evaluated. Through interviewing 38 students who were randomly selected from those enrolled on a first-year Psychology course in Australia, it was found that "humor aided teaching by providing amusement, breaking up content, bringing back attention, lightening the mood, increasing motivation, reducing monotony, and providing a mental break" (para. 1).

Whilst the aforementioned studies represent an attempt to make statistics learning more accessible and enjoyable, the current study would argue that the effectiveness of these attempts to improve statistics learning and teaching experience is limited due to their lack of emphasis on embedding statistics learning in a relevant and meaningful context. This study thus sets out to explore students' perceptions of using creative story writing whereby statistical knowledge is required to construct the story's narrative in order to help them develop their statistical understanding.

### **Creative stories as a learning tool**

Egan and Judson (2016, p. 4) argue that "the old distinction of arts dealing with imagination and academic subjects dealing with reason has led to a neglect of engaging students' imaginations in learning academic subjects". This, they argued, acts as a key barrier to effective teaching and learning. The use of creative stories (whether as consumer or producer) thus has a great potential to bridge this gap. The current study would argue that two key features underpin the creative story writing approach, namely 1) transferability and knowledge application in meaningful context, and 2) self-motivation through relevance of and emotional engagement in the story. As highlighted by Groth and Bergner (2005) with metaphor and Martin (2003) with analogy, transferability one's (statistical) knowledge and understanding from, for example, statistics textbooks (context-free) to their own story (context-rich) encourages them to first think carefully about what the concepts are, and then engage in higher order thinking by applying the concepts in a meaningful context. This process is crucial as Tannen (1999, as cited in Haven, 2007, p. 64) argues that "Story merges abstract information with common sensory details to create context and relevance for the abstract". Both context and relevance, as Haven (2007) argues "trigger the conscious mind to pay attention and to remember" (p. 64). Additionally, when learners get to think of a context or storyline for their own story, they are more likely to be engaged and self-motivated in their own learning process and become more emotionally invested not only in the story (Egan & Judson, 2016), but also in the ownership of their knowledge construction.

In terms of research, to the best of the author's knowledge, only one small empirical study has been conducted to explore the potential benefits of using creative stories in statistics learning. The study, by D'Andrea and Waters (2002), set out to examine how short stories can be used to reduce statistical

anxiety among her 17 graduate Education students enrolling on an introductory statistics course in the USA. Using the Statistical Anxiety Rating Scale (STARS), the survey results showed that the students' anxiety towards the statistics course steadily declined when their ratings before and after the course were compared. However, one key limitation of this study is how the short stories were written by the researchers (i.e. the course instructors) themselves, as opposed to providing an opportunity for the students to create their own stories – a shortfall that the current study aims to address.

### **Theoretical perspectives**

This study argues for a statistics teaching and learning strategy that is grounded in Papert's (1991) theory of constructionism. Unlike constructivism, constructionism places a great deal of emphasis not only on internalization, but also the process of externalization. More specifically, constructionists argue that construction of knowledge takes place both in the head (internalization) and supported by "construction of a more public sort 'in the world'" (externalization), whereby learners creating a public artefact of what they know that can be "shown, discussed, examined, probed, and admired" (Papert, 1991, p. 142). In turn, this process helps to shape and sharpen the knowledge (Ackermann, 2001). In the context of the current study, such public artefact is the story created by the learners where knowledge and understanding of the assigned statistical concept is first required before applying such knowledge and understanding to construct their storyline.

### **The current study**

The current study is exploratory in nature, and it sets out to investigate non-statistics-specialist undergraduate students' perceptions of using creative story writing to learn introductory statistics. More specifically, the key research question asks: *What are non-statistics-specialist undergraduate students' perceptions of key benefits of learning introductory statistics through creative story writing?*

## **Methodology**

### **Research design**

This study is predominantly qualitative, reflecting a recent call from the research field of statistics education and cognition to move beyond it being a purely quantitative field (Kalinowski, Lai, Fidler & Cumming, 2010). The data collection took place in May and June 2016, and it primarily involved semi-structured interviews with first-year undergraduate non-statistics-specialist students within the social sciences discipline. To allow the students to form well-developed perceptions of the approach, they were asked to attend a three-hour session where they mostly worked in pairs to independently research a given statistical concept for the first 30 minutes. This independent learning was supported by making a range of introductory statistics textbooks available to them during the session. They were also encouraged to watch tutorial videos available on Youtube on their electronic devices. For the remaining 2.5 hours, they were then asked to collaboratively produce a creative story to illustrate that concept. Before they started creating the story, the participants were asked to vote on the format of their story output, and everyone voted for the picture book format, over two other choices, namely the graphical novel and the story book formats.

Audio recordings were made of each team's discussion whilst they were working on separate tables. A week after the session, each team was interviewed separately and they were asked to reflect on their own experience of using creative story writing to learn introductory statistics at the interview. Together with the stories produced, these multiple sources of data were used as a form of triangulation to maximise the degree of reliability in the analysis.

Standard deviation, as a measure of variability, was chosen as an introductory statistical concept for the participants to base their story on, for its importance as a building block to more advanced statistical knowledge, such as sampling distributions, inference, and p-values (delMas & Liu, 2005).

It is beyond the scope of this paper to present in detail examples of the picture books created by the students in this study. Examples and brief discussions of these picture books were presented in the author's CERME10 presentation.

### **Sampling strategies and sample size**

The participants were seven undergraduate Education students, who nominated themselves to be part of the study after a recruitment call. The students are English native speaking students of Caucasian origin, aged ranging from 18 to 19 years old. Non-random purposive sampling was used to ensure that none of the participants had a Mathematics or Statistics post-16 academic qualification (commonly referred to as *A Level* in England).

The students were split into two pairs and one triad: Team 1 (all male students) with Jim and Dylan (pseudonym), Team 2 (all female students) with Maria and Sarah, and Team 3 (mixed) with Rosie, Ryan and the additional student - Olivia. The reason for including both single-sex pairs and a triad of male and female students in the study was to minimise any impact certain type of pairing could have on learning. (One of the male students, Ryan, did not confirm his participation by the agreed deadline, prompting the researcher to recruit an additional student, Olivia, as no other male students were available. Thus, a total of 7 students attending the session. Ryan also did not turn up for the scheduled interview, resulting in having interview data from only 6 students)

### **Data analysis**

Due to the study being exploratory in nature and not aiming to test any particular existing theory, an inductive thematically-coded approach to qualitative data analysis was adopted. Audio recording transcripts of both the group discussions during the session and of the interviews after the session were read and reread to identify emerging themes. The process was done manually without the use of any software. The researcher alone did the coding, and thus fully acknowledges the limitation this presents in terms of the reliability of the analysis.

### **Results and discussion**

As previously mentioned, this study sets out to explore non-statistics-specialist undergraduate students' perceptions of key benefits of learning and teaching introductory statistics through creative story writing. The findings are presented and discussed below.

## Perceived cognitive benefits

Four key cognitive skills were developed through the creative story writing approach, namely *understanding*, *application*, *visualization* and *communication*.

Concerning *understanding*, in order for the participants to come up with a storyline, they first had to understand what the given statistical concept (standard deviation) was. For example, Rosie explained that “The process helped me because I had to concretely understand what the statistical concept was and what misconceptions there may be before we started writing the book”. This resonates well with Dylan’s view as he stated that “I think it helps because you have to completely get every single step of it ... know how to do it ... you will have to go over it all before you were able to even start thinking about how could we use this in the task [story]”.

*Application* is another key cognitive skill put forward by the students. Using creative story writing to learn statistical concepts requires learners to think carefully of a meaningful and purposeful context in which the concepts can be applied. This encourages them to contextualise statistical concepts. Dylan, for example, explained that “figuring a story that would fit around it [...] makes you think about how could I use it in real life – where it would be applicable. I think [...] having to put it in the story helps you understand it quite a lot.” Such view is also echoed by Maria who stated that: “having to work out a context for the story where there would be a need to use standard deviation further helped. [...] If it doesn’t have a context, it doesn’t really make sense. It’s harder to understand it”. From the observation, students’ conceptual understanding of standard deviation was evidently developing through their discussion about the context for and application of the concept. This highlights the role of what Donaldson (1987) referred to as embedded thinking.

As previously mentioned, all participants voted to present their story in the picture book format. Whilst originally not central to the key research question, several participants cited the benefits of the format, particularly *visualization*, as contributing to the development of their understanding of standard deviation. More specifically, they highlighted how the format encourages them to think about how statistical concepts can also be represented visually through illustrations. Jim explained that “I think it gives you different ways to learn because you might be a visual learner. The pictures will help”, highlighting how producing creative story in the picture book format could cater for diverse learning styles.

Finally, *communication* – another key cognitive skill that came up several times in the interview with the students. This is primarily concerned with how the creative story writing approach explicitly requires authors to break down the concept and communicate it to their readers. Jim, for example, explained that “It’s also about breaking it down into a narrative that other people can understand because you write it for other people, so you have to ... not dumb it down ... but you would certainly break it down, and I think it helps you understand it that way”. For Maria, she linked this aspect of the approach to teaching: “You’re teaching it and you remember it better when you’re trying to teach something rather than when you’re just listening. We’re writing a story to teach other people what it was”. The participants who were not at all familiar of the concept prior to the session were later able to articulate that standard deviation measures the spread of the different data points in relation to their mean average. While the definitions offered by Sarah and Ryan did not make clear the relationship between the data points and their mean average, it can be argued that their understanding is still

emergent. Even for Maria and Rosie who already had some understanding of the concept prior to the session, the definition of the concept that they offered after the session was more detailed. In line with Haven (2007), this demonstrates that creative story writing can be a powerful learning strategy for a wide range of learners.

### **Perceived affective benefits**

Different aspects of the story writing approach were highlighted by the participants as helping to make statistics learning more engaging. Rosie, for example, pointed out that “Personally, maths has always been my nemesis, so for me [the story writing] puts maths and statistics in a lighter viewpoint rather than being factual and quite off putting”. Similarly, Olivia – echoing Egan and Judson’s (2016) – found herself fully engaged in the process as she explained that:

Before the session, the thought of statistics was fairly scary to me and seemed like something I would struggle to engage with. [...] But, as the story writing process began, I was able to view standard deviation from a less scary lens. Before I realised, I was fully engaged with the story writing activity, rather than focusing on how scary the topic was initially.

Through its hands-on approach, Sarah and Jim commented about how the story writing approach helped to make them more engaged in statistics learning than they would otherwise be in traditional lectures. Sarah, for example, highlighted that:

The activity was enjoyable and therefore more engaging than if I’d just read about standard deviation in a text book or been told about it in a lecture. Being able to have fun with it and produce something creative helped me to really get into it and actually want to pay attention to getting it right.

Jim also highlighted how learning statistics through story writing is more enjoyable and less scary when “you’ve got a picture involved for a start and you’re making a narrative”. This resonates well with Maria’s view. Not only did she attribute the positive statistics learning experience to the story writing, Maria also attributed it to the picture book format specifically, as she explained “Picture books are also associated with happiness and adventure and putting statistics into a picture book can make statistics seem more exciting”. Her view emphasises how the combination of story writing and the picture book format seems to compliment each other quite well.

The way these students described statistics and its learning in itself is revealing: ‘nemesis’, ‘scary’, ‘factual’, ‘struggle’, ‘complicating’, ‘mundane’ and ‘off putting’, highlighting how disengaged these students would have carried on feeling towards the subject had it not been because of the story writing approach to learning statistics. When examining how the same students described statistics and its learning using the story writing approach, the positive attitudes towards statistics learning became apparent: ‘fun’, ‘fully engaged’, ‘more exciting’, ‘creative’, ‘more engaging’, ‘more accessible’, ‘immersed’, ‘more switched on’, ‘lighter viewpoint’ and ‘your own knowledge’.

## **Conclusions**

### **Key findings and discussions**

Overall, the approach, according to the students, appears to make use of four key cognitive skills, namely *understanding*, *application*, *visualization* and *communication*, and these are labelled as

*perceived cognitive benefits*. Concerning **understanding**, in order for the participants to come up with a storyline, they first had to understand what the given statistical concept (standard deviation) was. **Application** is another cognitive skill that is put forward by the students. Using creative story writing to learn statistical concepts requires learners to think carefully of a meaningful and purposeful context in which the concepts can be applied. This encourages them to contextualise statistical concepts, and highlights the role of what Donaldson (1987) referred to as *embedded thinking*. The students themselves highlighted that the picturebook format encouraged them to think about how standard deviation could be represented visually through illustrations. This is particularly relevant when **visualization** is often seen to be a key mode of representation that can help learners develop their mathematical and statistical understanding (e.g. Bruner, 1966; Haylock, 1982; Haylock, 1984; Haylock & Cockburn 2013). Finally, **communication** is another key cognitive skill that came up several times in the interview with the students. This is primarily concerned with how the creative story writing approach explicitly requires authors to break down the concept and communicate it to their readers. Equally important, the students reported that the creative story writing approach motivated them to engage in learning introductory statistical concepts, as this is labelled as *perceived affective benefits*. The students particularly enjoyed incorporating humour in their storyline and page illustrations. The fact that laughter could be heard throughout what was essentially a statistics lesson was very encouraging as it demonstrates that it is entirely possible to have an enjoyable statistic teaching strategy that, according to the students, also helped them learn an introductory statistical concept. This is in line with the findings of Neumann et al.'s (2009) study that found students to be more motivated in their statistics learning process when they were able to include humour in their statistics learning.

### Implications

The study highlights the potential benefits of using creative story writing, particularly in the picture book format, as an effective introductory statistics learning tool for non-statistics-specialist students. Such benefits are both cognitive and affective in nature. Additionally, whilst the students in this study were undergraduate students, this study would argue that both high school and postgraduate students would too find the approach beneficial.

### Limitations of the study

The participants in the current study created their story in an arguably clinical setting, as opposed to their authentic learning experience. Additionally, it is important to remember that these participants volunteered to be part of the study. Taken together, it can be argued that the views and attitudes of this group of participants might be potentially different from those who are required to engage in creative writing as part of their course. Thus, any findings emerge from this study must be treated with caution, and this highlights the need for this study to be replicated in an authentic learning environment.

*Current secondary school statistics curricula focus on procedural knowledge and pay too little attention to statistical reasoning. As a result, students are not able to apply their knowledge to practice. In addition, education often targets the average student, which may lead to gifted students missing challenge. This study explored ways to enhance grade 8 (Pre-University level) students' statistical literacy through within-class differentiation. The developed course materials consisted of a differentiated module in the Digital Mathematics Environment (DME), combined with investigation activities during classroom sessions. The material focused on statistical reasoning using visual representations made with TinkerPlots. We concluded that this teaching arrangement indeed increased students' statistical literacy.*

### Introduction

Statistical literacy has become important for all of us, and statistics will only continue to become more critical in the future (Shaughnessy, 2010). Despite the global effort to innovate the ways in which statistics is acquired, current statistics education is still viewed as a field with a need for significant improvement (Garfield & Ben-Zvi, 2008). Strong educational foci on methodological skills, procedures and computations result in the limited ability to reason statistically and to apply statistics in practice (Allen et al., 2010; Gal, 2002).

The Netherlands are no exception to this. In grade 8 of the Dutch pre-university stream, for example, the statistics curriculum stresses the calculation of mean, modus and median. Statistical investigation and use of technology hardly occur in the current approach. The emphasis on calculating statistical measures contributes insufficiently to interpreting, critically evaluating and reasoning with data (Van Streun & Van der Giessen, 2007).

As a second concern, the current educational approach pays too little attention to gifted students. PISA research shows that the best quartile of Dutch students performs relatively poorly (Kordes, Bolsinova, Limpens & Stolwijk, 2013). It is plausible to assume that the education received is insufficient for these students. This is endorsed by the KNAW (2003), which calls for more differentiation between students and for offering enrichment material.

To address the abovementioned issues this study focuses on the following key question: Does a differentiated learning trajectory that focuses on statistical reasoning with visual representations increase students' statistical literacy in grade 8? The hypothesis is that an educational approach in which differentiated online tasks are combined with investigation activities in class will increase statistical literacy.

## Theoretical framework

The theoretical framework we used integrates notions of statistical literacy and level differentiation.

### Statistical literacy

Gal (2002) defines statistical literacy as interpreting, critically evaluating and reasoning with statistical information. This requires, in addition to procedural statistical skills, reasoning with and about data (Tolboom, 2012). Students should be taught the necessary skills to interpret and reason with statistical concepts. Research indicates that students in an early stage can reason meaningfully about distributions (Bakker & Gravemeijer, 2002). According to Piaget and Inhelder (1951), students have an intuitive sense of statistical reasoning. This intuitive concept can be used to develop statistical literacy. Moreover, research literature suggests that students become statistically literate by conducting their own research projects (Abel & Poling, 2015).

Web-based tools like TinkerPlots (Konold & Miller, 2011), which focus on the use of dynamic visualizations, may support statistical reasoning and literacy. The use of such software, in addition to manual data processing experiments, has the advantage that problems are taken care of, so there is more room for reasoning. There is evidence that the use of ICT in statistics can improve learning results (Morris, Joiner & Scanlon, 2002) and, especially if embedded in classroom discussions, can lead to increased statistical literacy (Bakker, 2004). Based on these findings, we focus in this study on literacy and reasoning using digital tools.

### Level differentiation

The Dutch education system<sup>1</sup> is based on homogeneous streaming. Nevertheless, within a class of a specific achievement level, major differences between students in intelligence and performance may exist. Students' learning progress may suffer from neglecting these differences. In differentiated teaching, teachers provide individual learning paths to students, adapted to their levels, to learn as much as possible (Tomlinson, 1999). That level differentiation leads to better academic performance in primary education (age 4-12) has been shown by several researchers (e.g., Vernooy, 2009). With respect to differentiation in secondary education (age 12-17), less is known, even if Terwel (1988) and Van Dijk (2014) suggest that differentiation within mathematics lessons may lead to improved performance.

Differentiation assumes the classification of students. The RTTI model (Drost & Verra, 2015) can be used to identify the cognitive level of a learner. Dutch secondary schools and textbook editors increasingly use this model. It is based on four learning levels: Reproduction (R), Training (T1), Transfer (T2), and Insight (I). Based on RTTI test scores, the students can be clustered into level groups (Berben & Teeseling, 2014). In terms of the RTTI model, statistical literacy relates to T2 and I levels. Based on the aforementioned findings, in this study we opted for a differentiated educational approach based on the RTTI learning levels.

## Methods

---

<sup>1</sup> For an overview of the Dutch educational system see <https://www.epnuffic.nl/en/study-and-work-in-holland/dutch-education-system>.

We successively describe the design, intervention, participants, data collection, and data analysis of the study.

## Design research

Since teaching materials that aim at increasing the statistical literacy by offering differentiated teaching arrangements and using digital tools for this group hardly existed, we used a design research method (Bakker & van Eerde, 2015; Plomp & Nieveen, 2013). Because the learning objectives differ from the current curriculum in grade 8, no control groups were used; we compared the students' learning gains during the intervention through pre- and post-tests. This research can be characterized as a "proof of concept" of an intervention that focuses on statistical literacy and reasoning through a technology-rich, differentiated approach based on RTTI.

## Intervention

The intervention consisted of statistics modules within the Freudenthal Institute's Digital Mathematics Environment (DME, see [www.dwo.nl/en](http://www.dwo.nl/en)), combined with investigation activities during the classroom sessions using Tinkerplots. The DME is a digital environment in which students work on mathematical activities. It includes opportunities for differentiated education by offering several learning routes. The work of students is saved in the DME and teachers can monitor the results (Bokhove & Drijvers, 2012). In this study the procedural skills, e.g., calculating central tendency and variation measures and values of various graphs including boxplots, were offered within the DME. The DME modules were individually run and consisted of two learning routes: the basic route and the plus route. The students were assigned to these conditions according to their RTTI achievements during the past schoolyear. Students with average score T2 and I less than 65% followed the basic route, and others the plus route. Within the designed DME modules, students could check their work and correct it when necessary. Adjacent to each classroom session, students worked at home on the DME module. The hypothesis was that the procedural skills of students will strengthen through the DME-modules, so that they can use them in reasoning with statistical information.

Statistical reasoning in the frame of investigation tasks was central to the eight 60-minute classroom sessions offered in parallel to the DME modules. During this classroom sessions students worked in homogeneous teams (clustered according to the RTTI learning levels). The investigation activities were based on the stages of the statistical investigation cycle (Franklin et al., 2005). The students analysed their data manually and by using the software TinkerPlots<sup>©</sup> (Konold & Miller, 2011). This software provides rich visualization opportunities, flexible and investigative functions, and is user-

friendly. Figure 1 shows some examples of the visual possibilities in TinkerPlots. The hypothesis was that clustering of students while working on investigation activities and using visual representations in TinkerPlots, sharpens and reinforces the

**Figure 1: Examples of visual representations in TinkerPlots<sup>©</sup>**

statistical literacy of students at the different levels.

## Participants

In the pilot the designed material was tested in a classroom at the school of the researcher, the Csg Prins Maurits in a rural area in the Netherlands. The pilot class consisted of 25 pre-university grade 8 students (14-15 year olds), with sixteen students turning out to be basic students and the other nine plus students. The students had no previous experience with statistic education.

## Data collection and data analysis

To verify whether the intervention improved statistical literacy, we examined students' DME progress, results on two statistical tests, logbook data from the teacher-researcher and students' final investigation task. The data of basic and plus students were analysed separately. To analyse the DME work we used data on score and time investment. Further to the DME modules two individual tests were taken. One of these tests was a RTTI standardized test conducted with 45% of questions at learning level R and T1 and 55% of questions at level T2 and I, the latter corresponding to statistical literacy. This ratio is in line with the standard approach in the research class, so the results can be compared with previous RTTI scores on math tests. The additional test consisted of questions at learning level T2 and I with a higher difficulty compared to the RTTI standardized test, so as to obtain additional information about the level attained.

The logbook of the teacher-researcher contained information about students' progress in interpreting, critically evaluating and reasoning with statistical information during the investigation activities in class. To find out whether the students in the end applied the statistical methods in practice, a final investigation task was administered in homogeneous level groups of 3-4 students. A rubric was developed for the analysis of this task to assess performance at learning level T2 and I.

	<b>DME data</b>	<b>RTTI test</b>	<b>Test at T2 and I</b>	<b>Log</b>	<b>Research task</b>
Statistical literacy in solving concrete problems	X	x	x	x	x
Statistical literacy in investigation activities	x	x	x	X	X

**Table 1: Table of triangulation of research instruments**

To ensure the quality of the research data triangulation is used. Table 1 shows how the statistical literacy has been measured with multiple instruments. The font sizes for x indicate the degree to which each instrument measures statistical literacy.

## Results

We now present the results of the learning process using the DME, the test results and the development during the investigation tasks.

### Learning process using the DME

<b>Average time investment per DME module in minutes (sd)</b>							
	<b>Mod. 1</b>	<b>Mod. 2</b>	<b>Mod. 3</b>	<b>Mod. 4</b>	<b>Mod. 5</b>	<b>Mod. 6</b>	<b>Total</b>
Basic students (n = 16)	36(21)	30(13)	36(19)	39(21)	27(14)	33(29)	34(20)

Plus students (n = 9)	42(28)	25(16)	30(27)	37(23)	19(16)	21(22)	28(22)
<b>Average score per DME module in percent (sd)</b>							
Basic students (n = 16)	87(9)	81(23)	80(13)	79(16)	70(30)	53(31)	75(24)
Plus students (n = 9)	79(24)	91(8)	72(27)	61(33)	65(37)	43(35)	67(32)

**Table 2: Time investment and score using the DME**

The investment of time and scores of the DME work for each level group and per module are summarized in Table 2. The students used the DME with an average time investment of more than half an hour per session. During the learning trajectory the time investment, in particular for the plus students decreased. Initially, the students needed extra time for getting acquainted with the material. Moreover, the students indicated that over time they thoughtfully chose their way through the module by skipping known problems.

The students' scores on the DME show an average of about 70%. The basic and plus students respectively achieved an average score of 75%(24) and 67%(32) per module. The exercises in the plus route were more difficult. The scores decreased during the learning curve when difficulty increased. In the last module there is a substantial decline. This module contains no new material, but includes joint exercises from the completed chapters. The plus students show more variability in score. The considered choices in learning exercises by these students might have strengthened this trend.

### Test results

Table 3 provides an overview of the pre-test score (RTTI average score on nine math tests over the past schoolyear) and post-test score (RTTI score on the final statistics test). The RTTI pre-test scores indicate the achieved learning level of the students at the end of each chapter. This means that based on the presented pre-test scores the expected RTTI post-test scores should be on average 55% at the

	Whole class (n=25)		Basic students (n=16)		Plus students (n=9)	
	Pre av.	Post	Pre av.	Post	Pre av.	Post
Score on R and T1 in percent (sd)	79 (16)	85 (10)	79 (13)	85 (10)	80 (20)	86 (10)
Score on T2 and I in percent (sd)	55 (18)	64 (21)	47 (16)	59 (24)	69 (10)	73 (12)

**Table 3: RTTI scores before and after the intervention**

levels T2 and I. However, the RTTI post-test scores reached on T2 and I, the parts that measure statistical literacy, show a 9% higher score of 64%. The dissimilarity in progress between the basic students (12%) and plus students (4%) at the levels T2 and I may be caused by a ceiling effect or maybe the exercises in the RTTI standardized test gave too little space to plus students to exhibit their knowledge.

On the additional test both level groups exhibit a high score on T2 level, in spite of the increased difficulty. A smaller increase appears on learning level I. The results cannot be compared with previous tests because the difficulty of the conducted questions was considerably higher.

### Learning process during investigation activities

The usual statements of students' written work at the start of this intervention can be characterized as short answers with a calculation of the mean. The used visual representations were limited to bar and

**Figure 2: Students' work on the first investigation task**

**Figure 3: Students' work on the first investigation task**

pie charts. Figure 2 shows students' work on the first investigation task: Investigate the colour composition of a bag of M & M's. In the final investigation task the students' work contained detailed descriptions and rich visualizations with a wide diversity of graphs. Attention was paid to the interpretation of the data. Learning progress was visible in terms of interpreting, critically evaluating and reasoning with statistical

information. Figure 3 shows a small part of students' work on the final investigation task in which they formulated and investigated their own research questions using datasets within TinkerPlots. The results on the final investigation task with respect to learning level T2 (65% of the total score) and I (35% of the score) are shown in Table 4.

	Whole class (n=8)	Basic groups (n=5)	Plus groups (n=3)
Score on T2 in percent	89 (7)	85 (6)	95 (4)
Score on I in percent	51 (24)	35 (6)	79 (10)
Total score in percent	70 (26)	60 (27)	87 (11)

**Table 4: Scores on T2 and I at the final investigation task**

On level T2, for example, we evaluated in the assessment-rubric correctly representing and summarizing the data and on level I we examined the choice of an appropriate visual representation and the critical interpretation of the results. In comparison to the basic groups, the plus groups show a higher score on learning level I. This investigation task probably provided more room to gifted students to exhibit their statistical reasoning.

## Conclusion and discussion

The main question in this research was: Does a differentiated learning trajectory that focuses on statistical reasoning with visual representations increase students' statistical literacy in grade 8? The results suggest it does. The RTTI scores reached on T2 and I, the parts that relate to statistical literacy, were much higher than would be expected according to the pre-test scores. Moreover, the final investigation task showed strong progress on interpreting, critically evaluating and reasoning with statistical information according to the start of this trajectory. This is consistent with the theories by Bakker & Gravenmeijer (2002) and Abel & Poling (2015) on developing statistical literacy. Both basic and plus students showed considerable improvement during the learning trajectory which suggests that both groups were challenged in this differentiated approach as suggested by Terwel (1988) and Van Dijk (2014). The use of all kinds of visual representations within TinkerPlots helped the students to explore their data. In summary, the results suggest that the designed educational intervention, which consisted of differentiated online modules within the DME combined with investigation activities using TinkerPlots during classroom sessions, led to increased statistical literacy. However, this study has its limitations: no control with other groups was possible; we cannot indicate whether the differentiated approach or the focus on statistical literacy and reasoning caused the increased level; the pilot took place in just one class, taught by the researcher. Therefore, the results cannot be generalized and further research is needed.

# Implementing the statistical investigative process with real data: Effects on education in secondary schools

Martin Andre

Pädagogische Hochschule Tirol, Innsbruck, Austria; [martin.andre@ph-tirol.ac.at](mailto:martin.andre@ph-tirol.ac.at)

*Keywords: Statistics teaching, learner engagement, technology integration, problem-based learning*

## Theoretical background

In the Guidelines for Assessment and Instruction in Statistics Education (GAISE) College Report (2016) endorsed by the American Statistical Association following the GAISE College Report of 2005, the ASA revision committee recommends in addition to the teaching of statistical thinking and focusing on conceptual understanding, to use software combined with real data and to foster active learning. The main goal of the given recommendations for students is to develop statistical literacy and achieve the ability of thinking statistically. Therefore, students should understand the nature of data and all parts of the statistical process from obtaining and generating data to the communication and interpretation of the results after the analysis. In an international meta-analysis of 70 studies from the past 40 years Larwin & Larwin (2011) show that students in postsecondary statistics education strongly benefit from computer-assisted instruction (CAI) under certain circumstances, for example, when CAI is continuously and supplementary applied in lessons and homework. They also warn, however, of an overestimation of CAI. Several studies show the advantage of student-centered (e.g., Kuiper, Carver, Posner & Everson, 2015) and problem-based learning (e.g., Cantürk-Günhan, Bukrova-Güzel & Özgür, 2011) supported by technology (e.g., Koparan, 2015). Neumann, Hood and Neumann (2013) explored the benefits of using real data in statistical education. Gil & Ben-Zvi (2011) underline the importance of context in the emergence of younger students' informal inferential reasoning in an inquiry-based, technology-rich learning environment.

## Research questions

The focus of the presented research lies on the beneficial implementation of statistics software in classes, considering, for example, the characteristics of various software programs. Another field of this research is how the use of statistical software in an inquiry-based learning environment leads to the development of conceptual understanding and not to dependence on the software and the learning of tools and procedures. This leads to the following research questions. First: How is the situation about the context- and inquiry-based learning of statistics supported by technology in Austrian secondary schools? Second: Is there an evident connection between context and using real data on the one hand and CAI on the other hand to provide a meaningful learning of the overall statistical process. Third: How should software under a given context in classes of higher secondary schools be installed to support conceptual understanding of the statistical investigative process and which characteristics of statistical software are especially beneficial to this purpose?

## Research design

Various learning sequences for the 10<sup>th</sup> grade of Austrian higher secondary school are being created and will be inserted in different Austrian secondary schools. According to Strauss and Corbin's approach of Grounded Theory, diagnostic interviews will be carried out before and after the implementation of the

learning sequences. Some students' work on the sequences will be filmed and worksheets will be analyzed. The goal is, to develop provable hypotheses relating to the research questions.

The poster gives an overview of the theoretical framework, the research questions and design and focuses on a created worksheet that will be applied for this research. First results show that software in Austrian schools is commonly used in other mathematical fields, e.g. for plotting graphs, but not even in 30% of the cases for calculating statistical key figures.

# **Metaphorical representations of multifaced statistical concepts: An access to implicit dominant interpretation by teachers?**

Corinne Hahn

ESCP Europe and LDAR Université Paris Diderot, France, [hahn@escpeurope.eu](mailto:hahn@escpeurope.eu)

*Keywords: Metaphors, image, concepts.*

Statistical concepts often have multiple faces and deep understanding of these concepts requires combining these different perspectives. For example, mean is a complex concept (Mokros & Russel, 1995) that can be thought as a typical value, fair trade or center of gravity (Gattuso, 1994). The teachers who teach statistics in social sciences curricula have very different backgrounds (Hahn, 2015). The question is whether this variety of backgrounds leads them to implicitly favor one of the dimensions of the concepts when they teach.

To answer this question, I chose to use metaphoric representations. Lakoff and Johnson (1980) have shown the central role of metaphors in the process of construction of scientific concepts. This question has been widely explored in mathematics education, a working group was specifically devoted to this topic at Cerme 2 to 5 (Parzysz, 2015). Soto-Andrade (2006) explains that a metaphor connects a concept already built in a familiar area with a concept to build in an area that is not familiar. These representations are usually “image like” (Sfard, 1994). That is why I chose to use depictive representations of these metaphors. In this research, these representations are external to the subject as they were not drawn by them.

The protocol for this research involves six steps:

1. Choice of statistical concepts
2. Didactic analysis of these concepts and identification of the different perspectives from the literature
3. Identification of metaphors who are used to teach these concepts and selection of the metaphors that can be associated with the different faces of each concept
4. Drawing of representations of these metaphors
5. Pretest with teachers from different backgrounds
6. Semi-structured interviews of professors who teach statistics in a business school.

The poster presents step 1 to 5 of this research. I chose the concepts of mean, sample and confidence interval. Following the review of the literature, different perspectives were identified and assumptions were made about the perspectives that should be preferred by teachers considering their background. From informal discussions with professors and the study of textbooks, I identified a few metaphors and selected those that seemed directly linked to the different faces of the selected concepts. I then draw for each concept, three pictorial representations of these metaphors. Through the pre-test, it seems that teachers do not at first always identify the concept behind the drawings. They associate the pictorial representations with concepts directly related to the target concept and linked to the perspective chosen. For example, regarding the mean, interviewed teachers “saw” the concept of distribution when they were shown the image referring to the “fair share” and the variance in the image referring to the “balance point”.

# Non-mathematics majors doing statistics: Factors behind performance

Theognosia Michailidou

University of Leeds, UK; [edtgm@leeds.ac.uk](mailto:edtgm@leeds.ac.uk)

*Keywords: Statistics education, cognitive and non-cognitive factors, achievement.*

## Main objectives and theoretical foundation of the research study

Nowadays, a large proportion of undergraduate university students are required to undertake at least one statistics or statistics-related course. The main consideration guiding my research study is the exploration of several cognitive and non-cognitive factors, the “other” outcomes of statistics education (Schau, 2003), and their relationship with the students’ academic performance in introductory statistics courses offered at tertiary institutions. Cognitive, affective and motivational factors under investigation include: students’ feelings, attitudes and beliefs about statistics; students’ anxiety feelings and perceived self-efficacy regarding statistics; motivational orientations, achievement goals, students’ interest in and engagement with statistics (such as effort, persistence, learning strategies); resilient behaviour characteristics when learning and studying statistics; and prior mathematics or/and statistics background and performance. A proposed theoretical causal model, including direct and indirect effect of these variables on achievement in statistics, will be tested. Moreover, the study focuses on exploring and documenting non-mathematicians’ perceptions, behaviors, challenges and experiences when completing a statistics course.

My theoretical foundation is supported by some key theories: Social-cognitive learning theory (Bandura, 1997) and Self-efficacy theory (Bandura, 1977), Expectancy-Value theory (Wigfield and Eccles, 2000) and Achievement Goal theory (Dweck, 1986). Some ideas behind these theories have been adapted to statistics learning experiences and they have been used as a guide for both the quantitative and qualitative strands of my research work.

## Research design and methodology, and data collection and analysis procedures

In order to accomplish the research aims and goals, a mixed-methods research design (that is a combination of quantitative and qualitative data collection methods) has been employed. A self-reported questionnaire, which was designed and developed specifically for the purposes of the doctoral study, has been administered to a larger sample of students in university classroom settings. It comprised of open- and closed- ended questions, and Likert-type questions on a 5-point scale.

Individual (and pair) face-to-face semi-structured interviews were conducted with a sample of participants who had completed the questionnaire and consented to be interviewed.

The data collection procedure can be summarized in three many stages (not in chronological order): quantitative data-gathering (executed in two phases - at the beginning and at the end of the period of instruction of various statistics courses); qualitative data-gathering; and participants’ final grades obtained at the end of a statistics course from each of the instructors. The data collection was carried out over a period spanning two academic semesters, the fall semester 2015 and the spring semester

2016. I collected data from six universities – all the recognized universities (both public and private) operate in Cyprus. I observed and gathered data from 35 statistics classes (23 courses) taught by 15 different instructors. I collected over 1000 questionnaires and I executed 60 face-to-face interviews. The participants, with a variety of mathematics background and experience, came from diverse academic departments and degree programmes.

The quantitative data will be analysed using a variety of methods: basic statistical techniques (descriptive statistics, reliability estimates, correlation coefficients,  $\chi^2$  tests, t-tests, analysis of variance and regression analysis); advanced statistical methods (multilevel analysis, factor analysis and structural equation modelling techniques). The qualitative data will be coded using thematic analysis approach.

### **Potential significance and contribution**

This study may act as a springboard for further research in Cyprus and cross-cultural comparisons between Cyprus and other countries. The major findings and recommendations of the research work may constitute a helpful tool for the statistics instructors and stakeholders of statistics education in implementing interventions, innovations and instructional strategies/ practices to develop and improve the quality, the efficacy and the relevance of statistics courses that provided for non-mathematics majors.

The poster for the CERME-10 conference includes a brief introductory statement of the background, context and objectives of this doctoral study as well as information about the research design and methodology and data collection and analysis processes. Also, some preliminary findings (along with visual and graphical representations) are presented.

# Relating theoretical and empirical probability - Developing students' conceptions of probability and chance in primary school

Kristina Penava

TU Dortmund University, Germany; [kpenava@math.tu-dortmund.de](mailto:kpenava@math.tu-dortmund.de)

*Keywords: Student conceptions, probability, chance.*

## Theoretical framework and research questions

Most of the recent studies emphasise the challenges when dealing with probability problems. As Horvath & Lehrer (1998) show, young children are able to see a relationship between theoretical probability and empirical outcomes, but „[t]he children never understood the role of the sample space without significant support and, hence, never completely understood the reasons why patterns were more predictable than simple outcomes“ (Horvath & Lehrer, 1998, p. 132).

The largest challenge for the development of conceptions of probability and chance seems to be coordinating empirical and theoretical perspectives on probability. This means to relate the (relative) frequency of outcomes (empirical law of large numbers) and theoretical assumptions considering the distinction between long-term and short-term on random processes (Schnell, 2014; Horvath & Lehrer, 1998). A core condition for emerging conceptions of probability seems to be the change of perspective from focussing on single outcomes to the long-term results (Prediger, 2005, p. 40) and changing from long-term to short-term perspective (Johnston-Wilder & Pratt, 2007).

This project aims at providing insights into the development of students' conceptions of probability and chance during a board game. Towards this end, this study pursues the following research questions: Which elements of a teaching-learning arrangement can support the distinction between long-term and short-term? (RQ1) Which elements of a teaching-learning arrangement can support students in relating empirical and theoretical probability? (RQ2)

## Method

In this project, students' conceptions of probability and chance are identified within game interviews based on the board game „Who wins?“ (see Figure 1). Players take turns in throwing dice with asymmetrical colour distribution (green: 3 sides; red, blue and yellow: 1 side) and taking one step with the token of the matching colour. The goal of the game is to predict the winning token. During the interview the game is played several times, so that the learning environment provides stochastic experiences in a short-term context.

**Figure 1: Who wins?**

**Figure 2: single game list and many games list**

The students are asked to systematise the results with the help of different record types: a *winning list*

recording the winner of each game, a *result list* recording each individual thrown dice, a *single game list* providing histograms of colours thrown for individual games, and a *many games list* providing a histogram of the aggregated colours thrown over all games (see Figure 2). Simulated long-term documents provides opportunities to relate short-term to long-term results.

In total, 27 students were interviewed in groups of three. Each group met for three interview sessions. The 27 sessions were videotaped and fully transcribed (including oral statements, actions, and results of games and throws of dice). The students' conceptions on probability were identified in a qualitative interpretative analysis.

## First conclusions

A first analysis of the empirical data shows that the learning environment can initiate a change of perspective from short-term to long-term. In particular, comparing long-term results with short term AND with other long term results revealed the difference between the contexts. Experiencing variability in a short-term context may support changing perspective from long-term to short-term. Different record types (e.g. single outcomes, cumulated outcomes) seem to support "seeing" the distinction between long-term and short-term on random processes.

Relating the outcomes and the colour distribution of the dice support the understanding of the relationship between empirical and theoretical probability. Reflection on mathematically unexpected outcomes may initiate explanations of the relationship in a more detailed way.

### Introduction

Mathematical modelling and its teaching at various educational levels are widely accepted all over the world. There is consensus of the need to integrate mathematical modelling and applications in curricula and this has already taken place in many European countries. However, there is no unanimity on how to integrate mathematical modelling and applications into the processes of teaching-and-learning mathematics. In addition, there is little secure empirical knowledge available on how to implement efficiently the necessary new learning environments. In its discussions at CERME 10, the thematic working group TWG 6 on modelling and applications aimed to contribute answers to these open questions and hence further develop the work from previous ERME conferences. The contributions discussed at the congress are characterized by a strong and fruitful diversity in the research questions considered, the school levels addressed and the theoretical approaches taken. On the whole, the papers address theoretical, methodological, empirical or developmental research on the teaching and learning of applications and modelling. The group involved 35 participants from 16 countries – participants were from Europe, and also from South and Central America. A total of 20 papers and four posters were presented and discussed during the working group sessions.

In the following, we describe all presented papers, although not all have been submitted for the proceedings, grouped around eight comprehensive themes, which refer to current issues within the teaching and learning of mathematical modelling.

As a first important theme, we identify the *interplay between disciplines into modelling activities* referring to the specificities of interdisciplinary modelling activities, especially in engineering teaching. The second theme relates to the *connection of the problem solving perspective and mathematical modelling* and to the development of problem solving strategies and competences, when students work in groups and develop individual competences. The third theme covers *developing modelling strategies and competences*, for example theoretical and empirical work focused on the analysis and use of heuristic strategies adopted by teachers and/or students which illuminates strategies used to foster students' performance when solving modelling problems. The fourth theme refers to the *tools and methodologies used to analyse modelling processes*, namely

studies focusing on elaborating specific methodologies for analysing and evaluating modelling practices. The fifth theme focuses on *teachers' beliefs in relation to the teaching of mathematical modelling*, including, for example, research on the role of teachers to foster modelling practices. The sixth theme covers *teachers' interventions in mathematical modelling*. The seventh theme refers to *experimental materials and technology in modelling*, which covers two topics, a first primarily focused on the role of the auxiliary material and its impact on modelling and a second concerned with how to combine different resources with technology in concept development by means of real word contexts. The eighth theme refers to the *assessment of modelling practices*.

## Overarching themes

### Modelling and interdisciplinary teaching

This theme focuses on the interplay between disciplines in modelling activities. The first study by *Borromeo* and *Mousoulides* describes theoretical reflections about the differences and similarities between mathematical modelling and interdisciplinary mathematics education. Besides its focus on underlying similarities and differences, this paper provides some examples of projects that make connections explicit and how these may be useful for teachers while discussing modelling as a means for solving interdisciplinary problems. Within this thematic strand, other empirical works were presented based on particular case studies involving interdisciplinary projects with mathematical modelling as a central issue. In particular, *Brake* and *Lantau* described a pilot study of an interdisciplinary project used with experienced students of grade 12 based on modelling segways which supported them to build models based on linear systems of differential equations. Furthermore, *Sala*, *Font*, *Barquero* and *Giménez* reported on the design and analysis of an implemented interdisciplinary project, where mathematical modelling was embedded into an archaeological context. The study showed how the complementarity between two subjects (history and mathematics) can be an important tool in supporting modelling and inquiry. Besides the potential of designing interdisciplinary modelling situations, such as those presented in these papers, a couple of important question remain unresolved:

- What are the specificities of interdisciplinary mathematical modelling in relation to mathematical modelling more generally?
- How is it possible to manage the interplay between mathematics, mathematical modelling and non-mathematical knowledge to enrich teaching practices in the learning of mathematics?
- Can some analytical tools widespread in the research frame of modelling, such as the modelling cycle, be adapted to analyse mathematical modelling in interdisciplinary contexts? And, if yes, how?
- What relationships exist between the mathematical modelling cycle and the inquiry process?
- How do we best integrate different disciplines in developing modelling tasks?

Another important topic referred to modelling in the particular case of teaching of engineering. The papers from *Romo*, *Tolentino* and *Romo-Vázquez*, and *Siero*, *Romo* and *Abundez* reported intentions to design and analyse modelling activities for the mathematical education of teachers. Both studies were based on the Anthropological Theory of Didactics. They focused on analysing the roles and interplay of institutions in the educational programmes of engineers and on the institutional

conditions that the design of the study and the research activities expose in the teaching of modelling in such contexts. Some of the questions discussed were:

- How can different institutions become involved in mathematical modelling in engineering education?
- How can practical knowledge be grounded on mathematical knowledge?
- How can the steps of an engineering project (design, mathematical model, prototype) be described? How are these steps interrelated? How are they connected to the modelling cycle?

### **Connection of the problem-solving perspective and mathematical modelling**

The second theme refers to the connection between problem-solving activities and mathematical modelling. First, *Clohessy* and *Johnson* examined the relationships between the problem-solving performance of small groups with that of individual students in order to identify the influence of group work as an effective instructional strategy when teaching problem solving. Second, *Karatas*, *Soyak* and *Alp* presented an investigation about mathematical non-routine problem solving processes of fifth grade students in small groups. Their study aimed to determine problem solving behaviours within different episodes of problem solving. As both papers focused on the description and measurement of problem solving competences in small groups and individually, some common questions appeared:

- How might individual competences improve when students are participating in a group?
- What instruments can we use to measure the improvement of individual competences before, during and after mathematical modelling processes? Which are the most valuable indicators we might use to measure these changes?
- What are the cultural aspects that have most impact on planning the implementation of problem-solving activities?

### **Developing modelling strategies and competences**

This third theme concerns the use of heuristic strategies to support modelling practices. The paper from *Stender* and *Kaiser* presented a study on the usage of heuristic strategies by students in school within modelling activities and the promotion of strategic help provided by academic tutors, who guide the modelling activity of the school students. The paper of *Schmelzer* and *Schukajlow* focused on the relationship between reading comprehension and mathematical modelling. The study identified strategies to help learners comprehend a modelling problem and described ways these strategies might be implemented in the classroom. The following important questions emerged from discussions of the working group:

- How far can heuristic strategies developed in the frame of problem solving be transferred to mathematical modelling?
- Can their identification and characterisation be helpful in supporting teachers' strategic interventions?
- How, in different teacher education programmes, may these heuristics be made explicit? If we make them explicit, do we risk narrowing the radius of action of teachers when guiding modelling activities?

- What are the effects of text length and superfluous elements on reading comprehension in modelling problems?
- How can we prepare teachers to foster students' reading comprehension in modelling?

A closely related topic was that focused on the metacognition of modelling competencies as an essential part of developing competence in modelling. *Vorhölter, Krüger* and *Wendt* presented their results from a pilot study about the identification and measurement of metacognitive modelling competencies in small groups when working on modelling activities. The following relevant questions were discussed:

- How might we best define metacognitive competencies? How can their characterisation be used to evaluate students' development of competencies?
- How is it possible to separate the individual progress of metacognitive competences from that of the collective group?
- How might a detailed evaluation of students' teamwork enrich the understanding of metacognitive competences?

### **Analysis of modelling processes**

This fourth theme addressed tools and methodologies used to analyse modelling processes. On the one hand, *Barquero, Monreal* and *Ruíz-Munzón* presented a study, proposed within the frame of the Anthropological Theory of Didactic, about how to forecast the increasing number of Facebook users. The analysis of the implemented research path was based on three dialectics essential for mathematical modelling: the questions-answers dialectic, that of the media-milieu and that of individual-collective dynamics. On the other hand, the paper from *Delgadillo, Viola* and *Vivier* presented an analysis of a modelling task in the context of pre-service teacher education based on the theory of the Mathematical Working Space. In this latter study, the modelling cycle was used as an essential tool to analyse the personal Mathematical Working Space of students solving a modelling task. Some questions appeared in the discussion of both papers:

- Which different dimensions, or levels, of analysis may be taken into account when analysing mathematical modelling practices?
- Which are the most valuable observables (depending on the focus of study)?
- Up to what point can tools for analysis be used as tools to help with designing mathematical activities? In which more general approaches to task-design do they appear?
- How do we carry out analysis that takes into account both individual activity and collective interactions in modelling processes?

### **Teachers' beliefs on teaching modelling**

This theme refers to a study on teachers' beliefs on modelling tasks. The paper from *Ramirez* explored mathematics teachers' beliefs about teaching and learning mathematical modelling and about modelling itself. It presented an exploratory study of responses from teachers collected in an online questionnaire related to the characteristics of modelling practices. Several questions came up about the relation of teachers' beliefs with their experience and knowledge about modelling:

- While analysing beliefs many aspects have to be taken into account, which are difficult to separate. Thus, what is the relation between ideas, beliefs, previous experiences, and modelling competences?
- The role of teachers' beliefs in connection with teachers' knowledge is examined. Therefore, the question arises: How do we take into account teachers' knowledge about modelling?
- The role of teachers as individuals within institutions is studied. Thus, which cultural and school conditions influence their opinions?

### **Teachers' interventions in teaching modelling**

This section refers to teachers' interventions in teaching mathematical modelling. *Ferrando, Donat, Diago* and *Puig* presented an analysis of the different kinds of interventions teachers made during a project in which students worked on a modelling task about the intensity of sound distribution throughout a classroom. The study aimed to identify the influence of such interventions on students' learning opportunities. The following questions arose:

- How do available resources and means influence the openness of the task and students' possible responses?
- Who validates the final answer in a project?

### **Experimental materials and technology in modelling**

This theme focused on the role and use of experimental materials and of technology. Two topics were dealt with. The first focused on the role of auxiliary material and its impact on modelling and, the second concerned the combination of different resources with technology to assist concept development by means of real-world contexts. *Guerrero-Ortiz, Mena* and *Morales* discussed how the handling of auxiliary material can favour knowledge transfer between real world situations and mathematical models. The research, which was conducted within pre-service teacher education in Chile, presented insights into the design of modelling tasks and the affordances of auxiliary materials in supporting modelling. *Carreira* and *Baioa* base their research on an episode of a modelling activity with grade 9 students which aimed to reflect on the authenticity of the modelling task and to examine how students used experimental work to help them succeed in modelling activities. Some of the matters discussed were:

- How can auxiliary material support the learning process? Is it necessary to support students in its use or is it self-explanatory?
- Does the auxiliary material simulate the real processes taking place in the real setting?
- How far are problems authentic or meaningful to students?
- To what extent can we include the way things are really done in the real world in modelling tasks for students?

Regarding the second topic, *Karimianzade* and *Rafiepour* presented a study about the introduction of decimal numbers. The study showed how different resources were introduced and how experimental work helped fifth grade students to develop their knowledge and understanding of decimal numbers in the context of measurement. *Lieban* and *Lavicza* reported about students' work in using dynamic geometry systems in a geometric modelling situation. They suggested the use of some new manipulative resources together with digital applets that progressively enrich the development of the modelling process by students. Several ideas were debated around the questions:

- Which alternative ways exist to introduce decimal or rational numbers taking into account the introduction of standard units?
- How can we produce computer simulations of physical models?
- What are the goals for the different people (students, teachers and researchers) involved in creating GeoGebra models?

### **Assessment of mathematical modelling**

This last theme refers to the assessment of mathematical modelling. The paper of *Greefrath, Siller* and *Ludwig* analysed the official school leaving examination in Germany allowing university entrance, the so-called Abitur examination, which is supposed to contain elements that examine mathematical modelling. For this purpose, they based their analysis on certain criteria: reference to reality, relevance, authenticity, openness and partial competence of modelling, to analyse the potential of problems included in the official examination. In addition to the difficulties of deciding how to evaluate modelling practices in these kinds of official examinations, several questions were discussed:

- Which criteria can be used to describe good examination questions for modelling?
- Can all the sub-competences of modelling be assessed within examination tasks?
- How can we design school examination tasks that cover various aspects and goals that include mathematical modelling?

Within this strand, *Ärlebäck* and *Albarracín* proposed an analysis of various definitions of Fermi problems from a modelling perspective. They focused on analysing how the definition and descriptions of Fermi problems in the literature align with different perspectives on modelling. They also discussed how far Fermi problems and modelling are connected and how strongly that connection is influenced by the definition of Fermi problems.

### **Concluding remarks and perspectives**

The overarching themes tackled in TWG 6 show the variety of research questions the papers dealt with, for example concerning the theoretical frameworks used or the underlying perspectives on the teaching and learning of mathematical modelling (Kaiser & Sriraman, 2006, Kaiser et al., 2007). Furthermore, the educational levels involved span from primary to tertiary education.

In their analysis of the development of the teaching and learning of mathematical modelling over the last decades, Cai and colleagues (2014) introduce five perspectives, which can be helpful in order to identify the progress made during ERME conferences and potential future development.

The first perspective, the mathematical perspective, describes the differences between modelling at practitioner level and at school level. However, industrial examples can play a powerful role in education, because they are authentic and of varying complexity. There is a long tradition of discussing examples from engineering education in TWG 6 at various ERME conferences. In addition, the relation to other disciplines has always played an important role and needs to be mentioned under this perspective.

The second perspective, the cognitive perspective, focuses on students' cognitive processes when modelling, and cognitive barriers, when students work through the modelling cycle. Cognitively oriented analyses have played a prominent role in many sessions of the modelling group at previous

conferences. At CERME 10, this aspect can be found within two thematic strands, that on developing modelling strategies and competences and also that on the analysis of modelling problems. The discussions there broadened our focus on the cognitive perspective and helped us develop further our thinking.

The third perspective, the curricular perspective, refers to the inclusion of mathematical modelling in the curricula. This question was addressed in all meetings at previous conferences and is addressed in nearly all thematic strands of TWG 6 at CERME 10 and highlights the significance and urgency of this theme.

The fourth perspective, the instructional perspective, claims the necessity of high quality modelling education in order to promote effective learning. The question on how to implement effective modelling environments is a hot topic that has persisted for decades and was addressed at CERME 10 within various strands of TWG 6, especially within the themes that addressed experimental materials and technology in modelling and teacher interventions.

As a final and fifth perspective teacher education and teachers' activities in school are addressed, because of the obvious necessity of preparing pre-service teachers for the teaching of mathematical modelling, although the importance of this topic at the various sessions of the Applications and Modelling TWG at previous ERME conferences was less prominent than at this. At CERME 10, teachers and their role in teaching as well as teacher education played a prominent role within the work of the Applications and Modelling TWG. This was integrated into various themes such as modelling strategies, teacher interventions and teachers' beliefs. This shift shows a clear further development of the discussions and the work of TWG 6 and needs to be fostered and broadened. Teachers and their education are the key for the effective and efficient integration of mathematical modelling into mathematical education at various levels.

# Developing a classification scheme of definitions of Fermi problems in education from a modelling perspective

Jonas Bergman Ärleback<sup>1</sup> and Lluís Albarracín<sup>2</sup>

<sup>1</sup>Linköping University, Department of Mathematics, Sweden; [jonas.bergman.arleback@liu.se](mailto:jonas.bergman.arleback@liu.se)

<sup>2</sup>Serra Hünter Fellow, Universitat Autònoma de Barcelona, Spain; [lluis.albarracin@uab.cat](mailto:lluis.albarracin@uab.cat)

*In this paper we use a modelling perspective to analyse three descriptions and definitions of so-called Fermi problems found in the literature. We discuss how the three definitions align with, and what they potentially have to offer to, realistic or applied modelling, contextual modelling, educational modelling (either a didactical or conceptual), socio-critical modelling, epistemological or theoretical modelling, and cognitive modelling. Our findings show that the definitions share some similarities, but for the most part are formulated in loose terms. From a modelling perspective, we found that the conceptualisation of Fermi problem we studied foremost and directly align with contextual modelling and both strands of educational modelling. We also discuss the seemingly incompatibility between Fermi problems and the other modelling perspectives, and suggest new lines of research on Fermi problems in particular, and on conceptualizing modelling in general.*

**Keywords:** *Fermi problem, modelling, modelling perspectives.*

## Introduction

The notion *Fermi problem* is tributed to the Italian Enrico Fermi (1901-1954), the 1938 Nobel Prize winner in physics, who had a special liking for posing and solving problems like *How many shopping malls are there in the United States?* (Anderson & Sherman, 2010). Fermi's philosophy was that any thinking and reasonably educated person should be able to solve problems of this type by just combining one's capabilities of making quantitatively accurate realistic and intelligent order of magnitude estimates, reasoning, and doing simple calculations (Efthimiou & Llewellyn, 2007). The perhaps most famous and classic *Fermi problems* is *How many piano tuners are there in Chicago?* Allegedly Fermi repeatedly gave this problem to his physics students at the University of Chicago many times over the years, and illustrated of the power of such reasoning by quickly calculating an astoundingly accurate and reasonable answer based on just a few sensible assumptions and estimates. Besides going under the name *Fermi problems*, these types of problems are also called *back-of-envelope calculation problems* or *order of magnitude (estimation) problems*.

Much due to the influence of Fermi, *Fermi problems* have been widely used in physics and engineering college courses in the US. Indeed, one can find many "shout-out" advocating and claiming various beneficiary effects for using *Fermi problems* in teaching, often exemplifying the assumptions and calculations involved in an explicit example as well as listing *Fermi problems* to try out in the classroom (see for example Carlson (1997)). However, it seems that systematic science- and engineering education research focusing on *Fermi problem* is sparse or at best marginalized. In recent years however, a number of studies in mathematics education have focused on the use of *Fermi problems* in the teaching and learning of mathematical modelling. Peter-Koop (2004) used *Fermi problems* to investigate third and fourth graders' problem solving strategies and among other things found that students' solutions "revealed multi-cyclic modelling processes" (p.

461). At the upper secondary level Ärleback (2009) investigated the potential of using *Fermi problems* as ‘miniature modelling problems’ to introduce modelling. Using so-called MADs (Modelling Activity Diagrams) the result showed the complexity of the modelling process involved when students at the high school level engaged in solving *Fermi problems*, something which recently also have been documented for college students (Czoher, 2016). *Fermi problems* have also been used to study students’ reasoning involved in solving so called *Big numbers estimation problems*, such as *How many persons can fit in the playground of our high school to attend a concert there?* Albarracín and Gorgorió (2013) showed that problems requiring equivalent mathematical solving approaches, but formulated using different context-specific wording, resulted in the students using differing solving strategies. Building and furthering this study, Albarracín and Gorgorió (2014) showed that some of the solving strategies the students used normally not would be considered valid as mathematics classrooms activities. For example, one such strategy found was *the exhaustive recounting of objects*, which requires excessive effort and/or time, or input from external sources which would eliminate the need to solve the problem altogether. However, it was concluded that 47% of the students’ strategies were based on mathematical models.

Sriraman and Lesh (2006) have argued for the introduction of *Fermi problems* as interdisciplinary tasks which potentially bridge and connect mathematics and other school subjects. In addition, due to the directness aspect of *Fermi problem*, one can also easily incorporate different social issues of interest within the task, such as estimating the amount drinking water consumed, the consumption of gasoline or other fuels, the amount of discarded food or other ecological types of problems (Sriraman & Knott, 2009).

In this paper we present our on-going work aimed at doing an exhaustive and systematically review of the literature on *Fermi problems* from all educational fields. As part of this endeavour, we in this paper analyse three different definitions and descriptions of *Fermi problems* in the literature from a modelling perspective. We use the classification of perspectives on modelling by Kaiser and Sriraman (2006), and map the key features of *Fermi problems* in the definitions and description onto the different perspectives and discuss the potential of using *Fermi problems* in a modelling setting from different viewpoints. Our aim is that this preliminary analysis will point out areas and directions that are worth to further explore in the larger study.

The research question that guided our work in this paper was: *How does the definitions and descriptions of Fermi problems in the literature align with different perspective on modelling?*

## Methodology and method

Three of our goals with doing a systematic review of *Fermi problem* is to i) elaborate a research grounded coherent definition that characterize *Fermi problems* as completely as possible; ii) find and describe the connection between *Fermi problems* and modelling in general and connections between modelling perspectives in particular; and iii) create a research agenda for future research (Ärleback & Albarracín, in preparation).

The literature for the exhaustive review was identified using a) search engines such as Academic Primer, ERIC, Google Scholar, and Scopus, and key word searches on *Fermi problem/question/estimate, back-of-envelope problem, order of magnitude estimate, “how many piano tuners”,* b) snowballing (using literature already found and concluded relevant for the research to identify

further literature; cf. Petticrew & Roberts, 2006), and c) asking colleagues with other mother tongues than our own for papers in their native language. It should be noted that there are similar notions and concepts in chemistry and physics, and hence the searches will result in large numbers of hits. However, the majorities of these can be dismissed since they are not about education. The papers that did have an educational focus were skimmed and paper that only mentioned Fermi problems in the passing was excluded from the final selection. This resulted in a list of 59 papers from mathematics education and other educational subjects (such as science, economics and engineering), written in English, Spanish, German, Japanese and Dutch. All 59 papers were read and three representative definitions and descriptions were selected. We then used the characterisation of perspectives on modelling by Kaiser and Sriraman (2006) as an analytic lens to compare the three definitions as well as contrast them relative to the different modelling perspectives. We chose this high-level framework to structure the analysis rather than a more specialized and “derived” framework (such as a framework classifying modelling tasks) for two reasons. Firstly we wanted to use the existing definitions and descriptions of Fermi problems in the literature as the point of departure for the analysis, and secondly we wanted to use a neutral framework not based on too specific cultural or epistemological stances.

### **The three definitions and descriptions of Fermi problems**

Although the number of papers related to *Fermi problem* found is numerous, many of them do not offer any explicit definitions of the notion, but are rather based on shared knowledge and often provide some elaborated examples to characterize how *Fermi problems* are conceptualized and understood.

For the analysis and discussion in this paper we have chosen to focus on the following three different definitions and characterisations of *Fermi problems* in the literature: Ärleback (2009), Goodchild and Fuglestad (2008), and Sriraman and Knott (2009). All three sources are selected from the mathematics education research literature and use and discuss characteristics of *Fermi problems* and how students work with these. Ärleback (2009) is included since the characterizing of *Fermi problem* in this paper is one of the most cited and used definition in the more recent literature (in 9 of the 59 papers in our list of research paper on *Fermi problem*). Goodchild and Fuglestad (2008) and Sriraman and Knott (2009) are both included since their papers are representative for much of the other papers in literature. One can discuss whether the expressed conceptualizations of *Fermi problems* in the three papers are definitions in strict sense or mere characterizations or descriptions, but to avoid ambiguity and awkward formulations in the paper we will from now on refer to the three simply as definitions.

The first quote, from now on referred to as (Ärleback), comes from Ärleback (2009) who suggested and adapted so-called *Realistic Fermi problems* defined by:

- their *accessibility*, meaning that they can be approached by all individual students or groups of students, and solved on both different educational levels and on different levels of complexity. A realistic Fermi problem does not necessarily demand any specific pre-mathematical knowledge;
- their clear real-world connection, to be *realistic*. As a consequence a Realistic Fermi problem is more than just an intellectual exercise, and I fully agree with Sriraman and Lesh (2006)

when they argue that “Fermi problems which are directly related to the daily environment are more meaningful and offer more pedagogical possibilities” (p. 248);

- the *specifying and structuring of the relevant information and relationships* needed to tackle the problem. This characteristic prescribes the problem formulation to be open, not immediately associated with a known strategy or procedure to solve the problem, and hence urging the problem solvers to invoke prior constructs, conceptions, experiences, strategies and other cognitive skills in approaching the problem;
- the absence of numerical data, that is the *need to make reasonable estimates* of relevant quantities. An implication of this characteristic is that the context of the problem must be familiar, relevant and interesting for the subject(s) working in it;
- (in connection with the last two points above) their inner momentum to *promote discussion*, that as a group activity they invite to discussion on different matters such as what is relevant for the problem and how to estimate physical entities. (Ärlebäck, 2009, pp. 339-340, italics in original)

The second definition of *Fermi problem* is by Goodchild and Fuglestad (2008), who draw on (Swan & Ridgway, n.d.). Their definitions will be referenced as (Goodchild & Fuglestad):

These [*Fermi problems*] are ‘plausible estimation’ tasks, which consist of one or two easily-stated questions which at first glance seem impossible to answer without reference material, but which can be reasonably estimated by following a series of simple steps that use only common sense and numbers that are generally known or amenable to estimation (Goodchild & Fuglestad, 2008, p. 52).

The third and last definition, from this point referred to as (Sriraman & Knott), is from Sriraman and Knott (2009):

Fermi problems are estimation problems used with the pedagogical purpose of clearly identifying starting conditions or assumptions and making educated guesses about various quantities or variables which arise within a problem with the added requirement that the end computation be feasible or computable by hand. (p. 220)

## **Analysing and situating Fermi problems from different perspectives on modelling**

We now briefly summarise the main characteristics of the different perspectives in Kaiser and Sriraman (2006) and discuss how the three definitions of *Fermi problems* above “fits” with the respective perspective and why. The brief characterization presented of *realistic or applied modelling*, *contextual modelling*, *educational modelling* (either a *didactical* or *conceptual*), *socio-critical modelling*, *epistemological or theoretical modelling*, and *cognitive modelling* are based on Kaiser and Sriraman (2006) and Blomhøj (2009).

The *realistic or applied perspective of modelling* stresses the importance of using authentic problems from science and industry as well as for the students to engage in the whole modelling process rather than fragmented parts thereof. Although none of the definitions explicitly excludes authentic contexts from science and industry, they all tend to suggest and promote more mundane

and everyday problem contexts: “the context of the problem must be familiar, relevant and interesting for the subject(s)” (Ärleböck); “reasonably estimated by following a series of simple steps that use only common sense” (Goodchild & Fuglestad); “making educated guesses” (Sriraman & Knott). It could be noted that the use of the word ‘realistic’ in Ärleböck’s definition might be misleading with respect to the realistic and applied perspective of modelling. This wording merely stresses that the *Fermi problem* should have a meaningful real-world connection and not be purely intellectual in nature. However, in the sense that *Fermi problems* that focus on issues like the number of piano tuners in a city, or the number of grains of sand in a glass, are not normally relevant questions for students. On the other hand, problems that ask students to estimate the amount of trash produced, or the volume of fresh water consumption, connect with the students’ physical and social environment and have meanings by themselves. The meaning of ‘realistic’ in the realistic or applied perspective on modelling is much stronger. This suggests that Fermi problems, at least as portrayed in the definitions discussed here, have little to offer to the realistic and applied perspective on modelling.

*Contextual modelling*, having its roots in the word problem solving tradition, is centred around the design of carefully structured and meaningful situations, where the students develop, refine, and extend their own mathematical constructs as well as apply these in different contexts. The emphasis on meaning-making in the contextual modelling perspective can be seen echoed in (Goodchild & Fuglestad) and (Ärleböck) but not evidently in (Sriraman & Knott). In (Goodchild & Fuglestad) the students have to meaningfully understand and come to grips with the context of the *Fermi problem* at hand to overcome the “easily-stated questions which at first glance seem impossible to answer”, whereas (Ärleböck) stresses the problem formulation to “be open, not immediately associated with a known strategy or procedure to solve the problem, and hence urging the problem solvers to invoke prior constructs, conceptions, experiences, strategies and other cognitive skills in approaching the problem“, which resonates with the ‘traditional’ problem solving tradition that historically has been strongly associated with the contextual perspective on modelling. (Sriraman & Knott) on the other hand describe *Fermi problems* as intentionally designed with the explicit “pedagogical purpose of clearly identifying starting conditions or assumptions and making educated guesses about various quantities or variables which arise within a problem”. This focuses more on solving (meta-) strategies than stressing meaning-making or for the students to develop, refine, and extend their own mathematical constructs.

Both ‘flavours’ of *educational modelling* (didactical and conceptual) are so-called integrative perspectives in that they seek to combine modelling as a learning goal in its own right as well as modelling as a vehicle for learning other content matter. The two strands within this perspective forefront pedagogical goals such as using modelling as a didactical tool for structure learning processes and modelling as a mean to introduce concepts and promote concept development. Within this perspective, the cyclic view of modelling (aka the modelling cycle) has a prominent role. Looking at the three definitions, we argue that (Ärleböck) and (Sriraman & Knott) both put forward *Fermi problems* as vehicles for learning other curricula objectives as well as have explicit didactical considerations as central features. On the one hand the two characteristics of *accessibility* and *discussion promoting* in (Ärleböck) address classroom dynamics and classroom norms as innate components of the *Fermi problems* themselves. (Sriraman & Knott) on the other hand explicitly

describe the use of *Fermi problems* as having a “pedagogical purpose”. Looking at the definition in (Goodchild & Fuglestad) however, these educational aspects are not emphasised.

Central from the *socio-critical perspective on modelling* is critical reflection and critique of mathematics role and function in society as manifested in the use of mathematical models and modelling. Although it is an innate feature of *Fermi problems* to engage the problem solver in making reasonable, and arguable critically realistic, assumptions and estimates, these need not inherently nor explicitly focus on or be connected to the social dimensions involved in the context of the problem. Similarly as for the realistic and applied perspective on modelling, there are nothing in the definitions that explicitly stresses the fundamental core characteristics of the respective perspective. That is, with regards to the socio-critical perspective on modelling, neither of the definitions analysed forefronts the social aspects and implications of the use of models and modelling in society. However, it is worth noticing that (Goodchild & Fuglestad) use a formulation that indicates that *Fermi problem* can be used to get students to appreciate the potential and power of mathematics to address and make sense of real problems in the world, namely “questions which at first glance seem impossible to answer without reference materials”.

*Epistemological modelling* focuses on theory building and uses modelling as a mean to re-construct topics and branches of mathematics as a discipline. Neither of the three definitions (Ärleböck), (Goodchild & Fuglestad) and (Sriraman & Knott) express the ambition to draw on *Fermi problems* to derive theory in terms of re-building and constructing mathematical (sub-)topics or (sub-)areas. Indeed, as pointed out in Ärleböck (2009), *Fermi problem* can be experienced as limited with respect to various mathematical content, and given a particular learning goal within mathematics, it might be very challenging to design and formulate a *Fermi problem* that focuses on eliciting this content in a natural way.

The *cognitive modelling perspective* is sometime described as meta-perspective in the sense that it focuses on fundamental research questions related to various aspects of modelling from a cognitive perspective. From the point of view of the cognitive modelling perspective being a meta-perspective that guides research into the practices of mathematical modelling and all that goes around and into the modelling process, we find it difficult to elaborate on what the different definitions might offer in this respect. We fear that such a discussion would be far too speculative to be constructive or productive and not inform our aim about how to classify definitions of *Fermi problems*.

## Discussion, conclusions, and future research

The limited analysis we have presented in this paper points to some of the challenges in developing a classification scheme of definitions of *Fermi problems* from a modelling perspective. Having engaged in this exercise, we conclude that the level of interpretation needed to apply the different perspectives on modelling as analytical lens introduces uncertainty in the results. Partly we believe this has to do with the fact that the definitions and characterizations of *Fermi problems* in the papers found in literature are vague and ambiguous. However, we also contribute some of this difficulty to the used perspectives on modelling in Kaiser and Sriraman (2006), which describes the modelling debate from evolutionary viewpoint, connecting today's trends and approaches with their historical traditions and roots. This suggests on the one hand, that an overarching and general characterisation and definition of *Fermi problem* could make the research on *Fermi problem* more connected and

coherent, rather than scattered and compartmentalized. On the other hand, it also suggests that alternative ways of thinking about and characterizing different aspects of the on-going modelling debate might provide new insight into the growing literature on the teaching and learning models and modelling – ranging from basic ontological and epistemological considerations to different aspects of both general and particular designs and practices involved in the teaching and learning of mathematical models and modelling.

In going through the papers in our list of research on *Fermi problem* and looking at the definitions, we found that most definitions adapted in the different papers are of a local and pragmatic nature in the sense that they are relevant and work fine in the particular setting and study described and reported on the paper. We also identified patterns of linkages between the work of some authors who draw and build on each other's work, whereas some pieces of research are more like isolated islands. To us this is a second indication motivating the need for a more coherent view and characterisation of *Fermi problems*, in order to coordinate the various research findings in the literature and advance our collective experiences and knowledge with respect to *Fermi problems*.

As we mentioned before, there is no consensus of what the characteristics of *Fermi problems* are in the research literature. This is perhaps not surprising since this type of problems have been part of everyday mathematics and science teaching in various degrees and in various forms for decades, but only in recent time have been subject for more systematic investigations. Doing the analysis of the three definitions have pointed to some commonalities and differences in general and from a modelling perspective in particular. We are of the opinion that *Fermi problems* have much to offer from a modelling perspective, both as a tool to promote modelling (cf. (Ärlebäck, 2009)) and as a research tool. Hence we would like to promote the use of *Fermi problems* in schools, and through our systematic literature review (Ärlebäck & Albarracín, in preparation) we hope to lay the foundation for finding a common ground for promoting these types of problems in education and research. Our next step is to build on the initial ideas and results presented in this paper to make a more careful analysis of our sought-out literature, with the ambition, to among other things, come up with a tentative and coherent definition of *Fermi problems* together with a rationale for how, when and why to use them in connection to mathematical modelling.

*This paper presents the a posteriori analysis of an study and research path (SRP) on comparing reality versus forecasts of Facebook users, which appears as a teaching and learning proposal for mathematical modelling. We present the main elements of the SRP that have been designed through a virtual platform developed in the frame of the European project MCSquared and experienced in a first-year course at university in management sciences degrees. The three-layer analysis we present is based on three main study dialectics: the questions-answers, media-milieu and individual-collective dialectics, which are central for an SRP and for mathematical modelling. In particular, we focus our a posteriori analysis on how these three dialectics were fostered and which are the main weaknesses as well as strengths of the SRP experienced.*

**Keywords:** *Mathematical modelling, study and research paths, dialectics, university level.*

## Introduction: The SRP as teaching proposal for mathematical modelling

During the last decades, researchers and practitioners agree that teaching should not be focused only on the formal transmission of knowledge, but also should provide students of the tools for enquiring into the study of real phenomena and integrate mathematics as an essential modelling tool. It is thus important to foster a change of the school paradigm, with new functionalities to mathematical knowledge, novel responsibilities to teachers and students, different ways of questioning mathematical knowledge, that is, moving from a school paradigm which most of the time focused on introducing students to already built mathematical knowledge devoid of its rationale to a paradigm of questioning it, ‘questioning the world’ in the words of Chevallard (2015). In the particular case of the research on modelling and their applications and on inquiry-based approaches some big steps have been made showing how, under certain suitable conditions in different educational levels and curricular frames, modelling activities may be successfully put into practice (Artigue & Blomhøj, 2013; Burkhardt, 2008; among others). Hence, the dissemination and long-term survival of activities based on modelling, enquiring and other innovating proposals are one of the main challenges for Mathematical Education. Therefore, to support and analyse any kind of alternative teaching proposal, researchers need reference models that allow them to analyse and evaluate the impact that these innovative teaching practices have on the way mathematics is conceived, on the nature of the didactic systems and milieus emerged through these practices, and on the conditions and constraints that help or hinder the viability of these practices.

In our research, developed in the framework of the anthropological theory of the didactic, we bet on the use of the study and research paths (SRP) as epistemological and didactic model (Chevallard, 2015; Winslow et al., 2013) to face the problem of moving towards a functional teaching of mathematics and, particularly, where mathematics are conceived as a modelling tool for the study of problematic questions.

## Traits and levels of analysis of an SRP

According to Barquero and Bosch (2015), the starting point of an SRP should be a ‘lively’ question of real interest for the community of study (students and teacher/s). The study of  $Q_0$ , called the *generating question*, evolves and opens many other *derived questions*  $Q_1, Q_2, \dots, Q_n$ . The continuous looking for answers to  $Q_0$  (and to its derivative questions) is the main purpose of the study and an end in itself. As a result, the study of  $Q_0$  and its derived questions  $Q_i$  leads to successive temporary answers  $A_i$  that can be helpful in elaborating a final response  $R^\heartsuit$  to  $Q_0$ . These first characteristics can be associated to the first level of analysis of the SRP that we here consider, it consists in the dialectic establishing between the questions posed and the likely answers appearing (*questions-answers dialectic*) which also provide the basic structure of an SRP to be implemented and to be enriched after each implementation. This first layer can be linked to the *cronogenesis* dimension of the teaching and learning practices, referring to the evolution of questions to be faced and the necessary knowledge to be used.

Another central dimension for an SRP is the *media-milieu dialectic*, which constitutes the second level of analysis. As described in the aforementioned investigations, the implementation of an SRP can only be carried out if the students have some pre-established responses accessible through the different means of communication and diffusion (that is, the *media*), to elaborate the successive provisional answers  $A_i$ . These *media* are any source of information, such as: textbooks, treatises, research articles, class notes, or the teacher acting as main media. However, the answers provided are constructions that have been elaborated to provide answers to questions that are different to the ones that may be put forward throughout the mathematical modelling process. Thus they have to be de- and re-constructed according to the new needs. Other types of *milieus* will therefore be necessary to test the validity and appropriateness of these answers. This second level of analysis put attention to the *mesogenesis*, that is, the evolution of the experimental milieu. Finally, we may consider the collective dimension of the research and study of questions in an SRP. This third dimension focuses on the roles and responsibilities that, far from the traditional didactic contract, students and teachers may assume in experiencing an SRP and how the individual work is shared, transferred and agreed with the wider community, and vice versa. We will denote this third level as the *individual-collective dimension*, which refers to the *topogenesis*.

## Didactic analysis of a mathematical modelling process: The case of an SRP about comparing reality against forecast

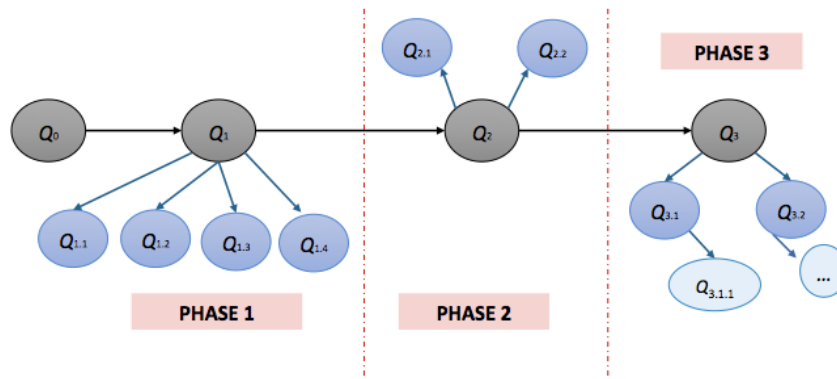

We focus on analysing the case of an SRP on *comparing forecasts against reality in the case of Facebook users' evolution*. This SRP was designed in the frame of the European project MCSquared (<http://www.mc2-project.eu>), the goal of which is the design of innovating teaching proposals (the so-called c-book units) to foster creative mathematical thinking. This c-unit in particular has been produced by a group of five multiple background designers: 2 Maths Education researchers, 2 university lecturers, who were then in charge of its implementation, and an expert on modelling in the field of Operations Research, which enrich a lot the way to structure the teaching sequence to prompt mathematical modelling. The teaching proposal was made in the virtual socio-technical environment developed along the project, the c-book that integrates some narratives with several applets of different factories of different educational technologies. Next we present the details about the design of the SRP experienced, combining the virtual environment offered by the c-unit with face-

to-face sessions during the winter term of the academic year 2015-16 with first-year students of Business Administration Degree and of Innovation Management (BAIM), all from the 'Escola Superior de Ciències Socials i de l'Empresa-Tecnocampus', Pompeu Fabra University.

The initial situation starts from a real news about a research developed by Princeton University in 2014, in which it was predicted that Facebook would lose the 80% of its users before 2017. Hence, the initial question  $Q_0$  presented to students is about: *Can these forecasts be true? How can we model and fit real data about Facebook users' evolution to provide our forecast the short- and long-term evolution of the social network? How can we validate Princeton conclusions?* The experimentation was structured in three interconnected phases linked to the generating question  $Q_0$ , building up the a priori design of the SRP, then reflected in the design of the c-book unit. A first phase that focuses on the open research of real data about Facebook users, a second one focused on which mathematical models (mainly based on elementary functions) can provide a good fitting to real data, and a third one about the use of these models to provide the short-, medium- and long-term forecasts of Facebook users and about how to decide about best and most reliable model. The students, working in 'consultant teams' of 3-4 people, got the order from MS2 Consulting ('Mathematical Solutions Squared') previously described as  $Q_0$  and they were asked to deliver a final report by the end of their work as an oral presentation as response to the order. The implementation combined face-to-face sessions in the teaching device called 'Math modelling workshop' (in a total of six 90-minuts weekly sessions) for the miss-in-common of the junior consultant teams' partial reports, with work out of the classroom. The guiding c-unit that gives the workshop support was ready before starting in order to let the different teams attach their answers, pose new questions by providing an interacting device (as chats or shared spread-sheets) and use some applets designed especially to get through the different phases of the SRP. Next we sketch how different dialectics were prompted by both: (a) the c-unit design (by its initial design but also by the different changes that were introduced according to students' requirements: new questions and answers not envisioned, new media required, etc.) and (b) the didactic gestures and devices to manage its implementation.

### **The questions-answers dialectics**

We can visualize the first level of description of the SRP designed and experienced as an arborescence of the *questions* that were proposed and faced and the *answers* foreseen and appeared. This questions-answers structure constitutes a first layer of analysis of the process designed and of the trajectories followed in the implementation of the SRP. As introduced above the generating questions  $Q_0$  of the SRP on comparing forecasts against reality in the case of Facebook users' evolution was broken into three main derived questions (see Figure 1 for the SRP questions' organization), which guided the successive phases of its implementation. A first phase that focuses on the open research of real data about Facebook users, a second one focused on which mathematical models (mainly based on elementary functions) can provide a good fitting to real data, and a third and last one about the use of these models to provide the short-, medium- and long-term forecasts of Facebook users and about how to decide about best and most reliable model.

**Fig 1: Tree of questions and answers of the different phases of the SRP**

$Q_1$ : Which data sets about Facebook users are better to consider in our research?  $\rightarrow A_1$ : Each group look for the data set to be used and shared; the whole community agree on the terminology (year, period, units, etc.) and on the dependent and independent variables to consider.

$Q_{1.1}$ : Which time intervals may be considered?  $Q_{1.2}$ : How can data be well-organized?  $Q_{1.3}$ : How to organise and visualise data?  $Q_{1.4}$ : What can we say about the growth tendency of the data analysed?

$Q_2$ : Which mathematical models provide the best fitting of real data about FB users?  $\rightarrow A_2$ : Each consultant group is asked to propose and justify three mathematical models fitting real data.

$Q_{2.1}$ : Which models (based on elementary functions: linear, parabolic, exponential, etc.) may fit the data?

$Q_{2.2}$ : How can the coefficients of the model be determined?

$Q_3$ : How can we decide about the ‘best’ models fitting data? Can we use this model to predict the future evolution of FB users?  $\rightarrow A_3$ : Need to create tools to justify why a mathematical model/s is/are the ‘best’ with respect to: (a) fitting data and (b) forecasting the evolution of FB users.

$Q_{3.1}$ : How can we compare the error committed between reality and forecasts provided by models?

$Q_{3.2}$ : Can be the same model used for the short- and long-term forecasts?

Let us comment the main aspects of the *a posteriori* analysis of the experimentation referring, in particular, to the questions-answers dialectic level. About the first phase, we should remark the ease with which the students found real data about the evolution of the social net. The most format they found the information was by means of a graphical representation (for example, a bar chart). This fact strongly determined their analysis, since they focused mainly in the graphical analysis of the data growth tendency, but not in their numerical versant (variation tax, that appeared in a tangential way). Besides, the fact that many groups found the same data triggered an intense debate and interchange of ideas among them, which took us to consider a brainstorming session about the previous hypothesis in the classroom, and as a consequence, the duration of the first phase was extended from 3 to 4 sessions. Due to the wealth of answers collected by the teams during the brainstorming session we decided to ask the students to deliver a first report in a poster format, so that each team could synthesize their findings and share their conclusions at that moment. About the second phase of the SRP, since many groups worked finally with very similar data on the worldwide evolution of FB users, we made two new decisions: (a) give each team a second set of different data, corresponding to different geographical areas, in order to contrast their hypothesis and extend their study; and (b) ask for more than one fitting model for each data set. The analysis of the teams proposals made arise

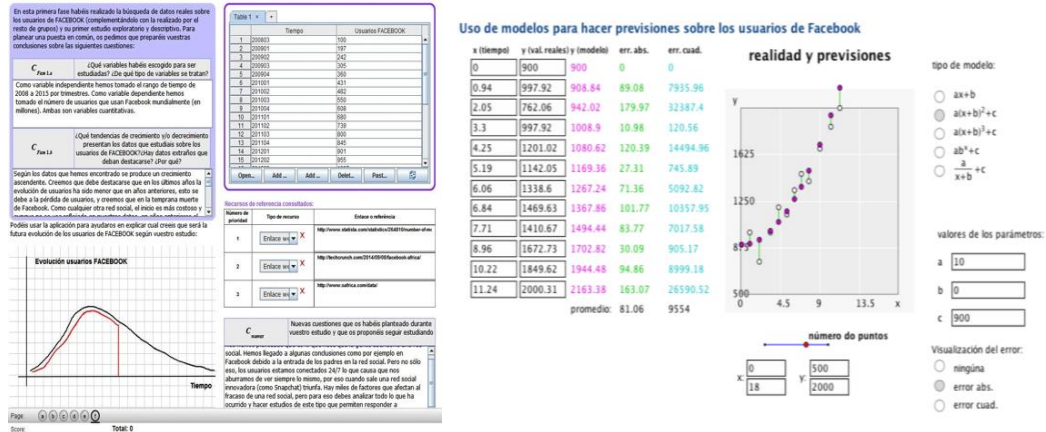

a non-expected aspect: many of them proposed using piecewise functions, so that the expected answers to  $Q_2$  about the consideration of models based elementary functions (linear, quadratic, exponential, etc.) was extended. Otherwise, during the brainstorming in the first phase the teams started enquiring in the history of FB and about the possible reasons of the changes in the tendency of the data or number of users (IPO, new rival social nets, purchases of the company, new developments, etc.), and also the moments of change of tendency. New questions and answers appeared at this stage about changing the fitting model in accordance to a particular action or decisions of FB. Concerning the third and last phase, we only dedicated two face-to-face sessions of the workshop (one with the whole group and the other for the consultant teams' doubts) and were not enough for a rich development of  $Q_3$ . Although this time constraint, there were some applets designed and integrated in the c-unit to help on the simulation of models and its contrast to real data, as we explain in the following section about the media-milieu.

### **The media-milieu dialectic**

Since we have the first layer of analysis of the SRP in terms of the arborescence of the questions-answers, it is important to ask when, where and how questions can arise and answers can be developed. It is at this new level when there may appear the different elements taking part of the milieu, composed of varied elements: questions, temporary answers, pre-existing answers in or out school, means to validate answers, experimental data, etc., accessible through different kind of media (textbook, lectures, website resources, etc.). The relation among these elements can be analysed through the *media-milieu dialectic*. In our SRP it has been central the constant dialectic between the search for data (for instance, real data about Facebook users, or about the company changes) and of pre-existing answers (ways to organise data, common models to fit population evaluation, elementary functions, tools to control error, etc.) that exist in different media that were available to students, such as web resources, contents of Mathematics course, answers from lecturers from other courses; and the creation of the appropriate means (milieu) to integrate (or refuse) them in their SRP path study. Let us stress the importance of some of them.

In the first phase of the SRP, it was important to count on the help of the teacher of another course called 'Introduction to digital communities' (running in parallel to the workshop) who helped on providing a general sense and functionality to  $Q_0$  and to show how the students could look for real data about FB and some techniques to organise them. Also, having open access to the news and papers published by Princeton University about FB, as well as FB answer to Princeton or their monthly report about users growth was very useful for students. All these elements took part of the *media* accessible to students, at the time it enriches students' *milieu* mainly composed at this stage of the data sets that each team chose to work with, shared and debated with the whole class sessions. All these elements helped them to prepare a first report with the first temporary answer  $A_1$ , in a poster format given in the c-book platform, and then shared and debated in the face-to-face session (see Figure 1, left side). With respect to the second phase, the a priori design of the c-unit contained some applets (designed with Geogebra) proposed to help students to explore different models based on elementary functions ( $Q_2$ ). These applets provided the main *media* for students to visualize data jointly with model simulation, and also took part of their *milieu* as main tools for contrasting, comparing and deciding on the 'best' models to choose. As aforementioned, in the SRP experienced students suggested using piecewise functions, which pushed designers to make changes in the

questions and applets as these necessities were coming up. Moreover, some groups started to present new hypothesis about model to use with non-elementary functions (such as Gaussian function), most of which were part of their milieu because they had been introduced in previous courses. So that, designers had to quickly cover this demand by designing a new applet with Geogebra to let them manipulate also these types of mathematical models.

Maths course now changed their role to become only a guide of the study and research process, transferring most of the responsibilities to students on elaborating their answer. Moreover at the end of the implementation, two external persons carried out the *validation* and *evaluation* of the final consultant team's answers, in coherence with what was asked at the beginning and trying to make students assume these responsibilities. Second, students were organised all the time in *consultant teams* with an autonomous functioning, who were asked since the beginning to jointly deliver a collective report, although in its evaluation each of them had to be responsible of explaining responses to one of the phases and all could be asked about any phase. To help on assuming this autonomy, lecturers took several decisions: (a) distribute different data sets to help them not to be very influenced by other teams work and rhythms; (b) use the workshop sessions for the common debate of groups work and to share the main advances in finding answers (although different) and new questions emerged, and (c) constantly introduce changes in the design of the c-unit design, which work as the shared support, with the new questions that had emerged and with the media that could help them at each step. For instance, at the last of phase 1, designers decided to integrate a poster format to fix the things students had to share with the rest of the groups and dedicate a workshop session when consultant's teams could explain their answers to  $Q_1$ ; or, as explained in the previous section, in phase 2 and 3 designers decided to create new applets to deal with new models proposal and to facilitate them the media and milieu to make the SRP progress.

## Final remarks and conclusions

In this paper we focus on the case of an SRP on comparing forecasts against reality in the case of Facebook users' evolution to show the use of three dialectics: the one of the questions-answers, of the media-milieu and of the individual-collective, corresponding to the three complementary level of didactic analysis of teaching and learning processes (Chevallard, 2008). Besides their analytic use, they suppose a productive framework to enrich teaching and learning practices, in particular, on modelling.

In what concerns to the *questions-answers dialectic*, since the beginning of the workshop, the generating question  $Q_0$  about the controversy of the article by Princeton was adopted by the students with a great interest and, up to the end of the process, was kept alive. From its implementation we can underline very important conditions that were created. First, the flexibility of the lecturers and designers team that were opened to readjust the schedule according to students' team work, that is why we devoted more sessions to the first phase and consequently reducing the ones to the last phase. Furthermore, they were very attentive to integrate in the c-book unit all new questions and means that students asked for. Second, students were very active on workshop session to share their proposals from which many derived questions appeared, some of them planned in the a priori design, some others that extended the initial proposal. About the *media-milieu dialectic*, in the case of this SRP and with the support of the c-unit infrastructure, we took several decisions along the implementation of transforming the media offered to students to help them in the modelling process and also to observe the impact new media had on students' milieu. We may again insist on the importance of very important contributions, such as: collaboration with other subjects (as the one of 'Introduction to digital communities'), focusing some workshop sessions on the discussion external answers that students brought, or by the creation of widgets to foster students' experimental work, etc. Last but not least, about the *individual-collective dimension*, we may underline that students easily accept the

request of presenting their final response in front of an external committee. The last session that we dedicated to these presentations brought to the light the richness and variety of answers given to the stated initial question, as well as the complementarities of consultant teams' answers. But, we are aware of the weakness and insufficiency of mechanism to collect individual and teams internal work, as most of the workshop sessions were dedicated to the common debate. This is one aspect to be improved in the following experimentations and to integrate means to get access to the dynamics established between the individual and collective work.

*In the last years the discussion for promoting Science, Technology, Engineering, and Mathematics (STEM) education became a central goal of educational policy in many countries worldwide, in an attempt to prepare students for a scientific and technological society. However, interdisciplinary mathematics teaching and learning is not limited to the “STE” and should include other disciplines across the curriculum. Mathematical modelling, as a mathematical practice and key competence within mathematics education standards could be interpreted as an excellent example for promoting not only modelling competencies, but also interdisciplinary mathematics education (IdME) in school. In this paper we focus theoretically on the question, ‘Which core similarities and differences can be stated between the two fields along three perspectives?’, by presenting a piece of theory describing the interplay between IdME and mathematical modelling.*

*Keywords: Mathematical modelling, interdisciplinary mathematics education, theory development.*

## Introduction

The purpose of the present study is to examine, from a theoretical point of view, the interplay between mathematical modelling and interdisciplinary mathematics teaching and learning, and to propose how mathematical modelling can promote interdisciplinary mathematics education. Following our theoretical approach, we present an example of an activity, based on our previous work, which exemplifies the key features and components of such a modelling activity that can promote interdisciplinary mathematics teaching and learning.

In the following sections, we present mathematical modelling as a means for teaching and learning mathematics through an interdisciplinary lens, by referring to the characteristics of modelling that make this approach feasible. We later present the teacher perspective on using modelling in promoting an interdisciplinary approach, and an example of an interdisciplinary modelling activity. We finally present and discuss a model of the interplay between mathematical modelling and Interdisciplinary Mathematics Education (IdME).

## Mathematical modelling as means for interdisciplinary teaching and learning

In this section we firstly give a brief general view on mathematical modelling and interdisciplinary mathematics teaching and learning by defining the two fields and by posing some initial thoughts for consideration. Although these definitions show strong overlaps, one has to look deeper concerning their differences, to understand both fields as exclusive as well. To make this more transparent we discuss mathematical modelling as a means for interdisciplinary teaching and learning, along the following perspectives: (a) the modelling cycle perspective and the individual modelling routes, (b) the teachers’ perspective and the cross-link approach, and (c) the

interdisciplinary activities and the students' work. These perspectives are presented in the following sections.

### **General view and definitions**

Whereas there is a strong consensus in the international discussion that mathematical modelling can be described as an activity that involves transitioning back and forth between reality and mathematics, the definition of interdisciplinary mathematics education is very vague. Recently several researchers from different disciplines, including both authors of this paper, published a monograph entitled “Interdisciplinary Mathematics Education – State of the Art” (Williams et al., 2016). Without going into detail here, it became clear that describing a ‘discipline’ is much easier than to think about, if more disciplines could be multi-, inter-, trans- or meta –disciplinary. So what does interdisciplinary mean? An interesting paper by Nikitina (2006) described three core approaches to the teaching of science and mathematics in integrative ways, that differ from one another in form and purpose. These three strategies, namely conceptualizing, contextualizing, and problem-centering, ask different questions of mathematics and science, and serve different learning goals. The authors discussed these strategies based on their empirical study and furthermore they claim that understanding the strengths and weaknesses of each strategy can help educators choose the optimal way to present their interdisciplinary material. In contrast, a brief pragmatic definition is formulated by Roth (2014), who stated that: “Interdisciplinarity denotes the fact, quality, or condition of two or more academic fields or branches of learning. Interdisciplinary projects tend to cross the traditional boundaries between academic disciplines” (p. 317). In the following we use this definition of IdME as a basis for our theoretical reflections in this paper. Following Roth’s (2014) definition, some thoughts arise by contrasting it with mathematical modelling: Without having a real life problem, mathematical modelling activities are not possible. At first, real life questions come out of another ‘(scientific) discipline’ than mathematics. This makes sense and so we have the solution and found the overlap between these fields by arguing that mathematical modelling is the same as interdisciplinary mathematics and vice versa! – Stop, this would be too easy! Can we easily speak about ‘disciplines’ or is it better to say that real life questions of modelling problems come out of other ‘realities’? Do modelling problems always include or promote further disciplines/realities and what is the importance when having one or more of them? If there are other disciplines implicitly and explicitly distinguishable in a modelling problem, is it the teacher’s goal to connect them and make them understandable for the students? Are modelling problems per se a prototype for interdisciplinary mathematics education? In the next section the cycle perspective gives some answers to the raised questions and again new thoughts are presented.

### ***Cycle perspective and individual modelling routes***

Recently the importance of modelling cycles, independent of type (see Borromeo Ferri, 2006), became clear for the teaching and learning of mathematical modelling in the classroom. In addition to promoting general modelling sub-competencies, fostering the meta-cognitive modelling competency can be seen as a strong goal in the learning process as well. Research on students’ cognitive processes while modelling also showed that the individual’s process of modelling is far from linear. So, individual modelling routes (Borromeo Ferri, 2007) better describe students’ jumps backward and forward within the cycle. These jumps could be empirically reconstructed between phases, not only inside “reality” or “mathematics”, but mostly between “reality” and “mathematics”.

Looking from the cycle perspective on modelling and interdisciplinary mathematics we would like to formulate two main thoughts/ideas, where (b) is dependent on (a).

(a) The modelling cycles which were developed in the field of applied mathematics and mathematics education during the last decades have a strong focus on the mathematics itself of course (Pollak, 1979; Blum, 1985). The interdisciplinary view is not explicitly visible. The often used terms in the modelling cycles, like “simplifying” or “working mathematically” do not imply that other disciplines are involved. This shows exclusiveness and no overlap when just focusing on the cycles. The same phenomenon can be observed when looking at modelling cycles in physics or chemistry (e.g. Goldhausen & DiFuccia, 2014), because they indeed focus on their discipline, but applying mathematics, if necessary, is only a side product.

(b) Considering that the interdisciplinary view is not explicitly visible in the known cycles, it is clear that it can only happen in connection with appropriate modelling problems. The individual has to interpret by reading the problem the other disciplines/realities that are included in the problem. This means that the extra-mathematical knowledge is not only limited to one’s own experiences, but to the knowledge of other disciplines, like physics or ICT. One could argue that the stronger the “discipline knowledge” and the “mathematical knowledge” the better a student’s modelling process will be. Speaking on an abstract level, the individual modelling routes are on a multi-dimensional level, when the other discipline(s) included in the modelling problems is understood by the students. From this point of view, we see strong overlaps between mathematical modelling and interdisciplinary education.

### ***Teachers' perspective and the cross-link approach***

With respect to the previous section we focus now on the teachers’ perspective. If we want teachers to be qualified in interdisciplinary mathematics, is it expected from them to become experts, for example, in all of the four STEM (Science, Technology, Engineering, and Mathematics)-fields? This question was the starting point for our theoretical conceptualization of STEM from a teaching and educational perspective, which is also based on the existing debate in STEM-education. Borromeo Ferri and her colleagues (2016) distinguish between the single-field teaching approach and the cross-link field teaching approach. The first approach describes promoting a single discipline in school very deeply, like for example an engineering learning environment (e.g. English & King, 2015). The other disciplines are not fundamentally included within this environment. The second approach means to promote multiple disciplines; at least two disciplines are promoted in *one* learning environment in order to cross-link these disciplines (see Star et al., 2014 for an example). Within the empirical classroom study of the “Leonardo-da-Vinci Project” (Borromeo Ferri et al., 2016) mathematics, physics, engineering and art were explicitly included in one learning environment. Grade 9 students (14 year olds) built and modelled the Leonardo bridge in an Inquiry-based Learning environment. The main goal of the lesson-unit was the permanent reflection of cross-linking the disciplines. On the basis of the empirical data and theoretical thoughts “cross-link” could be characterized as follows: One can speak from cross-linking, if at least two (scientific) disciplines are combined during one lesson or within the whole lesson-unit and are reflected with students on a metacognitive level (Borromeo Ferri et al., 2016). Again, the main aspect of making several disciplines explicit is at the foreground. If the teacher decided to look at the Leonardo bridge from only a strong mathematical perspective by neglecting the other disciplines, it is also possible.

The students had the opportunity to understand and to model the bridge by also using and naming the other disciplines.

### ***Interdisciplinary activities and students' work***

A great number of research studies has focused on the development of activities and learning materials, following an interdisciplinary approach. In this paper, we focus on the development (and the characteristics) of learning activities that have adopted a modelling perspective (e.g. English & King, 2015; English & Mousoulides, 2015; Mousoulides, 2016). Such activities are set within authentic contexts, and allow for students' multiple interpretations. With regards to mathematics, such activities provide students with opportunities to be engaged in important mathematical processes, such as describing, analysing, constructing, and reasoning (Lesh & Doerr, 2003).

Research in the field listed six design principles for developing such learning activities, following a modelling perspective. These design principles are based on the work of teachers and researchers and that have subsequently been refined by Lesh and Doerr (2003). The 'Model Construction Principle' ensures that the solution requires the construction of an explicit description, explanation, procedure, or justified prediction for a given mathematically significant situation. The 'Reality Principle' requires that students can interpret the activity meaningfully from their different levels of mathematical ability and prior knowledge. The 'Self-Assessment Principle' ensures the inclusion of criteria that the students themselves can identify, and use to test and revise their ways of thinking. Specifically, the modelling activity should include information that students can use for assessing the usefulness of their solutions, for judging when and how their solutions need to be improved, and for knowing when they are finished. The 'Model Documentation Principle' ensures that while completing the modelling activity, the students are required to create some form of documentation that will reveal explicitly how they are thinking about the problem situation and their solutions. The fifth principle is the 'Construct Share-Ability and Re-Usability Principle', which requires students to produce share-able and re-usable solutions that can be used by others, beyond the immediate situation. The 'Effective Prototype Principle' ensures that the modelling activity is as simple as possible yet still mathematically significant. The goal is for students to develop solutions that will provide useful prototypes for interpreting other structurally similar situations.

By adopting the principles mentioned above, Mousoulides and colleagues (e.g. English & Mousoulides, 2015; Mousoulides, 2016; Williams et al., 2016) have developed a number of interdisciplinary modelling activities for students. These activities have been piloted and mainstream tested in various schools in a number of countries. Such an example, the '*How can I lose weight*' activity is presented in the monograph by Williams and colleagues (2016). The activity, which targeted 11-12 year olds, focused on the balance between nutrition and physical activity for a healthy life. The activity required students to actively participate in the collection, presentation and interpretation of data regarding their nutrition and exercise habits. Based on an analysis of their own data, students had opportunities to explore the variables (and their dependencies) that may affect the amount of energy intake on a daily basis (e.g. height, mass, age) and suggested specific diet and exercise plans, always taking into consideration the need of balancing the two.

The activity consisted of three parts. In the first part, the case of Mary, a 14-year-old girl who cannot fit into her favourite clothes, was presented. The students then considered the general question, "Is

not eating the best approach to losing weight?” Students, with teachers’ support, quickly realised that the question needed to be refined in order to be answered meaningfully. On refining the question in their own ways, students acknowledged that real (actual) data on nutrition, and also on physical activity are needed. Students were then encouraged (by teachers) to work with their parents to collect the required data, through an anonymously completed questionnaire. Using their own data, students worked in groups to summarise their results, by categorising data into the different food categories (e.g. protein, carbohydrates, dairy products, fruits, vegetables, sweets, etc.), and by discussing the advantages and disadvantages of each category (Reality Principle). Students also explored trends and relationships in their data, by using a spreadsheet software (Self-Assessment Principle). An example of their work is presented in Figure 1.

During the second part of the activity teachers guided a student-centred exploration for identifying the factors that determine a person’s daily calorie intake (age, gender, height and body mass). Students worked on analysing tables and graphs by using an applet software, designed to support the interdisciplinary activity.

**Figure 1: Student eating habits**

In the third part of the activity students worked on suggesting a balanced diet plan (for a single day), taking into consideration the daily amount of energy a person needs (Model Construction Principle). Students could use the provided ‘food database’ for creating the person’s diet for a day (Model Documentation Principle) and then explore the appropriateness of the diet with regards to the calories taken and the food categories (Figures 2 and 3). After completing the tasks and sharing their results in a whole class discussion, students then moved to the last part of the task, in which they designed their own balanced nutrition and physical activity case (Construct Share-Ability and Re-Usability Principle).

**Figure 2: Creating a person's diet**

**Figure 3: Examining the appropriateness of a diet in terms of calories and food quality**

The interdisciplinary nature of the activity focused on the role of the bridging concept (balance between calories intake and exercise) (Effective Prototype Principle). The quite complex activity setting provided opportunities for students to explore important concepts from mathematics and biology. The implementation of the activity revealed that both teachers and parents found the interdisciplinary nature of the activity challenging; for teachers, it provided a new way of thinking and working, while for students it provided a real world problem framework, in which they could explore and connect concepts from different, yet connected, school subjects.

## Theorizing the interplay between mathematical modelling and interdisciplinary mathematics education

When summarizing the presented theoretical analysis, it becomes clear that there are strong overlaps between mathematical modelling and IdME. The real context of modelling problems, like the case presented in the previous section, in fact evokes interdisciplinary activities, but the teacher is at first the person who should make them more explicit to students, and finally actively connect the different fields, through her/his teaching. Although in some ways mathematical modelling could serve as a prototype for interdisciplinary mathematics education, mathematical modelling has its own conditions. Theorizing the interplay between mathematical modelling and IdME is a challenge, which we like to think about furthermore and also find an appropriate visualization. At this point we argue that mathematical modelling has its own “theory(-ies)”, because the characterization of mathematical modelling, and further terms/ concepts/ processes like “problem understanding”, and “validation”, are part of the theory(-ies) of modelling. This can be seen as the theoretical part of

mathematical modelling, based on the theoretical and empirical research in this field in the past decades. It is rather difficult to separate mathematical modelling from IdME, because on one hand mathematical modelling as itself is (can be) a part of IdME, but also on the other hand we can view mathematical modelling as a comprehensive research field. By adopting this modelling oriented approach in the “nutrition-exercise” case study, students could work in finding/proposing a model for balancing the intake-consumption of calories. For instance, students could be asked to propose models for different people (e.g. peers, professional athletes, teachers, parents), which balance their daily diets and their exercise habits. In doing so, the emphasis of the activity would not be within mathematics or biology, but rather on modelling.

IdME can be situated in its own field, if the (interdisciplinary) task does not fulfil the criteria of the modelling problems, e.g. when you have some kind of a “word problem”. Not every interdisciplinary task, which has (some) mathematics in it, is a modelling problem per se. IdME can be done differently and cannot be connected with a modelling problem, so one can cross the disciplines of mathematics, and for example biology in a task, but only focusing on mathematics when dealing with the problem at last. This is what we mean with pure crossing disciplines. The interplay of modelling and IdME is clearly observed, when a real life question is embedded in a real modelling problem, in which students understand the context, recognise all the disciplines involved, and use or get to know about the extra-mathematical (other disciplines) knowledge. By adopting this perspective, in the Nutrition-Exercise case study students could work in solving a problem related to finding algebraic formulae for calculating the number of calories in various types of food and/or sport activities. In doing so, students have to work with both mathematical and scientific concepts, in solving the required problem, but the emphasis would be on the mathematical concepts or the biology ones (e.g. different types of food and relation to calories per gram, etc.).

There is a number of possible implications, especially for the teachers, in promoting both modelling competencies and IdME-competencies. By using modelling problems, teachers can work with their students in crossing the boundaries between disciplines. In doing so, interdisciplinary modelling activities can provide unique opportunities for teachers to collaborate, synthesize and integrate more interdisciplinary pedagogies and teaching methods in their teaching (Berlin, & White, 1995), and for students to develop better and more coherent solutions for complex, yet interesting and real world based problems. Such approaches raise teachers and students’ expectations and confidence in working in a more interdisciplinary way, and lessened their focus on the difficulties in using and working with interdisciplinary modelling activities.

# Mathematical modelling of dynamical systems and implementation at school

Martin Bracke and Jean-Marie Lantau

University of Kaiserslautern, Germany; {bracke} or {lantau}@mathematik.uni-kl.de

*Dynamical systems like a segway can be described by linear systems of ordinary differential equations of the form  $\dot{x} = Ax + Bu$ . Obviously, modelling of dynamical systems at school is a huge mathematical challenge for students and teachers. Therefore, in a pilot study with a math course consisting of 12 students of grade 12, it was analysed if, and up to which depth, modelling projects of dynamical systems (using the example of a segway) can be implemented at school. The interdisciplinary project was based on the modelling cycle of Blum and Leiss (2007). First of all, we describe the implementation and results of the pilot study. Then, we outline the design of a follow up study that will be carried out during school year 2016/2017. In this part we formulate our research questions, mainly the design of teacher training with a special focus on teachers' attitudes, which are driven by the findings from the pilot.*

*Keywords: Dynamical systems, interdisciplinary project, mathematical modelling.*

## Introduction

In a pilot project the modelling of dynamical systems at school (with a math course of twelve grade 12 students) was carried out by the example of a segway. The project was designed as an interdisciplinary project and started with the students independent modelling that lead to a physical description of acting forces of a segway. After a review on the appropriate linearisation of nonlinear terms, a linear time-invariant system for the segway was proposed. This introductory phase took five lessons. Next, we had three full project days where the students worked in groups of up to four students to concentrate on one of the several interdisciplinary aspects of the project. Namely they worked on 1. How to construct and control a segway and the basics of the Lego Mindstorms® EV3-brick, 2. How to simulate a segway by the help of suitable software and 3. The mathematical model of a segway, including finding of a mathematical solution for the theoretical stabilisation. The project was completed by a final presentation of the students for a mixed audience of teachers as well as university staff members. Obviously, the theoretical and practical issues are highly challenging for students and teachers and therefore the research issue of the pilot study was if an interdisciplinary modelling project of this complexity can be realised at school. The results of the pilot project were impressive, because the students managed to construct and control a Lego Mindstorms® segway as well as acquiring mathematical knowledge about systems of ordinary differential equations and their solutions and eigenvalues to assess the stability of solutions of a system of linear ordinary differential equations. Furthermore, they applied a theoretical and a practical control of a segway by using a proportional derivative control (PD-control). Based on the outstanding results of the pilot study, but with concern that the data set of 12 students is not representative for a quantitative analysis, the following main research questions are raised for a follow up study: Which form of modelling supervision (*open* = research-based, *fine-structured* = content-based, or *semi-structured* = connecting the two approaches) promotes the best development of mathematical competencies for the students during this kind of interdisciplinary projects? Secondly, it will be discussed how teacher training with respect to modelling projects for dynamical systems has to be designed. Altogether there will be a short introductory meeting at the beginning followed by a two-day teacher training focussing on possible implementations in class (with a focus on different aspects of the whole STEM project). The third part is going to be the implementation of the project by the teachers participating in our study. Accompanying the whole study, the attitude of teachers (regarding self-efficacy and prior experience) as well as self-assessment (regarding

opportunities and difficulties for themselves and their students towards interdisciplinary modelling projects of dynamical systems) will be evaluated by a series of pre and post surveys (and interviews). Furthermore, it will be researched, which competencies can be promoted through an interdisciplinary modelling project. The study shall be conducted with 10 to 15 math teachers and 100 to 150 students from grade 10 to 12.

## The pilot project

The pilot project (cf. Lantau, 2016) will be described in detail since due to the complexity this is necessary to understand the generation of our research questions as well as the design of the upcoming study.

### A short mathematical background of modelling a dynamical system, such as a Segway

The mathematical analysis of a dynamical system is based on the comprehension of system and control theory. A real dynamical object, in this case a segway, is at first described by physical equations to model the acting radial- and horizontal forces. After using suitable simplifications for nonlinear terms in the equations of forces (by using linear Taylor approximations) the physical model is transformed in a mathematical model by the introduction of variables like angle and position and their derivatives into a state-space vector  $x$ . Considering the force  $u$  of the regulating motor, after linearisation of nonlinear terms one can model a dynamical system by a linear time-invariant system  $\dot{x} = Ax + Bu$  of ordinary differential equations. In the case of a segway, the state-space vector  $x$  includes the variables angle, angular velocity, (horizontal) position and (horizontal) velocity. This linear time-invariant system can be shifted into a linear system of ordinary differential equations by feedback-regulation  $u = Fx$ , to get  $\dot{x} = (A + BF)x$ . Now, the theorem of Wonham (Sontag, 1985) yields that *if and only if the linear time-invariant system is controllable (which means that every possible state  $\tilde{x}$  can be reached due to a regulation of the motorforce  $u$ ; that holds true for the segway), for every real monic polynomial  $P$  there exists a matrix  $F$ , such that  $P$  is the characteristic polynomial of the matrix  $A + BF$* . Since the eigenvalues of the matrix  $A + BF$  are the roots of the polynomial  $P$ , the goal is now, to place all eigenvalues of the matrix  $A + BF$  into the open left half complex plane  $\mathbb{C}_-$ , such that the segway stabilizes itself to the rest position  $x = 0$ . Another approach to control a segway can be realised by a proportional-derivative control. The basic idea of a proportional-derivative control, e.g. for the control of the angle  $\varphi$ , is to choose the motor force  $u = -\alpha \cdot \varphi - \beta \cdot \dot{\varphi}$ , to stabilise the segway to its rest position. To implement this type of control, some conditions on the parameters  $\alpha$  and  $\beta$  have to be fulfilled.

### Realisation of the pilot project

The pilot study was inspired by the modelling cycle of Blum and Leiss (2007) consisting of the seven steps Constructing (1), Simplifying/Structuring (2), Mathematising (3), Working mathematically (4), Interpreting (5), Validating (6) and Exposing (7). In what follows, the seven steps of the modelling cycle will be connected to corresponding parts of the pilot study. During the project the teacher played different roles (research guide/advisor, leader of phases with questions and development) that will be explained in detail in what follows.

#### 1. Constructing:

The introduction into the project was given by means of a video showing the popular German entertainer Stefan Raab unsuccessfully trying to control a segway (URL: <https://www.youtube.com/watch?v=m3YBSQYGUw>). After this motivating start, the students were asked to create their own model of a segway. This task, carried out through a group work of four students per group, lasted 30 minutes and was done as an independent work. The construction of three fitting models for a segway has successfully been realised by the students (cf. Figure 1) who were experienced in modelling real-life situations, since many modelling tasks have been

established in this class. But in general it is not necessary to be experienced in mathematical modelling to participate in teachers trainings or as a student in the project.

**Figure 1: The independent modelling of a segway – Three different approaches**

## 2. Simplifying/Structuring

Figure 1 shows, that the students recognized that the description of acting forces is a necessary part to obtain a mathematical model of a segway. In the next step the three different approaches to model a segway were summarised in one model, to describe the acting forces of a segway.

**Figure 2: Model of a segway based on acting forces**

The part of simplifying and structuring was supported by a matching task, where the students should match acting forces, such as radial forces and horizontal forces, to equivalent terms. In the sequel the different forces were collected to describe the horizontal forces and the radial forces in two equations:

$$u = (M + m) \cdot \ddot{d} + m \cdot l \cdot \cos(\varphi) \cdot \ddot{\varphi} - m \cdot l \cdot \dot{\varphi}^2 \cdot \sin(\varphi) \quad (\text{horizontal forces})$$

$$0 = m \cdot l \cdot \ddot{\varphi} + m \cdot \cos(\varphi) \cdot \ddot{d} - m \cdot g \cdot \sin(\varphi) \quad (\text{radial forces})$$

At this point it has to be mentioned, that during the project three different approaches to model a segway were proposed to the students. The first one, presented in this paper, leads to a control of a segway using the variables *angle* and *position* of the segway as well as their derivatives. Another possibility to model a segway, is by modelling acting horizontal forces for the variables *position of the wheels and the centre of gravity* of the segway (and their derivatives). The third approach is to model the segway as an inverted pendulum by describing radial forces. This leads to a proportional-derivative control for the *angle* and the *angular velocity* of a segway. Due to the fact, that in the modelling approaches 2 and 3, only the variables position (of wheels and centre of gravity) and angle, respectively, are analysed, the number of physical terms to describe the segway is less in comparison to the first approach. However, it has to be clarified, that the physical comprehension of acting forces is essential to promote a mathematical model. And this motivates some deep mathematical concepts: (linear) ordinary differential equations and their solutions as well as a stability analysis through the concept of eigenvalues/-vectors.

## 3. Mathematising

The transfer from the physical model to a mathematical model is achieved by a linear Taylor-approximation around the rest position taking into account the nonlinear terms in the equations of

forces. The linearisation for the functions sine, cosine and quadratic function were discussed geometrically on the blackboard but the general concept of Taylor-approximation has not been introduced to the students. After linearisation, the two equations can be summarised into a linear time-invariant system introducing a so-called state-space vector. This phase of the project was designed by lessons with question and development. The introductory phase of the study preparing the three project days was concluded by the formulation of the linear time-invariant system that was jointly developed on the blackboard.

**Figure 3: Development of a linear time-invariant system on the blackboard**

#### 4. Working mathematically

To emphasize the interdisciplinary character of the project the three project days (each lasting from 8 am to 2 pm) started by the formation of three groups. The task of the first group was to construct a segway by using a Lego Mindstorms® set. Afterwards, the aim was to control the segway, specifically regulating the segway into the rest position, using the Lego Mindstorms® Software or using the Java-based software lejoEV3 – in each case with the help of a gyro-sensor. The students were highly experienced in working with Lego Mindstorms®, since they have managed several projects in the past, where the use of Lego Mindstorms® was necessary. For the second group four exercise sheets were designed in which the students were introduced to new mathematical concepts, namely: One-dimensional ordinary differential equations and their solutions, linear systems of ordinary differential equations, the matrix exponential function as a solution for linear systems of ordinary differential equations, stability theory for solutions of linear ordinary differential equations, eigenvalues in a non-geometric concept, proportional-derivative control and at last, feedback-regulation for linear time-invariant systems. The task of the third group was to carry out computer simulations according to the mathematical concepts worked on by the second group. To this end, a single exercise sheet including six tasks was designed to guide these students. All exercise sheets can be found as an appendix to the master's thesis of Lantau (2016). During the three project days the students worked nearly autonomously in class on their tasks and the teacher supervised the work of the different groups following the concept of minimal help.

#### 5. Interpreting and 6. Validating

The interpretation and validation of the mathematical model also took place during the three project days and was motivated by the interdisciplinary character in a very natural way. In particular, this can be seen in the application of the proportional-derivative control: While groups 2 and 3 used the inverted pendulum to model the segway in order to use the proportional-derivative control for the angle and angular velocity, the first group used the information about the theoretical restrictions for the proportional- and derivative parameters  $\alpha$  and  $\beta$  to practically stabilise the Lego segway for about 10 seconds. While two groups established a theoretical concept to model and control a dynamical system, including the development of fitting constraints for the control (*interpretation*), the third group used the results of the other groups to practically stabilise the segway (*validation*).

Considering steps 2, 5 and 6 of the modelling cycle, we observe that a successful modelling of dynamical systems, such as a segway, includes several disciplines like physical comprehension of acting forces, engineers' competencies to construct and control a Lego Mindstorms® segway, scientific programming for the control and finally, mathematical competencies to acquire a theoretical comprehension for the control of dynamical systems. The students also observed that several disciplines must be considered in a highly connected sense to promote the success of the modelling task.

### 7. Exposing

In order to collect and structure the theoretical and practical results of the project the students were asked to create a final presentation. This promoted the mathematical learning success in a holistic sense because the students who worked more practically on the project got a deeper insight into theoretical results through the explanations of their classmates and the connection of the theoretical results to practical results. The same also holds vice versa. During the creating of a final presentation the students needed to prepare their newly acquired knowledge properly to present it for a mixed audience of math teachers, students, schoolmates, parents and math professors. The exploration of the pilot study shows that the phase of presenting (*exposing*) the results of the modelling project promotes many mathematical competencies. Hence, in our view, this step is essential when modelling dynamical systems at school.

### Main results of the pilot study

Considering the project's realisation it can be observed that a modelling project of a dynamical system sets a high demand on physical-, engineering-, computer science- and mathematical competencies for both students and teachers. Therefore, the main question of the pilot study was if this kind of interdisciplinary projects can be realised at school. The pilot gives a positive answer, and it also shows that fundamental mathematical competencies, as proposed by the German Education Minister Conference (KMK, 2012), are highly promoted by the students during the project. Next, the six fundamental mathematical competencies are listed and connected to processes that promoted the corresponding competency during the interdisciplinary project.

1. *K1: to argue mathematically*: This competency was promoted at three different stages of the project. At first it was promoted during the discussion of linearisation for nonlinear terms, secondly during the development of stability criteria for linear systems of ordinary differential equations and thirdly during the discussion of constraints for the parameters of the PD-control.
2. *K2: to solve problems mathematically*: The research issue for the students was how a segway can be theoretically and practically stabilised. This problem has been solved practically by a PD-control based on the Lego Mindstorms® Software and theoretically, by learning the concepts of feedback- and PD-control.
3. *K3: to model mathematically*: The competency of creating mathematical models has been the centre of the pilot and was highly promoted. The students got the insight that mathematical modelling is very useful to solve real-life problems.
4. *K4: to use mathematical forms of representations*: By the preparation of a final presentation the students were requested to illustrate their main results in a mathematically correct way.
5. *K5: to work with technical, symbolic and formal elements of mathematics*: During the development of a linear time-invariant system as a model of a dynamical system the students used technical, formal and symbolic elements. This competency was also highly requested for the two groups that worked out the concepts of eigenvalues, PD-control, feedback-regulation and ODE-theory.
6. *K6: to communicate*: During their creation of a model for a segway and especially during preparation of the final presentation the students communicated frequently to discuss models, mathematical solutions and open questions. Furthermore, this competency was promoted through the final presentation itself.

Corresponding to the development of mathematical competencies during the project, the mathematical learning success of the students has been detected. To investigate the learning success a multiple-choice test was developed containing 10 questions regarding the mathematical concepts that are introduced during the project. The test has been carried out one week after the final presentation and was analysed by counting the correct answers of the content-related questions. More than half of the class reached at least 83 % of the maximum score and two students answered every question completely correct. This shows that the concept of ordinary differential equations, their solution and the stability of solutions, the concept of eigenvalues considering the stability of solutions for a linear system of ordinary differential equations, modelling a segway as a linear time-invariant system and controlling it by means of feedback-control or PD-control can be taught through an interdisciplinary modelling project. The concepts of eigenvalues (embedded in a geometric context of linear mappings and its characteristics) and (one-dimensional) ordinary differential equations and their solutions are part of the curricular standards in mathematic for secondary level in Rhineland-Palatinate (MBWWK, 2015). Both of them can not only be taught through an interdisciplinary modelling project, but also the connection between a classical algebraic concept (eigenvalues) and a concept of analysis (ordinary differential equations) can be established. But not only these two fundamental mathematical concepts for secondary level courses could be transmitted; even concepts that are usually taught in master degree courses for mathematics teachers can be included. From our point of view, the combination of promoted mathematical-, physical-, engineering-, and computer scientific competencies and a huge learning success in advanced mathematical concepts legitimates the implementation of interdisciplinary modelling projects in secondary level courses. Beside the description of the pilot project, the paper focuses on research issues concerning a follow-up study, explained in the next section.

## Research issues for a follow-up study

Regarding the results of the pilot study two main research questions are aimed to be analysed within the framework of *Grounded Theory*:

1. How shall teacher trainings for interdisciplinary modelling projects be designed?
2. Which competencies can students acquire, depending on the implementation and the type of supervision of an interdisciplinary modelling project?

As explained in Kaiser (2013) the most advanced approach of including mathematical modelling in school is by an interdisciplinary project which requires each discipline – in our case of modelling dynamical systems: physics, mathematics, engineering and computer science – to share its concepts and information in order to guarantee success of the modelling project. This task is very challenging for math teachers, considering the fact that some teachers neither have the specific mathematical knowledge to understand real problems (here: theory of dynamical systems) and its didactic transposition (Chevallard 1985) nor they are experts in other required fields like physics or computer science. Therefore, one aim is to design appropriate trainings that help teachers to convey the interdisciplinary character of modelling dynamical systems. In our example this includes the adequate physical-didactical preparation of detecting acting forces of a segway as well as an introduction to basic concepts for the control and programming of a Lego Mindstorms® segway. However, in order to promote mathematical competencies and a mathematical learning success, it is also necessary to design trainings for the inner mathematical concepts required by this project. For this purpose it is planned to design learning material for complex mathematical concepts like *stability theory for ordinary differential equations* as well as an *introduction to linear time-invariant systems and their control*. To this end the material designed for the pilot study will be analysed and modified based on the students' and teachers' comments.

During the follow-up study the attitude of teachers towards mathematical modelling of dynamical systems, represented by the example of a segway, will be explored and evaluated through a series of

surveys. The attitude of teachers will be measured by analysing three connected questions. Since the mathematical foundation of a dynamical system is located within the scope of *systems and control theory* and the project requires knowledge from several disciplines, one question is which inner and extra mathematical comprehension issues do maths teachers have or expect when they think of modelling a dynamical system. According to this question it will also be analysed how far the teachers are engaged to fill their content-related gaps. Additionally, teachers will be asked for possible implementations of each step of the modelling cycle in secondary level math courses. During the first teacher training (end of 2016) there will be pre and post surveys to answer these questions. Then, the results will be considered to prepare the second teacher training in spring 2017. Moreover, the teachers' expectations on possible obstacles will be assessed before, in between an after a series of trainings regarding the design and supervision of the modelling of a segway. Regarding these questions it is planned to design a survey, based on the theory of planned behaviour (Ajzen, 1991). The survey shall point out to what extend the teachers' attitude to modelling projects, their subjective norms and their perceived behavioural control influence their intention and, later on, the execution of their modelling project of dynamical systems. Additionally, teachers shall comment on the possibilities of developing each of the six mathematical competencies K1–K6 by modelling a dynamical system. Furthermore, they shall assess the potential learning success regarding the two fundamental mathematical concepts of *ordinary differential equations* and *eigenvalues/-vectors* that can be addressed by this modelling project. Finally, we want to analyse the correlation between the teachers' attitudes and the students learning success.

Beside the teacher focussed research, our second research question is *Which mathematical (physical, engineering- and computer scientific-) competencies of the students can be strengthened significantly through an interdisciplinary modelling project of dynamical systems.* It is planned to use video recordings to detect the enhancement of students' mathematical competencies during the project. The video material will be transcribed based on the work of Mayring (2015). To evaluate the enhancement of mathematical knowledge there will be pre-and posttests. Furthermore, the mathematical working techniques preferred by the students will be evaluated. For the analysis of the students' prerequisites surveys will be designed and it is planned to use video recordings to analyse the mathematical working techniques and to detect the phases of the project in which competencies of the students are promoted.

For the teacher trainings, options for different ways to conduct and supervise the project will be designed: The first approach is an open modelling process in which the initial problem of a segway to be stabilised is given to the students without further hints or work sheets. The main idea is to develop the students' independence in modelling activities including the competencies of „developing productive dispositions, flexible strategies, and foster student persistence and independent thinking” (Common Core State Initiative 2010; National Research Council, 2001 as cited in Doerr & Ärlebäck 2015, p.1). As described in the paper of Doerr and Ärlebäck (Brodie 2011; Lobato & Ellis, 2005; Magiera & Zawojewski, 2011 as cited in Doerr & Ärlebäck, 2015, p.1), this type of modelling challenges the teacher „to tackle classroom discussions, to structure group interactions and to provide effective feedback to students.” Regarding the task of modelling a segway we would like to find out how far students can model a segway independently in a way that develops mathematical techniques (e.g. PD-control) to solve the real problem. This question refers to the framework of Wake, Foster and Swan, who proposed that students' competencies of a simplification of the reality and the development of a mathematical structure that represents and simplifies the reality are under-emphasised in school mathematics (Wake et al. 2015, p. 8). Following the theory of Wake et al. it is also planned to create material that promotes a pre-structured and more teacher-controlled modelling of a dynamical system as an alternative. Our aim is to check which approach teachers prefer for their class and to analyse which competencies are

promoted in a modelling project depending on the conduction and supervision in one of the two specified ways.

## Introduction

Worldwide school mathematics curricula embrace the goal of ensuring the knowledge, skills, and competences that will enable individuals to understand today's highly mathematized and technological world and to allow them to critically and consciously engage in processes that involve mathematics and its applications. This strategic goal of mathematics education is clearly echoed by the rhetoric of international tests such as PISA and TIMSS. However, mathematical modeling is admittedly a demanding activity for students, not only because each step of the modeling cycle can become a potential blockage (Blum, 2015) but also because, for example, the focus for many students seems to be to arrive at a single solution instead of developing a suitable mathematical structure for a real world problem situation.

Recently, Blum (2015) has reaffirmed that the aims of teaching applications and modelling can be seen as having a dual function. On the one hand, the knowledge of mathematics and its use is vital to the real world and its progress, mainly in solving real problems and carrying out complex projects; on the other hand, the real world and the way it incorporates mathematical knowledge is extraordinarily important as a vehicle to provide meaning to the learning of mathematical concepts and generally to mathematics as a discipline.

Bonotto and Basso (2001) also discussed another dual nature: that of cultural artifacts, which besides belonging to the world of everyday life are also part of the world of symbols. If artifacts can be the basis for understanding the mathematical structures underlying reality, they can also be used for vertical mathematization, where the concepts embedded in real-world objects and processes become material for reflection and problem solving.

In this article we want to reflect on this duality of goals of modelling real situations and, in parallel, on the duality of roles that a particular type of task, here labeled as an experience-based task, can play in the application/understanding of the concept of direct proportionality. Experiential mathematics is a way of students dealing with living and practical knowledge of a problem or situation in the context of mathematical modeling at school. It intends to develop students' ability to collect and interpret data in addressing real world situations as well as the ability to develop mathematical thinking and communication, while reporting their ideas and findings to others. The experiential mathematics puts

the real situation as an integral part of the students' work, allowing them to understand how it works in reality and how they can "handle" it mathematically (Palm, 2008, 2009; Vos, 2011, Galbraith, 2006).

## **Theoretical perspective**

### **Authenticity of a modelling situation**

The question of the authenticity of the examples proposed for the implementation of mathematical modeling has been dissected by several researchers and gains particular emphasis on educational environments informed by a socio-critical view of mathematical modeling. For example, Rosa and Orey (2016) advocate the use of ethno-modeling as a tool for teaching purposes where rather than distorting the cultural and ethnic reality, the aim is to help students learn how to find and work on authentic situations and real-life problems emerging from cultural and historical artifacts, embracing mathematical ideas, thoughts and practices as developed by cultures across time and space. In any case, the perspective of the actors who actually participate in the actual settings has long been emphasized by Niss (1992), in pointing out that genuine problems, issues and situations must be recognized as such by the people who actually work in them. Despite such concerns, there is still considerable lack of authenticity in many situations that school mathematics presents to the students, which often end up just mimicking real-world scenarios, prioritizing educational goals and curriculum alignment over facing the ill-defined reality of many problems (Vos, 2011; Palm 2008, 2009; Eames, Brady & Lesh, 2015).

Blum (2015) explicitly notices that the motivating or the marketing role often attributed to mathematical modeling tasks in textbooks and curriculum materials results in the creation of problems that are only a disguise of a real situation. But other authors have strongly criticized the pseudo authenticity of modeling problems, particularly in the PISA tests. This does not invalidate the accepted notion that an out-of-school scenario cannot match completely a proposed scenario in a school mathematics assignment. And that seems to be even more unquestionable when it comes to formulating problems in assessment tests.

A school task can, of course, never completely simulate an out-of-school task situation. Nevertheless, sometimes the school situation can be organized and the assignment formulated in such a way that many of the aspects of a real life task situation may be simulated fairly well following that the students' task solving can take place under conditions fairly close to those in the simulated situation. Other times, for example in largescale high stakes testing, the conditions under which the task solving takes place put severe restrictions on the possibilities to simulate many of the aspects with high fidelity (Palm, 2008, p. 40).

According to Palm (2008), students have been predominantly faced with unrealistic mathematical tasks and have given in many cases unrealistic answers to them. At the same time, it is not totally obvious to what extent the realism of the tasks would produce greater caution and attention from students to the realism of their answers. Furthermore, Palm notes that there is a lack of consensus in the mathematics education community on the concept of realism of a task in terms of adjustment between a school assignment and a real life situation. And the evidence of that may be found in the variety of different terms for tasks that somehow try to emulate real situations (authentic tasks,

realistic tasks, real life tasks), together with the many different meanings that have been attached to each of them.

Vos (2011, 2015) has been systematically addressing the issue of authenticity and suggesting criteria that allow us to judge the more or less authentic trend of a task. Her first concern is the use of the term authentic tasks because the educational environment will require adaptations in the same way as with a flight simulator: the criteria of the *effectiveness* of the learning environment and the *realism* of the proposed situations should therefore prevail. The leading proposal is that the concept of authenticity of a task is first and foremost a social construct, so never universally definable. Therefore, a task may have some authentic aspects but it may also have others that are deliberately introduced and designed to respond to educational purposes. In short, it must be acknowledged that not all aspects of a task need to be authentic while accepting that the tasks are more engaging if a number of issues that have their origins in the situation are respected.

Once put into perspective the question of authenticity of modeling tasks, the consequent challenge concerns the search for principles to guide the construction of interesting modeling tasks, that are both effective and intellectually honest (Blum, 2015; Galbraith, 2006; Palm, 2009). To a great extent the challenge is to convert a fruitful idea rooted in a real-world situation in a problem that is fairly well framed by the details of the situation and that is accessible to a resolution that also respects the authentic school mathematics (Vos, 2011).

There are at present some proposed formulations of basic principles to inform the authentic character of modeling tasks in school mathematics. Here we will consider the work of Palm (2009), Galbraith (2006) and Vos (2015).

Palm (2009) considers a number of variables: Event; Question; Information; Presentation; Solution Strategies; Circumstances; Solution Requirements; and Purpose. Galbraith (2006) proposes a number of principles: Link to the real world; Tractable question; Feasible solution process; Existing knowledge; Evaluation available; Structure. Vos (2015) offers a set of criteria within a pragmatic definition of authenticity where the purposes and methods of the modelling researchers and task designers converge: authentic aspects in the field of mathematics (symbols, research questions, research experience) and authentic non-mathematical aspects (apparatus, professionals, mathematics applicability, problem settings).

In this study, we will concentrate on the aspects which directly relate to experiencing the real-world situation and developing a mathematical solution. We will thus select the following parameters: the *event* and the *question*, the *link to the real world*, the *apparatus* and the *problem setting*.

### **Experiential learning**

The use of cultural artefacts and, in particular, objects that are part of children and adults' everyday experience is suggested by Bonotto and Basso (2001) as a strategy to make connections between the mathematics involved in real-world situations and the mathematics that is targeted in the classroom. They found that for students to bring mathematics into reality, it is helpful to introduce mathematical facts that are embedded and encoded in artefacts. According to their reports, in carrying out mathematical experiences from the interpretation of artefacts, the students make the transition from the real world to the world of symbols (horizontal mathematization) but in addition the use of artefacts also give them the opportunity to advance the construction of mathematical concepts (vertical

mathematization). The artefacts (concrete materials) may also be used as tools for the application of previous knowledge in new contexts and for consolidating the existing mathematical knowledge, pushing it to a higher level (Bonotto & Basso, 2001).

Bonotto (2007) advocates the need for change if we want to create realistic situations in mathematical modeling activities, i.e., recommends less stereotypical and more realistic situations, namely with the use of concrete materials; those are relevant to the students as part of their life experience, offering meaningful references related to concrete situations.

Other theorists also argue that fundamental knowledge and skills may be more easily accessible if students are directly involved in practical and experimental activities, as those can promote not only the perception of the usefulness of the materials in question but also a better understanding of the concepts explored. The discovery learning and the learning in practice are ideas inherent to the experiential education model. The model of learning by doing, developed by Kolb (1984), consists of a four-process cycle. The four processes are: experience (perform an activity); reflect (ask questions and talk about what happened in the experiment, analyzing possible inconsistencies between the observed and the predicted); abstract (generate a new idea or modify a previous idea); and apply (use what was learned in a similar or different situation, which can in turn create the need for new experiences). Experimental activities lead students to interact, analyze, question, reflect and transfer. The activity comes first; learning comes from the thoughts and ideas that arise as a result of the process of learning by doing. Accordingly, the drive for the development of new concepts is provided by new experiences. “Learning is the process whereby knowledge is created through the transformation of experience” (Kolb, 1984, p. 38). “Learning by doing” therefore appears as a natural learning perspective if modeling is seen as an activity that is similar to the methods in the experimental sciences or to the applied mathematics research.

The perspective of experimental modeling environments described by Halverscheid (2008) focuses on activities supported by experiments that give the opportunity to build mathematical models and produce mathematical knowledge around the questions investigated during experimentation. The role of experience is to lead the search for a suitable mathematical model that can explain the real data and results. The practical experience, as advocated by the author, becomes the rest of the world inside the classroom or school laboratory. The models are therefore produced to explain and interpret that intended authentic world.

Our theoretical approach, intends to combine the matter of authenticity with the idea of experimental modeling environments. We therefore consider that the authenticity of the school modelling task requires a clear account of an *event* that takes place in an out-of-school situation and the formulation of a *question* that is relevant and pertinent in that real world. But we add that the search for a solution entails a *link to the real world* that is made by an experimental *apparatus*, and a *problem setting* which is experientially emulated in the classroom.

## **Methodological approach**

This study adopts a qualitative methodology of action research as the pillar of the methodological approach is a teaching experiment on the implementation of a new pedagogical approach involving modeling and applications in mathematics classes (Loughran, 2007; Latorre, 2003). The pedagogical motives of the teaching experiment corresponded to the need of providing meaning and practical

sense to mathematics, to contribute to change the negative view that many students held about mathematics, and to develop their appreciation for mathematics in their daily lives.

Two classes of 9th graders participated in this study. The ages of the students ranged between 14 and 17 years old, with an average of 14 years old. They were usually collaborative and committed students. Most of the lower achievers worked hard to improve their performance but showed many difficulties in applying mathematical concepts and in problem solving. None of the students had come across modeling activities in previous school years.

The modelling activities included 4 sections. The first is the introduction to the topic under study. The second consists of a practical activity, using manipulatives and everyday objects. The third comprises the analysis of the data obtained in the experimental stage, with the purpose of creating a model that might be used in similar situations. Finally, a written report should entail the following points: explanation of the experimental situation, assumptions made, strategies used, results, evaluation of the work and the difficulties found.

To solve the tasks students worked in groups of three or four elements organized at their will. The time allocated to each task was between 90 minutes (1 lesson) and 180 minutes (2 lessons). During the activities, the students had the opportunity to move around the room and discussing with colleagues the ideas from another group.

The data collection included participant observation and field notes from the teacher. The classes were recorded on video and audio with a mobile camera and the activity of a target group was also recorded on video and audio with a still camera. For each activity, a target group was randomly chosen. The written reports delivered by all the groups at the end of each activity were also collected. Here we will focus on the activity and work of a single group of four students. We will consider in particular what they developed in the experimentation phase and on the model proposed.

The task involved color dispensing and mixing paint solutions. It aimed to simulate the procedure used in industrial machinery called tintometric systems. In a tintometric system once the white base has been dispensed the container automatically positions itself under the volumetric tinting system, which dispenses all the coloring pastes and then mix them. The task was presented as follows:

*Introduction.* An indoor and outdoor paint shop uses a mixing paint machine in which it is only necessary to place the can with the neutral paint and introduce the code of the chosen color in the catalog. But a problem arose in the machine and it partially crashed. It no longer dispenses the required pigments, it can only mix them. Now the shop assistants must manually place the pigments to obtain the color chosen by the client. This means a new problem. They do not have information about the quantities of pigment to be used for each color of the catalog. So, your mission is to create a palette of colors and provide the amount of pigments to be used for each color.

*Practical activity.* You have at your disposal white liquid (milk) and colored liquid pigments (food coloring), a gauge and 1 ml syringes. Your mission is to produce a color palette that involves two primary colors and a reference table with the precise amounts to be used by the assistants.

*Analysis.* Choose two primary colors and prepare a palette of colors with various shades and make a table with the amounts of pigments for tins of 1L, 5L, 10L and 20L.

*Report.* Record all your procedures and results and submit your final report.

## A case of proportional reasoning

The process held with the experimental apparatus was the same in most of the groups. It was clear that the students knew the idea of a paint catalog and knew that colors are labeled with names. Therefore, in general, they were creating a sequence of shades and were making labels for each shade. They used a small amount of pigment at a time and always added that amount to the previous mixture. At the beginning they only had milk (equivalent to the neutral paint) and then added color by the addition of two pigments. Throughout the experiments all groups recorded the values in the tables and subsequently calculated the amounts of pigment for different paint tins. Some of the groups did not present a formula to generate any amount of paint (unknown value) and only made the calculation of the amounts necessary to make the quantities asked in the problem.

The target group used yellow and green pigments. In their report the group described how they created a palette of four shades:

Using the syringe we started with 0.1 mL of yellow pigment in the cup with milk (60 mL) and this color was **Vanilla**. Then we added another 0.2 mL of yellow pigment to the glass that already had 0.1 mL of yellow and the color was **Cream**. After we added another 0.2 mL of yellow pigment and 0.1 mL of blue pigment to the glass which already had some amount of pigment and the color was **Mint**. Lastly we added to the glass another 0.4 mL of yellow pigment and another 0.5 mL of blue pigment and the color was **Amazon Green**. Now, using the results of our table, we will determine the amount of pigment to be used with 1L, 2L, 5L and 10L of paint. To obtain those values, we use the rule of three. For the case of Vanilla we get:

$$\begin{array}{rcl} 60 & \text{-----} & 1000 \\ 0.1 & \text{-----} & x \end{array} \quad x = \frac{1000 \times 0.1}{60} = 1.(6) \text{ mL}$$

To complete our description of the results of the group we note that they created a table for each tin size and the four shades, showing the quantities of *paint*, yellow pigment and blue pigment. For the Amazon Green, the table indicated: 20000 mL of paint, 300 mL of yellow, and 200 mL of blue.

## Discussion and conclusion

In this teaching episode and from the empirical data presented we want to emphasize that the students apparently attributed significant authenticity to the task, namely: to the *event* of producing a color catalog of paint; to the *question* of finding the quantities of pigments for manual mixing; to the *link with the real situation*, that is, helping the assistant to retrieve the quantities of pigments for each shade; and to the use of the experimental *apparatus* which was essential for the ongoing mathematization and emulated the real process.

However it seems that some aspect of authenticity has lacked. At a certain point the mathematical model is clearly formulated by the students and it shows their awareness of the fact that there is direct proportionality between the quantities of white paint in the experimental model and in the real sized tin, as well as direct proportionality between the quantities of a pigment in the model and in the real sized tin. That is obviously a sound conclusion. However, they went on assuming that the amount of white paint in the real tin was equal to the capacity of the tin, which is equivalent to say that the tin would be completely full with white paint and thus with no capacity available for an additional amount of color paste.

We are suggesting that the missing aspect of the modelling situation concerns the authenticity of the *problem setting*. The students had actually visited a paint supplying store in the neighborhood and could learn about a machine used to automatically dispense and mix the paints and produce the desired color. But one detail is relevant on the machine operation: it begins by asking the operator the size of the tin and then retrieves the amounts of neutral and of colored pastes. The total of the mixture has to be equal to that volume (or slightly below). Instead, the setting in which they worked was a scenario involving much lower quantities than the actual tins. Therefore, no absolute urge for correctness of the calculations was at stake, as Vos (2011) points out. Indeed, the initial volume of milk was little and imperceptibly changed by adding small doses of pigments. In other words, there was almost no distinction between the volume of white and the volume of the mixture in the glass of the experiment (Figure 1). But that is no longer valid when we want to produce a can of 20 liters of Amazon Green color. In this case, the value obtained for the combined quantities of yellow and blue pigments was 500 mL and that would be a quantity which, if added to the neutral paint, greatly exceeds the capacity of the tin.

**Figure 1: Two shades and not distinguishable volumes**

Surely, other factors can be considered as responsible for the inaccurate mathematisation carried out. One of them refers to the difficulty students have with the notion of ratio, which is well documented in research. In fact, the rule of three was a ready strategy for students. And the ratio was never really considered. In any case, what happened is that students did not differentiate the amount of colored paint from the amount of white paint, as it is evident from their table that shows 20000 mL of “paint” instead of “white paint”. Still, that value was the correspondent to the 60 mL of milk in their rule of three. In conclusion, the concept of ratio was never activated and instead proportionality was used as a process of enlarging the “size” of each ingredient in the mixture (enlarge a small cup to a large tin). Therefore, questions of authenticity that are recognized by those who work with them in practice (Niss, 1992) seemed to have been absent from the process of translation between students’ real model of the mixture produced in the classroom and the actual process of paint production.

# Examining the role of group work as an effective instructional strategy when teaching problem solving

Eamonn Clohessy and Patrick Johnson

University of Limerick, School of Education, Ireland; [eamonc1@hotmail.com](mailto:eamonc1@hotmail.com);  
[patrick.johnson@ul.ie](mailto:patrick.johnson@ul.ie)

*This paper reports on a post-primary classroom intervention conducted to investigate the effect that carrying out problem solving in small groups as an instructional strategy has on the problem-solving performance of individual students. Over the course of the 6-week intervention students were introduced to an explicit problem-solving framework and challenged to solve weekly problems both in small mixed-ability groups and also individually during their traditional mathematics classes. It was found that there was a strong correlation between the problem-solving performance of the small groups and that of the individual students which suggests that group work could be utilised as an effective instructional strategy when teaching problem solving.*

**Keywords:** *Group activities, problem solving, secondary school students, secondary school mathematics.*

## Introduction

In 2008 in Ireland there was a change in the mathematics syllabus in secondary education in response to a number of studies and publications (e.g. Conway & Sloane, 2005). All of these studies identified that there were major deficiencies in the mathematical competency of students in secondary education and those commencing third level education. These concerns, along with others, fuelled the introduction of a new secondary mathematics syllabus in Ireland in 2008 named *Project Maths*. Project Maths identified five key skills that they saw as being central to effective teaching and learning across the new curriculum - *information processing, being personally effective, communicating, critical and creative thinking and working with others* (DES, 2015).

This new secondary mathematics curriculum also places an increased emphasis on group work and the development of problem solving skills within the classroom. This syllabus change should lead to an increase in the amount of group work occurring within Irish classrooms, but this begs the question as to how effective group work actually is? Can we measure what effect group work will have on the individual student, particularly when dealing with activities such as problem solving?

In terms of problem solving it has long been accepted that increasing the problem solving skill set of students is one of the primary goals of mathematical instruction (Travers, 1977). In the early nineties in America, the National Council of Teachers of Mathematics (NCTM) set out the goals for promoting problem solving as a curricular focus by declaring it as one of the three main goals of mathematical instruction in a second level school (Szetela & Nicol, 1992). In Ireland this focus on problem solving has only taken place in recent years due to the change in the syllabus brought about by the new Project Maths course. Many research papers focus on the individual problem solver but others have focused on the idea of problem solving in small groups (Artzt & Armour-Thomas, 1992). In addition to the obvious benefits of improving the problem solving skills of the students research highlights the additional benefits that working in small groups yields e.g. developing personal and social skills (McGlenn, 1991), enhancing self-esteem (Slavin, 1991) and reducing the dependency of

the students on the teacher (Sandberg, 1990). In light of these benefits and the emphasis that the new syllabus places on working with others and problem solving, this current research project decided to examine whether working in small groups to complete mathematics problems would improve the general problem solving ability, and overall mathematical ability, of individual students. This research aimed to address this hypothesis by answering the following questions:

1. Is there a relationship between an individual student's problem solving achievement scores and their achievement scores when solving problems as part of a group?
2. Do students believe that working in small groups to solve problems is beneficial in the development of their individual problem solving ability or overall mathematical ability?

## Framework for problem solving

With the increased emphasis placed on problem solving in the new syllabus, and the relative newness and unfamiliarity of both teachers and students with problem solving, it was deemed necessary to provide students with guidelines to assist them during their initial problem solving exploits. The instructional framework selected by the authors to assist in the problem solving activities in the classroom was developed by Artzt & Armour-Thomas (1992) and was specifically tailored for problem solving in small groups. This framework was based on an earlier framework developed by Schoenfeld in 1985 but expanded and added additional episodes. Schoenfeld (1985, p. 292) defined an episode as “a period of time during which an individual or a problem-solving group is engaged in one large task”. Artzt & Armour-Thomas (1992) finally settled on eight episodes when looking at problem solving in small groups – *read, understand, analyse, plan, explore, implement, verify, and watch and listen*.

## Methodology

### Participants

34 students from a medium sized rural secondary school in the west of Ireland participated in the research project. 22 of the students (12 male and 10 female) were from a mixed ability first year class (average age 13 years) whereas the remaining 12 students (7 males and 5 females) were from an ordinary level<sup>1</sup> third year class (average age 15 years). The first year cohort only had two classes per week with their teacher as part of this intervention whereas the third year group had four classes per week with their teacher over the course of the six week intervention. A typical mathematics class lasts for 40 minutes.

### Selection of content and questions

The selection of content for this study was primarily based on the Project Maths Junior Cycle<sup>2</sup> syllabus. The topic covered by the first year students during the six week intervention was ‘area and perimeter’, whereas the third year students covered the topics of ‘circles and cylinders’ and ‘area, perimeter, and volume’. Note that the third year cohort covered more material due to the extra contact

---

<sup>1</sup> After first year all classes in Irish secondary schools are streamed into two groups, Ordinary and Higher, with higher being the more challenging stream.

<sup>2</sup> The Junior Cycle caters for students aged from 12 to 15 years and covers the first 3 years of post-primary education.

time with their teacher during the intervention. An example of a question given to the first year students whilst working in groups is provided here:

*The first rectangle has a perimeter of 30 units and an area of 50 square units. The second rectangle has a perimeter of 24 units and an area of 20 square units. Charlie wondered if he could find a rectangle, with a side of length 10 units, whose perimeter and area have the same numerical value.*

Each week during the intervention the students were challenged to solve some combination of either purely mathematical or worded problems based on the previous week's mathematical content. Verschaffel, Greer, and De Corte (2000) use the term 'word problem' to refer to any mathematical task where significant background information on the problem is presented as text rather than in mathematical notation and this is also the meaning that the authors have adopted as part of this study. Problems were selected from past examination papers, books and online websites and were deemed appropriate for the age and ability levels of the students.

### **Intervention and assessment**

The intervention took place in the students' traditional 40 minute classes over a period of six weeks. Normal teaching operations took place during the intervention with approximately 10 minutes of certain classes being assigned to the testing of the students' problem solving abilities. In the first week of the intervention the students were given an individual assessment to gauge their initial problem solving skills prior to working in groups to solve problems. During the following five weeks students were regularly placed in small mixed ability groups of 3 or 4 and asked to solve 4 problems together during that week. At the end of each week students were asked to individually solve 2 problems so that their individual progress could be monitored. Individual students and all the members of a group were awarded a single correct mark if the problem was answered correctly and awarded no mark if they failed to correctly solve the problem. A focus group with 6 students randomly selected from both the first and third year groups was conducted following the intervention.

### **The role of the teacher during the intervention**

Throughout the intervention the primary role of the teacher was that of a facilitator or a time-keeper. The teacher answered any questions that the students had with regards to the use of the problem solving framework or specific questions such as issues regarding units of measurements (i.e. is  $cm^3$  associated with volume). When asked a question related to the solving of the problem the teacher declined to answer directly and instead used probing questions to try and guide the students towards a solution. The frequency of questions directed at the teacher lessened after the initial weeks of the study as students began to rely on the other members of their group for assessing their ideas and potential solution strategies and not the teacher. Fewer questions were directed at the teacher during

the individual problem solving sessions as the students viewed these more as ‘tests’ and therefore assumed that they were not supposed to ask questions of the teacher.

## Findings

### First-year students

Looking at the assessment trend among the individual students it can be seen from Figure 1 that over the course of the intervention there was an upward trend in the number of questions answered correctly. The pre-test resulted in only 5 correct answers (11.36%) out of the possible 44 (22 students times 2 problems). This number of correct answers increased to 16 (36.36%) in week 1, 28 (63.63%) in week 2, 30 (68.18%) in week 3, 31 (70.45%) in week 4, and finally 38 (86.38%) in week 5. From Figure 1 it is clear that there is an almost linear increase in the number of correct responses between the pre-test and the week 2 assessment but this increase is then followed by 2 weeks of a much slower advancement by the students before increasing more significantly in the final week.

**Figure 1: Individual assessment scores for first year students**

In terms of the group assessment, Figure 2, there was evidence of a positive increase in the number of correct group responses as the weeks progressed. Out of a total score of 24 (6 groups times 4 problems) possible correct responses each week 8 groups (33.33%) answered the problems correctly in the first week. This increased to 17 (70.83%) in week 2, remained at 17 for week 3, increased marginally to 18 (75%) in week 4 and increased again to 19 (79.16%) in week 5.

**Figure 2: Group assessment scores for first year students**

Comparing the number of correct individual solutions against the number of correct group solutions each week it was found that there was a strong correlation between the number of correct answers among individual students and among the groups ( $r = 0.95$ ). This suggests that as the first year students became more efficient at solving problems within groups so too did they become more efficient at solving problems individually.

### Third-year students

Similar trends are noticeable among the third year group in both the individual and group problem solving assessments, although the scale of the improvement is not as significant as with the first year students. The pre-test of the individual students problem solving ability resulted in 2 (8.33%) correct responses out of a possible 24 (12 students times 2 problems). At the end of week 1 the number of correct responses had decreased to 1 (4.16%) before increasing to 14 (58.33%) at the end of week 2, 15 (62.5%) at the end of week 3, 22 (91.66%) in week 4 and then dropping slightly again to 19 (79.16%) in week 5 as seen in Figure 3.

**Figure 3: Individual assessment scores for third year students**

In terms of the number of correct responses from the groups of third year students there appears to be less fluctuation in the results. Out of a total score of 12 (3 groups times 4 problems) 4 groups (33.33%) answered the problems correctly in the first week. This increased to 6 (50%) in week 2, 7 (58.33%) in week 3, 10 (83.33%) in week 4 and 11 (91.66%) in week 5 as seen in Figure 4.

**Figure 4: Group assessment scores for third year students**

Comparing the number of correct individual solutions against the number of correct group solutions each week for the third year class again found that there was a strong correlation between the number of correct answers by individuals and among the groups ( $r = 0.889$ ).

The second research questions focused on whether the students felt that working in small groups to solve problems had been beneficial in enhancing their individual problem solving skills or their overall mathematical skills. Overall the students were positive in their responses to the focus group question relating to whether they felt that their individual problem solving abilities had improved as a consequence of the intervention.

Interviewer: Do you feel that your problem solving ability has improved? Why do you think this?

Student4: I think it has because I have been finding it easier to figure out my homework, so I think it has.

Most students responded in a similar manner although two of the group did confuse the question slightly and make reference to working in groups.

Student2: Ah, yes because I now know that I can ask others for help and use their opinions to build on to get my answer.

As already alluded to by some of the students in the previous question, all of the students responded that they found working in small groups enjoyable and some even stated that it increased their confidence in the mathematics classroom. Worryingly some of the students appeared to suggest that this type of active is not common place in their traditional classroom which is in opposition to the overall aims of the new syllabus.

Interviewer: How did you find working in groups as part of your mathematics class?

Student1: I enjoyed doing maths more because I got a fair share of trying to work it out and it wasn't as boring as a normal maths class. I felt like my opinion mattered which is different to other classes. I found it weird that the teacher encouraged us to talk while in class, usually they are trying to keep us quiet.

Student5: I feel more confident because maths seems a bit more fun when you can talk to your friends. Also it improved my ability to say I could do things when I thought I couldn't. I now try a different way of answering the question if I get stuck when I try it the first time around.

When asked about whether working in groups was beneficial in helping them solve the problems all the students agreed.

Student5: Am, yes because it helps it go faster and if you're stuck you'd have another person's opinion to help work it out. It was really fun working with your friends in class like that.

The final question focused on whether or not the students felt that, as a result of their participation in the intervention, their overall mathematical knowledge had improved. The responses to this question were positive, but varied. Some students focused on the idea of being able to approach questions differently now because they were able to ask other students their opinions and then solve the problem

themselves, based on the insight from the other student. Another student spoke about being able to analyse the ideas of the other members of their group and how it forced them to look at the problems from different perspectives.

Interviewer: Have the classes improved your overall mathematical knowledge? In what ways?

Student2: I think that I have new ways of solving problems. Before the group work, I used to look at the question and if I couldn't understand I used to leave it because I didn't know what to do. Now I would ask someone else if they could do it and see if I could use their idea to answer it.

Student3: I found it improved my knowledge because I think I had to think more about the question.

Interviewer: What do you mean by 'think more'?

Student3: Am, well because if someone in the group had a different opinion, I would try to see where they got that idea from and try and see if that would work. I also tried to see if it was the same as my idea but said in a different way.

## Conclusion and discussion

The primary aim of this study was to investigate whether problem solving in small groups had any effect on a student's problem solving achievement when working on their own. Solving problems in small groups affords students the opportunities to ask questions, challenge assumptions, discuss opinions and share work among colleagues. The results of this study found that there was a strong positive correlation between the weekly number of correct responses to the problems solving tasks in small groups and the problems solved by individual students in both of the student groups. This would suggest that working in small groups to solve problems has had a positive impact on the individual problem solving skills of the students. Reading too much into this results could be misleading though as the unfamiliarity of the students with problem solving, or problem solving approaches, meant that the improvement in overall problem solving skills shown by the students could be a consequence of being introduced to a problem solving framework rather than from working in small groups, or some combination of both.

This been said, all of the students commented positively when asked about whether they felt that working in small groups had been beneficial to them. The students highlighted how they liked the ability to talk to this classmates and discuss the problem which was not something that was common in their previous mathematics classes. This seems to contradict the aims of Project Maths which stresses the importance of developing the key skills of *communicating* and *working with others* (DES, 2015). In line with the finding of Slavin (1991) students commented positively about several qualities which they felt that working in groups had helped to develop, such as feeling like this opinions mattered and feeling more confident towards mathematics. Additionally Sandberg (1990) found results that coincide with the findings of this study in that students are willing to persevere when faced with a problem that they cannot solve straight away and overall become less dependent on the teacher. These are all key skills that need to be developed in students and this would suggest that the teaching of a problem solving framework in conjunction with working in small groups to solve problems appears to be an effective instructional strategy.

Finally it is worth noting that the students did highlight some issues with the intervention in its current form. Two students commented that they felt that there wasn't enough time allocated to the group work activities at the end of the classes and that they always felt rushed. Another two students commented that in one instance one student in their group had taken over the activity and proceeded to solve the problem by themselves without consulting or involving the other members of the group. Obviously there are limitations to every study but going forward it is important that more focus be placed on the roles and monitoring of individual students within the groups.

# Modelling problems in German grammar school leaving examinations (Abitur) – Theory and practice

Gilbert Greefrath<sup>1</sup>, Hans-Stefan Siller<sup>2</sup>, Matthias Ludwig<sup>3</sup>

<sup>1</sup>University of Muenster, <sup>2</sup>University of Wuerzburg, <sup>3</sup>University of Frankfurt

[greefrath@uni-muenster.de](mailto:greefrath@uni-muenster.de); [siller@dmuw.de](mailto:siller@dmuw.de); [ludwig@math.uni-frankfurt.de](mailto:ludwig@math.uni-frankfurt.de)

*Examples of mathematical problems in German school leaving examinations are examined in detail as to the extent to which they verify the competence of mathematical modelling. For this purpose, the relevance, the authenticity of the context, the openness of the task and the partial competencies as criteria are examined in more detail. It is shown that authentic contexts but no relevant contexts are contained in the problems. As a rule, the use of mathematics is not authentic and problems are not open. The partial competencies in modelling are quite unequally divided and are not covered completely. It is recommended to use all the criteria for the design of future examination questions.*

*Key words: Modelling, examinations, Abitur, authenticity.*

## Introduction

In Germany, an overall policy of the Conference of Education Ministers has been in place with respect to “Educational Monitoring” since 2006. The intent is to enhance competence orientation within the educational system. In mathematics, the focus also lies on the general competence in the field of modelling. From the year 2017 onwards, a task pool of Abitur examinations will be available out of which all Federal States can take problems for Abitur examinations. This is an important step towards improving the quality of examination problems and to align levels of requirements between the Federal States step by step. Such examination problems have been developed on the basis of educational standards and also contain, in particular, elements examining mathematical modelling. Studies regarding problems in written Abitur examinations are rare. Still today, it is obvious that there are very few theoretically and methodically profound and empirically substantiated approaches in respect of examination problems in the framework of the written Abitur examinations, which at times just focus on individual standard-related aspects (Kühn, 2016, p. 75). Therefore, this applies in particular to problems regarding mathematical modelling. At the core of mathematical modelling lie the translation of a problem from reality into mathematics, the work with mathematical methods and the application of mathematical solutions to the real problem. Usually, the entire modelling process is represented as a cycle. Idealisation here means that the representation itself is, again, a model. In Borromeo Ferri et al. (2006) the creation of a mathematical model is contemplated in detail, representing the process of the individual, creating the model, from the starting situation to the mental representation as a first step.

## Modelling competence

Blum et al. (2007) describe modelling competence as the capacity to execute the relevant process steps required when switching between reality and mathematical problem adequately as well as to analyse models or comparatively evaluate such models. This can be discussed in more detail on the basis of modelling cycles by Blum and Leiss (2005, p. 19). Thus, it is possible to analyse the various partial processes of modelling activities considering various details and other aspects. It is

also possible to consider the capacity to implement such a partial process as a *partial competence* of modelling (Kaiser, 2007; Maaß, 2004). In consideration of the modelling cycle one could characterise such partial competences as shown by Greefrath and Vorhölter (2016, p. 19). We do not mention inner-mathematical working between the mathematical model and the mathematical results as a partial modelling competence since this is not specific for modelling processes.

## Characteristics of modelling problems

It is not always easy to select or develop the right modelling task. As an indication, characteristics may be specified that a modelling task should fulfil. In her comprehensive classification scheme for modelling problems, Maaß (2010) focuses in particular on the type of relation to reality, to the openness and the modelling activity as criteria for modelling problems. With respect to the focus on the modelling activity, partial competences of modelling will be observed more closely. As regards the relation to reality, the relevance and authenticity of the context will be examined more closely (cf. Greefrath et al. 2013).

### Relevance

Initially, we deal with the classification of reality-related problems handed down in German discussions. In connection with the factual context of problems, we traditionally talk about “*embedded problems*“, *problems formulated in text form* and “*factual issues*“. These types of problems provide facts about the relevance of the factual context used for students.

*Embedded problems* have no real relation to reality. The factual context is of no importance regarding the solution of problems and can be exchanged arbitrarily. The intention of embedded problems is the application and practice of numeracy skills. An embedded task as a modelling task is suitable only to a limited extent since the mathematical model is already implicitly contained in the problem. *Word problems* are problems formulated in text form – sometimes complemented by figures. Similar to the embedded problems, the issue is basically exchangeable as reality is often represented in a very simplified manner. The intention is to promote mathematical skills. It is not really about an autonomous development of a mathematical model because of the lack of reality and the given simplifications. Nevertheless, one major problem for students is the translation of the text into the corresponding mathematical symbolism such as terms or equations. For this reason, the known term “mathematisation“ in the field of modelling is normally used in this context (Schütte, 1994, p. 79). In the case of problems formulated in text form the mathematical problem dominates the embedding of it. Another focus then lies - depending on the specific problem - on the interpretation of the mathematical results in the factual situation and in the wording of a corresponding answer. The substantial and - particularly in connection with factual problems - frequently exclusive treatment of problems formulated in text form in mathematics classes has been strongly criticised. One reason is the lack of genuine reference to reality. Another reason is the process of practising similar mathematical issues, formulated in text form, as a result of which a real reflection about the context used becomes redundant. In the case of *factual issues* a factual environmental problem is of primary importance. In this context, the function of “Factual Calculation“ is described by Winter (2003) as “Environmental Development“. In this context, real data are frequently given in respect to which authentic questions are then asked. Since the processed issue plays a real role, information about the respective matters must be gathered and processed.

Therefore, the processing of factual issues is also to be considered as interdisciplinary or - ideally - even as discipline-linking. In this context, the factual issues can be viewed as modelling problems (Franke & Ruwisch, 2010).

### **Authenticity**

Authenticity is one central characteristic of modelling problems. Authenticity means both the authenticity of the extra-mathematical context and of the application of mathematics in this particular situation. The extra-mathematical context must be real and not be specially designed for a certain arithmetical problem. The application of mathematics in this situation must also be reasonable and realistic and should not just be used in mathematics lessons. Authentic modelling problems are problems that genuinely belong to an existing subject or problem area where they are accepted by people working in those areas (Niss, 1992). Thus, an authentic task becomes credible and at the same time a realistic task for students from an environmental point of view. Authenticity helps students take problems seriously and avoid superficial substitute processing strategies as in the case of embedded problems (Palm, 2007). In the case of authentic problems, students can assume that the things they are dealing with really exist and that the task they are presented with is a real task that finds its justification outside mathematics lessons as well (the task have an out-of-school origin and a certification (Vos, 2015)). Authenticity of problems helps students take such problems seriously. However, authenticity of problems does not mean that the problems are actually important for the students' present or future lives.

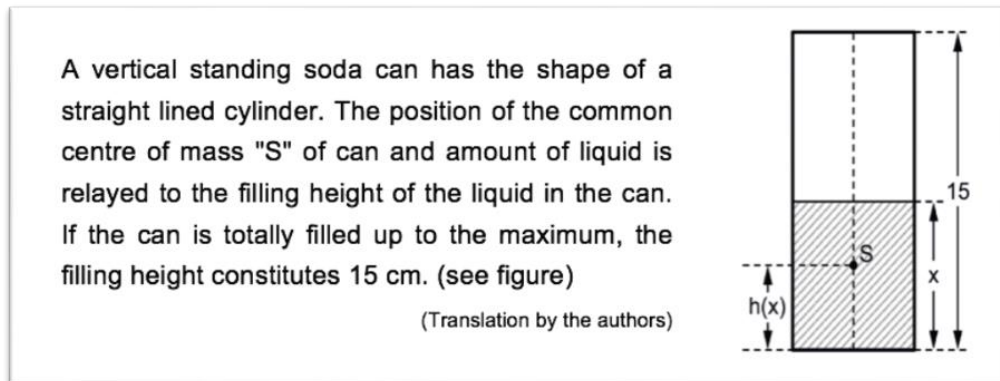

### **Openness**

Open problems are those problems that - for instance - allow for more than one approach or solution. Openness enables students to choose their own approaches or solutions regarding the problems. There are various classifications of open problems. We limit ourselves here to the examination of openness by initial state, transformation and target state (cf. e.g. Wiegand & Blum 1999). Said classifications use the known problem-solving psychological description of a problem through its initial state, target state and a transformation that transfers the initial state into the target state and are not limited to modelling problems (Klix, 1971). Open problems are divided by the clarity of their initial and target statuses as well as by transformation. Maaß (2010) suggests another classification of open modelling problems based on Bruder (2003) which includes seven different types and which distinguishes between overdetermined and underdetermined problems.

### **Criticism concerning Abitur examination problems with modelling elements**

The use of modelling in examination problems, however, is not unreservedly viewed positively. The fact that in many cases the relevance of the factual context used is not at the focus of examination problems, gave rise to (fundamental) criticism on the part of some expert representatives with regard to modelling in examinations. On the one hand, the criticism is directed against the fact that "modelling competence" is not at all examined by the problems (Kühnel 2015, p. 76). On the other hand other authors show the categorical refusal of modelling problems (cf. Bandelt & Weidl, 2015, p. 4). Strong criticism is also directed against the greater part of texts in examination problems (cf. (Jahnke et al. 2014, p. 120): "Instead of dealing with mathematical problems, A-level students have to tackle wording problems".

Criticism regarding examination problems can be absolutely justified, in particular if it is about embedded problems and not about factual problems in examinations (cf. Fig. 1). Henn and Müller (2013, p. 205) comment: “Unfortunately, most of the so-called “modelling problems“ at school - and in particular in the Abitur exam are not at all modellings according to our way of thinking. Almost always one starts out from a more or less complex function equation, allegedly describing a ski jump, a tower, a playground or another construction. Now, with this function, a common functional examination is to be made. However, the whole thing is not a modelling task, but entirely a mathematical problem.”

**Figure 1: Stimulus text of an examination task (www.iqb.hu-berlin.de)**

This brief insight shows that the use of the term “modelling problem“ - in particular in examinations - does not at all guarantee the clear characterisation of a certain type of problem. It should be considered, however, that the conditions given in examination or in normal lesson situations are different from each other (cf. Siller et al., 2016, p. 381/382). Ultimately, in examination situations the focus is on the term of “measuring“ the students’ performance as outlined by Siller et al. (2016, p. 384). Thus, less attention may be paid to a creative phase in a test situation. In addition, psychometric findings (cf. Rost, 2004) reveal that - for the measurement of performance - such performance must be addressed explicitly and structured into small units in order to obtain a valid statement.

## Research issue

Against the background of criticism directed towards current Abitur examination tasks and in consideration of the importance of competence of mathematical modelling for German levels of education and of international discussions as well as of the theoretically clarified criteria for modelling problems, we have to ask ourselves the question, how to evaluate the quality of existing Abitur examination problems with modelling elements in Germany. We limit ourselves here to the calculus subject area, which accounts for the largest part of the Abitur examination in mathematics in Germany. With regard to the criteria discussed above, the question is: How can German Abitur examination problems in calculus be assessed with regard to the partial competences of modelling, to relevance, to authenticity and to openness?

## Research method

For preparing for the pool of Abitur examination problems which will be available from the year 2017 and from which all Federal States can easily draw Abitur examination problems, the Institute for Educational Quality Improvement in Berlin will provide a collection of examples (cf.

[www.iqb.hu-berlin.de/bista/abi](http://www.iqb.hu-berlin.de/bista/abi)). Such samples were chosen as a basis for the examination because they best fit with the Abitur examination problems of 2017. Among the sample problems there is a total of four examination problems for calculus for general grammar schools. Two of the problems are of an increased level and a further two are intended to be used in Computer-Algebra-Systems (CAS). All in all, the four examination problems include 50 items.

.... b) Initially the empty can gets filled up slowly with liquid until the maximum filling height of 15 cm is reached. Describe the movement of the center of mass „S“ during the filling cycle. Constitute schematic the can, filling height and center of mass at that point the center of mass is conditioned to the minimal height and describe the characteristic of this situation and describe the feature of this situation.

(Translation by the authors)

**Figure 2: Part b) of an examination task ([www.iqb.hu-berlin.de](http://www.iqb.hu-berlin.de))**

Problems were evaluated by items according to different criteria. The selection of criteria follows the frequently quoted central characteristics of modelling problems (cf. Bruder 1988, Greefrath & Vorhölter 2016, p. 17, Maaß 2004, p. 22). Problems were discussed and evaluated per item and on the basis of Tab. 1 in the framework of a qualitative research process including three evaluators. Finally, all items could clearly be allocated the corresponding characteristics (cf. Bortz & Döring 2006) – by using 0 (does not match – e.g. Relevance 0 in Fig. 2) or 1 (matches the criteria – e.g. Authenticity in Fig. 2). In this way, a detailed compilation of the examined items was created and an allocation to the aforementioned criteria became possible.

Reference to reality	Does the problem refer to an extra-mathematical factual context?
Relevance	Is the factual context relevant to the students (factual problem)?
Authenticity	Is the factual context authentically related to the actual situation?
Authenticity	Is the factual context authentic with regard to the use of mathematics?
Openness	Is there more than one possibility to solve the problem (solution variety)?
Partial competences of modelling	Which partial competences of modelling are required for dealing with the problem (simplifying / structuring, mathematising, interpreting, validating)?

**Table 1: Criteria used for the Assessment of Items**

## Results

In an initial assessment of the existing data material, we focus on the criteria reference to reality, authenticity, openness, relevance and modelling competence. Due to the small data basis, it was not possible to make valid quantitative statements. However, certain trends are visible. 20 items out of a total of 50 contain a reference to real life situations. The problems, though, included in the basic level more items with reference to reality (52 %) vs. items without reference to reality than in the higher level group (31 %). Correspondingly, on average, problems with the use of CAS contain more items with reference to reality (46 %) than in the group without the use of CAS (33 %).

*Authenticity:* If one looks at the problems considering the requirement that the respective items should contain realistic situations, our analysis reveals that such items appear both at the increased

level and at the level where CAS are used. More than one half of the items with reference to reality also contain realistic situation at both levels. Regarding a realistic use of mathematics which from our point of view represents a further aspect of authenticity (cf. table 1), this has been identified in just three items. Students were required to explain in the factual context of a parabolic modelled trajectory that only certain parameter values are possible. It should be noted here that quadratic functions are used even by experts for modelling trajectories.

*Openness and Relevance:* Open problems have not been identified in the items examined. Also with respect to the relevance of the problem, no item can be identified in the present examination problems that would fulfil this requirement.

*Modelling competences:* The analysis concerning the partial modelling competences show that the items normally address one of the partial competences. However, the partial problems are not designed in such a way that the sequence of an idealised modelling cycle reflects the appearance of the partial competences of simplifying, mathematising, interpreting and validating one after the other. Most items focus on mathematising, followed by required interpretations. Simplifying or structuring or the validation within one item is not required by the current examination problems. One item requires both mathematising and interpreting. This item requires the determination of an intersection point on the basis of a model given by a function equation with an unknown parameter with self-determined conditions interpreted in the framework of the factual context.

## Discussion

Generally, it can be said that around 40% of the items examined include reference to reality. However, this does not mean that such items also contain modelling problems. The application of common criteria for modelling problems shows that we can talk about modelling problems only to a limited extent. Not a few items include an authentic factual situation, but a realistic use of mathematics is given just in exceptional cases. None of the problems is open or relevant. This is why criticism towards Abitur examination problems must be taken seriously if one must conclude – as already concluded by Henn and Müller (2013).

It is comprehensible that in individual items only a partial modelling competence is dealt with due to the examination situation or to performance measurement, respectively. This can also be observed essentially in respect to the problems examined. It would be desirable though, that all partial competences of modelling were contained in a test problem and that this problem was tested in the typical sequence as in the modelling cycle. This is not the case with regard to the problems examined. There are even partial competences, which are not tested at all, such as simplification.

Numerous general conditions must be observed when preparing examination problems. In order to actually test the modelling competence, it is necessary not just to use problems with reference to reality which describe an authentic situation only partially and to test just a few competences of partial modelling competencies, but to start with an intensive and criteria-led development of modelling problems for an examination on the basis of the current educational standards.

In order to improve the competency modeling and the development of modelling problems for examinations, the criteria used here should also be used for the development of examination problems and for training problem developers. In order to increase the share of suitable modellings

in examinations, it seems that a substantially greater proportion of reality-related problems or a substantially targeted development of suitable items is needed.

# The investigation of mathematical problem-solving processes of fifth grade students in small groups

Firdevs İclal Karatas, Öznur Soyak and Ayşenur Alp

Middle East Technical University, Faculty of Education, Ankara, Turkey;

[iclal.karatas@metu.edu.tr](mailto:iclal.karatas@metu.edu.tr); [osoyak@metu.edu.tr](mailto:osoyak@metu.edu.tr); [alp.aysenur@gmail.com](mailto:alp.aysenur@gmail.com)

*The purpose of the study is to investigate mathematical non-routine problem solving processes of students in small groups. The study was conducted with nine fifth grade students in three small groups. A framework developed by Artzt and Armour-Thomas (1992) for protocol analysis of problem solving in mathematics is used for this study to determine problem-solving behaviors observed within different episodes of problem solving. The findings revealed that although the understanding episode was coded as the greatest percentage, the analyzing episode was coded as the lowest percentage within the three groups.*

**Keywords:** Problem-solving process, small groups, fifth grade students.

## Introduction

Problem solving has become an integral part of learning mathematics since it helps students to understand mathematical contents. It also leads students to understand how to apply their knowledge into their daily lives when solving problems. The NCTM (2000) also emphasizes the mathematical problem solving activities from pre-kindergarten to grade 12 in all mathematics classrooms. Moreover, problem solving is strongly emphasized in recent Turkish elementary mathematics curriculum. It is considered as a basic skill that should be developed in each content area (MoNE, 2005). Besides, students should be able to develop their own strategies and apply them to solve their real-life problems when solving problems (MoNE, 2005).

Moreover, problem solving entails engaging in a task for which the solution process is not identified beforehand (NCTM, 2000). Mayer (1992) defines problem solving as a cognitive process in which one figures out how to solve a problem of which the solution is not already known. Most definitions of problem solving emphasize problems that require problem solvers to use information and procedures in unfamiliar ways. Problem solving is an extremely complicated human endeavor. It is considerably more than the implementation of well-learned procedures or the simple recall of facts. Problem solving involves the construction of sequential procedures that build strategies in addition to the application of the structure (Hammouri, 2003). Problem solving also entails arranging several cognitive and metacognitive processes, deciding and performing suitable methods, and regulating behavior for varying demands of problems (Montague, 1991).

A variety of models are proposed that describe the processes that problem solvers use from the beginning until they finish their tasks (Garofalo & Lester, 1985; Mayer, 2002; Montague & Applegate, 1993; Polya, 1957). For example, Polya's model comprises of four stages; namely, "understand the problem, make a plan, carry out the plan, and look backwards" (Polya, 1957). Later, Garofalo and Lester (1985) revised the model proposed by Polya and include cognitive and metacognitive components. Their model is described in four stages as orientation, organization, execution, and verification. Montague and Applegate (1993) presented a model focused on seven

cognitive processes “reading, paraphrasing, visualizing, hypothesizing, estimating, computing, and checking” and three metacognitive processes “self-instruction, self-questioning, and self-monitoring”. Mayer (2003) proposed another cognitive process model that included translating, integrating, planning, and executing processes. In particular, Artzt and Armour-Thomas (1992) developed a framework to examine the problem-solving processes of individuals as they work in small groups.

Furthermore, non-routine problems are problems where how to solve the problem is not obvious immediately, or they have not been encountered before in the curriculum. Non-routine problems require critical thinking and an extension of prior knowledge that may include concepts and techniques which will be explicitly taught at a later stage, and may include finding connections among mathematical concepts (Schoenfeld et al., 1999). The findings of this study support that challenging problems are likely to enable metacognitive process so that students consciously adjust and regulate their cognitive processes (Montague & Applegate, 1993).

All over the world the importance of exploring elementary school students’ problem solving abilities is highlighted. There are some international examinations such as Program for International Student Assessment (PISA) and National Assessment of Education Progress (NAEP) to determine the performance on non-routine problems and in problem solving. In the 2012 version, students’ PISA ranking scores in problem solving show that Turkey is among one of the worst in the world (42<sup>nd</sup> out of 65 countries, 2012 PISA). Therefore, researchers need to find out why this is so. As a country students’ problem solving abilities can be improved if how students think, and their awareness of their actions while solving non-routine problems are determined. In addition, exploring cognitive and metacognitive abilities is difficult in problem solving. Especially, elementary school students may not be aware of what, and why, they are doing. As a result, the purpose of this study is to investigate problem solving processes of fifth grade students when they solve non-routine mathematical problems.

### **Significance of the study and research question**

Many research studies and projects have pointed out the importance of learning problem solving in school mathematics courses (Higgins, 1997; NCTM, 2000; Verschaffel et al., 1999). One of the major goals of mathematics education is the acquisition of the skill of learning how to solve problems. However, there are conflicting views about the attainability of these goals (Verschaffel et al., 1999). Despite long years of instruction many research studies show that children are insufficient and not confident in having the aptitudes required for approaching mathematical problems in a successful way (Higgins, 1997; Doorman et al., 2007). The reasons for these deficiencies, particularly in elementary students, can be attributed to two factors. The first of them is the lack of specific domain knowledge and skills (concepts, formulas, algorithms, problem solving). The second factor is shortcomings in the heuristic, metacognitive and affective aspects of mathematical competence. When confronted with unfamiliar complex problem situations, students mostly do not spontaneously apply heuristic strategies such as drawing a suitable schema or making a table. They usually only glance at the problem and try to decide what calculations to perform with the numbers. In addition to this, many students have inadequate beliefs and attitudes towards mathematics itself, learning mathematics, and problem solving. These beliefs exert a strong negative influence on their willingness to engage in a mathematical problem. Some examples of such beliefs and attitudes are

that there is only one correct way to solve a problem; that a mathematical problem has only one right answer; and that ordinary students cannot solve problems which requires higher order thinking. These insufficiencies in students' beliefs are related to the nature of the problems given in the lessons and the classroom culture. Hence, problem solving activities should give opportunities to students for investigation, reasoning and deciding on the solution process and improve their problem-solving skills. Small groups in problem solving may provide natural setting for interpersonal monitoring and regulating of students' goal directed behaviors. In this study, the problem-solving processes that occur as individuals engage in mathematical problem solving in small-group settings are examined.

The findings of the study may contribute the studies on the process of fifth grade students' thinking. The determination of these students' thought processes will helps teachers to design and adjust problem solving instruction and better support the development of students. The findings of this study may be applicable for developing teaching methods and materials to enable the development of fifth grade students' problem solving skills in future non-routine problem solving classrooms. In addition, this study can be significant for the design of curriculum in that the results support the design of educational or special programs that can be more effective and supportive of elementary students. Thus, the research question of the study could be stated as follows:

Which are the most dominant problem solving processes of fifth grade students when solving non-routine problems?

## **Theoretical framework**

It is necessary to appraise the information about problem solving processes to develop a framework that can explain how students figure out mathematical problems. Mathematics educators and psychologists have suggested various problem solving process models. Polya (1957) proposed four phases called "*heuristics*" to understand problem solving processes. The phases are known as "understanding the problem, devising a plan, carrying out the plan and looking back". Polya also proposes several strategies that can be used when students solve problems. His strategies include using diagrams, looking for patterns, trying special cases, working backward, intelligent guessing and checking, creating an equivalent problem and creating a simpler problem. Considering the problem-solving processes, an appropriate strategy can be essential to reach the solution of the problem.

After that, Schoenfeld (1982) developed a model for mathematical problem solving based on the Polya's model. The model includes five episodes; namely, "reading, analysis, exploration, planning/implementation and verification". Adding cognitive and metacognitive aspects of problem solving to Polya's and Schoenfeld's model, Garofalo and Lester (1985) proposed a framework with orientation, organization, execution and verification phases. Montague and Applegate (1993) also proposed cognitive-metacognitive aspects of mathematical problem solving. This model focused on seven cognitive processes "reading, paraphrasing, visualizing, hypothesizing, estimating, computing, and checking" and three metacognitive processes "self-instruction, self-questioning, and self-monitoring". These various models have been used to investigate problem solving processes, but only two models by Garofalo and Lester's model as well as Montague and Applegate's model have been used with gifted students as a framework to describe problem solving processes in the literature (Garofalo, 1993; Montague, 1991; Montague & Applegate, 1993; Sriraman, 2003). Several metacognitive actions during problem solving were described in each phase of those models by

cognitive theorists, in mathematical problem solving. To examine the problem-solving behaviors and cognitive processes of individuals as they work in small groups, Artzt and Armour-Thomas (1992) developed a framework based on Schoenfeld's (1982) framework. Schoenfeld (1985) defined an episode as "a period of time during which an individual or a problem-solving group is engaged in one large task" (p.292). The framework for the protocol analysis of problem solving in mathematics is used for this study to differentiate between cognitive and metacognitive problem-solving behaviors observed within the eight episodes (read, understand, analyze, plan, explore, implement, verify, and watch and listen) of problem solving. The framework synthesizes the problem-solving phases identified in mathematical research by Garofalo and Lester, Polya and Schoenfeld, and of cognitive and metacognitive levels of problem solving behaviors studied within cognitive psychology, in particular, by Flavell (1981). This framework used in this study is to examine the interactions between two levels of cognitive processes (cognitive and metacognitive) observed in the problem-solving behaviors of students working in small groups on mathematics problems.

## Methodology

This project consists of qualitative research in which case studies are employed. A qualitative design is appropriate for this study because the study focuses on gaining in-depth information about what actually occurs during the problem-solving process. The study conducted with nine fifth-grade students in a private school in the capital of Turkey. Purposeful sampling was used to select the participants as the researcher wanted to obtain more knowledgeable information about the problem-solving processes within the groups. Voluntary participants were involved in the study. The students who have high self-expression skills were selected by two mathematics teachers.

This study used multiple methods including a think aloud procedure when the students are engaged in solving problems, researcher's field notes of observation, and analysis of students' solution papers to collect data. Prior to the data collection, the participants practiced the think aloud technique with a sample problem. The procedure provides participants with important practice for understanding and developing confidence prior to utilizing the technique with the research problems. Over the one day 3-hours period of data collection, three mathematical problems which were selected from PISA problem solving sample questions (going to the cinema, transportations system and holiday) from decision making units (OECD, 2005), were given to participants to solve in small groups by using think aloud method. All three students in small groups had their own paper and problem sheet to follow the process. They continuously spoke aloud while they work on the problems explaining their thoughts. Also, they had unlimited time to solve each problem. Since misinterpretations of the data might have resulted with only a single researcher as the data collector, the researcher maintains a record of field notes explaining her reflections about the activities. The field notes included the explanations of questions, reactions, and behaviors that occurred during data collection.

In the study, group members were chosen from different classes, and they had never studied together before. Data collection was in a one-to-one setting between the participants and the researcher to have some field notes. One researcher observed exactly one group and took field notes. The researcher videotaped all the processes to record the participants' behaviors, how they responded to the problems, and what mathematical language they used. All data from the think aloud session, participants' solution papers, and researchers' field notes were transcribed for analysis by the

researchers. To generate the categories, the researchers read through all transcribed data sentence-by-sentence and identify words or phrases that described the participants' responses. For example, in group 1, student 1 says for cinema question: "First we will read the question then we will discuss". This sentence is coded as *Read*. Again in group 1, student 1 says for cinema question: "Until now, what did you understand?" and student1 suggests: "Let's underline the important sentences" These two sentences are coded as *Understand*. Also, student 2 says: "They cannot go to that film because it is for above 18 years old". This sentence is coded as *Analyze*. For the second question, student 1 says: "Let's try the other way" and coded as *Explore*. Student 2 says: "They cannot go to Children in Deep, Carnaval and Pokemon" coded as *Implement*. Student 2 says: "Let's look at it carefully. They can all go to Mystery. Let's check" coded as *Verify*.

After each interview is transcribed, participants check the accuracy of the described experiences and themes. Then, the codes were applied based on a review of the data and the concepts emerging from the data. The responses of one student were compared with those of other students in the same problem, as well as the same student across other problems. Multiple data sources were used to triangulate and confirm patterns that emerged. Each response was compared with other responses with the same idea, regarding the source of the responses. The codes were grouped into categories. At this point, preliminary categories were developed. Responses were compared across categories in terms of similarities and differences. Next, the researchers revised categories with transcribed data again and again until the final categories are confirmed. The final categories were also reviewed against the transcribed data for the last time.

## Findings

The coding for each of the three groups was done and the behavior of each group was categorized by episode. As it was suggested by the study, the three groups' episodes or problem solving behaviors were recorded and ranged. The audio records of the groups were coded in 1-min intervals based on the emergent behaviors through sentence-by-sentence and identify words or phrases that described the participants' responses. Groups were differentiated from one to another by giving numbers such as Group 1, Group 2 and Group 3.

Table 1 lists the number and percentage of behaviors across all groups, of the 519 behaviors that were coded, 25% belonged to Group 1, 21.65% belonged to Group 2 and 53.4% were demonstrated by Group 3.

According to the results students in Group 1, out of 130 items (sentences, phrases, words), show "understanding" behavior (e.g. Student 1 says: "Stanley cannot come to the cinema on Sunday also he cannot watch Pokemon" which represents rephrasing the questions in different ways) 44 times, 33.8%, which is the most frequent behavior observed, "exploring" behavior 25 times, 19.2% which is the second most frequent behavior observed and "implementing" behavior, 22 times, 16.9% which is the third most frequent behavior. As it was mentioned, the greatest percentage of existing behaviors was in understanding followed by exploring.

For Group 2, out of 112 items, students show "understanding" behavior 53 times, 47.3%, which is the most frequent behavior observed, "exploring" behavior 19 times, 16.9%, and "implementing" behavior, 15 times, 13.3%, which is the third most frequent behavior observed.

For Group 3, out of 178 items, students show “understanding” behavior 75 times, 42.1%, which is the most frequent behavior again, “exploring” behavior 27 times, 15.1%, which is the second most frequent behavior observed and “planning” behavior 19 times, 10.7%, which is the third most frequent behavior observed among the other behaviors. Differently from Group 1 and Group 2, this group shows more “planning” behavior than other groups.

**Table 1: Percent distribution of behavior categories (episodes) by problem solving group**

Behavior Category	Groups					
	Group 1		Group 2		Group 3	
Read	12	(9.2%)	6	(5.3%)	17	(9.5%)
Understand	44	(33.8%)	53	(47.3%)	75	(42.1%)
Analyze	1	(0.7%)	2	(1.7%)	1	(0.6%)
Explore	25	(19.2%)	19	(16.9%)	27	(15.1%)
Plan	7	(5.3%)	9	(8.0%)	19	(10.7%)
Implement	22	(16.9%)	15	(13.3%)	15	(8.4%)
Verify	11	(8.4%)	4	(3.5%)	10	(5.6%)
Watch & Listen	8	(6.1%)	4	(3.5%)	14	(7.8%)

Of all the episodes coded, the understanding episode was the coded as the greatest percentage within three groups while analyzing behavior was very rare. Among 419 items, 172 items represent “understanding” episode, 71 items represent “exploring” episode, 52 items represent “implementing” episode. The percentages of each episode are given in Figure 1.

**Figure 1: The percentage of the problem-solving behaviors for each episode in all groups**

## Discussion

According to Artzt and Armour-Thomas (1992) the greatest percentage of time was exploring (60.4%). In contrast to their study, we found that understanding was the most frequent observed behavior (33.1%). Watching and listening can play an important role in addressing the issue of communication between group individuals. These low and high percentages of watching and listening behaviors may be as a result of different reasons. For example, in Group 1, one student interrupted the other two students and also this student was writing the majority of the solution. The records and observations indicated that in each group some students assumed a leadership role. Therefore, it was possible that this kind of act would discourage the other two students in the group. However, during the problem-solving procedures, some productive interactions occurred while Student 1 (in Group 2) was not only supporting and guiding others but also got benefits from group members' ideas. These

results are in agreement with Artzt and Armour-Thomas' (1992) findings which showed different patterns interactions between group members and show the significance of intergroup relations for active and productive contribution.

The framework contributed the observation of individuals while working in small group settings. As it can be realized from the records and observations, group composition affected the group life. As group members were chosen from different classes, it is interesting to note that in all three groups students reflected a pragmatic desire in order to achieve the common goal by working together productively. With the exception of one student in Group 3, the small group study enabled researchers to observe peer to peer communication in a small group environment.

'Understanding' was the behavior that was coded the greatest percentage by students in this study. It would be expected that after this phase, students could decompose the problem into basic components and examine the relations between given elements and common goals at the analysis level, and then explore the problem by guessing and testing. In our study, understanding led group members to the exploration without making visible analysis.

*We report on the experience gathered in a study using a geometric modelling approach based on dynamic geometry systems complemented by physical modelling. Our strategy intends to strengthen the interconnections between the current trends in Science, Technology, Engineering, Art and Mathematics Education. To help students to better understand how certain physical mechanisms work, some da Vinci machine prototypes were reconstructed and used as a starting point for this study. Building upon previous experience, our work currently concentrates on the analysis of connecting physical and digital resources and on how they contribute to students' creative thinking and problem-solving. We discuss the concept of geometric modelling, focusing on spatial thinking, joints and their movements. Further, we present some new manipulatives that are being tested together with digital applets and discussions from this practice.*

*Keywords: geometric modelling, GeoGebra, problem solving, creative thinking.*

## Introduction

Geometric modelling has been used in a wide range of contexts, but continues to deserve more attention in mathematics education. The term “geometric modelling” usually refers to different digital techniques for representing specific objects or surfaces. This concept seems to be associated mostly with computer-aided design, the tasks of which are usually related to shape and to improving models in order to approximate real structures by means of sophisticated algorithms and software. This work intends to bring geometric modelling, supported by dynamic geometry systems (DGSs) and combined with physical resources, to the classroom. While an analogue model provides “hands-on experience” to students so they can comprehend certain mechanical movements (and their restrictions), a digital model forces them to develop suitable strategies for transcribing such actions. Students must therefore think about how to apply mathematical concepts properly in order to use them successfully in their digital models. In our case, creating a digital representation is not only a mathematical exercise, but also an opportunity for the students to refine and review their comprehension processes and to improve their physical models. In this modelling approach, students are faced with problem-solving in Science, Technology, Engineering, Art and Mathematics (STEAM) contexts.

Modelling is characterized as the branch of mathematics that deals with the translation of a real-world situation into mathematical language. In publications discussing mathematical modelling (e.g., Brinkmann & Brinkmann, 2008; Lingefjård & Holmquist, 2001), data are used to optimize particular processes or to develop algorithms for analysis or prediction. Geometric modelling approaches also concentrate predominantly on processes rather than on actual goals and concepts (e.g., Mason, 2001; Henning & Keune, 2008; Siller, 2008). We use geometric modelling for both the virtual (on the computer screen) and physical (concrete manipulative) representation of objects, which allows both the objects' functionalities and the interactions between them to be analyzed. Exploring linked

mechanisms by using either concrete manipulative or digital tools such as GeoGebra, students can examine mathematical ideas in order to improve their constructions. We focus on the process of using modelling to support geometrical relationships and vice versa. Our goal is that students gain a better understanding of how certain mechanisms work, beyond connect such STEAM areas. As a starting point, we used some mechanisms introduced by Leonardo da Vinci and shared them in an interactive GeoGebra book (see <https://ggbm.at/AnHK7nCX>). Although da Vinci invented them more than 500 years ago, their basic physical principles are still used in engineering and in education. Reconstructing these models does not only mean redoing what has already been done; it means connecting ideas and strategies for learning and using new resources based on some classical ideas, and maybe even improving them along the way.

In this paper, we present an activity developed within a vocational course in Brazil. Building upon this preliminary experience, we intend to investigate (in the form of a PhD project) how the combined use of physical and digital tools is of mutual benefit and promotes learning in science and mathematics.

## **Theoretical framework**

### **Enhancing geometric modelling through Dynamic Geometry Systems**

More than a “mathematical playground”, dynamic geometry systems (e.g., GeoGebra) must be considered as a proper space for transforming students into explorers – a platform where mathematical understanding takes on another dimension and goes beyond merely applying formulas. Numerous studies have advocated this (e.g. Schumann, 2004; Gawlick, 2005; Bu & Hohenwarter, 2015) and stress the importance of transcending traditional geometry courses before the increasingly sophisticated and widespread application of geometry in science and daily life. In particular, they highlight how DGSs have supported changes in mathematics teaching and learning as well as in professional mathematical practice. Among the perspectives associated with the DGS approach, we outline those that are closer to geometric modelling: problem-solving, concept formation, construction, measurement, visualization, exploring, and variation/animation. DGSs often grant access to information that would otherwise be inaccessible. For instance, in spatial geometry, GeoGebra enables users to see an object from different points of view and its cross sections. Such features provide an important link between 2D and 3D representation. Investigating whether some ideas established in 2D also work in 3D or how they should be adapted is a promising strategy for promoting spatial thinking. Consider an example where the reasoning based on circles in a plane can be extended to a sphere in space: We have a point given in a plane and a line at a certain distance  $d$  from the point. In order to mark those points on the line that are located at the same distance  $e > d$  from the point, one could use a circle in 2D, but this would not suffice in 3D space (a more appropriate approach would be to use a sphere in this case). The attempts to find a solution using DGS software enhance the students’ conjecturing processes – another benefit of DGSs.

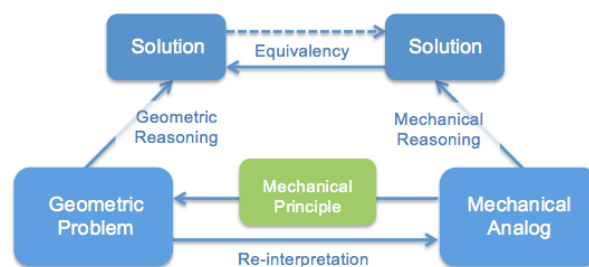

### **Teaching approach using analogues and DGS**

In the didactic domain, Alsina (2007) proposed that students gain insights from the functionality of objects and thus engage themselves in a creative process because they can identify the potential or restrictions of a particular phenomenon. Gravina (1996) suggested that dynamic geometry can foster an approach to geometric learning in which assumptions are made from experimentation and the

creation of geometric objects. In the same vein, Swan et al. (2007) stated that students can refine their own thinking by interacting with different representations of problem situations. In our case, the aligned and parallel modelling process led students to a practice where they had to hone their ideas in every construction step. Facing the need to convey their ideas, students tapped into their previously acquired understanding (an example is discussed in more detail further below).

Recent studies (e.g., Sinclair, Bussi, de Villiers, et al., 2016; Camou, 2012; Lesh and Sriraman, 2010) support the positive effect of the design and implementation of a multi-representational approach to exploring 3D objects using crafts, computer technology, and paper-and-pencil methods. In this context, we seek to provide an integration of geometry with algebra and trigonometry (using the example of joints with circular movements) that goes beyond technical instrumentation.

In our case in particular, the use of mechanical principles provides the background for the modelling process, as can be seen from the diagram in Figure 1, which was adapted from De Sapio and De Sapio (2010): they considered the relevance of applying an approach to problem-solving at an elementary stage through constructing mechanical analogues to geometric problems. In this case, mechanical reasoning supports geometric reasoning. Note that we added the arrow in the opposite direction, since the reverse case (geometric reasoning supports mechanical reasoning) is equally possible, as shown in our study: On the one hand, mechanical reasoning was essential to discussing the proper ratio for a pulley system in one case. On the other hand, with the help of rotational simulations (i.e., geometric reasoning) by means of digital modelling, the students figured out how to build a functioning physical prototype in another case.

**Figure 1: the solution's correspondence come out in both directions**

Concerning the activity's driving, the activity is consistent with DeHaan (2009), who stated that some strategies can transform the lecture hall into a workshop or studio classroom (even partially), and stressed the use of computer-based interactive simulations as a promoter of creativity instruction.

In fact, researchers investigating creativity generally argue that projects tend to be more creative when the solution is redefined, revisited, and questioned numerous times during the process (Lee & Carpenter, 2015). Furthermore, there are many different ways of developing prototypes. The process of refining ideas and designs puts students on an unrestricted path. Siswono & Novibasari suggested that problem-posing activities using the "What's another way?" strategy could improve students' abilities in creative thinking (as cited in Siswono, 2010). In our study, the students discussed their different ideas, especially in digital modelling. In this phase, they considered various points of view and also tried to gain some insights to check whether their ideas were feasible or not in order to do make the model as simple as possible.

## Methodology

Our experiment started in September 2015 at the Federal Institute of Education, Science and Technology in Brazil. It took approximately four months and had the form of a partial extra-class activity with two weekly meetings to follow the progress. The students (most of them were 16 years old) participating in the vocational (informatics) course were supported by two additional teachers (physics and mathematics). Although supervised by teachers, they chose their own topics to investigate. We first present the Da Vinci Rotatory Bridge Project (Figure 2) developed by 4 students. It was agreed that they should develop both physical and digital models in order to try to improve the joints of the existing mechanisms. Our intention was that, by comparing similarities and differences between the models, the students should be able to use one to support the other. No particular order was prescribed, but parallel development was suggested. Use of GeoGebra was also optional but recommended, since we were exploring it during class. In fact, da Vinci projects have been promoted since 2011, but this was the first time GeoGebra materials and GeoGebra 3D features were integrated. Particularly in the digital modelling process, the students concentrated on principles of rotation, translation, and spatial geometry.

**Figure 2: The digital prototype developed using the GeoGebra 3D feature (left) and the physical model made of wood (right) were developed in parallel**

As a further development we are combining this activity with a new resource, 4Dframe<sup>1</sup>, which is a flexible material and easy to manipulate. In the next example (Figure 3), we follow the development of a digital catapult in two versions. The second one is based upon the 4Dframe model.

**Figure 3: Catapult evolution and becoming easy to represent**

Since mechanical principles are highlighted in a simple way, it becomes easier for students to represent them in GeoGebra. Furthermore, elementary models with straws and connectors become part of the digital modelling more easily when only segments and points are used to represent the structures. The functional principle of the joints, however, is preserved. In addition, various colours are used to represent the corresponding elements and to contribute to the visualization and facilitate spatial comprehension.

<sup>1</sup> For some examples, see <https://www.geogebra.org/m/xCxJUyyx>.

Finally, another important benefit is that the digital model allows a wide range of representations to be created by simple cursor movements (in the example in Figure 4 by dragging the blue points). Using 4Dframe, the students can think freely about different possible solutions and the constraints arising for an eventual construction, and are engaged in a learning process involving critical and creative thinking.

**Figure 4: Multiple representations promote creative thinking. By dragging the blue points in the digital model, students can create a range of possible solutions.**

## Construction's ideas and discussion

In order to illustrate some basis used by students to support such models, we share some parts of them. The students were free to construct according to their own previous knowledge and were not required to use any specific content. However, if the need arose in a particular task, the students received proper support. In such cases we enjoyed discussing the problem at hand with them and, together, introduced new concepts or strategies, as presented below.

Given a circle with its centre in A (located on the x-axis) and an arbitrary radius<sup>2</sup> we started the task (Figure 5). First students investigated the relative position of a point B on the circle in relation to its center while sliding along a line. Since the goal here was to simulate the movement of a wheel, they needed to implement rotational movement. To figure this out, they changed the definition of point B to  $(x(A) + \sin(x(A)), y(A) + \cos(x(A)))$ . Naturally, this result was obtained after several attempts and discussions. Note that, in this case, the point B is a function of point A.

**Figure 5: Three-frame cycles represent the transition from a “dragging circle” to a “rolling circle”**

In a 3D representation, the same logic is preserved, but this concept was totally new for the students: Each point then has three inputs. If a circle is perpendicular to one of the standard axes, then all points belonging to this circle have a constant input regarding to such axis. The other two coordinates repeat the idea from the previous 2D example. For instance, in the case below (Figure 6), B is given by  $(x(A) + \sin(x(A)), 0, z(A) + \cos(x(A)))$ . The connected elements can be completed by rotation or symmetry. Additionally, some principles applying to spatial coordinates were used to define proper points as a

<sup>2</sup> The radius could also be controlled by a slider. In this case, the scale had to be in accordance with the remaining construction.

basis for such constructions. In the boat example (Figure 6), a first reference segment was built to guide the following marks through translations and reflections.

**Figure 6: Developing a 3D representation in 3 steps**

In this activity, the students should preserve the coherence between analogue and digital model as much as possible. To illustrate this, we refer to the bridge example, where the relation between the turns of the driver pulley and the bridge was to be determined; this is an issue easily identified in the physical prototype but not as readily in the digital model. When the students realized that the models were not in agreement, they concentrated on the geometrical problem and concluded which ratio between the number of turns of the bridge and of the pulley should be appropriate. In contrast, when students modelled only the digital boat (in a previous experiment), they recognized the following misconception before building the physical model: if the paddle wheels spun together at the same speed, the boat would move only forward and backward. They then fixed this problem in the physical model. This suggests that it does not matter which model they build first as long as the whole model contributes to their experience and improves their learning process. When digital geometric modelling was the goal, students needed to use their knowledge of trigonometry and parameters (functional thinking) in order to establish links between elements to obtain the desired representation. Questions such as “*If you want to change the direction of the rotation, what do you have to do?*” often initiated their investigative process and sometimes became a challenge.

## Conclusion

“Inviting” students to reconstruct historical models is one of many possible ways to teach mathematical concepts and to promote students’ creative thinking processes. Students must decide how they can use their previous knowledge in order to solve a given task. In this way, students increase their autonomy and become more involved in their own learning processes. An important step of Pólya’s heuristic strategies can be outlined: “If you cannot solve the proposed problem, try to solve first some related problem” (as cited in Schoenfeld, 2016).

While we promote STEAM on the one hand, we introduce different dimensions of learning to students and enable deep learning driven by their own interests on the other. Problem-solving and geometric modelling can also become a basis for the integration of mathematical learning into trans-disciplinary educational frameworks, currently referred to as STEAM.

In the course of this study, students left some testimonials on Moodle. One such testimonial referred to some physics aspects: “*I enjoyed two videos posted by the teacher that showed how da Vinci’s bridge worked. They enabled a better understanding of the functioning of the rotatory bridge. I understood better how the system of ropes and pulleys works in order to reduce the workforce.*”

Feedback such as this and examples such as those reported above illustrate the students' interaction with different resources that supported them. They indicate that the geometric modelling approach can motivate and contribute to their learning process. We therefore seek to evaluate and promote this activity among teachers as part of our current research. We are now working on developing new resources that connect the physical and the digital world and will report on these at a further occasion.

<sup>3</sup>Université Paris Diderot, Paris, France; [laurent.vivier@univ-paris-diderot.fr](mailto:laurent.vivier@univ-paris-diderot.fr)

*In this paper we report on students' work in Argentina and in France when performing a modelling task. The problem given, named the "gutter", is quite a classic in university calculus courses. Analyses have been realized by using the Mathematic Working Space (MWS) research model in relation to mathematization of a modelling process. We are mainly concerned with the influence of the teaching in students' productions. Since the modelling process is an important issue of teaching, we have chosen the population of the study among pre-service teachers.*

**Keywords:** Mathematical Working Space, paradigms, modelling task.

## Introduction

Nowadays, modelling is fostered in secondary school and at the university level, and one expects teachers and engineers to be trained to achieve the modelling competence. For instance, modelling constitutes a specific competence that has to be developed by civil engineers in Latin America, according to Tuning project (Guerrero, 2013). But, what modelling problems have to be considered in upper secondary school and in university? Are the modelling problems used in high school, and in the university, standardized by the institutions? Do they refer to real situations? We think that mathematical objects, different representations used, and properties involved in the modelling process give a richer sense for students in term of the knowledge they can construct. Teachers have of course an important role to play that highlights the importance of the teachers training. In that way, the population of this study was mainly chosen in secondary teacher training.

In this study we present a relation between the Mathematical Working Space research model (Kuzniak & Richard, 2014; Kuzniak, Tanguay & Elia, 2016) and the modelling cycle (Blum & Borromeo-Ferri, 2009) that could be understood as a *first cycle* for the resolution of the modelling task. Mathematical Working Space (MWS) is a model that is used in research in mathematics education, first developed in the field of geometry. When a student starts with the given situation, one assumes that he/she begins a horizontal mathematization process which is a foundation for bringing the situation problem into a mathematical domain. Then a vertical mathematization process takes place where the MWS framework and the modelling cycle can interact with each other. That is our approach in this study.

We first present how to use the MWS model to analyse a modelling activity. Then, we study a modelling task given to pre-service teachers in Argentina and in France. Our aim is not to make a comparative study, since both populations are different, but rather to identify the personal MWS of the students when solving this modelling task. The focus is mainly on three levels of teachers training in Argentina. We also looked at primary teachers training in France in order to have an idea of no scientific students' answers.

## MWS and Modelling

We consider a MWS that depends on a specific mathematical field (Kuzniak, Tanguay & Elia, 2016) such as, among others, analysis, geometry, algebra or statistics. Paradigms in an MWS, depending of the domain, serve to characterize the work according to a community or an institution. We develop the paradigms for analysis (Montoya Delgadillo & Vivier, 2016).

### The MWS model

Three types of MWS may be distinguished: (i) **MWS of reference**, which is defined according to the relation to knowledge, ideally under mathematical criteria; (ii) **suitable MWS**, which depends on the institution involved, and is defined according to the way that this knowledge is supposed to be taught in the institution; (iii) **personal MWS**, which depends on the individual and is defined by the way in which the individual handles a mathematical problem with his or her own knowledge and cognitive capacities.

MWS is an environment in which reflection results from the interaction between an individual and a problem in a mathematical domain. It is an environment organized for an expert of this domain, by means of two interconnecting planes: the epistemological and the cognitive planes (Kuzniak & Richard, 2014; Kuzniak, Tanguay & Elia, 2016).

The *epistemological plane* is composed of three poles (Figure 1a), namely *referential* (properties, theorems, definitions...), *representamen* (semiotic signs), and *artefacts* (material or symbolic). The *cognitive plane* consists of the processes of *visualization*, *construction* and *proof*. The functioning of a MWS must not be understood as a union of single components lying on the epistemological and cognitive planes, but rather as links activated by two or three geneses, *semiotic*, *instrumental* and *discursive* geneses, that articulate the two planes.

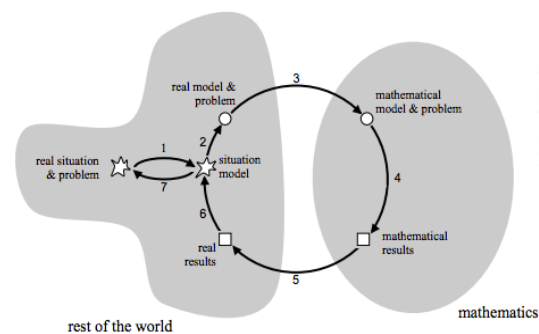

**Figure 1a:** The Mathematics Working Space, geneses and vertical planes (Kuzniak & Richard, 2014)

### Paradigms of analysis

The situation we propose (see following section) is an optimization task. Hence, using (mathematical) analysis is quite natural, even if the problem can be solved in various ways. In order to identify the paradigms of analysis in the answers of the students, we present the three working paradigms of analysis identified by Montoya Delgadillo and Vivier (2016):

- **Arithmetic/Geometric Analysis (GA):** it enables interpretations with implicit assumptions based on geometry, arithmetic calculations or the real world.

**Figure 1b:** The modelling cycle (Bloom & Borromeo-Ferri, 2009)

- **Calculation Analysis (CA)**: the rules of calculation are defined more or less explicitly and are applied independently of reflection on the existence and nature of the objects.
- **Real Analysis (RA)**: it is characterized by work involving approximation and neighbourhoods; definition and properties are set theoretically; an “ $\epsilon$  work”.

## Modelling

The development of the modelling skills (Blum & Borromeo Ferri, 2009) mobilizes notions and mathematical objects of different mathematical domains, where the knowledge that the students can learn is grounded on arguments that belong to different domains (analysis, probabilities, geometry, etc.). This gives rise to different MWS and paradigms.

Recently, two doctoral theses in probability in Paris Diderot university proposed a use of MWS in modelling processes<sup>1</sup>. The whole modeling cycle (Figure 1b) is not taken into its totality: the focus is on phases 3 to 5 of the cycle and our aim is to analyse, with the MWS model, the mathematization process when students solve a modelling task. We expect to identify, in students’ work, the solving mathematical domain and mathematical objects, representations or signs, artefacts, mathematical knowledge, and the working paradigm. We show below how the two frameworks may be used together and their complementarity.

In the following, we do not consider all the modelling process with the lens of the MWS model, but rather how is it possible to analyse mathematical activity. In particular, we set the following questions: Given a specific task, what domain and (personal) MWS will a student choose during the modelling process? Is it possible to see an influence of a suitable MWS?

## Experimental study

The "gutter" situation (see below) was given to three groups of future secondary mathematics teachers in Argentina: two groups of a private training institute, namely 1PC of 1<sup>st</sup> year and 2PC of 2<sup>nd</sup> year, and one group of 4<sup>th</sup> university year, 4PF, of the Universidad Nacional de Córdoba – unfortunately, a 3<sup>rd</sup> level group was not available. The study focuses on these pre-service teachers, but the task was also posed in France, in an examination of 3<sup>rd</sup> year future primary teachers, at the Université Paris Diderot. This extra population helps to understand what kind of solving processes one can expect from non-scientific students. Students of the study are named L1 to L28, 1PC1 to 1PC24, 2PC1 to 2PC15, and 4PF1 to 4PF12 accordingly.

As announced above, it is an optimization task, quite classic except for modelling aspects. Here, we make the hypothesis that the majority of students who followed a calculus course that provided a method for solving a class of optimization problems (derivation or optimum of quadratic functions) will work in paradigm CA, and that they will resort to functions.

The aforementioned was the case for 4PF students trained at the university, since these students had courses on mathematical analysis. But CA paradigm was not expected for 1PC students and 2PC students, since in Argentina the first calculus course takes place during the second year and the experimentation was at the very beginning of the academic year. We then expected more GA methods (see below).

---

<sup>1</sup> See also the poster “Modelling tasks and mathematical work” in TSG6 of CERME 10.

On the other hand, French students were in a multidisciplinary third university year after the validation of two disciplinary university years (mathematics, or biology, or history, or English...). Students' profiles were very diverse and a few of them studied mathematics, and specifically calculus. We make the hypothesis that, spontaneously, most of L-students work in GA paradigm, whether or not using functions.

### The gutter situation: a priori analysis

First, we give the statement of "the gutter", then we make an a priori analysis.

We have a rectangular metal sheet of 30 cm width and of big length. We fold up perpendicularly edges on each side to make a gutter (see dotted lines on the figure below). For obvious reasons, both side edges of the gutter will have the same size.

How should we fold up the metal sheet in order to obtain a gutter with a maximum flow?

This is a partially modelled task, since many parameters are fixed and, moreover, the geometrical mathematization is given. The choice to fold perpendicularly allows simplifying the task by eliminating other cases. There is a lack of parameters to study the flow, among them, the slope of the gutter (that we shall not discuss) and the length of the sheet.

The latter is not necessary because we can replace the study of the flow by the study of the area of a cross-section of the gutter supposing that the flow through this section is constant. Nevertheless, it is simpler to work with the volume than with the flow which is a quotient magnitude. Thus, some students may choose a length to make a calculation of volume. Is this length considered as a parameter or either as a numerical value added to the statement? This length is used in calculations or is it only a useful intermediary to think of the situation?

Let us note that there may be problems of understanding of the proposed geometrical modelling. An inadequate understanding of the situation corresponds to the addition of an idea or a belief, which is not correct regarding the situation. We expect in particular to have equitable answers with 10 cm for each of the three edges, as well as the assertion that the area, and thus the flow, does not vary because of the constant 30 cm.

On the other hand, there is no indication on the mathematization allowing to make calculations for solving. We focus our analyses on this phase of mathematization, which we interpret as the choice of a MWS by students, and the phase of solving. We then look at students' answers with an adequate understanding of the modelling situation: good geometrical shape (specified in the statement), and considering the area of a cross-section, or a volume, to study the various values (the variations) of the flow. We also look at a schema of the gutter: cross-section, in 2D or in 3D.

In the following, we present the types of answers expected for solving the modelling task. Before that, let us notice that the task can be solved in the geometry field of the statement, with magnitude and a knowledge on the areas of rectangles of given perimeter: By taking two "gutters", one forms a rectangular pipe the section of which has a perimeter of 60 cm. Since the area is maximal for a square,

the solution is obtained for a 60 cm/4 side, that is, 15 cm. So, the basis has 15 cm of length and one has to fold in  $15 \text{ cm}/2 = 7.5 \text{ cm}$ .

The resolution can be made in a numerical MWS, that is, by doing several calculations of the area or the volume. Several levels are possible: choice of some values of the length of the edge, calculations, and then decision-making. Numbers to be considered are essentially whole or decimal numbers. The solution being 7.5 cm, considering only integers multiples of cm does not allow to find the optimal value (unless changing the unit of length). These values can be grouped in a table or not, obtained in an organized way or not (for example, with all integers from 0 to 15, or by an oriented search), with a sign (as the letter  $x$ ) to denote the length of the edge or not. A formula allows to automate calculations and, possibly, the implementation in an instrument of calculation. Obtained values can be also put in a graph.

The production of a formula can allow to change of MWS to a functional MWS, in calculus. One expects the introduction of a quadratic function<sup>2</sup>:

- Using only algebra, with the expression of a global variational principle:  $f(x) \leq f(a)$  where  $a$  is the candidate value, that has to be find, to be the optimal value;
- With recognition of a quadratic function, its properties, vertices or symmetry axis of a parabola, allow to solve the problem. This is a work in CA paradigm.
- Using the derivative of the function. Is the theorem quoted? Is the change of sign of the derivative evoked or forgotten? This is mainly a work in CA paradigm.
- Setting a values table or a graphic, recognizing or not a parabola, in GA paradigm. The difference with numerical MWS mentioned above may be difficult to identify.

## Results

Let us note that 12 L-students do not answer, and utterances from 5 students of 1PC are not classified. Three of these 1PC-students gave the solution 7.5 cm without any justification: possibly an exchange of information between students or, for at most two students, the divisions of 30 cm by 4 like for a square<sup>3</sup>. There is also the atypical 1PC24's production, which will be mentioned later on.

In Table 1 there is a summary of the results with four groups of indicators:

1. Representamen: cross-section of the gutter (CS), letter for the edges (Ledg), letter (L) or value (V) for the fixed length of the gutter (Par), table (T) and graph (G);
2. Objects used: function (Fu) or formula (Fo);
3. Knowledge: derivation (Der), vertex of a parabola or quadratic function (Ver) in a MWS of function, CA paradigm; numerical calculations (Num) in a numerical MWS;
4. Non adequate modelling: 10 cm for each edge (10), no variation (noV) and also extreme folding (ExtFold) for “the edge must be the lower” or “the greater”.

---

<sup>2</sup> A quadratic function limits the technical difficulties. The task was also chosen for this reason.

<sup>3</sup> That method is not expected here: since  $(a,b) \rightarrow ab$  is bilinear, optimizing the area of rectangles with fixed perimeter  $p$  is the same than optimizing the area of rectangles of sizes  $a$  and  $b$  with  $a + b + a = p$ .

Table 1: Students' answers to the "gutter task"

	CS	Ledg	Par	T/G	Fu/Fo	Der	Ver	Num	10	noV	ExtFold
4PF (12)	8	12	6L,0V	0T, 3G	12Fu, 0Fo	7	5	0	0	0	0
2PC (15)	3	2	0L,1V	2T, 0G	0Fu, 1Fo	0	1	5	4	5	2
1PC (24)	7	2	1L,2V	0T, 0G	0Fu, 0Fo	0	1	11	5	2	0
L (16)	0	7	2L,3V	2T, 2G	4Fu,2Fo	2	0	5	2	0	4

There is a lot of 2D schema, close to the statement schema, but only four 3D schema. On the other hand, a cross-cutting (see Table 1) seems characteristic of 4PF-students, more advanced mathematically. It is the same with formalization, introduction of letters (variables and parameters) or using functions: the 12 4PF-students used a modelling with functions. It is also the same with the use of knowledge: 4PF-students work in CA paradigm, either by using derivation or the formula giving the vertex of a parabola (rarely justifying that it is a maximum; only two students justified it, by calculating the second derivative). There were a few students that used this knowledge in the three other groups, or in an empirical way by working in GA paradigm (by numerical calculations, more or less organized, or graphs).

Although the work seems largely guided by the knowledge the 4PF-students have, with few variations, modelling was adequate, what is not the case in other groups. For students who do not well understand the situation, either no MWS rises from modelling, or a very poor MWS appears, not allowing a substantial mathematical work. Answers of inadequate modelling are:

- Equitable length of the three sides: 10 cm each (5 students);
- There is no variation, all is constant (4 students);
- An extreme folding, the littlest lateral side possible (5 students), but sometimes with the (real) constraint that 0 is forbidden, so that the water remains in the gutter;
- L27: a pyramid (to have a pipe?) without understanding the geometry of the statement;
- 1PC24 drew a roof explaining: "if there is a few water that does not go strongly", and "if there is a lot of water and with great strength".

Although the productions of the group 1PC are very poor, with not much formalization, in the groups 2PC and L we find a various types of rich productions: trying values with calculations, sometimes leading to the accurate solution when the student thinks out of the integers domain (some students remain in the field of the arithmetic of integers, sometimes with answers with two solutions, 7 and 8, and even the constraints to have a basis of even length in order to be able to divide by two), graphs and tabulations which can lead to the awareness of a symmetry (L6, L28 below).

L14 proposes a formula with a letter  $x$  for the length of the edge and  $l=10$  for the length of the gutter, to calculate what he calls Dmax (figure 2). He uses this formula to find a values table for a whole number between 1 and 15. He writes: "we notice that the maximal flow is achieved for an edge between 7 and 8 cm". Other students stop at this stage, while L14 continues with another table for the values of  $x$  between 7 and 8 with a step of 0,1. This allows him to conclude correctly, in GA paradigm, that "to have a maximal flow, edges have to be 7.5 cm each".

Student L6, after the introduction of the function  $f(x) = (30-2x)x$ , establishes a valuable table for integers and draws the graph of  $f$  (figure 3). She concludes with visualization on the graph to determine the solution by drawing what seems to be the axis of symmetry of the curve.

On va chercher le débit maximal de la gouttière.  
 $D_{\max} = l \times l \times h$   
 $D_{\max} = (30-2x) \times 10 \times x$

Figure 2 : Answer by student L14

Figure 3 : L6's graph

L28 declares the same function but in a more formal way: " $\forall x \in (0,15) f(x) = (30-2x)x$ ". He then calculates the values for the whole values of  $x$  that he associates two by two, which is an organization adapted to the function at stake. "We notice a symmetry in the values of  $f(x)$  when  $x$  varies between 1 and 15. We deduct that the maximum is in the middle of the values, that is:  $f_{\max}(x) = f(7.5) = 112.5 \text{ cm}^2$ ."

On cherche donc ce volume maximal.  
 $V(x) = ax(30-2x)$  et on fixe  $a = 200 \text{ cm}$   
 donc on a  $V(x) = 200x(30-2x)$   
 $V(x) = 6000x - 400x^2 = x(6000 - 400x)$   
 Avec la calculatrice, on trace cette fonction polynomiale de degré 2. Il semblerait que le maximum soit atteint pour  $x = 7.5 \text{ cm}$  et que le volume maximal vaille  $V \approx 22500 \text{ cm}^3$ . Essayons de trouver la valeur exacte de  $x$ .

Figure 4: Production of L10

L10's work is very complete (figure 4). She uses a formalism (she fixes the parameter  $a$  to 200 cm), a function, and a graphic calculator to propose a conjecture for the candidate maximum value in a visualization work in GA paradigm. She strengthens her conjecture by considering the middle of the function roots. She continues by calculating, algebraically, in paradigm CA,  $V(x) - V(7.5) = -(20x - 150)^2$ , what allows her to justify her conjecture and to conclude.

Finally, 2PC4 has an atypical production with a modelling by means of a paper model: he takes two paper strips, which he folds to form a pipe and gives, by a reasoning close to the solution in the MWS<sub>Geometry</sub> described above, the right solution.

## Conclusion

The recognition of a function in the situation, like the introduction of a letter, is an important modelling activity, because a concept is introduced, which a priori has no relation to the situation. But more than a letter – by using it the work can remain in a numerical MWS –, the introduction of a

function switches the work to a MWS of functions with specific techniques (e.g. derivation) and representations (graphic, table value). However, the work done can be very different and the personal MWS involved can also be different from a student to another.

The understanding of the situation and the asked question made each student choose a MWS, that is to say, mathematical objects, knowledge, theorems, signs (letters, graphics,...), artefacts (calculator, spreadsheet,...) and the processes of visualization, construction and proving in various domains – in other words, the MWS... –. Those are complex issues for a teacher to control the various knowledge involved.

Then we wonder whether the modelling process for some students is a routine that has been "normalized" by the institution, mostly for a specific class of problems, or a mathematical activity which has been taught in their institution. It seems that for 4PF group, students' answers are standardized with only a *choice* between two knowledge on functions. This is a first influence of the suitable MWS that we point out. The diversity of the L-students productions reinforce this standardization and we set the problem of the possibility for teachers to be aware and open to alternative answers that their students may have.

MWS model allows us to analyse in depth the concepts and mathematical objects coming from mathematization identified in the modelling process. However, the possibility that different MWS from this process are generated makes an attractive but complex task to control for the teacher, overall for a *second modelling cycle*. Indeed, this study focus on a *first cycle* where one asks to students to solve a modelling task. Then, teachers may use a *second cycle* in order to reorganize and to point out knowledge that arose during the first cycle.

### Acknowledgments

This study was supported by mobility project of USPC and ECOS-Sud project C13H03.

*In this study, a teaching experiment was used in which fifth grade students developed their own knowledge about decimal number based on their prior knowledge and real life actual experiments. A Realistic Mathematics Education approach was used for designing this research. Participants in this study were 27 students from a primary school and they did not have formal instruction at school on decimal number until participating in the current study. These students engaged in some measuring activities during four sessions in two weekends. They discovered the idea of calibration of a measurement unit and tried to use this idea for measuring the length of objects. This study shows how real life experiments of students help them to calibration a measurement unit.*

*Keywords: Decimal number, measurement activities, realistic mathematics education, primary students.*

## **Introduction**

Understanding of decimal numbers is very important for people who live in twenty first century because they use computer, calculator, digital monitor and other measurement activities in their real life experiments. Usually, people encounter with decimal number in their real life. For example nutrition facts written on foods, factors for buying products, vaccination card of children and ... have a lot of things related to decimal number. All children encounter with decimal number before formal education at school, although its meaning is not understood. According to Bonotto (2009) connection between outside of school experiments of children and formal education can support students' conceptual understanding.

In traditional teaching, decimal numbers developed through place value. Usually students use tens and hundreds blocks for consolidating decimal numbers concept. Operations and procedures explain by teachers abstractly and then ask students to do some similar exercises. Indeed, students hadn't active role in developing their own knowledge and there is no connection between out of school students experiment and their math classroom activities.

It seems to we need to develop new approaches for teaching decimal number. One of the useful ideas in this regard is realistic mathematics education approach. In current study, we try to use this approach for finding some real contexts which are authentic for students and these contexts used for starting point for constructing mathematics by students themselves. Indeed, this paper will be introducing a teaching experiment in decimal number domain. During this teaching experiment, students do sequence of measuring activities to develop a measurement unit and calibrate it for measuring different lengths. Students also discover different representation for decimal number through these activities. The main purpose of this research was that show how students develop their

own knowledge about decimal number in the context of real world with using their common sense and prior knowledge.

## **Literature review and theoretical framework**

Decimal number is one of important topics in school mathematics which has plenty of application in students' real world experiments. But several studies show that students and even adults haven't good understanding about decimal numbers (Moloney & Stacey 1997; Steinle, 2004; Lai & Tsang, 2009; Sengul & Guldbagci, 2012). Lai and Tsang (2009) show that procedural knowledge of students in decimal number was very good, but their conceptual knowledge in decimal number and decimal notation were so weak.

One of the important concerns of Lai and Tsang (2009) is that do the mathematics teachers know how to deliver decimal conceptual knowledge to the students? Bonotto (2001) believe that students' difficulties in decimal number rooted in teachers teaching strategies which have no connection to real life of students. Indeed, students usually encounter with decimal number in format of some stereotype word problems. Niss, Blum, and Galbraith (2007) said word problems exist several centuries in school math curricula and used as application of mathematics, but these types of problems in fact are a pure math problem in cover of words. Greer (1997) believes that word problems are artificial. Verschaffel (2002) states that emphasis on word problem cause to suspend common sense during mathematical problem solving.

Bonotto (2004) in the line with realistic mathematics education, believe that engaging students into the contextual activities that related to their own personal life, help them to enhance their conceptual knowledge in mathematics and having positive attitude toward math. She mentions two below factors that separation between school mathematics and real life facts: Stereotype problems of mathematics textbooks and Classroom environment.

If teachers of mathematics wish to establish situations of realistic mathematical modeling in problem-solving activities, Bonotto (2005) proposes below suggestions:

- The type of activity to which teachers delegate the process of creating interplay between math classroom activities and everyday-life experience must be replaced with more realistic and less stereotyped problem situations;
- Teachers must endeavour to change students' conceptions, beliefs, and attitudes toward mathematics;
- A sustained effort to change classroom culture is needed.

Bonotto (2001) maintains that children's understanding of decimal numbers can be fostered by classroom activities where learners can transfer their out-of-school knowledge and utilize familiar tools, such as the ruler, that they also use in out-of-school contexts. She believes it is possible to attempt an innovative teaching trajectory in which decimal numbers are introduced through contextualized measuring activities. Indeed, measuring activities requiring vast use of a ruler can offer children good opportunities to move toward the construction of a comprehensive understanding of decimal number and notation. For example, a study of Astuti (2014) shows that, if students use paper strip and calibrate it by themselves, then their understanding about decimal numbers and notation will be more developed.

## Method

In this study, a teaching experiment about decimal number will be introduced. Based on the research aim, the type of the research is categorized as design research. This research contributes to develop a Local Instruction Theory (LIT) to support students develop the understanding of decimal number and notation. LIT has cyclic spirit (Gravemeijer, 2004) that in this study is prototyped by a Hypothetical Learning Trajectory (HLT) (Simon & Tzur, 2004) which is elaborated and refined when conducting the design. The initial step of HLT in this study is developed based on the analysis of key areas of decimals from literature review, the analysis of Iran mathematics curriculum, and the analysis of the potential use of contexts and model based on the framework of RME.

Current study is part of larger study that investigates conceptual understanding of fifth grade students in several aspects such as constructing a measure, calibration a measure unite, familiarize with decimal and notation, comparison of decimal number, density of decimal number, and submission and multiplication of decimal number. This study concentrates only on constructing a measure, calibration a measure unite, familiarize with decimal and notation. Main purpose of this study was familiarizing students with concept of decimal number. In this regard five activities designed which related to students real life facts (see figure 1).

1. Select a measuring unit arbitrary and measure length and width of classroom board, approximately. Represent length and width of classroom board with mathematical symbol.
2. How we can get better approximation? Write your proposed method completely, then record measured length in a mathematical form.
3. Select an object that smaller than your measuring unit. How you measure the length of this object? Explain your method and write measured length.
4. In this week a one meter non-graded tape give to each group of students and ask them where do you hear about “half” concept? What is the meaning of “half”? What is mathematical symbol for that?
5. Divide non-graded tape in 10 parts. Then try to measure a selective object approximately, and then show it with new mathematical symbol (decimal number).

**Figure 1: Activities of first week**

These activities implemented in four 80 minutes sessions in two continuous weekends' day. First three activities implemented in session 1 and 2 in the first weekend. Fourth and fifth activities implemented in session 3 and 4 in the second weekend.

This study conducted in a primary school in the beginning of school year (Fall 2014). Participants of this study were 27 fifth grade (10-11 years old) female students. These students had no formal program in these two days and all of them participate in this extracurricular class voluntarily. All students work on activities in group. Each group contains three students. Two types of complementary communications occur in this study: group discussion and whole class discussion.

During these teaching experiment sessions, second author and two other math educators record all communication of students in group. In the end of each session, students' group works collected also. Below considerations navigate activities designing process, data collection and data analysis.

- Using of non standard measuring units for measuring objects in the classroom;
- Measuring with high accuracy;
- Calibrating a measuring unit;
- Numerical representation of length of object with using calibrated unit;
- Importance of decimal division and decimal representation of length of object.

After each session, video record of session and students' group works and researchers note analyzed and use them for leading teaching experiment in next sessions.

## Results

### Results of first day (Sessions one and two)

The students used different tools for measuring the length and width of classroom board, such as notebook, math book and A4 paper size. As it was asked them to measure the length and width approximately, so they write these sizes as follow and in term of a complete unit. In fact, the extra parts were neglected. A group of students who chose their notebook size as measuring unit (module) had stated that the classroom is 23 and a half notebook size length. Using the term "half" showed that they know the decimals informally.

In the second activity, it was asked them to measure the length more carefully. In all the groups it was seen that they divided the measuring unit (module) to small sections. The difference between group operations is in the numbers of divisions and choosing denominator. The mathematical symbols which were used in this activity are as the length of a natural number plus a fraction or a Mixed number.

To guide students to a more accurate calibration, they were asked to measure the length of an object that is smaller than the length of their module and write its mathematical symbol in the third activity. In this activity, student should choose smaller objects than unit. They chose the length of pencil lead packet, pen, notebook and etc to measure. The students' performance was divided in three classifications.

- Four groups of students neglect the previous division and creating the new one for their measuring. They changed the number of their part and explained that the length of chosen object is smaller than their unit, so they change the numbers of divisions. Indeed, they divided the length of measuring unit into larger equal parts.
- Three groups of students keeping their previous division. They just divide their previous division again.
- Two groups solve this problem in different way. They divide the unit into the five parts and then divide each part into the five parts again.

Maryam: we divided our set unit into 2 parts. We divided each into 3

Researcher: can you represent the length of measurement in math symbols?

Aida: one second (one a half) and three of this part.  
(i.e.  $1/2$  and  $2/3$  of this part).

Researcher: would you please represent it in math symbols?

Aida: we should calculate it.

Maryam: we should add  $1/2$  and  $2/3$ .

Marjan: no, it's not the  $2/3$  of the notebook length. It is  $2/3$  of one half of its length... It means its  $5/6$ . (She shows it on the picture to her partners).

In fact, this group is faced with a challenge in calculating the length with mathematical symbols. They needed to be able to add the fractions in unequal denominator. Dividing the previous parts into same part numbers, the operation of one group was different. First, they divided the unit into 5 divisions and do it again for each part. They stated:

"Although we can re-divide each part into 5 sections and we repeat it again and again for smaller parts. But if we want to notate the length, it will be difficult. For example, we have to write one fifth plus two twenty fifth plus ... so, probably the next denominator is 125. Again 125 times 5 ... then set the common denominator..."

The fourth group operation was, writing the numbers in base 5. They stated interestingly that they can continue this trend. They expressed that for setting the denominator, it's necessary to multiply the denominator to 5, so it was obvious that they found a regular algorithm for approximating the length of object.

In the classroom discussion, which is performed at the end of the first session, students expressed that writing the mathematical symbol for the length is very important. They have some problems in irregular dividing of parts, so they choose the third method as the best way to calibrate the units of measuring.

### **Results of second day (Sessions Three and Four)**

In the first activity in the second session, the students were asked to express that where in real life have seen the word half and their symbol "half" and its mathematical symbol. Some of the students' expressions were as the following ones.

- We usually say in the grocery store: I need 2.5 kg lentils or in my mother's shopping list it was written 1.5 kg beans.
- The house is 15.5 m length.
- The jar contains 2.5 litter of water.
- The volume of the coke bottle was specified 1.5 liters of water.
- We need 1.5 meters fabrics for making this shirt.

All these written expressions showed that the students have seen and heard of these decimal symbols during shopping, in parents' shopping lists, food labels such as cokes etc. and they understand this concept. The following classroom discussion was conducted:

Researcher: what does one half mean?

Student: it means a half.

Researcher: what does number 5 mean based on 0.5?

Fatemeh: half a kilogram means a half of one kilogram, it is 500 grams. Half a meter means a half of a meter, so it is 50 centimetres. You can find number 5 in both of them.

Zahra: in my opinion, one second is equal to one half, so  $\frac{1}{2}=0.5$ .

Rezvan: ....so it means that there are many fractions which are equal to  $\frac{1}{2}$ .... For example,  $\frac{1}{2}=5/10=50/100$  ...that all of them are half or a half.

Maryam: eureka, eureka.  $\frac{1}{2}$  is one out of two, so 0.5 is 5 out of 10.

Parisa: that's right teacher. 0.5 is 5 out of ten. It is the same as 50 out of 100 or 500 out of 1000. All are the same and mean a half.

Teacher: could you tell me that what 4 out of 10 looks like? Please, write down your answers on the paper (all the students wrote 0.4).

In this discussion, the teacher tries to help the students using their own knowledge of "half" concept in real world to find an equivalent phrase for  $\frac{1}{2}$  in mathematical world. Using the concept of one half and  $\frac{1}{2}$  and in regards to their knowledge about equal fractions, they can interpret 0.5 by their own and this process shows the horizontal mathematizing. In fact, these students are moving back and forward between the real and mathematical worlds for exploring this concept.

In the second activity in which a one meter ribbon was given to all the groups, all the students divided the ribbon into 10 parts. In fact, it was asked them to specify the decimetres on the ribbon and measure the object in decimetre or one tenth accurately. In other words, they realize the relationship between number 10 in denominator and decimal numbers go out one decimal place.

According to the class discussion in the previous session, the students divided decimetres into 10 parts for more accurate measuring and made the centimetres. They made a calibrated ribbon in centimetre accuracy. In fact, it was asked them to specify the decimetres on the ribbon and measure the object in decimetre or one tenth accurately. In other words, they realize the relationship between number 10 in denominator and decimal numbers go out one decimal place (figure 2).

**Figure 2: related to measuring the length of objects by calibrated ribbon in decimetre accuracy**

When the teacher pointed that the ribbon is one meter length while one of the students said:

“That’s interesting, we divided the ribbon into 10 parts, and re-divided it into 10 so it means we have one meter into 100 divisions. These are centimetres. We knew one meter is 100 centimetres but I perceive it now”

The process of making a calibrated tape measure helps the students to realize the relationship between meter, centimetre and decimetre.

## Discussion and conclusion

In the first session of teaching test, the students are allowed to calibrate a measuring unit freely but they had no idea about how to calibrate the unit. In the results of this study, it was seen that they faced a challenge with writing the mathematical symbol for the length, in the other words, these challenges caused to create a regular algorithm for calibrating the unit of measuring. The results of this study showed that choosing a division in base 10 is not natural. In the experience of Astuti (2014), the idea of direct division in based 10 was provided by researcher but here it was tried to conduct the students to dividing the unit in base 10.

This study confirmed the Van de Wall (2001) quote as said "students' mind is not like a whiteboard as entering the class". As it was mentioned, although the students had not learnt the decimal numbers formally and before the research but they used them in their real life frequently or found them on some objects covers, their parents' notes and etc. also they had seen the decimal numbers and separator mark. As Freudenthal (1991) stated, using students' background experience and information could help them in learning decimal notation and its concept. Measuring the length of an object for many times and in more accurate ways help them to realize the meaning of the digits after the decimal point. In fact, when they divided one meter into 10 sections and re-divided it again and again it means that they realize the position and concept of decimal and centesimal scales. One of them expressed, for more accurate scales; we can divide the centimetres into 10 and make it smaller and smaller. In fact, he noted the millesimal position and could guess the decimal demonstration correctly.

This study represented that if the classroom environment changes and better information in regards to the students’ real life experience are provided they can find new unknown mathematical structures by discussing and talking to each other and develop their mathematical knowledge.

# Teachers' beliefs about mathematical modelling: An exploratory study

Paola Ramirez

University of Bristol, Graduate School of Education, England; [paola.ramirez@bristol.ac.uk](mailto:paola.ramirez@bristol.ac.uk)

*Drawing upon a theoretical framework based on beliefs, learning and teaching of mathematical modelling as well mathematical modelling itself, this paper explores mathematics teachers' beliefs about these themes. Based on responses to an online questionnaire, teachers' beliefs, experiences, and mathematical modelling lessons were shared from the teachers' perspective; several similarities with the cyclical process of modelling emerged, as well as sharing a new point of view of the aspects that teachers consider as mathematical modelling for example, real-life situations and processes behind mathematics problems.*

*Keywords: Teacher beliefs, mathematical modelling, mathematical model, learning and teaching mathematical modelling.*

## Introduction

Mathematical modelling involves the development of models to explain real-world situations. Such models allow for making predictions, explaining phenomena, making decisions, and disseminating knowledge (Schichl, 2004). In addition, learning mathematical modelling is a cyclical process in which pupils' study a problem derived from the real world and create a mathematical model to explore, predict and explain in order to provide a solution to that problem (Mason & Davis, 1991).

Mathematical modelling may also be seen as an approach to learning that uses elements of reality to create models with mathematics. In this approach, students work together in a cyclical process that involves different stages, such as formulating a mathematics problem based on a situation in real life, setting up a mathematical model that explains the problem, attempting to find a mathematical solution for the problem, explaining the model and interpreting the solution, and comparing the solution with the original problem in real life (Mason et al., 1991; Blum & Borromeo, 2009; Lawson & Marion, 2008). It is important to note that while it is true that the students are engaged in the modelling process in a lesson, it is the teachers who initially implement the strategy, for example, by choosing the modelling task.

In this context, previous studies have suggested that, when applying mathematical modelling, teachers should consider, for example, 'teachers have to know ways how to support adequate student strategies for solving modelling task' (Blum et al., 2009, p. 54). Complementary to this idea, Tekin Dede and Bukova Güzel (2016, p. 1) suggest that 'some researchers indicate the teacher are not be sure about how they should act in this implementation process. Especially the teacher who are novice or have not enough experience in modelling can have difficulties in this process'.

Considering that the role of the teacher appears to be a crucial part of the development of the cycle of mathematical modelling; the question then arises of what beliefs teachers have about mathematical modelling that they could share with their students. As Kaiser (2006, p. 399) notes, 'teachers and their beliefs concerning mathematics must be regarded as essential reasons for the low realization of applications and modelling in mathematics teaching'.

Bearing these factors in mind, this study seeks to examine mathematics teachers' beliefs about mathematical modelling through an online questionnaire about teachers' backgrounds as well as their opinions about mathematics classes, mathematics models, and modelling. This study is the first part of an ongoing process of a doctoral research project; the aim of this paper is thus to examine teachers' beliefs and practices related to mathematical modelling in order to discuss future implications when conducting mathematical modelling.

## Theoretical framework

Thompson (1992) discussed the idea that teacher beliefs about the nature of mathematics should be considered – for example, concepts, meanings, and rules, among others – as well as teachers' beliefs about teaching and learning mathematics. In addition, as Stipek, Givvin, Salmon, and MacGyvers noted in their study on evaluating teacher beliefs, we should consider (2001, p. 213):

(1) the nature of mathematics (i.e., procedures to solve problems versus a tool for thought), (2) mathematics learning (i.e., focusing on getting correct solutions versus understanding mathematical concepts), (3) who should control students' mathematical activity, (4) the nature of mathematical ability (i.e., fixed versus malleable), and (5) the value of extrinsic rewards for getting students to engage in mathematics activities. (6) Teachers self-confidence and enjoyment of mathematics and mathematics teaching.

Handal (2003, p. 47) states that teacher beliefs can be related to 'what mathematics is, how mathematics teaching and learning actually occurs, and how mathematics teaching and learning should occur ideally'. It would appear that beliefs about mathematics share common themes with the field of mathematics itself, as well as with teaching and learning mathematics. Indeed, many researchers currently study beliefs about mathematics, practices, and teaching, so it is natural that many researchers would study beliefs within specific areas of mathematics (for example, mathematical modelling), since mathematical modelling is part of mathematics.

When examining beliefs about mathematical modelling, we should consider that 'beliefs in the context of mathematics education can be classified as beliefs about mathematics (as a science), beliefs about the learning and teaching of mathematics [,] and teacher self-efficacy beliefs' (Mischo & Maaß, 2013, p. 22). According to those authors, the first aspect – mathematics as a science – refers to the formal aspect of mathematics as theorems, rules, problem-solving, and applications as subjects to be learnt. In this context, mathematical modelling is part of this frame, since it is a process that involves a task that takes elements from reality to be explained mathematically. The second aspect – learning and teaching mathematics – refers to constructivist and socio-constructivist views as a way of teaching modelling. Finally, teacher self-efficacy refers to teachers' beliefs that should be carried out and activities that should be implemented in order to reach the teacher's goals within a lesson.

Ärleback J. (2009, p.2100) posits that in order to understand the beliefs from teachers about mathematical modelling and models it is necessary to take account of 'beliefs about the nature of mathematics, real world (reality), problem solving, school of mathematics and beliefs about applying, and applications of, mathematics'.

Previous studies from the literature review, however, do not seem to have taken into account the 'perceptions and beliefs about mathematics [that] originate from past experiences' (Mutodi &

Ngirande, 2014, p. 432); perhaps these studies would have had more to offer if they had included relations with past experiences, because if teachers have a history with mathematics (in particular mathematical modelling, because it is part of mathematics), then their beliefs about the field can be related to the background and experiences they have lived: for example, when they teach or learn mathematics.

According to the literature, we may observe that teachers' mathematics beliefs may be classified into different topics; these topics stem from the experiences that teachers have had with mathematics, either through teaching or learning or when they themselves have studied the subject. In this study, considering the idea that mathematical modelling is part of mathematics, teachers' beliefs about mathematical modelling will be classified into three dimensions on the basis of the literature review: (1) mathematics in itself, in particular considering mathematical models and modelling; (2) beliefs about learning and teaching mathematics modelling, considering students, behaviours, lesson planning, and task design; and (3) real-life experience with mathematical modelling, which means that the history described by each participant will be taken into account in relation with mathematical modelling and models, since our beliefs about mathematics stem from our past experiences. It is important to note that this third dimension cannot be separated from the first two, because the experience gained from any context will be enriched by the mathematics itself as well as by the experiences of teaching and learning mathematics.

## Methods

The aim of this study was to explore teachers' beliefs about mathematical modelling, therefore an exploratory research was adequate because this attempts to 'seek new insights' (Robson, 2002, p.59) on teaching mathematical modelling in light of my considerations in the introduction, consequently gaining familiarity with the beliefs of mathematics teachers.

Bearing in mind that beliefs are related with mathematics on different dimensions, the selection of the participant was through an activity that is related to mathematics, such as teaching mathematics, conducting research in mathematics education, or studying mathematics itself. Consequently, three of the participants were Chileans who worked at a university in Chile in the mathematics faculty where they are training future mathematics teachers; six of the participants were from the United States, where they worked at high-need schools<sup>1</sup>. The richness of these participants, helps me to have an international overview of the beliefs in this area.

In order to research the beliefs of mathematics modelling, an online questionnaire was designed, comprising ten structured and open-ended questions based on the literature review about mathematical modelling with a focus on the teachers' relationships with the field of mathematics education, mathematical modelling and models. In addition, there are similarities between online questionnaires and structured interviews, in that the researcher has the same direct pre-established questions for each participant without giving interruptions among questions. Those similarities,

---

<sup>1</sup> 'The school is located in an area in which the percentage of students from families with incomes below the poverty line is 30 percent or more; or in an area with a high percentage of out-of-field teachers; is in an area in which there is a high teacher turnover rate; or is in an area in which there is a high percentage of teachers who are not certified or licensed; is within the top quartile of elementary schools and secondary schools statewide, as ranked by the number of unfilled, available teacher positions at the schools' (No Child Left Behind Act of 2001, 2002, p.115, STAT.1656).

made me consider and exploring the online questionnaire as a way to approach at teacher beliefs. Furthermore, taking into account the limitations of distances between countries and accessibility, the online questionnaire was adequate.

The online questionnaires were distributed between December 2015 and January 2016. The answers were transcribed and analysed based on categories described above; the way that I used to analyse the answers was considering all of them, highlighting common factors that emerged and after that observing how these related to the theoretical framework described previously. It would have been preferable to include the questions, but this was not possible due to space limitations.

Because this is an initial study on mathematics teachers' beliefs about mathematical modelling, it is impossible to generalise from this point of view, but the study can present an opportunity to explore what occurs in beliefs of teachers about this subject on persons related with mathematics but not necessarily those currently working with mathematical modelling and thus provide insights within this large and expanding field, for example, when an implementation is carried out by teachers.

## Results

A few representative teacher examples are provided below to illustrate their responses; the responses were transcribed whole, to prevent loss of fluency. In the transcripts, certain parts of the texts have been put in italics font below for emphasis, showing the common factor highlighted on the analysis process. In addition, 'TUS' refers to teachers from the United States, while 'TC' refers to teachers from Chile. The number next to the initials indicates the person who has answered the question.

## Mathematical modelling

### Real-life situations and processes behind mathematics problems

According to teachers' responses about mathematical modelling, for example, what comes to mind when you think of mathematical modelling, teachers' beliefs may be categorised in two ways: (1) real-life situations or real-life problems and (2) the process involved in solving mathematics problems. Both considerations also take mathematics itself into account: more specifically, the real world and the application of mathematics, as Ärleback (2009) has noted.

- TC1: *Real situations*, math representation, solving, and interpretation.
- TC8: It came to my mind to think of applied math, i.e., to *relate math with nature* or a *daily situation*.
- TUS2: I explain to the students that we use mathematics to *model situations in real life* to be able to understand them better and, if possible, to find a solution to the situation ... I think of it as visuals that will simplify the situation I am reading. I think of equations or systems of linear equations that will allow me to find solutions.
- TUS4: I think mathematical modelling means *showing the students the thought process that is involved in solving a math problem*. It's the problem-solving techniques in regard to a given (abstract or *real-world*) math situation – explaining which

method, formula, etc., is going to work and why. That's what I think mathematical modelling is.

TUS5: The teacher needs *to model the way a problem should be processed* and thought through in order to come up with a valid solution.

As the reader may have noted, there is a link between the beliefs about mathematical modelling and the 'real situation' which can be interpreted, for example, with real life and is related to the modelling cycle mentioned previously. However, there is also a distinction between these beliefs because to others 'modelling' means modelling through a 'step by step' approach showing the process behind a mathematics problem.

### Mathematical models

In response to the question 'what do you think about mathematical models?', some of the teacher beliefs about modelling are related with the use of models within mathematics; in some of the teachers' responses, the teachers' beliefs were related to the nature of mathematics itself (Ärlebäck, 2009; Thompson, 1992; Handal, 2003; Stipek et al., 2001; Mischo & Maaß, 2013) as well as with mathematics learning (Handal, 2003; Stipek et al., 2001; Mischo & Maaß, 2013). In accordance with Mutodi and Ngirande's work (2014) about experience and beliefs, some of the teachers mentioned their past experience with models, when they were responding to 'what is your opinion about the statement: 'Modelling is everywhere'' (Mason & Davis, 1991, p. 9).

TUS7: Taking real-world data and using graphing tools and computers to assist in *obtaining models*.

TUS6: I think a mathematical model is a key factor in *describing measurement that is located in space*. [Models are] essential for describing the composition of matter in our universe.

TUS2: During college, we used mathematical models in *calculus and geometry* as well as *numerical calculus and number theory* ... I agree with 'modelling is everywhere'. I believe some of the models are more elaborate than others, but in general, *I can see everything being a model of concepts*, including numbers and graphs.

TC9: *Visuals* are necessary; hands-on [teaching] is almost vital for understanding.

From the transcript, it is possible to infer that the teachers viewed mathematical models as ways to understand mathematics with a factor of utility of model, using words such as assist, essential or necessary.

## Learning and teaching mathematical modelling

### Experience with mathematical modelling

In terms of experience in modelling, some of the teachers mentioned that they had studied modelling at their universities (i.e., dynamic systems and geometry, among others); they also discussed their experience in teaching (or not having experience in mathematical modelling). This situation relates to what Mutodi and Ngirande (2014) discuss in their work: our beliefs about

mathematics come from our experience with mathematics. In addition, some of the teachers recognized that they had limited experience with mathematical modelling, or they lacked the time to do it; one of the teachers, however, also mentioned her intention to learn more about modelling.

These ideas could help to explain why teachers are often unsure of how to act when they work with mathematical modelling, which results in necessary (and time-consuming) planning during the implementation stage, as mentioned by Tekin Dede and Bukova Güzel (see the introduction to the current paper).

TUS2: As a school teacher, I would love to be able to *have the time to read and understand more about mathematical modelling*.

TUS3: *I have not spent nearly enough time* doing mathematical modelling.

TC8: My experience with *mathematical modelling is with dynamical systems*. In this area, you can find many examples of different situations where modelling is present. In the classroom, you can use simple examples and particular cases of this area to show the students.

### Mathematical modelling class

After the question, ‘how do you imagine a mathematical modelling class?’, several teacher beliefs have presented several similarities when using elements from reality yet only one teacher mentioned focussing on models, as has been mentioned by several authors in this paper (Mason & Davis, 1991; Blum, 2009; Lawson & Marion, 2008); In addition, teachers’ beliefs as to how mathematics teaching and learning can occur as Handal (2003) described previously were present. For example, some of the teachers’ responses in the present study suggested that mathematical modelling lessons could be very creative, active, and didactic, where the students could take part in the learning process.

TUS2: I imagine [that mathematical modelling class] *focusses on models* more than a specific area of mathematics.

TUS6: Let’s take, for example, the concept of geometry. *The setting within a classroom could be used as mathematical modelling*. Without going outside the four walls [of a classroom], one could introduce to students the concept of angles, lines, planes, perpendicular and parallel lines, congruent angles and similar figures, and so on ... I think of [mathematical modelling class] *as very creative*; it is an atmosphere where *students are launched into using their minds* so that they will become creative, inquisitive, and analytical... Mathematical modelling is one of the most *intriguing, creative, and thought-provoking subjects that one can teach*. It blends into other subjects, such as art, physics, and chemistry.

TC8: I imagine a mathematical modelling class as being very *active and didactic* – *students working in groups and discussing the problem that has been assigned*.

### Discussion

Through this study, we can observe that the beliefs are quite similar in both countries. Teachers link mathematical modelling with situations to be modelled; this situation stems from real-life

experiences. This belief shows a similarity with mathematical modelling as a subject that can involve the development of models to explain real-world situations (Schichl, 2004). One teacher, however, said that mathematical modelling was how ‘a problem should be processed’; in this case, the teacher’s beliefs were not related to real-life situations but to the process involved in solving mathematics problems. Perhaps this particular belief about mathematical modelling could be understood in light of some of the teachers’ limited experience with mathematical modelling or, as Tekin Dede and Bukova Güzel (2016) have stated, because the teachers were unsure how to act when working in a class that involves mathematical modelling.

On the other hand, teachers’ beliefs about mathematics modelling classes in general showed that they felt that classes could be very creative, intriguing, and thought provoking; as one teacher said, they could be taught with the participation of the students. One teacher did recognise, however, that it can be difficult to break down some students’ beliefs. Even so, other teachers stated their intention to learn more about mathematical modelling.

In terms of mathematical models, sometimes teacher’s beliefs referred to the utility of using a model as a way to demonstrate mathematics concepts. In this sense, mathematical model beliefs are related to the nature of mathematics (Mischo & Maaß, 2013; Stipek et al., 2001; Thompson, 1992; Handal, 2003; Ärleback, 2009) as well as with the experiences that they have had in the past (Mutodi & Ngirande, 2014). Then the questions that naturally arise include, In which ways can the utility beliefs of a model influence the implementation of mathematical modelling? What kind of decision does the teacher take during an implementation? What types of feedback can the teacher give to the students?

Finally, through this particular study and in consideration of teachers’ beliefs about mathematical modelling, more questions and insights have emerged; for example, how to lead an implementation of the mathematical modelling cycle that would bear teachers’ beliefs in mind, and how can the usefulness and reliability of online questionnaires be linked to carry out an exploratory study on beliefs.

*In this paper we present a methodology to design didactical activities for training engineers. One phase of this methodology is selecting an extra-mathematical context, allowing identification and analysis of mathematical models used by engineers. We selected an industry beer context and we identified the Pareto chart as a tool to solve different problems, for example faults in production lines. This work uses elements from Anthropological Theory of Didactics. We present a praxeological analysis as basis of didactical activities.*

*Keywords: Beer industry, Pareto chart, training engineer, didactical activity.*

## Introduction

Over the past 30 years, mathematical modelling and applications have been a subject of study and development in the field of Educational Mathematics, as in the ICMI 14 study, edited by Blum, Galbraith, Henn and Niss (2007). Mathematical modelling and applications are activities in which math is used to solve problems in various contexts (math, engineering, economy, medicine, etc.). They are based on developing competencies associated with the application of mathematics and constructing mathematical models in extra-mathematical contexts (Niss, Werner and Galbraith, 2007). However, mathematical modelling and applications are not widely used in primary and secondary education, which give more importance to concepts and procedures. At the university level, modelling has emerged as a new educational paradigm (Bissell & Dillon, 2000). In the future, teaching professionals will be required not only to create but also adapt mathematical models to solve practical problems (Bissell & Dillon, 2000) related to interpreting solutions proposed by other professionals and to employ technology to perform mathematical tasks. This demands teaching math in such a way that it includes the use, adaptation, handling, and interpretation of mathematical models in order to adequately deal with tasks in extra-mathematical contexts. One of perspectives that comes closest to this demand is known as the realistic perspective, which is described in the proceedings of the Topic Study Group 21 (TSG21) of the 11<sup>th</sup> International Congress on Mathematical Education in 2008, as follows: “In this perspective, mathematical modelling is viewed as applied problem solving and a strong emphasis is put on the real life situation to be modelled and on the interdisciplinary approaches” (Blomhoj & Carreira, 2009). In this work, we consider the work of Kadijevich (2009), which illustrates this perspective, is a very interesting approach to the mathematical modelling due to the type of problems chosen to address it and to the use of information technology that is proposed. However, we believe that is not clear, from a theoretical point of view: how do you choose the actual context? How is a modelling activity generated in the context chosen? How is analyzed their relevance to the classroom? In general, it seems that the question of choosing the extra- mathematical context in order to propose the modelling activity has been theoretically little worked, it appears as a little cloudy element, leaving the emphasis on the characteristics of didactic activities (Galbraith & Stillman 2006) and on the modelling cycles that

allow to describe and analyse it (Blum & Borromeo Ferri, 2009). In an effort to attend to this lack of theoretical framing of the choice of additional mathematical context for the design of didactic activities, we have proposed a methodology based on the extended praxeological model (Castela & Romo, 2011) for designing didactic activities based on modelling that incorporate elements of the use of models in real contexts.

## Elements of the Anthropological Theory of Didactic

Since the extended praxeological model (Castela & Romo, 2011) is based on the Anthropological Theory of Didactics (ATD), we present in this section some of its elements. The ATD is an epistemological model that allows the study of human activity in its institutional dimension. An institution is a stable social organization that defines the human activities generating resources that make them possible. These materials or intellectual resources, which are made available to the subjects, have been produced by communities along the confrontation of problematic situations with the objective of solve them in a regularly and effectively way (Castela & Romo, 2011). The classic praxeological model, proposed by Chevallard (1999), recognizes the praxeology  $[T, \tau, \theta, \Theta]$  as a minimal unit of analysis of human activity. Its four components are: the task type ( $T$ ), the technique ( $\tau$ ), the technology ( $\theta$ ); and the theory ( $\Theta$ ). The ‘task’ refers to what is to be done; the ‘technique’ is how it is to be done; the ‘technology’ is a discourse that produces, justifies and explains the ‘technique’; while the ‘theory’ produces, justifies and explains the ‘technology’. Mathematical praxeologies or mathematical organizations can be of different level and they serve to a hierarchy of levels of determination proposed by (Chevallard, 2002). Mathematical institution imposes a model of subjection to the mathematical praxeologies: it rests on a structure that organizes praxeologies in different interlocked levels that are in increasing order of size as follows: specific, local, regional and global. The most basic level of a mathematical organization is the punctual  $[T, \tau, \theta, \Theta]$  and it has only one technique for performing such tasks. The next level is the local, which groups all punctual mathematical organizations associated with the same  $\theta$  technology. The regional level regroups all punctual organizations associated with same theory  $\Theta$ , global or domain regroups certain regional mathematical organizations; discipline is the top level and combines all domains.

## Codetermination of the mathematical and didactic

Chevallard (2002) develops the model presented below, in order to take into account the subjections that weigh on the didactic organization of the study of praxeologies. In this work, the author notes that didactic organizations cannot be developed if they are found far from higher levels, domain and discipline; reciprocally these levels cannot be imposed without considering the conditions of the educational institution. In that sense yields a co-determination of mathematical and didactic organizations.

[...] each level imposes, at a given moment during life of educational system a set of constraints and support points: ecology that results is determined both by what restrictions prohibit or drive, and the exploitation that actors make to the support points that different levels offers. (Chevallard, 2002, p.49)

As you can see the fact that Chevallard be interested in teaching leads to extend the range of levels. He introduces three higher levels: society, school and pedagogy, noting that levels of domain and discipline are also subject to restrictions imposed by these three levels that complement the scale

upward: Society → School → Pedagogy → Discipline → Domain → Sector → Local → Specific. This hierarchy makes us consider that the study of mathematical praxeology or modelling praxeology in an institution that is subject to various restrictions imposed by institutions of higher levels.

### **Moments of the study**

In the frame of ATD, the study is seen as the construction or reconstruction of elements of a mathematical praxeology, in order to perform a troublesome task (a task type for which a mathematical praxeology does not exist or is not available). In order to finely describe this process of construction or reconstruction, the ATD proposes a model of study of a punctual mathematical praxeology. This model distinguishes six moments, which are also associated with groups of activities. A moment is a dimension of the activity, a phase in the process of study, which may appear several times but following an internal global dynamics. Chevallard (2002) presents the model as follows:

#### **Group I (Study and Research Activities [SRA])**

1. Moment of *the (first) meeting with T*;
2. Moment of *the exploration of T and technical emergency  $\tau$* ;
3. Moment of construction of *the technological-theoretical block*.

#### **Group II (Synthesis)**

4. Moment of *institutionalization*.

#### **Group III (Exercises and problems)**

5. Moment of *work of the mathematical organization (specifically of the technique)*.

#### **Group IV (Controls)**

6. Moment of *the evaluation*.

These moments are not detailed in this paper, but they are presented with the aim of showing how the ATD in the process of construction and reconstruction of a praxeology is conceived.

In particular, we are interested in considering group I and generating an SRA: a didactic device for students to construct, in this case, a modeling praxeology involving the Pareto Diagram. One of our questions is, what legitimizes the chosen mathematical modeling praxeology? Why is it important for students to build this praxeology? And in particular, future engineers. For us it is important that the mathematical modeling of the classroom is related to the mathematical modeling of its professional practice, which is seen as a relationship between institutions as shown below.

### **Training in mathematics and the professional world seen as institutions**

In the framework of the ATD, analysis of mathematical activity is considered in its institutional dimension. Given that our proposal is to generate a methodology for designing activities based on mathematical modelling that links mathematical knowledge teach at the training institution and the one used in the professional field, we must identify institutions that are adequate to participate in this process, and their interrelations. Romo-Vázquez (2009) argued that training engineers involves three types of institutions: Production (*P*), where praxeologies are produced, Teaching (*E*) responsible for transmitting the praxeologies. Use or users *Ip*, where the praxeologies are employed. By producing institutions we refer to mathematics *P(M)* seen as a discipline, together with its

intermediate disciplines  $P(DI)$ , which we will also call Engineering Sciences (e.g. signal processing, control theory, electrical circuits, etc.). Teaching institutions are represented by mathematics  $E(M)$ , and the intermediate disciplines  $E(DI)$ ; while the practical institution is  $Ip$ . The latter is examined at two levels: the professional practice of engineers, and the devices that, upon approaching practice, are developed in schools; for example, a project to innovate a product or service. Also taken into account were three inter-institutional tours that can be followed by a mathematical praxeology by going from  $P(M)$  to  $Ip$ . These can be represented schematically as follows (Figure 2):

**Figure 1: Institutional tours of a mathematical praxeology to go from  $P(M)$  to  $Ip$**

The transpositive effects (changes that occur upon moving from one institution to another) can be so large that a mathematical praxeology in  $Ip$  may not be recognized as mathematical. Research by Hoyles, Noss and Pozzi (2000) shows that some professionals utilize techniques and strategies in their practice that are based on mathematical models, but that when automated are no longer recognized as such. This begs the question: what sorts of didactic activities can be generated so that the mathematical models used in  $Ip$  practice or  $E(DI)$  find a place in methods of teaching mathematics  $E(M)$  (see Figure 2)? To answer these questions we propose the following methodology.

**Figure 2: News institutional relations between  $Ip$ -  $E(M)$  and  $E(DI)$ - $E(M)$**

## Methodology for designing didactic activities (SRA) based on mathematical modelling

This methodology for designing didactic activities based on mathematical modelling emerged from research by Macias (2012). Here, modelling activities are seen as praxeologies (mathematical and/or modelling) to be performed in  $E(M)$ , but in relation to praxeologies of  $E(DI)$  and/or  $Ip$ . It consists of four phases: 1) Selecting an extra-mathematical context, 2) Praxeological analysis and identification of a mathematical model. 3) Analysis of the mathematical model identified and its relation to  $E(M)$  and 4) Design of the didactic activity (SRA) for  $E(M)$ .

**1) Selecting an extra-mathematical context.** First, we must consider the educational level at which teaching will take place, then the contexts where the mathematical applications will be put to use. For example, if we consider teaching programs for engineers, the natural contexts of use are specialty training  $E(DI)$  and professional practice  $Ip$ . After that, one must identify some of the elements (resistance of materials, control theory, data structure, among others) that are of macro scale and may include various sub-institutions for the analysis of the modelling activity that occurs there. Selecting this context must be based on an approach to the institution or sub-institution

through interviews with one or more of the subjects involved (e.g. professors, expert users, researchers), a review of relevant documentation (suggested by the aforementioned subjects, and/or one's own search), and visits aimed at identifying the type of mathematical and modelling activity that is used. Specifically, it is important to analyse whether the mathematical models identified as being in use correspond to those that are actually taught  $E(M)$ ; examples could include functions, vectors, matrixes, mathematical optimization, or differential equations, among others. In this way, one can determine whether the context chosen provides a suitable analytical basis for designing the didactic activity.

**2) Praxeological analysis and identification of a mathematical model.** In this phase mathematical modelling activity is analysed through praxeologies. Modelling activities in an extra-mathematical context may consist of mathematical praxeologies and/or mixed praxeologies.

**3) Analysis of the mathematical model identified and its relation to  $E(M)$ .** A mathematical model that is in use but that is also taught in  $E(M)$  is identified and then analysed through the functions of the technology practice; i.e., describe, validate, explain, facilitate, motivate and evaluate. Describing the model in use allows us to elucidate the reasons relative to context on the basis of which that particular model was chosen to resolve tasks in the extra-mathematical context. Identifying the elements that validate the use of the model, and under what conditions, makes it possible to understand what contextual elements must be considered in designing didactic activities. For example, many mathematical models are used in “ideal” conditions such that they make it possible to resolve certain tasks more easily, though the solutions obtained will later need to be adapted to reality. This adaptation is conducted on the basis of certain elements that *validate* it. Recognizing the *explanations* of use allows us to understand what each element of the model represents and to what degree the model used allows us to model the context (or part of it). Analyzing the elements that *facilitate* the use of the model reveals the process of mathematical modelling, which entails not only assuring that the mathematical model chosen will make it possible to resolve a problem in an extra-mathematical context but also that the resolution reached will be the least complex one. Identifying precisely what it is that motivates the use of the chosen model is a medullar phase in designing didactic activities, but this analysis of use must be complemented by a didactic analysis of the model in the context in which it is taught.

**4) Designing didactic activities (SRA).** Designing a didactic activity must be based on both the praxeological analysis of use (praxeologies present in an  $Iu$ ) and the mathematical model identified; i.e., one must recognize the praxeologies of both use and teaching in order to perceive the relations between them. One must choose the types of tasks that, because they emerge from use, can be adapted for a type of school task; for example, studying the behavior of a continuous signal, determining the total cost of an inventory, or calculating the inverse of a mixed matrix, etc. These types of tasks require mathematical techniques that may be school-related (being part of curriculum) but are also used in the professional field, so mathematical and non-mathematical technologies will have to be built by the students (3<sup>rd</sup> moment) in order to validate, explain and justify techniques that emerges when confronting the problematic tasks. Specifically, technologies of use (part of practical praxeologies) must be adapted in such way the students can build them in the first college courses. The objective of the didactic activities must be oriented towards the type of praxeologies that figure

in the activity, whether this be constructing, mobilizing, or searching, for knowledge. It is intended that this activity may be an SRA which allows building a praxeology of modelling.

### The context proposed: Pareto chart in beer industry

To make a praxeological analysis we are chosen a Beer industry that is constituted by ten production lines and produce about one million hectoliters of beer per month. Apart from domestic beer this industry produce lots of beer for export to countries in all continents. To meet domestic demand and shipments abroad, it requires each of the ten production lines, meet high levels of efficiency. However, in each production line problems requiring immediate attention in order to achieve the planned goals they are presented. Thus various problems for the maintenance of thousands of machines, components and parts that make up each of the production lines are also presented. And logistics to control the flow of materials required in the production and control of shipments. In Tolentino (2015), these questions are studied: What Mathematics used in this industrial environment? Are there some common mathematical tools to manage the wide range of problems in the brewing? Tolentino, was both a master's student of mathematics education program and he was working in the industry as an engineer, he found that a Pareto chart is used to solve problems in the industry. This chart is based on the principle that if 20% of the causes of problems is attended a solution of 80% is obtained in effect.

### Praxeology faults problems

**Type of task.** Identify the most important causes of faults in production lines of an industry. **Task.** To solve faults (time) that arise in different production lines of beer production. **Technique. Step 1. Data collection.** It is recorded in a table stop time of production lines due to operational faults, faults in machinery or material defects. **Step 2.** Is ordered from highest to lowest the time column of this table, the percentages of stop time are obtained for each line, in relation to the accumulated from 157.62 hours. A column for cumulative percentage is added.

Line	Wasting time (h)	Percentage	Cumulative Percentage
Line 2	41.02	26.02	26.02
Line 8	25.65	16.27	42.30
Line 12	24.34	15.44	57.74
Line 6	14.73	9.35	67.09
Line 10	14.17	8.99	76.08
Line 3	13.8	8.76	84.83
Line 11	11.03	7.00	91.83
Line 5	8.33	5.28	97.11
Line 4	4.55	2.89	100.00
cumulative	157.62		

**Table 1: Wasting time of production lines**

**Step 3.** Two graphs are performed in Excel: in the bar graph the columns for each line indicate stop time. Graph of the Lorenz curve or cumulative percentage. On the right vertical axis measures the time from 0 to 41.02 h. For the Lorenz curve on the right vertical axis the percentage of 0 is measured at 100 percent (See figure 3). **Step 4.** Identify the diagram. Finally add a line from the 80 percent that intersects the graph of the cumulative percentage, and descends to the x axis, to separate lines that are to the left of this line it is the line 2, 8, 12, 6 and 10 (see figure 4). These are the lines that generate 80 percent of the total time of overall production stoppages during this time period.

Figure 3: Bars and Lorenz curve

Figure 4: Analysis of the Pareto Diagram

**Step 5. Analyze the Pareto chart.** As a result of the above analysis, attention is directed to lines that generate 80 percent of stop time, *ie* lines 2, 8, 12, 6 and 10. Therefore proceeds to Pareto analysis of each one of these 5 lines, starting at line 2. Leaving as trivial the 4 lines: 3, 4, 5 and 11. That is although the line 11 was stopped 11 hours during this week, is considered out of importance according to the analysis Pareto realized. In this case, the Pareto Diagram is used again to analyze lines 2, 8, 12 and 6, to make decisions about the elements that must be repaired urgently, in each of the lines. The Pareto Diagram is made by engineers and allows them to identify the main causes of the problem, however a deeper analysis of the industry is necessary to recognize how the practical and theoretical knowledge allows solving the identified causes. This analysis is repeated in the brewing industry several times to have elements to act and address problems optimally, using fewer resources and obtaining the greatest benefits.

## Conclusion

We consider that this praxeological analysis (phase 2 of methodology), briefest presented, allow us to see the importance of Pareto chart on the beer industry. To design the SRA, it is necessary to analyze university courses likely to identify a local Praxeology the Pareto chart. However, analysis of the Pareto chart of the beer industry gives elements for SRA: from data of different problems ask propose a model that allows the company to identify the major causes of the problems. Considering the problem of faults, you can ask students a model to identify the line that causes the greatest wasting time or the lines that cause 50% of the strikes, then 75% and then 80%. The interesting thing about this proposal may lie not only that students can work with data from businesses, but they reach handle the Pareto Principle, the 80-20 ratio. The Pareto Diagram also involves mathematical elements that support them as the Lorenz Curve, which has hardly been mentioned here. In Tolentino (2015) the mathematical analysis of the origin and evolution of the Pareto Diagram is presented and this must also be considered in the design of the SRA, involving three institutions  $P(M)$ ,  $E(M)$  and  $Ip$ .

# Mathematical modelling in an archaeological context: Their complementarity as essential tool for inquiry

Gemma Sala<sup>1</sup>, Vicenç Font<sup>2</sup>, Berta Barquero<sup>3</sup> and Joaquim Giménez<sup>4</sup>

University of Barcelona, Faculty of Education, Spain; [gsala@ub.edu](mailto:gsala@ub.edu)<sup>1</sup>; [vfont@ub.edu](mailto:vfont@ub.edu)<sup>2</sup>; [bbarquero@ub.edu](mailto:bbarquero@ub.edu)<sup>3</sup>; [quimgimenez@ub.edu](mailto:quimgimenez@ub.edu)<sup>4</sup>

*This paper focuses on analyzing the potentialities of using a codisciplinary inquiry context to enhance the appearance of mathematical modelling in teaching and learning practices. We focus on an archaeological context where modelling becomes an essential tool to enquire into and progress on the study of questions emerged from the interplay between two main disciplines: Mathematics and History. We present the design, implementation and analysis of a teaching sequence based upon the ruins of a Roman theatre discovered in Badalona (Catalonia) to promote inquiry and modelling students' competences. The sequence was implemented in 2015 with 12 and 14-year-old students. The central question introduced (what kind of building could have been the discovered ruins) involved students in a reflective inquiry process that facilitate them to progress on modelling, at the time modelling facilitate that the inquiry process could follow.*

*Keywords: Inquiry competence, mathematical modelling, co-disciplinary context, geometrical model, task design.*

## Introduction

The main aims of our research are to (1) design codisciplinary teaching sequences to promote inquiry students' competence, (2) implement them and (3) analyze their affordances to enhance inquiry and modelling students' competences. In particular, this paper focuses on the design, implementation and analysis of a teaching sequence based upon an archaeological context—the ruins of a Roman theatre discovered in Badalona (Catalonia, Spain) and how modelling became an essential tool to enquire into several questions that emerged from this extra-mathematical context, in order to progressively build up the necessary subject knowledge to provide and validate answers.

As aforementioned, the sequence started with an initial situation that leads to the formulation of the specific initial question and became the core of the students' research. The starting situation which is presented to students is the discovery of some Roman ruins in a Badalona's suburb by the archaeologists' team of the city Museum. The archaeological report that is provided explained that these ruins could belong to an ancient Roman building, but *what kind of building could it have been? Could be a theatre? A circus? An amphitheatre?* In order to face these questions, it is essential to make students unfold their inquiry and modelling competences and help teachers to guide student's reflections and to organize inquiry activities so that (mathematical and historical) knowledge could emerge and be used.

In the research we present, the codisciplinary context here considered for the design of the sequence—an archaeological context adapted from a real research—presents several advantages, which will be further developed in the following sections. On the one hand, requires that Mathematics and History work together to face most of the questions that appear in the teaching and learning

sequence. This no so common complementarity between both disciplines allows us to provide authenticity (Vos, 2011) to the questions faced and to promote the blend of inquiry and modelling in different steps of the study, as also some previous investigations have shown (Sala, Giménez & Font, 2013; Sala, Barquero, Font & Giménez, 2015). On the other hand, this codisciplinary context is enough close to students (as it is located in the same city that the school is) that facilitates that students can have access to the real ruins and to experts' answers about their real investigations, providing legitimacy to their inquiry process and responses. After describing the main theoretical frameworks upon which the design of the teaching sequence was proposed and analysed, we present the main research questions about how the use of codisciplinary inquiry contexts can help to break disciplinary boundaries (in particular between Mathematics and History) and about how their interaction leads to a rich complementarity between inquiry and modelling.

### **Theoretical framework and research questions**

The research we present in this paper considers different theoretical aspects. First, it is assumed the notion of *basic competence* considered in Catalan curriculum. More concretely, we are interested in the notion of *inquiry competence* that, following Sala (2016) and framed according to the Catalan curricula of Primary and Secondary school education, it is defined as:

The ability to mobilise the suitable knowledge and the appropriate resources that facilitate the development and application of a logical and critical methods —under the teachers' guidance— in order to look for and find answers to problematic questions or situations in some school and/or out-school context. (Op. Cit. 2016, p. 64)

In the same line than Artigue & Blomhoj (2013) underlines, an important step in legitimising inquiry-based approaches was the publication of the National Science Education Standards (NSES; NRC, 1996), which called for students to do and know about scientific inquiry, and that teachers should foster the development of inquiry skills. When the inquiry-based approaches migrate towards mathematics, it seems important to consider approaches paying attention to establishing connections among mathematical and extra-mathematical world, such as modelling approaches. In this sense, some of the inquiry requirements (such as making observations, posing questions, examining sources of information, identification of assumptions, considering alternative explanations; NRC 1996, p.23) are closely related to some essential steps of the cycling process through which mathematical modelling is developed. So that, sometimes, it is difficult to find the differences between both processes (see for instance, the modelling and inquiry cycles presented in Blomhoj, 2004) and the linked competences. In particular, as pointed in Niss, Blum & Galbraith. (2007, pp.3-8), modelling constitutes a competence in its own right, which needs to be developed through appropriate modelling activities. From our viewpoint, to promote inquiry mathematical modelling should be placed at the core of the mathematical (and scientific) teaching and learning practices to ensure the right and rich development of important enquire abilities. Also, in the other way round, to promote and ensure mathematical modelling practices, inquiry should nourish some essential steps that may make modelling successfully progress.

Second, we considered different theoretical elements to ensure that the sequence design could offer a rich and functional teaching and learning of mathematics. With this aim, the mathematical and

didactic design quality is justified based on the three criteria of didactic ‘suitability’ —*emotional suitability*, *ecological suitability* and *epistemic suitability*— proposed by the onto-semiotic approach (Godino, Batanero & Font, 2007). Different aspects of its design considered justify the emotional suitability of the teaching sequence: the students could work with real data evidence —data from the research report of the discovery of real Roman ruins—; they could interact with the archaeologists’ team of the city Museum and could share their results with them, etc. In turn, *ecological suitability* was justified by the curricula of these secondary-school students having a competency-based approach. Likewise the implementation allowed students to unleash relevant processes of mathematical activity, in particular processes of mathematical modelling that justifies the *epistemic suitability* or mathematical quality.

Finally, we also use the notion of *research and study path* (SRP) proposed in the framework of the anthropological theory of the didactic (Chevallard, 2015) and their main characteristics to design the sequence of tasks to achieve a high epistemic suitability (see also Sala et al., 2015). The SRP proposal emphasises the necessary dialectics between ‘research’ or ‘inquiry’ (facing open-problems, problem posing, making observations, examining different media or source of information, etc.) and ‘study’ (attending teachers’ explanations to provide mathematical knowledge, building up models, testing the validity of mathematical tools, etc.). As underlined in Barquero, Serrano & Serrano (2013), mathematical modelling cannot be considered only as an aspect or modality of mathematical activity but has to be placed at the core of it. Modelling is not only as a way to make the functionality of mathematics visible, but also as a key tool for the functional construction and connection of mathematical and extra-mathematical knowledge. In this sense, inquiry and modelling have to be mutually enriched. On the one hand, modelling activity needs from more inquiry moments (posing questions, looking for external resources, looking alternative proposals, etc.). For instance, in the SRP the role of the questions and of question-posing is essential (as the starting point of an SRP with a generating question, powered enough to pose many derived questions) so that it is essential to help students develop some reflective inquiry gestures such as posing new questions along their particular study or using extra-mathematical context to validate mathematical models and make new questions emerge and thereby starting new loops in the modelling cycle. And, on the other hand, inquiry needs from modelling processes (when mathematical tools and models are build, used analysed, validate, etc.) to make the study progress.

### **Research questions**

The aim of our research is to analyse if the implementation of the sequence we had designed, with features as the ones detailed above, could promote the inquiry students’ competences and how modelling could become an essential tool to enquire into the inquiry questions that were emerging in order to provide and to validate answers.. Therefore, our main research questions that we focus on are the following:

Can a teaching sequence based on the study of an archaeological problem in a codisciplinary context help students to face an inquiry that needs modelling processes as an instrumental tool to find, test and validate answers? Which is the relationship between modelling and inquiry in this kind of teaching sequence?

## Design and implementation of the teaching sequence

As it has been introduced, the starting situation is based on the discovery of certain Roman ruins, some years ago, in the centre of Badalona (a city next to Barcelona, Catalonia) by the archaeologists' team of the Badalona's Museum. They concluded that these ruins could have been an antique public building belonging to the classical *Baetulo* (the Roman old name of Badalona), surely a theatre, and they explained their research in an article (Padrós & Moranta, 2001).

The sequence was named «*What are these ruins hiding? Investigating the Roman ruins of Baetulo*» and all the sources, devices designed, links recommended and the worksheets that they had to follow were available in the blog designed by the authors: <http://ruinesdebaetulo.blogspot.com/>

We implemented the teaching sequence with a group of a 30 students (12-13 year-old) of a Secondary school education in Badalona during two weeks of June in 2015. The selection of the participants was intentionally chosen due to the facility that the first author of the paper had to the school, and the age and syllabus adequacy of the group class. Students worked during all sessions in 'inquiry teams' of three or four members, set up in the first session. They worked as real research teams, formulating hypothesis and doing tasks to validate them, discussing the partial results obtained during the process, finding points of agreement and writing an inquiry report to gather all the ideas, proofs and work done. Each team had on member in charge of explaining and defending their temporary report. Moreover, during all the study process, students got an inquiry guide to help them to progress in such a new activity.

## From the archaeological reality to the emergence of questions

The didactic sequence was inspired in a real archaeological investigation, a situation very close to a real extra-mathematical context, which was introduced to the students by the teacher and the first researcher paper signatory. The aim of the inquiry proposed to the students it is the same of the original aim research: discovering with which kind of building the ruins could be identified. In this sense, the context used to design the didactic sequence was an *authentic* situation (Vos, 2011) because the situation introduced to the students is clearly not created for educational purposes even though some elements are included for educational purposes.

Therefore the students had to investigate —from real data, archaeological reports, and canons of Roman architects— what type of building the discovered Roman ruins could have been and its features. In the first session, they could explore the map of the zone where the ruins were located by the link in the blog. They also visited later the place of the discovery accompany by one of the archaeologists of the Museum of Badalona and asked questions, took photographs, and measurements. The current constructions in this zone, houses and streets, followed a curious curved shape—easily perceptible in the map. It indicated, surely, that all these constructions were built on top of the ancient structures.

## The role of the context in the students' process of enquiring

Students looked up and investigated information about the Roman architecture to find what type of buildings had a curved part of their perimeter. They found few buildings that showed this feature at least. For instance, theatres were circular, amphitheatres were elliptic or circuses had a part circular

and other part quadrangular. This fact generated some other questions that promoted the developing of the inquiry process because the students could formulate their first hypothesis about that kind of building the ruins could belong to: *Which Roman building (theatre, circus, amphitheatre, etc.) shape would concur with the shape of the part of the Roman wall found? What do the geometrical shape of the partial Roman wall discovered determine?*

In the first stage of the process, the problematic situation was introduced to the students by the History teacher and the first author. Then, first questions emerged and the students started to look up information about the public Roman buildings in the links, maps and books. At the end of this stage most of the students should have understood the context of problem. So, they could formulate their preliminary hypothesis and conjectures about which kind of public building the ruins could have been only based on the historical information found. So that, at this stage when they had only took into account this historical information, their assumptions included more than one building (all the buildings that could have a curved part). Each inquiry team had to write in their report the agreed hypotheses they reached.

Actually, the inquiry was based on a mainly discovery: a part of a Roman curved wall, a metre and half high. This partial wall belonged to a building that was the centre of the inquiry. It was the external wall of the public building and determining its shape could mean to know which type of Roman building it was. The students had to follow their inquiry from the study of this element and the context where it was found. The number of types of Roman buildings existing limited the quantity of different type of shapes the students had to consider; but other information deduced from the context directly as the orography and the dimensions of the place where the ruins were discovered, or the dimensions of the curved Roman wall discovered, also limited the options that the students could choose in order to formulate their hypothesis about the building the ruins would fit with. In this case, the context influence on the inquiry helps students to deal with a problem that would be very difficult to resolve from an only mathematical point of view and completely unachievable to their level.

### **Improving the first hypothesis: Building up models to systematise and mathematize the archaeological system**

The second stage started with an important session that had the objective of discovering the geometrical shape that the Roman wall described (a circumference, an ellipsis, etc.) and test their first hypothesis. From this stage the teachers of Mathematics, Technology and Catalan Literature had involved in the sequence management. The results obtained from this central task provided enough data that allowed formulate sufficient plausible hypothesis about the type of public building.

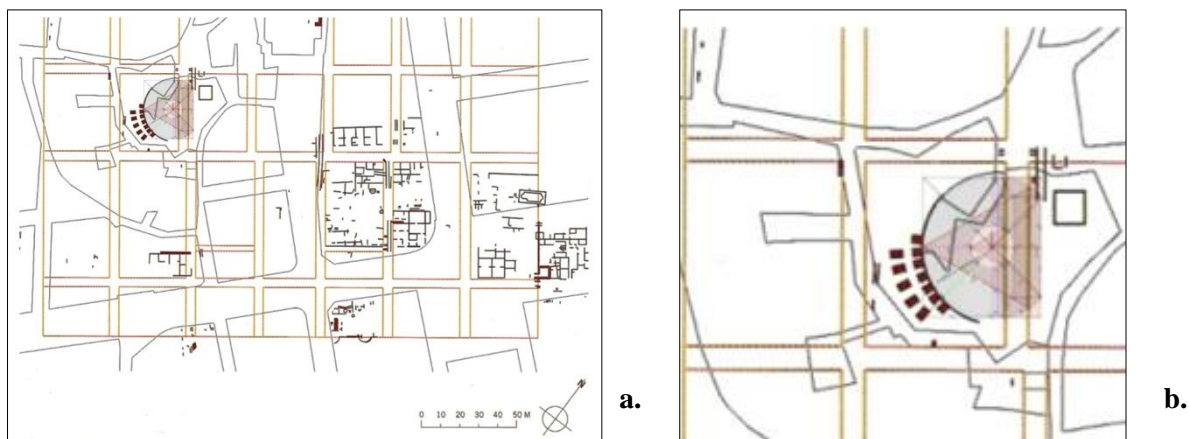

The session in where the problematic situation began to be systematised and mathematized were placed on the public square next to the school, and was recorded and afterwards analysed. The students work with an exact representation of the part of the roman wall drawing on the ground. They could experiment with different ways to proof what was the geometrical shape that fit with the Roman wall. After few tasks in which students had to construct and drawing different curves on the ground, all the teams could check that the perimeter of the curve Roman wall fits with a circumference and so, they could conjecture about the building would have been a theatre. Also,

this evidence lead students to think that it was necessary to find the radius of the circumference in order to know how large the building was. The students find the radius of the circumference (16 m.) with graphical methods, always on the ground of the square. Then they spread out on the square, drawing with their bodies the perimeter, to notice the likely real dimensions of the Roman theatre.

After this session they returned to the classroom and tried to explain the experimentation in their reports but it emerge the necessity to get a tool to draw the theatre properly. Moreover, the teacher introduced the book by *Vitruvius* (available in the blog), classical Roman architect who wrote several canons that Roman people followed to construct each type of public building. In this stage the technology had an essential role in order to allow students drawing their geometrical model of the theatre following the *Vitruvius*' instructions. The students constructed their model of the theatre using the software *Geogebra*.

### Interpreting and validating mathematical models within the archaeological context

When each team had their model of the theatre finished could export the file as an image and pasted it on the map of the area studied, fitting it properly in the exactly site where the ruins was discovered (Figure 1). This task allowed students interpret their model considering the specific context and verify if their construction and hypothesis were suitable.

**Figure 1. (a) Application the theatre model, which is construct with Geogebra, on the map studied from one of the inquiry teams report; (b) Detail enlarged**

To do the tasks in this second stage the students had to deal with information from the Mathematics —data related of geometrical shape of the wall, extracted from the activity on the square—and from the History —considering the features of the context in where the ruins were discovered—. Modelling, in that moment, became an essential tool that facilitated find answers.

Then, when the students were became competent researchers yet, it started the third stage of the sequence. They arrived at that point with an important collection of questions and doubts but in the following session they had the opportunity, firstly, to share it with other groups and, thereupon, preparing an interview to ask the archaeologist of the Museum. During this interview students could contrast and validate their results about the model selected. It was another especial time you could notice that in the real world different disciplines interacts in a natural way to find solutions of real

problems. After the session outdoors talking to the archaeologist, they could apply their geometrical model construct with *Geogebra* on maps with other ruins of theatres in Europe and thus could check how the same model fits there, too. The model also was useful counting how many people would fit in the theatre, the last task of this stage. Finally, the students finished writing the final report of their inquiry describing their process, the mathematical tools used, the result of verifying their hypothesis, new opened questions, etc.

## Conclusions

We would like to stress the importance that the context and the initial question studied had to deeply involved students in the inquiry activity. Moreover, the possibility to work with real data, the facilities to get access to the ruins and to other real archaeological investigation facilitated that students faced the inquiry questions from a wider approach. What the design and implementation of the activity shows is that the context easily offered different kind of information, such as the one coming from the history, from orography, from geometrical models used to measure and drew plans. It facilitated that students considered all these kind of different nature information and tried to systematise it and to work with it in order to provide answers.

On the one hand, we have shown how the enquiring process carried out in the implementation nests a sub-process of modelling that appears as a tool to contemplate information emerged from the context that could become mathematized (such as: the measure of the curved wall, of the ratio, of the building perimeter or the possible use of the Vitruvius canon) in order to be able to progress in looking for specific answers. Thus, at some stages, mathematics appears as an essential modelling tool to look into systems, build up mathematical models, simulate and test them.

More concretely, in the task done on the square next to the school, students wondering how could know the geometrical shape of the whole Roman wall from the partial wall in the map. But this is a difficult mathematical problem to resolve—to find the geometrical curve from a part of it— because there could be a lot of solutions. Besides, the methods to finds these solutions only from the mathematical point of view, are totally beyond the powers of secondary school students’.

On the other hand, the dialogue with History limits the possible answers because the Roman buildings only had three relevant shapes: ellipsis (amphitheatre), circle (circus) or semi-circle (theatre). Due to the contribution of the historical information the problem became achievable at the students’ level of mathematical knowledge and allows the beginning of modelling.

Last but not least, it was also very important the possibility that students know about the experts’ work (the real research of archaeologists) and to realise that the process they follow are quiet similar to the process of enquiring and modelling that they were following. It also had an important impact on their motivation and on the perception they had about the usefulness of Mathematics and of modelling. The interaction with the archaeologists allowed students to validate their whole process of enquiring and their results.

## Acknowledgment

The research leading to these results has received funding from the Spanish R & D project: EDU2015-64646-P, EDU2015-69865-C3-1-R and REDICE16-1520 (ICE-UB).

*A profound level of reading comprehension is essential for solving modelling problems, as a problem solver has to understand the real-life situation presented in the task in order to construct an adequate situation model, real model, and mathematical model. The aim of this paper is to present the theoretical grounds and a sample learning environment for fostering reading comprehension. In the first part of this article, we summarise research on reading comprehension while solving modelling problems, report on research on two strategies (text highlighting and self-generated drawing) that can help learners comprehend a modelling problem, and describe ways to implement both strategies in the classroom. In the second part, we present a learning environment that can be implemented to foster reading comprehension in the lower secondary classroom.*

*Keywords: Modelling, strategies, reading comprehension.*

## Introduction

Reading comprehension is important for learning in school and for students' everyday lives. As each school subject offers students different kinds of texts, fostering subject-specific reading comprehension strategies is necessary for learning and problem solving. In math classes, students have to read different kinds of texts such as proofs or word problems. We address word problems, which, in order to be solved, require a demanding transition from the real world to mathematics as *modelling problems* (Blum, Galbraith, Henn, & Niss, 2007). To solve a modelling problem, students need a profound understanding of the task, as a superficial combination of the numbers given in the task is not sufficient for finding a solution to a modelling problem. In this paper, we characterise the role of mathematical reading competency for the solution of modelling problems, summarise research on two strategies (highlighting and self-generated drawings) that might improve reading comprehension, and present a learning environment for fostering these strategies in the classroom.

## Theoretical background for reading comprehension and modelling

### Reading comprehension while solving modelling problems

Analyses of the cognitive processes that people engage in during mathematical modelling have often distinguished the following activities in the solution process: (1) The problem solver constructs a *situation model* on the basis of the information presented in the task and on his or her prior knowledge. The situation model reflects the learner's mental representation of the given situation. A profound level of reading comprehension is essential for constructing the situation model if a problem is partly or completely represented as text. (2) The situation model is then simplified and structured to obtain a *real model* that contains only the information necessary to solve the task. The problem solver needs a deep understanding of the problem to separate relevant from redundant information. (3) Mathematising the real model leads to the *mathematical model*. (4) Working

mathematically then serves to produce a *mathematical result*, which is then used to refer back to the real situation given in the task by interpreting and validating the *real result*. In the following, we concentrate on understanding and simplifying/structuring, for which reading comprehension is critically important.

Understanding and simplifying/structuring are expected to be essential for solving the entire modelling problem. These expectations were supported by the results of the study by Leiss et al. (2010). In this study, the strategies that students used in the construction of an adequate situation model and real model were found to have a positive influence on their modelling competency. Therefore, we conclude that it is important to support learners' reading comprehension by the use of strategies. Two strategies suitable for fostering reading comprehension in modelling problems are presented in the following chapter.

### **Highlighting and self-generated drawings for reading comprehension**

*Highlighting.* Highlighting is a cognitive strategy that aims at directing the learner's attention to the specific words or sentences in a text. To highlight important information, the learner has to identify and select the relevant information.

The prompt "Use the highlighting strategy" is not sufficient by itself to support the learner's reading comprehension, as the quality of strategy use has been found to be important for effects on students' performance. The use of highlighting has to be regulated by students in order to be efficient, otherwise the learner might highlight too many words in the text or might forget to highlight some important information. In a study of college students, Leutner et al. (2007) examined the effects of training the highlighting strategy with expository texts. They compared three groups: The first group did not receive any training and served as a control group, the second was given a strategy training in highlighting, and the third was given a combination of strategy and self-regulation training. The findings revealed that the third group outperformed the others in text comprehension. Thus, self-regulation seems to be an important factor for strengthening the appropriate and purposeful use of cognitive strategies such as highlighting. The combination of strategy and self-regulation training included the following elements: First, the learning goal was presented. Second, the participants observed how a fictive person applied the highlighting strategy. Third, they were given a strategy training in which the steps of the highlighting strategy were presented and then applied. Fourth, a self-regulation training followed, in which the steps of the highlighting strategy were recalled, and then the steps of the metacognitive strategy (monitoring, self-evaluation, and reaction) were introduced and applied.

Highlighting strategies can also be expected to be useful in the domain of mathematical modelling, as modelling problems with reference to real life often contain redundant information. In order to construct a situation model and a real model, students have to identify relevant information. In an exploratory case study by Leiss et al. (2010), some difficulties in the use of the highlighting strategy while solving modelling problems were observed. An analysis of students' solutions showed that some students highlighted all numbers written in numeric form given in the task, including numbers that were not needed to solve the modelling problem. Further, some students did not highlight numbers written in word form, even when these numbers were essential for the solution. These

observations demonstrate the limited quality of the highlighting strategy by students and emphasise the importance of improving the quality of the use of this strategy.

*Self-generated drawings.* Another important cognitive strategy that can be applied to support a learner's reading comprehension and problem solving is the creation of self-generated drawings. Whereas highlighting is aimed at selecting the most important information, drawings are aimed at organising and visually representing information given in the text.

A study by Leopold and Leutner (2012) revealed the advantages of drawing activities for the comprehension of science texts. Students in grade 10 were instructed to read text paragraphs and then make a drawing that represented the main ideas of the paragraphs. To train the students to use the strategy, they worked on an example that demonstrated how to process the text with a related drawing. The results showed positive effects of the drawing instructions on students' science text comprehension. Drawing activities encourage students to construct a mental model and seem to offer a useful strategy for facilitating students' deeper understanding. In the domain of mathematics, positive effects of drawing activities were found on 3rd-grade students' word problem solutions (Csíkos, Szitányi, & Kelemen, 2012).

Drawing activities might also support the construction of a situation model in the context of mathematical modelling (Rellensmann, Schukajlow, & Leopold, 2017). Strategic knowledge about drawing was found to have a positive effect on modelling performance. This effect was mediated by the accuracy of the *situational* and *mathematical drawings* and emphasised the importance of the quality of the strategy for solving modelling problems. In addition, the study revealed that the accuracy of mathematical drawings is a strong predictor of modelling performance, whereas the situational drawing had only indirect influences on performance by facilitating the construction of a mathematical drawing. These findings suggest that self-generated drawings offer a strategy that is useful for fostering modelling. The most promising was found to be the generation of accurate mathematical drawings. Thus, when instructing students how to generate a drawing, teachers should pay special attention to the accuracy of the mathematical drawing (namely that it contains correct relations and all relevant numbers). Learners should be encouraged to generate a situational drawing if they do not succeed in drawing a more abstract mathematical model in their first attempt.

Even though highlighting and drawing seem to be useful strategies for fostering reading comprehension during mathematical modelling, they need to be taught in rich learning environments. In the following chapter, we present some learning environments that are appropriate for teaching these strategies.

### **Highlighting and self-generated drawings in learning environments for improving modelling**

Several studies have investigated the effects of different learning environments on students' modelling competency. In the following, we present two studies that integrated highlighting and drawing strategies (among other elements) in their learning environments to foster modelling competency.

Verschaffel et al. (1999) revealed the positive effects of a certain learning environment on 5th graders' modelling and problem-solving competency. The learning environment contained the acquisition of an overall metacognitive strategy that involved five stages in the planning of the whole solution process. Eight strategies (e.g., "Distinguish relevant from irrelevant data" or "Draw a

picture”) were embedded in the first two stages (Verschaffel et al., 1999, p. 202). The distinction between relevant and irrelevant data is related to the highlighting strategy, as appropriate highlighting aims to make this distinction. Another condition under which the results were acquired was the instructional technique used in this study. It consisted of systematic changes between whole-class discussions and small group work. In both phases, the teacher encouraged the use of strategies and encouraged the students to reflect on their purposeful use in order to stimulate the regulation of strategy use.

A learning environment for modelling that included strategic elements was examined by Schukajlow et al. (2015). A scaffolding instrument called the *solution plan* with four steps was used in this study to support students’ modelling activities. Strategic prompts were assigned to each step. As a whole, the solution plan served as a metacognitive planning strategy that was designed to guide students through the process of solving a modelling problem. Fostering reading comprehension was not the sole focus of the solution plan, but it included cognitive strategies that were aimed at improving reading comprehension (e.g., strategies such as “Look for the data you need and, if necessary, make assumptions!” or the strategy “Make a sketch!”; Schukajlow et al., 2015, p. 1244). Although the highlighting strategy was not explicitly mentioned in the solution plan, it is closely connected to the strategy of looking for relevant data.

The student-centred *operative-strategic* learning environment used in this study is characterised by a systematic change between individual work in groups and whole-class discussions. The whole-class discussions included presenting solutions and reflecting on the solution processes (Schukajlow et al., 2015, p. 1243). The study found that an experimental group that was taught the solution plan outperformed a control group that was not taught the solution plan in solving modelling problems. Furthermore, students in the experimental group reported more frequently using self-reported strategies than the control group.

On the basis of the theoretical and empirical findings on the effects of highlighting and self-generated drawing, we developed a learning environment for fostering reading comprehension. We describe this learning environment which will be approved in the next step of the project in the following section.

### **Learning environment for fostering students’ reading comprehension while they solve modelling problems**

Based on the theoretical grounds presented in the first part of this paper, the following learning environment was developed to foster 9th graders’ modelling competence with special regard to the beginning of the modelling process, namely understanding, structuring, and simplifying. The aim of the learning environment is to improve students’ performance in these sub-competencies by fostering their reading comprehension via trainings in highlighting and the use of self-generated drawings. Similar to some other studies that implemented strategy trainings (see e.g., Leutner et al.,

2007, or Schukajlow et al., 2015), the duration of the teaching unit will be five lessons with a total of approximately 225 minutes<sup>1</sup>.

The modelling problems that will be used in the present learning environment include text and can be solved by applying the Pythagorean Theorem as a mathematical procedure. The Pythagorean Theorem was chosen because of the importance of this mathematical procedure for national and international curricula. Before the beginning of the teaching unit that was designed to foster reading comprehension, students are expected to know the Pythagorean Theorem and to practise it on intra-mathematical problems. A sample problem *Reaction time* is shown in Figure 1.

### **Reaction time**

During the 2016 European Championship, Germany played against Slovakia in the round of the last sixteen. With goals by Boateng (minute 8), Gomez (minute 43), and Draxler (minute 63) the German team won with a score of 3 to 0.

In the 14th minute, Germany was allowed a penalty kick after a foul by Slovakia. A penalty kick is shot from a distance of eleven metres from the goal, which has standard measures of 2.44 m in height and 7.32 m in width. The German penalty taker was Mesut Özil, and Matus Kozacik was in the Slovakian goal.

Unfortunately, the penalty kick was stopped by Kozacik so that Özil missed the chance to have an early score of 2 to 0 for Germany. His penalty kick was shot a bit too feebly and flew just over the ground to the lower right corner where Kozacik was able to deflect it away from the goal. Although the penalty kick was not shot very hard, the goal-keeper didn't have much time to react, as the football flew at a speed of about 80 km/h towards the goal.

**Calculate how much time the goal-keeper had after Özil's kick to reach the position where he stopped the ball just before the corner of the goal.**

**Figure 1: Sample modelling problem *Reaction time***

In line with the solution plan study by Schukajlow et al. (2015) and the study by Verschaffel et al. (1999), the learning environment that we chose for our teaching unit includes systematically changing between individual work, group work, presenting solutions, and reflecting on the solution process as a class (Schukajlow et al., 2015, p. 1243).

In the first lesson, both of the strategies of highlighting and using self-generated drawings are introduced. The students are given the modelling problem *Reaction time* (cf. Figure 1) and are requested to highlight important information and to generate a drawing while doing their own individual work in groups, but they are asked not to solve the problem. The task requires the application of both the highlighting and drawing strategies.

<sup>1</sup> Schukajlow, Kolter, and Blum (2015) measured effects after 205 minutes of total treatment. Leutner, Leopold, and den Elzen-Rump (2007) used a time of 150 minutes. Verschaffel et al. (1999) used 20 lessons to teach eight strategies, so five lessons for teaching two strategies seemed appropriate for our teaching unit.

After the individual work in groups, students present their highlighted texts and their drawings and describe how they proceeded in applying both strategies. To encourage a discussion about potential difficulties in the use of these strategies, the group that the teacher chooses to make the first presentation should be one that had difficulties with the generation of the highlighting or drawing. During the presentation and the subsequent reflection on the presented solution, the teacher should direct students' attention to typical problems that result from the misapplication of strategies. The teacher should then present the learning goal of the teaching unit to the students, namely to improve reading comprehension and the ability to solve modelling problems.

After that, the first two steps of the solution scheme (cf. Figure 2) are introduced. They save the results of the class discussion in written form and might also provide some advice that was not mentioned by the students. The solution plan by Schukajlow et al. (2015) was adapted to better fit the aim of fostering reading comprehension and to guide the application of both of the strategies of highlighting and producing self-generated drawings. The solution scheme with the reading strategies of highlighting (integrated in step 1) and the creation of self-generated drawings (integrated in step 2) is shown in Figure 2.

**Figure 2: The solution scheme used in the learning environment**

The entire solution scheme serves as a planning strategy for the whole solution process. In step 1, the highlighting strategy is presented. First, students are told to skim the task. This means they should get an overview of the task, which might contain a title, text, questions, pictures, tables, or diagrams. While skimming the text, students do not need to understand each word in detail. After skimming the text, the students are prompted to imagine the situation presented in the task. This might help to activate prior knowledge about the topic and facilitate reading the text in detail in the next step. These activities stimulate the *understanding* of the real situation. The highlighting is prompted after they read the question again, as the selection of relevant data depends on the question posed in the problem. After they finish the highlighting, students evaluate whether they highlighted only the most important information in the task and revise their highlighting if needed. The highlighting is aimed at helping students to *simplify* the given information.

In step 2 of the solution scheme, the students are asked to make a drawing and label it with relevant data from the text. These activities help them simplify and structure the information given in the text. During the following monitoring activities, students check whether their drawings contain all relevant data from the text and whether all mathematical relations are represented correctly. If students do not succeed in constructing an accurate mathematical drawing, they can first generate a less abstract situational drawing. At the end of step 2, students *mathematise* the information given in the drawing. In step 3, the students calculate a solution and obtain the mathematical result. They interpret, validate, and present the result in a final answer in step 3. The arrow pointing back towards step 1 indicates that the solution process might be restarted if the result does not fit.

In the first two lessons of the teaching unit, the students are familiarised with only the first two steps of the solution scheme in order to train their reading comprehension strategies and the sub-competencies of understanding, simplifying, structuring, and mathematising as part of the modelling process. In lessons 3, 4, and 5, students practise the entire modelling process by applying the entire solution scheme.

In line with Leutner et al.'s (2007) study, the current learning environment contains the same main elements to stimulate self-regulation. First, goal setting is realised in the first lesson. Students are confronted with a modelling problem that requires a profound level of reading comprehension. The teacher explains that the aim of the teaching unit is to learn strategies that support reading comprehension and to solve reality-related modelling problems. Second, instead of observing the application of the strategy by a fictive person, students analyse their classmates' highlighted texts and drawings in both the work done in small groups and the presentations involving the whole class. These practises are implemented in order to stimulate students' activities in the classroom. Third, the strategy training begins with a presentation of the steps that are necessary for highlighting and drawing and is followed by an application of the strategies while solving modelling problems. In contrast to Leutner et al.'s (2007) study, the self-regulation training is integrated in the strategy training. If requested, the teacher gives strategic advice by referring to the relevant steps of the solution scheme and stimulates reflection on the use of strategies during the individual work in groups and during the whole-class discussion when solutions are presented and reflected on. This process helps to encourage the use of strategies and to establish the solution scheme as a scaffold for solving modelling problems. In order to stimulate the self-regulation of strategy use, we included the prompts "Check your marks and change them if necessary" in step 1 and "Check your drawing" in step 2 of the solution scheme. Further, the validation of the results of solution problems is stimulated by the prompt "Check if your result fits approximately" in step 3 (cf. Figure 2).

## Summary and future steps

In the first part of this paper, we discussed the theoretical background for reading comprehension and modelling. Based on the theory, we presented in the second part of the paper a learning environment to foster students' reading comprehension while solving modelling problems. This learning environment will be evaluated in a project for pre-service teachers. The pre-service teachers will obtain the material and instructions to implement the learning environment in their classrooms to gain practical experience in fostering reading comprehension in mathematical

education. They will attend a seminar to prepare for the project and to reflect on the experiences they made while implementing the project.

## Acknowledgment

This project is part of the “Qualitätsoffensive Lehrerbildung”, a joint initiative of the Federal Government and the Länder which aims to improve the quality of teacher training. The programme is funded by the Federal Ministry of Education and Research. The authors are responsible for the content of this publication.

*The objective of this investigation is designing an activity research study in mathematical modeling for the training of future engineers in the subjects of linear algebra, and structural mechanics of composite materials, in an application of stress and strain calculation. Considering elements of the Anthropological Theory of Didactics (ATD) implementing a methodology within the mentioned theory. This allows the analysis of mathematical models in use, as basis for designing didactical activities, in order to create a link between these two subjects, showing the future engineers that mathematics can be used to solve problems in an extra-mathematical context. This took place in the Research Center for Applied Science and Advance Technology of the National Polytechnic Institute (CICATA-IPN) and in the School of Science of Engineering and Technology of the Autonomous University of Baja California (ECITEC-UABC).*

**Keywords:** Mathematical models, linear algebra, engineering training, ATD.

## Introduction

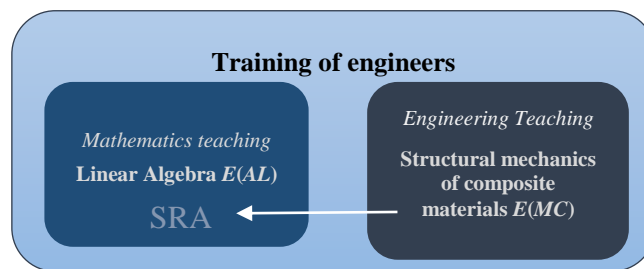

The objective of this work is to design modeling activities for a mathematical training of engineers. The design is based on mathematical modeling analysis on specialty training courses, focusing on laminated composite materials. This collaborative work involves aerospace, mechanical engineers and mathematicians that teach in the carriers of Aerospace engineering and mechanical engineering, having an opportunity to analyze a real context of modeling; namely Calculation of stress and strain of composite materials. This project was proposed on a structural mechanics of composite materials course; because the students wanted to know where they could use the mathematics they were learning. For this work we have considered elements of the Anthropological Theory of Didactics proposing a methodology associated to this theory that permits the analysis of mathematical models in use based on the design of didactic activities.

## Elements of the Anthropological Theory of Didactic

The ATD is an epistemological model that allows the study of human activity in its institutional dimension. An institution is a stable social organization that defines the human activities generating resources that make them possible. These materials or intellectual resources, which are made available to the subjects, have been produced by communities along the confrontation of problematic situations with the objective of solve them in a regularly and effectively way (Castela and Romo, 2011). The classic praxeological model, proposed by Chevallard (1999), recognizes the praxeology  $[T, \tau, \theta, \Theta]$  as a minimal unit of analysis of human activity. Its four components are: the task type ( $T$ ), the technique ( $\tau$ ), the technology ( $\theta$ ); and the theory ( $\Theta$ ). The ‘task’ refers to what is to be done; the ‘technique’ is how it is to be done; the ‘technology’ is a discourse that produces, justifies and explains the ‘technique’; while the ‘theory’ produces, justifies and explains the ‘technology’.

## The training of engineers through institutions

The training of engineers can be seen through institutions, Romo (2009) distinguish three types: production of knowledge  $P(S)$ , teaching of knowledge  $E(S)$  and use of knowledge or practices  $Ip$ . This distinction seeks to recognize the first vocation of the institutions and the production of knowledge correspond to scientific disciplines, such as mathematics or engineering sciences, are validated in these the existence of knowledge and the relations between them. The teaching of knowledge  $E(S)$  are responsible for displaying and disseminating praxeologies, meanwhile in the institutions of usage  $Ip$ , the praxeologies are used to solve problems of practice. This does not mean that within the institutions  $P(S)$  there is no teaching or usage praxeologies nor in teaching  $E(S)$  and practice  $Ip$  there is no production of knowledge. In this investigation linear algebra is considered an institution of teaching mathematics  $E(AL)$ , and in teaching engineering, structural mechanics of composite materials  $E(MC)$  and connect them through a Study and Research Activity (SRA). The SRA constitute didactic devices for the construction of a praxeology through three didactic moments that are: first encounter with  $T$ , exploration of  $T$  and the emergence of the  $\tau$  technique and construction of the technological-theoretical block, in this case coming from the structural mechanics of composite materials as outlined below

**Figure 1: The SRA as an element linking educational institutions**

In order to initiate the transition from the traditional paradigm in mathematics "visiting works" (to the teaching of pre-existing mathematical objects) to questioning the world according to inquiry-based mathematics education (IBE).

### Didactical design methodology of an SRA

The methodology initially proposed in Macias (2012) allows the design of SRA that involves non mathematical elements. Its four stages are: 1) Election of an extra-mathematical context; 2) Praxeological analysis and identification of a mathematical model; 3) Analysis of the identified mathematical model and their relationship with  $E(M)$  and 4) design of the SRA.

#### Election of an extra-mathematical context

To choose an appropriate extra-mathematical context for the design of an SRA, the following elements were considered.

1) Generation of surveys aimed at teachers and students about mathematical needs of engineers in training:

Students. Which of these subjects you thought more important, and why? Have you used or adapted a mathematical model? Which model and for what?

Teachers. In any of your subjects taught in an engineering career you use mathematics? Have you used a mathematical model or adapted one in any of your courses? Which model and for what?

67 students from 3rd to the 7th semester were surveyed, finding that the most useful subjects are calculus and linear algebra. 54% recognizes the work with mathematical models. All teachers who teach subjects of MC, integral calculus CI and AL were surveyed, 92% of them recognize the use of matrices in their courses

2) Interviews with the coordinator of the career of mechanical engineering, who noted that the subject of MC required early in the course of a review of linear algebra.

3) Approach with MC teachers, who pointed out that in general, students do not recall procedures or operations previous courses, AL for example.

4) Joint work with engineers-researchers in the area of materials.

### **Praxeological analysis and identification of a mathematical model**

The praxeology that is identified and analyzed is the calculation of stress, strain and elastic modulus in laminated materials. The type of task is to calculate the stress or strain of a laminated material, the technique is associated with the use of the matrix  $S$  (strain) or matrix  $Q$  (stiffness), the technology is Hooke's law and the theory is the mechanics of materials. The analysis is based on a technical report of basic mechanics of laminated composite plates (Nettles, 1994), suggested by an engineer-researcher, who indicated it, as a heavily used reference material. In this section the theoretical technological-block is shown, which displays how the stiffness matrix associated with the technique of calculating the stress and strain is presented. This will provide the basis to show in the next section full praxeology from the analysis of an exercise presented in a class of structural mechanics of composite materials.

*Technology: Generalized Hooke's law for anisotropic materials<sup>1</sup>*

Nettles explains that the relationship between stress and strain is independent of the direction of the force, and is provided by the constant of elasticity (Young's modulus), this is for isotropic<sup>2</sup> materials. In nonisotropic materials it should use two elastic constants at least. The relationship stress / strain for isotropic materials appears as follows:

$$\sigma = E\varepsilon \quad (1)$$

Where  $\sigma$ : is the stress,  $E$ : Denotes the Young's modulus and  $\varepsilon$ : is the strain.

For orthotropic materials<sup>3</sup>, the direction must be specified in the stress/strain relationship:

$$\sigma_1 = E_1\varepsilon_1; \sigma_2 = E_2\varepsilon_2 \quad (2)$$

where

$\sigma_1$ : Denotes the stress in the longitudinal direction

$E_1$ : Denotes the stiffness in the longitudinal direction (Young's modulus)

$\varepsilon_1$ : Denotes the strain in the longitudinal direction

$\sigma_2$ : Denotes the stress in the transversal direction

---

<sup>1</sup> Anisotropic materials: is the material that its mechanical properties differ according to the load direction

<sup>2</sup> Isotropic materials: It is the material that has identical mechanical properties in all directions regardless of the direction of the load

<sup>3</sup> Orthotropic materials: is the material in which mechanical properties are different in three perpendicular directions

$E_2$ : Denotes the stiffness in the transversal direction  
(Young's modulus)

$$S_{11} = \frac{1}{E_1}$$

$$S_{22} = \frac{1}{E_2}$$

$\varepsilon_2$ : Denotes the strain in the transversal direction

$$S_{12} = -\frac{\nu_{12}}{E_1} = -\frac{\nu_{21}}{E_2}$$

$$S_{66} = \frac{1}{G_{12}}$$

$E_1 = E_L$  Defines the stiffness in the longitudinal direction

and  $E_2 = E_T$  is the stiffness in the transversal direction. This law produces different techniques, Nettles initiated by the special orthotropic plates and is why we analyze them below..

#### *Stress and strain for special orthotropic plates*

The author begins by explaining that on a plate, stress can be given in more than one direction. Immediately he defines Poisson's ratio as the strain perpendicular to a given loading direction, showing the relationship for different loads.

For loading along the fibers:

$$\text{Poisson's ratio} = \nu_{12} = \frac{\varepsilon_T}{\varepsilon_L} = \frac{\varepsilon_2}{\varepsilon_1} \quad (3a)$$

For loading perpendicular to the fibers

$$\text{Poisson's ratio} = \nu_{21} = \frac{\varepsilon_L}{\varepsilon_T} = \frac{\varepsilon_1}{\varepsilon_2} \quad (3b)$$

The strain is equal to the difference between the stretched component deformation due to an applied force and contraction of the Poisson's effect due to other forces perpendicular to the applied force, thus:

$$\varepsilon_1 = \frac{\sigma_1}{E_1} - \nu_{21}\varepsilon_2 \quad y \quad \varepsilon_2 = \frac{\sigma_2}{E_2} - \nu_{12}\varepsilon_1 \quad (4a)$$

aplicando la ecuación (2)

$$\varepsilon_1 = \frac{\sigma_1}{E_1} - \nu_{21}\frac{\sigma_2}{E_2} \quad y \quad \varepsilon_2 = \frac{\sigma_2}{E_2} - \nu_{12}\frac{\sigma_1}{E_1} \quad (4b)$$

Subsequently, the author considers the presence of shear forces. The shear stress and shear strain are related by a constant called shear modulus, denoted by G.

$$\tau_{12} = \gamma_{12}G_{12} \quad (5)$$

Where:  $\tau_{12}$ : Shear stress,  $\gamma_{12}$ : Shear strain y  $G_{12}$ : Shear modulus

Equation (5) is similar to equation (1) it only considers shear stress and strain, where the indices 1-2 indicate shear in the 1-2 plane. The author mentions that a relationship exists between the Poisson constant and the Young's modulus in both directions, in the longitudinal direction and the transverse direction to the material, and then it holds that:

$$\nu_{21}E_1 = \nu_{12}E_2 \quad (6)$$

Equations (4b) and (5) can be written in their matrix form obtaining

$$\begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \gamma_{12} \end{bmatrix} = \begin{bmatrix} S_{11} & S_{12} & 0 \\ S_{12} & S_{22} & 0 \\ 0 & 0 & S_{66} \end{bmatrix} \begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{bmatrix} \quad (7) \quad \text{where,}$$

Here it is where we can see a relationship between the subjects of linear algebra and structural mechanics of composite materials as a matrix model for calculating stress or strain of laminated

materials whether they are isotropic or orthotropic. Calculating the inverse stress matrix  $S$ , we obtain the stiffness matrix  $Q$  turning out to be:

$$\begin{bmatrix} \sigma_1 \\ \sigma_2 \\ \tau_{12} \end{bmatrix} = \begin{bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{bmatrix} \begin{bmatrix} \varepsilon_1 \\ \varepsilon_2 \\ \gamma_{12} \end{bmatrix} \quad (8)$$

where,

$$\begin{aligned} Q_{11} &= \frac{E_1}{1 - \nu_{12}\nu_{21}} & Q_{22} &= \frac{E_2}{1 - \nu_{12}\nu_{21}} \\ Q_{12} &= \frac{\nu_{12}E_2}{1 - \nu_{12}\nu_{21}} = \frac{\nu_{21}E_1}{1 - \nu_{12}\nu_{21}} & Q_{66} &= G_{12} \end{aligned}$$

We can appreciate in equation 7 to 8, the calculation of the inverse matrix was made, to switch the stress matrix to the stiffness matrix, with basic operations taught in linear algebra. The author explains, broadly, the mathematical model based on the algebraic work, having left the reader the task of verifying the connections between the different equations, until reaching the mathematical model that relates the stress, strain and Young's modulus (which are the elastic properties of the material). All this is the technological component of the praxeology. To illustrate the types of tasks that can be solved and the associated techniques to the praxeology, we analyze below a classroom exercise from the subject of structural mechanics of composite materials.

### Analysis of the identified mathematical model and its relationship with $E(M)$

In the class of structural mechanics of composite materials (MC), where we analyzed and identified the praxeology of the stress calculation of a laminate material, with a task type  $T$ , calculate the modulus of elasticity of a laminated material in a particular direction, with two tasks,  $t_1$  y  $t_2$ :

$t_1$ : Calculate the modulus of elasticity of a laminated material in the  $X$  direction.

$t_2$ : Calculate the modulus of elasticity of a laminated material in the  $Y$  direction.

For laminate fiberglass polyester matrix that is laid up in a  $[45_2/-45_2/0]_s$  stacking sequence.

$\tau_1$ : Find the stiffness matrix of a laminate material, with the following information

$$E_1 = 40 \text{ GPa}$$

$$E_2 = 9.8 \text{ GPa}$$

$$G_{12} = 2.8 \text{ GPa}$$

$$\nu_{21} = 0.3$$

$$\begin{aligned} [Q] &= \begin{bmatrix} Q_{11} & Q_{12} & 0 \\ Q_{12} & Q_{22} & 0 \\ 0 & 0 & Q_{66} \end{bmatrix} \\ [Q] &= \begin{bmatrix} 40.90 & 3.01 & 0 \\ 3.01 & 10.02 & 0 \\ 0 & 0 & 2.80 \end{bmatrix} \text{ GPa} \end{aligned}$$

Determine the stiffness matrix of the lairs in  $45^\circ$ .

Using the expressions for the calculation of the stiffness matrix, for any fiber orientation it can be written by:

$$[Q] = \begin{bmatrix} \bar{Q}_{xx} & \bar{Q}_{xy} & \bar{Q}_{xs} \\ \bar{Q}_{yx} & \bar{Q}_{yy} & \bar{Q}_{ys} \\ \bar{Q}_{sx} & \bar{Q}_{sy} & \bar{Q}_{ss} \end{bmatrix}$$

$xy$  axes: global axes;  $1,2$  axes : material axes. Thus the stiffness matrix turns to be:  $[Q] =$

$$\begin{bmatrix} 17.03 & 11.43 & 7.72 \\ 11.43 & 17.03 & 7.72 \\ 7.72 & 7.72 & 7.01 \end{bmatrix} \text{ GPa}$$

For the  $-45^\circ$  the stiffness matrix is  $[Q] = \begin{bmatrix} 17.03 & 11.43 & -7.72 \\ 11.43 & 17.03 & -7.72 \\ -7.72 & -7.72 & -7.01 \end{bmatrix} GPa$

Stiffness matrix in the flat tension of the laminate material

$$[A] = \sum_i [Q]_i \cdot h_i \text{ where } h \text{ is the thickness of the material } [A] = \begin{bmatrix} 218.04 & 97.46 & 0 \\ 97.46 & 156.28 & 0 \\ 0 & 0 & 61.68 \end{bmatrix} 10^9 h \frac{N}{m}$$

Normalized stiffness matrix in the plane stress of the laminate is written as  $[A^*] = \frac{[A]}{10^9 h} = \begin{bmatrix} 21.8 & 9.75 & 0 \\ 9.75 & 15.63 & 0 \\ 0 & 0 & 6.17 \end{bmatrix} GPa$

**$\tau_1$ : Applying a tensile stress in the X direction**  $\begin{Bmatrix} N_x \\ N_y \\ N_{xy} \end{Bmatrix} = \begin{Bmatrix} N_x \\ 0 \\ 0 \end{Bmatrix}$ . As mean stress acting on the

laminate material  $\begin{Bmatrix} \sigma_x^0 \\ \sigma_y^0 \\ \tau_{xy}^0 \end{Bmatrix} = \begin{Bmatrix} \sigma_x \\ 0 \\ 0 \end{Bmatrix}$ ; The relation between the average stress and the strain of the material

is given by:  $\{\sigma\} = [A^*] \cdot \{\varepsilon\}$ ; Calculating the strain state for the loading state.  $\begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \gamma_{xy} \end{Bmatrix} = \begin{Bmatrix} 0.06362 \\ -0.03969 \\ 0 \end{Bmatrix} 10^9 \sigma_x$

In the direction of the X axes the relation between the strain and stress is given by:  $\varepsilon_x = 0.06362 (10^9) \sigma_x$ , on the other hand the apparent elasticity modulus in the X direction is presented as  $E_x = 1.572 GPa$

**$\tau_2$ : Applying a tensile stress in the Y direction**

Analogously the mean stress acting on the laminate material is

$$\begin{Bmatrix} \sigma_x^0 \\ \sigma_y^0 \\ \tau_{xy}^0 \end{Bmatrix} = \begin{Bmatrix} 0 \\ \sigma_y \\ 0 \end{Bmatrix} \text{ Therefore the strain state is } \begin{Bmatrix} \varepsilon_x \\ \varepsilon_y \\ \gamma_{xy} \end{Bmatrix} = \begin{Bmatrix} -0.03969 \\ 0.08874 \\ 0 \end{Bmatrix} 10^9 \sigma_y$$

Particularly in the Y axis direction the relationship between the stress and strain is:  $\varepsilon_y = 0.08874 (10^9) \sigma_y$ . Furthermore the apparent elasticity modulus in the X direction is given by  $E_y = 11.27 GPa$ . The praxeological analysis of the technical report and the classroom exercise presented here very briefly, allowed to identify the matrix as a mathematical model for calculating strain of a laminate (isotropic, anisotropic and orthotropic) material. Also, the matrix operations and calculating the inverse of the matrix are used to determine the modulus of elasticity of a composite material, specifically laminated materials.

### SRA design proposed for a tactile sensorial therapeutic ramp (RTEST)

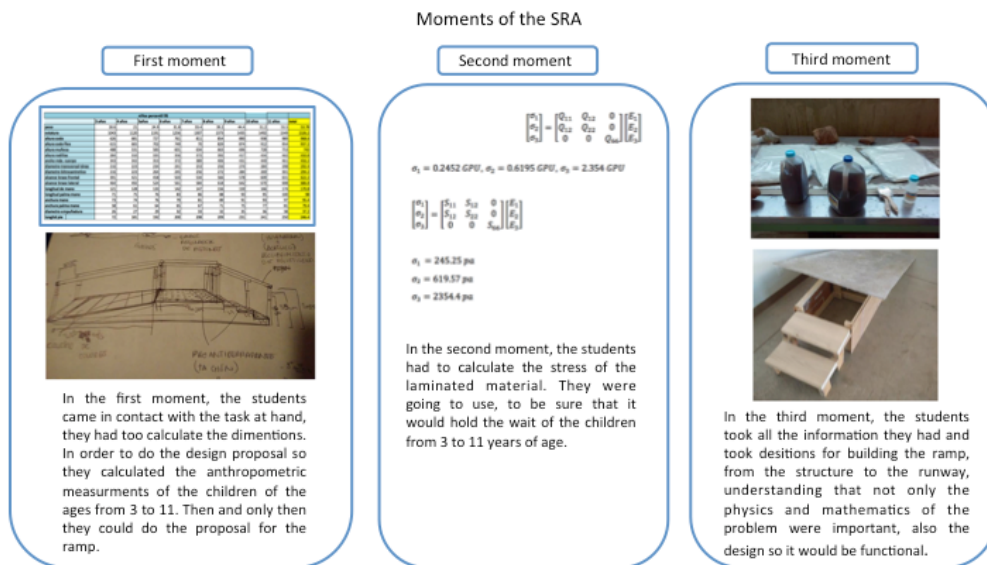

For the SRA design, we considered the construction of a product that requested the use of a laminated material and calculating the stress and strain of the material to ensure the usefulness of the product. Therefore, it was intended that the use of the mathematical model appear the way it happens in engineering projects. Determining that for students in the early college years, more than a structure was necessary to think of a product consisting of plates, which also would be useful for the

community. Thus, it came to the proposal of a tactile sensory therapeutic ramp (RTEST) with laminate material to help children from three to ten years to correct gait problems.

*Moment of the first meeting with T.* To design the ramp students must develop three basic tasks,  $t_1$ ) design the ramp,  $t_2$ ) choose the laminate and stress calculations,  $t_3$ ) determine the type of material with which the ramp will stimulate the sensory part. *Moment of the exploration of T and technical emergency  $\tau$ .* Students should find the technique or techniques to solve  $t_1$ ,  $t_2$  y  $t_3$ . For  $t_1$ , they should investigate the types of ramps, analyze and choose one. For  $t_2$ , they should investigate laminated materials, choose one and make the stress calculation (the technic, p. (3-5)). And for  $t_3$ , investigate the materials that promote sensory stimulation and choose one, justifying the reasons for their choice. *Moment of construction of the technological-theoretical block.* The third moment intersects with the second because here students must build the ramp, using drawings and stress calculations previously made, as well as the preparation of the composite material. In  $t_2$  students should know and apply Hooke's law, for the problem they are solving, they have to know how to build the stress matrix and determine the stiffness matrix. To perform these calculations students can use computer programs such as MathLab, Scilab and SolidWorks.

## First implementation of the SRA

Presenting a first implementation of the evolution of the SRA of one team:

**Figure 2: Momentum schematics of the SRA**

The implementation with students of the core curriculum of engineering, designers and aerospace engineering; Of three different semesters (2, 6 and 7), trying to mimic the form of work of the industry: as different specialties as well as novices and experts engineers. The SRA was proposed to each teacher of the course to see if the assignment was pertinent to their subject and if they could make it part of their class and grade it. The development of the SRA was parallel to the classes of the teachers that agreed to work on the project assigning a certain time in each course for doubts they might have. A report was requested for each of the three phases. Phase 1: Proposal of a design for a RTEST ramp (3 weeks), phase 2: Strain calculation of the laminate material (3 weeks) and phase 3: Elaborate and choose materials for the RTEST ramp: Laminate materials and for the tactile and

sensorial part of the project (4 weeks). The SRA had three phases associated with the first three moments described above.

## Conclusion

The SRA is proposed within the framework of the paradigm of questioning the world in the training of engineers. In this SRA unlike the commonly proposed projects of engineering the mathematical topics are highlighted. In addition the engineering topics are shown in a more important roll in the mathematics subjects. The SRA involved students and teachers from different specializations. The design of the material and the RTEST requires the calculation of stress -matrix model-, knowledge of materials and design. To do this the students must investigate and study elements from different disciplines as well as practical knowledge, students learn to do research, model, use available knowledge to create new, teamwork, communicate their ideas and justify the practice with theoretical elements of different levels. The analysis of the development of the SRA would allow us to understand the institutional necessary conditions for designing SRA in a more complex environment.

# The use of heuristic strategies in modelling activities

Peter Stender and Gabriele Kaiser

University of Hamburg, Germany; [gabriele.kaiser@uni-hamburg.de](mailto:gabriele.kaiser@uni-hamburg.de)

*For students working on realistic modelling problems as autonomously as possible the support by a tutor is indispensable. However, how this support can be realised is still not a sufficiently answered question. In the paper we describe a study in which students worked on complex, realistic, authentic modelling problems over three days supported by tutors. The tutors participated in a teacher training prior to the modelling activity. The focus of the study is the usage of heuristic strategies by students within modelling activities and the promotion of strategic help provided by the tutors. Based on videotaping of ten groups while they were working on the modelling problem of the optimal placement of a bus stop, the study could show that heuristic strategies are an indispensable basis for adequate decisions in the modelling process. Their promotion by the tutors seems to be highly adequate in order to foster modelling competencies under a broader perspective.*

**Keywords:** Mathematical modelling activities, heuristic strategies, modelling example.

## Introduction

Modelling and applications are receiving increasing attention all over the world, modelling competencies are required internationally by many curricula. However, the complexity of real world examples and the according modelling process to tackle the problem leads to a strong discrepancy between the high relevance of these kinds of activities in curricula and their factual relevance in school. In the following we will present a study, which examines how tutors can foster the tackling of complex and authentic modelling problems by students in special learning environments, the so-called modelling days. We will in particular focus on heuristic strategies from the problem solving discussion and their possible usage in modelling classrooms.

## Theoretical framework

### Mathematical modelling and modelling cycle

In our research modelling is understood as a process where a ‘real situation’ from the ‘Rest of the World’ (Pollak, 1979) comes up and needs to be understood and simplified and transferred into a realworld model. The real world model is transformed into the world of mathematics, i.e. the formulated mathematical problem is (partly) solved and the solution is validated according to the real world situation. Often the first results do not answer the primary problem adequately, so the modelling cycle is run through again with an adjusted real world model. This process is repeated until a solution is produced which is adequate for the real situation from the standpoint of the modeller. The according process can be visualized with the following modelling cycle (figure 1).

Figure 1: Modelling cycle (Kaiser & Stender, 2013, p. 279)

### Fostering student's independent modelling activities in cooperative learning environments

If it is intended that students work as independent as possible on the modelling task in cooperative learning environments self-directed learning environments as required by many scholars in the modelling discussion (e.g. Kaiser and Stender, 2013, for an overview see Blum et al., 2007), the support by a tutor has to be adaptive. We use the definition given by Leiss (2007) of an *adaptive intervention*:

Adaptive teacher interventions are defined as those kinds of assistance by the teacher to the student, which supports the individual learning and problem solving process of students minimally, so that students can continue to work at a maximal independent level. (Leiss, 2007, p. 65, own translation)

As guidelines for teachers supporting students who need help in their work, we refer to a framework developed Zech (1996), who suggests a five step approach to realise adaptivity: (1) *motivate*, e.g. 'You will make it'; (2) *feedback*, e.g.: 'Go on like this!'; (3) *strategic help* based on strategy what to do next, e.g. 'Simplify the situation by making it as symmetric as possible!'; (4) *content-related strategic help* gives a strategic help with additional information to the problem, e.g. which aspect should be described as symmetric; (5) *content-related help* shows the students aspects of concrete steps to work on.

If motivational and feedback support are not sufficient to enable the students to continue their work, strategic help is according to this framework the next step to support the students, as the students only get a possible way how to go on, but the students themselves still have to realise the work by their own. Important strategic helps are based on references to the steps of the modelling cycle: 'Simplify the situation!', 'Try to transfer this into a formula!', 'What does the mathematical result mean in the real world?', 'Does the result answers the real world situation meaningfully?' More specific support is offered by the use of heuristic strategies.

### Heuristic strategies

The usage of heuristic strategies is a well-known approach in mathematical problem solving (e.g. Pólya, 1973), that can be used while tackling modelling problems as well. Based on the work of Pólya and others we distinguish the following heuristic strategies, which were formulated in the frame of ongoing empirical research in mathematical modelling (for details see Stender and Kaiser, 2015):

- *organise your material / understand the problem*: change the representation of the situation if useful, try out systematically, (Pólya, 1973) use simulations with or without computers, discretize situations,
- *use the working memory effective*: combine complex items to supersigns, which represent the concept of ‘chunks’ (Miller, 1956), use symmetry, break down your problem into sub-problems),
- *think big*: do not think inside dispensable borders, generalise the situation (Pólya, 1973),
- *use what you know*: use analogies from other problems, trace back new problems to familiar ones, combine partial solutions to get a global solution, use algorithms where possible (Pólya, 1973),
- *functional aspects*: analyse special cases or borderline cases (Pólya, 1973), in order to optimise you have to vary the input quantity,
- *organise the work*: work backwards and forwards, keep your approach – change your approach – both at the right moment (Pólya, 1973).

Although these heuristic strategies are well-known in the problem solving discussion, there is only little empirical research known, how these heuristic strategies can be implemented in classroom teaching and how far these heuristic strategies can be transferred to other mathematical activities such as mathematical modelling.

### **Research Question**

In our research study we aim to evaluate, how far heuristic strategies developed in the problem solving discussion can be transferred into the teaching and learning of mathematical modelling. Furthermore, we examine how far these heuristic strategies are appropriate strategic interventions for the tutoring of students who are working on complex, realistic and authentic modelling problems.

### **Design of the Empirical Study**

#### **Modelling Days as learning environment**

As this kind of work is not very common in usual classes we established modelling projects in schools as learning environment, called modelling days and offer these to schools as special, project-oriented activity organised in their school. The problems, on which the students work, are developed by the university research group. The tutoring of the students, who work in groups of four to six, is organised either by the teachers or future teachers within their master studies. Both groups receive a special training, in which they become acquainted with complex modelling examples and how to support students during their modelling activities. During the modelling days students of grade 9 (15 years old at the end of lower secondary level) work on one modelling problem for three full days in school. The students can choose the problem out of three problems presented by the research group.

In the following we describe one example and describe exemplarily one possible solution.

#### **Modelling problem: The Bus Stop Problem – a possible solution**

We used the bus stop problem in two different versions within various modelling days: the more complex one asks for the best positions of the bus stops for the entire public transport system of the

city of Hamburg. The simplified (but still complex) version only asks for the bus stops of one single bus line.

A solution for the more complex version is based on the idea of covering the city with circles of the same diameter in a regular pattern where the centres of the circles are the bus stops. In a second step a rule is developed based on the adjustment of the bus stops to the requirements of the city-map. The diameter of the circles has to be calculated, which leads to the distance of two bus stops by a certain bus line. For this problem there are a lot of possible aspects that can be considered. One possible approach is to reduce the bus line to a straight line, where the bus stops all have the same distance to the next stop.

**Figure 2: Bus line**

In this solution the following aspects were taken into consideration: the average walking time from and to the bus station (velocity  $v_F$ ), the time the bus drives (velocity  $v_B$ ) over the distance  $s$  and the extra time ( $T_H$ ) each stop causes in between. An optimal bus stop distance shall minimize the total travel time  $T(x)$ .

This leads to the function  $T(x) = \frac{2r+x}{2v_F} + \frac{s}{v_B} + \frac{s}{x} \cdot T_H$  and setting the derivation as zero yields the following solution  $x = \sqrt{2v_F \cdot s \cdot T_H}$ . These formulae now can be interpreted according to the situation, e.g. in respect of the influence of the distance  $s$  or the walking velocity. Students usually will not receive this general result using variables, but with set numbers and they often produce a graph like figure 3. For a more detailed version of this solution see Stender (2016).

**Figure 3:  $T(x)$ : Travel time depending on the bus stop distance**

### Data collection and data evaluation

Within our study we videotaped ten groups of students who were working in five rooms at higher track school in Hamburg (so-called Gymnasium), overall about 40 students participated in the study. Over three days the students worked around 15 hours on this modelling problem. We transcribed the phases during which the tutor communicated with the students, including a short time before, so that we could identify the causes leading to the contact and a few minutes after the communication so it was possible to analyse the effect of the tutors' intervention. In total 238 contacts between tutors and individual groups were transcribed and coded using qualitative content analysis (Mayring, 2015). Based on the analysis of the codes for the phases before, during and after the intervention the success of the interventions could be determined. Detailed findings were presented in Stender & Kaiser

(2015). Interventions that were not successful or gave too strong content-related help were subject to a more detailed examination. In these cases we tried to formulate alternative strategic interventions for use in further teacher training. The solution processes of the students were reconstructed based on the work of different groups and hereby an idealised modelling process could be reconstructed (for more details see Stender, 2016).

## Results of the study

The reconstructed and idealised modelling process is in the first part of the results section used in order to identify, which heuristic strategies students used either intuitively or by referring explicitly to the modelling cycle, to which they had been introduced explicitly using the example of the length of traffic light phases. All students had worked on this example as introduction. The second part of the results section identifies possible interventions by tutors, introducing the students to the usage of heuristic strategies or by using these heuristic strategies by themselves in order to support the students.

### Reconstruction of heuristic strategies in the solution process

In the following we analyse this reconstructed idealised solution regarding the use of heuristic strategies, which are highlighted in *italic*.

The first step of every modelling process is the exploration of the situation, that means as heuristic strategy *organise your material / understand the problem*. The students explored public transport maps and collected important places like schools or hospitals. It took a longer time to *change* this point of view to a more abstract *representation* of the situation, where the bus line is a straight line and special places do not matter. In this situation the more abstract representation is less complex as a lot of details from reality (traffic lights, curves, crossings, hills, ...) are missing. So, here a heuristic strategy derived from the modelling cycle is applicable: *simplify* the situation as much as possible at the beginning! Describing the representation of a bus line as a straight line needs another heuristic strategy, namely to construct the situation *symmetrically*. Using this strategy leads to the assumption that the distance between two contiguous bus stops should be all the same. Figure 2 shows that even more aspects are symmetrical in this model. The transfer from the complete public transport system to one single bus line, that is used later to reconstruct the whole transport-system, uses as heuristic strategy to *break down your problem into sub-problems*! This is another way to *simplify* the situation.

To understand the problem of the simple straight bus line *two extreme cases* should be *analysed*, a powerful heuristic strategy: If there are few bus stops, the bus can drive fast without being interrupted by time consuming boarding, but the walk to the next bus stop will be very long for many passengers, which leads to a high total travel time. The other extreme situation has many bus stops, e.g. every 50 m. Now the walking time to the bus stop will be short for all passengers, but the bus will need a long time for a certain distance, because it is stopping every 50 m. So it becomes clear that between these two extremes there is an optimal distance between two bus stops that minimises the total travel time.

For the students the situation was still too complex and they were not able to formulate a functional based approach as they did not have enough experience with these kinds of problems. Now several heuristic strategies were employed: *use analogies*, *break down your problem into sub-problems*, *try out systematically or work on special cases*. As already mentioned all groups had worked on the length of traffic light phases as introductory example, they therefore knew the formulae  $s(t) = \frac{1}{2}at^2$

and  $v(t) = at$  and how to calculate acceleration processes. They reduced complexity again by the heuristic strategy *simplify* in the modelling cycle setting the distance between two bus stops  $x = 500$  m. This heuristic strategy is related to the heuristic strategy of *working backwards* as  $x$  should be the result of the calculation but is used here as if the result is already achieved. Then the students calculated the driving time between the two bus stops using certain values for the acceleration and the velocity of the bus and using *analogies* from the traffic light problem as heuristic strategy. This can be described again as using the heuristic strategy of *break down into sub-problems* as the calculation was not done for the whole bus line, but only for the part between two bus stops. As the choice of  $x = 500$  m was made as ad hoc decision it can be described as heuristic strategy of *trying out a special case*. The calculation itself that led to a certain driving time includes several steps and is mathematically challenging, but was achieved due to the use of the *analogy* from the traffic light problem. The result of this approach was the calculation of a certain traveling time that unfortunately was not the answer to the question of the best distance between two bus stops. So, in a second loop through the modelling cycle the students calculated the time for a longer distance of 12 km with a bus stop every 500m *combining the partial results from above*. Again this shows an interesting result but no answer to the initial question.

The next step was to vary the number of bus stops on the 12 km journey using a heuristic strategy *for optimisation you have to vary the input quantity*. The travel time was calculated in the same way as before so an *analogy* was used. The calculation was realised using a spreadsheet and used the heuristic strategy *trying out systematically* different distances. This approach yields the result that with increasing number of bus stops the traveling time increases proportionally. This was expectable as one of the crucial aspects – the walk to the bus stop – was not considered up to now.

Based on this insight an average walking time to the bus stop was included in the calculation while the rest of the calculation was *analogue* to the previous one. This led to a result similar to figure 3, but the students still used as variable the number of bus stops, not the distance between two bus stops.

With the heuristic strategy of *a change of representation* the students switched to the more meaningful variable, again the new calculation was *analogue* to the previous one. Still everything was calculated with a spreadsheet so it had the character of a *simulation* or just *trying out* special cases. Only few students were able to realise the next *change of representation* and combined the single steps of the calculation into one formula. They developed one function  $T(x)$  that included several steps of the calculation in one single mathematical term and  $T(x)$  works as a *supersign*, which is another, less discussed heuristic strategy. This approach opened the way to use the derivative and calculate a solution like it is shown above. This was done with concrete numbers instead of parameters ( $v_F$ ,  $v_B$ ,  $T_H$ ,  $s$ ,  $r$ ) by one group of students, but in another group there were students able to use parameters instead of concrete numbers, which again means the use of *supersigns* as each character stands for an infinite amount of numbers.

The results from different traveling distances  $s$  were compared and it became clear as meaningful result that on shorter trips the bus stops may be closer together. This result was *validated*, a heuristic strategy from the modelling cycle, by analysing the map of the public transport in Hamburg. Near the city, where people often use the bus only for the short distance to the next metro station, the bus stops were much closer than in the outer parts of Hamburg. The calculated distances matched very well to the distances in the map.

The subsequent step was to go back to the public transport network and cover the city with circles of a certain diameter. Now the results from the single bus line were used, which uses the heuristic strategy to *combine partial solutions to get a global solution* in order to choose meaningful diameters. These diameters were not the same over the whole city according to the previous results and in opposition to the initial idea.

To summarise, the analyses of the modelling activities by the students showed an intensive usage of heuristic strategies, partly referring to the various phases of the modelling cycle and partly as intuitive usage.

### **Heuristic strategies as strategic interventions**

The heuristic strategies that were used quite often intuitively by the students in the modelling process can be transferred into strategic interventions by tutors, if the students are not able to continue their work on their own. In the following examples for these activities are described, which were shortly included in the teacher training beforehand and which were used by the tutors, but not as intensively as wished, probably due to their low importance in teacher training.

In each situation, where an analogue acting to previous work occurs, the following hints are possible: “This work is analogue to something you have done before!” or “Calculate this in the same way you did in the traffic light problem”.

While constructing the real model the simplification of the situation is essential. “In your first approach build the real model as simple as possible – for this, it’s a good idea to describe the model as symmetric as possible!”

The idea to break down the problem into sub-problems can be initiated by “For this problem you have to work on several steps – try to solve only one simple part at the beginning and then try to use these result for the next steps!”

The idea of using special cases can be implemented as follows: “If you have no idea how to go on, select specific numbers and work with them! Just work on special cases in the beginning!” As shown above this strategic intervention is a powerful mean for modelling activities.

The heuristic strategy *For optimisation you have to vary the input quantity* can be helpful for students who are not familiar with functional thinking. The following hints can be given: “You calculated with 23 bus stops. What happens if you use more or less bus stops?” “Vary the number of bus stops!” “If you look for an optimal solution you have to make sure that a nearby situation is less good!”

To summarise, these examples show how a heuristic strategy can be used to create a strategic intervention. Depending on the work of the students, more or less information on the concrete modelling problem can be included in the intervention in order to give a less abstract input to the students if necessary.

### **Summary and conclusions**

The empirical study displays a great variety of heuristic strategies used by the students within their modelling activities, a few were developed intuitively, a few derived from the description of the modelling cycle introduced beforehand.

An important result of the study is that strategic interventions often were successful when a tutor supported students working on complex modelling problems, because the usage of these heuristic

strategies is not self-evident. Because the usage of adequate strategic interventions by tutors is very hard, it often only will be possible if prepared beforehand. In order to react on the students in class in an adaptive way the tutor needs a deep insight into the modelling process, the modelling problem, possible solutions as well as heuristic strategies and strategic interventions.

# Metacognitive modelling competencies in small groups

Katrin Vorhölder, Alexandra Krüger, and Lisa Wendt

University of Hamburg, Germany; [Katrin.vorhoelter@uni-hamburg.de](mailto:Katrin.vorhoelter@uni-hamburg.de)

*Metacognitive modelling competencies are an essential part of modelling competence. When working on a modelling problem in small groups, the metacognitive modelling competencies of an individual may be less important, but in particular those shared in the group are of major importance. In this paper, results of a pilot study are presented which clearly indicate that measuring metacognitive group competencies is challenging. Furthermore, it is shown that the measurement of metacognitive competencies of individuals is not sufficient to get insight in the students' metacognitive behavior.*

*Keywords: Modelling competencies, metacognition, group work.*

## Introduction

Solving complex modelling tasks in mathematics education in school in Germany is usually done in small groups, at least in tandems. The reason for this is not the promotion of skills for cooperative collaboration - basic skills in this regard are taken for granted. Rather, there is the conviction that such complex problems can only be solved by students, if the ideas and skills of many are shared. This does not only refer to the so called sub-competencies of modelling competencies, which are necessary for getting from one phase of a modelling cycle to the next, but also concerning overarching skills such as metacognitive modelling competencies. However, in recent years, research on modelling competencies has merely focused on individual students. Thus, group dynamics were often neglected. This paper presents first results of a pilot study, in which students' perception and attitude towards metacognitive strategies used by themselves as well as by group members were measured by using different instruments for data collection.

## Theoretical background

### Modelling competence

Working on modelling problems successfully and goal-oriented requires modelling competence. Although there is no in general accepted concept about which competencies are comprised, the definition of Maaß (2006) is widely accepted. According to her definition, modelling competencies include “abilities and skills to conduct modelling processes adequately and in a goal-oriented way; as well as the willingness to put these abilities and skills into practice.” (Maaß, 2006) Here it becomes obvious that those competencies, necessary for getting from one step of a modelling cycle to another, are surely part of modelling competence (Kaiser, 2007). Furthermore, the definition given above, indicates that appropriate beliefs and insights as well as comprehensive competencies such as working cooperatively in groups, communicating with each other and metacognitive competencies are necessary as well.

### Metacognitive competencies

The concept of ‘metacognition’ is a fuzzy one. Schneider and Artelt (2010) define metacognition as “people’s knowledge of their own information-processing skills, as well as knowledge about the nature of cognitive tasks, and of strategies for coping with such tasks. Moreover, it also includes

executive skills related to monitoring and self-regulation of one's own cognitive activities." This definition provides the most common distinction of metacognition into metacognitive knowledge from metacognitive skills (often called metacognitive strategies). Thus, metacognition comprises metacognitive knowledge about the specifics of modelling tasks, the knowledge about appropriate strategies for working on modelling tasks successfully and knowledge about person's own skills and competencies and as well as those of other people involved the modelling activity. Furthermore, the procedural aspect of metacognition contains the use of strategies for planning, monitoring, regulating and evaluating the whole modelling process (see Vorhölter & Kaiser, 2016)

For solving a modelling problem successfully and goal-oriented, both aspects of metacognition mentioned above are necessary: A complete lack or only a very low level of meta-knowledge about modelling processes and problems can result in considerable problems when working on such tasks. For transitioning between the stages of a modelling process and for dissolving cognitive barriers while working on them, meta-knowledge as well as metacognitive strategies are needed (Maaß, 2006). Regarding problem solving processes, for example Schoenfeld (1992) points out the importance of planning the solution process. Furthermore, monitoring each other by reciprocal asking and answering metacognitive questions while working on a complex task can improve mathematical performance as well as metacognitive competencies at the same time (project IMPROVE, Mevarech & Kramarski, 1997). This finding is confirmed by the conclusion of Goos (1998): collaborative interactions deliver metacognitive benefits. However, not only metacognitive strategies referring to planning, monitoring and regulating the modelling process are of great importance for solving modelling problems: Blum (2015) points out that reflecting one's own activities is crucial for transferring knowledge and skills from one task to another.

### **Important metacognitive strategies for working on modelling problems in small groups**

The influence of metacognition on learning results was investigated in many studies, but the conclusions are ambiguous, as mentioned above. A reason for the ambiguity may be the fact, that metacognition is normally measured regarding a single person and correlates with her/his own mathematical performance. Solving modelling processes, however, is usually done in small groups. Therefore, one has to distinguish between the performance and metacognitive competencies of single team members and those of the group as a whole. But research on metacognition in the past has merely focused on individual processes. „By focusing on the individual student, researchers have failed to address the dynamics required for progressive knowledge building by collaborative learning groups“ (Chalmers, 2009). However, “team cognition emerges from the interplay of the individual cognition of each team member and team process behaviors.” (Cooke, 2004) So to solve a modelling problem successfully, not the individual, but the group competencies are crucial: Students have to share their knowledge and their competencies (Artzt & Armour-Thomas, 1992).

Thus, for working on modelling problems successfully in small groups, metacognitive strategies are of great importance. In previous studies at the University of Hamburg the following strategies were identified as those, that were used by students as well as classified as useful or even necessary:

- Strategies for planning:
  - P1: Subdivide the solution process in several steps,
  - P2: Allocate parts of work to different team members,

- P3: Structure the solution process according to the time available,
- P4: Choose useful solution strategies
- Strategies for monitoring and, if necessary, for regulating the working process
  - M1: Identify different kinds of red-flag-situations
  - M2: Notice incomprehension
  - M3: Keep track of the time available
  - M4: Check the work habits
  - M5: Reconsider solution strategies
- Strategies for evaluating the modelling process to improve it
  - E1: Evaluate the strategies used
  - E2: Reflect on the working habit
  - E3: Validate on the solution (cf. Schroeder, 2013)

The identified strategies were used for developing instruments for measuring students' use of metacognitive strategies while modelling, as shown in the next paragraph.

### **Measuring metacognitive strategies**

In general, for measuring procedural metacognitive modelling competencies, two possibilities exist: Online-methods such as thinking aloud, observations, eye-movement or logfile registration enable process diagnostics concurrent to task performance. Thus, a deeper look into the metacognitive behaviour of students is possible without disturbing and influencing them too much. However, these methods cost a lot of time and money. Therefore, they can only be used for small samples. While using offline methods like (prospective or retrospective) interviews or questionnaires, the results rely on the students' self-reports. These methods bear the risk that strategies may be used unconsciously or their use may be forgotten by the students. Furthermore, the item formulation may remind the students on the usefulness of certain strategies. Consequently, they will answer according to their metacognitive knowledge and not on basis of their behaviour. However, in contrast to observations and thinking-aloud-protocols, processes which were not verbalized because of different reasons can be measured with the help of questionnaires or interviews. In addition, questionnaires can be used for bigger samples. (Veenman, 2011).

For obvious reasons, the development of a questionnaire is desirable. For doing so, the identified metacognitive strategies mentioned above were used as a basis. The questionnaire used in this study consists of 40 items divided into the sub-processes of planning, monitoring, regulating and evaluating, 27 of them concern individual metacognitive strategies, 13 items regard group strategies. Students are asked to judge their use on a five-point-scale. Furthermore, students are asked to judge their motivation to work on the task, the task difficulty and their satisfaction with their small group. To give an impression of the questionnaire, selected items and the relation to the coding guideline presented above are shown in Table 1.

Item	Relation to coding guideline
1.1 I have thought about how to solve the Problem best on my own.	P1
1.2 We tried to recognize possible steps together.	P1
2.1 I questioned my own ideas.	M5
2.2 I questioned the others' ideas.	M5
3.1 When we found a solution, I reconsidered the whole solving process.	E1
3.2 When we found a solution, we were wondering what we can do better next time.	E2

**Table 1: selected items of the questionnaire**

## Research questions

As presented above, metacognitive competencies seem to be necessary for working on modelling processes successfully. Therefore, teaching units for fostering these kinds of competencies are desirable. To evaluate these teaching units, instruments for measuring metacognitive competencies are needed. Thus, a questionnaire for measuring students' individual metacognitive modelling competencies as well as those of a small group was developed. In the study presented in this paper, the students' self-reports in the questionnaire were compared to experts' ratings on the students' use of metacognitive strategies while working on a modelling task and to students' self-reports in an interview afterwards. Hence, the research questions of this study are:

- *For which metacognitive strategies – at an individual as well as at group level - do the students' statements in the questionnaire correspond with experts' ratings as well as with students' statements in interviews?*
  - *Which metacognitive strategies can be measured more reliable by students' self-reports?*
  - *Is any further information required to interpret students' self-reports?*
  - *Which metacognitive strategies can be measured more reliable by experts' ratings?*

## Design and methods of the study

For answering these questions, students of grade nine of three different classes were introduced to a modelling cycle and then worked in groups of four on a modelling problem. The working process was videotaped. After working on the problem, the students were asked to fill in the questionnaire presented above. While doing so, they were not allowed to speak to each other and discuss the items. In the afternoon, students were interviewed using a stimulated recall-interview (Gass & Mackey, 2000). For this, selected scenes from the video were shown to them and they were asked to comment them. Afterwards, some questions about their attitude towards the importance of metacognitive strategies were posed.

To answer the research questions, the videos as well as the interviews were analyzed using the items of the questionnaire as coding guideline, following qualitative content analysis (Mayring,

2010). Those codings were compared with the answers in the questionnaires. In the next section, first results from the study of one of the small groups are presented.

### First results of the study

The group consists of four girls, which are named Anna, Julia, Olivia and Lea in this paper; three of them were interviewed afterwards. Anna, Julia and Olivia all mentioned in their interviews that they were used to work together in this group; Julia indicates in the interview, that Lea is a new student and is not familiar with the other students. She assumes that this might be the reason for Lea not taking part during group work.

In the following, special attention is paid to items that were answered very differently by the students within the small group or items for which the different sets of data provide different information. Thus, students' statements in the questionnaire concerning selected items of the sub-processes of planning, monitoring and evaluation will be compared with the respective statements in the interviews as well as with outcomes of the analysis of the videos. An overview of the students' statements in the questionnaire is shown in Figure 1.

**Figure 1: selected students' judgements in the questionnaire**

In the questionnaire, Julia and Anna indicate that they worked out a plan on their own before planning the solving process together, whereas Olivia only did this partly and Lea did not plan on her own at all. Their perception of developing a plan in the whole group differs (see Figure 1). Thus, questions on the causes of these differences arise. When analyzing the video, one can clearly identify a scene in the beginning, in which the group is discussing how to proceed. You can see that Anna is the one, who develops a plan, whereas Julia and Olivia are not convinced and ask several questions. Before their questions are answered satisfactorily and before they are convinced, Anna starts to work. This scene was shown to the girls during the interview. When asked to comment on the scene, Olivia did not say much about the planning process:

Interviewer: How did you proceed in this situation?

Olivia: I don't really know. Actually, Anna said we should use a scale and then we knew what to do.

Only when asked about the necessity of having a plan, she talked about the importance of planning:

Olivia: Most times, planning is better, because you then know this is the next step, and then that step.

Anna on the other hand spontaneously commented her behavior:

Interviewer: In this scene, you have decided how to solve the problem. How did you decide?

Anna: I said how to, I don't know. We have. I had the idea of scale and then, Julia wanted to calculate the volume. But then we decided for the scale.

Summing up, the statements in the questionnaire express the level of conviction concerning Anna's plan. This suggests that the students' perspective on group planning was measured correctly, although the statements regarding group planning differ.

Regarding the sub-process of monitoring, both Anna and Olivia state in the questionnaire that they have not or only to a very small extent questioned their own ideas, but to a higher extend others' ideas (Table 1, 2.1 and 2.2). Comparing this data with those from expert ratings and from the girls' statements in the interview, different reasons for these statements are revealed. By analyzing the video of the girls' working process, Anna can be described as the one, who brought in the most ideas and managed the group in some ways. Although she wasn't aware of doing so during group work, she recognizes her behavior in the interview when asked to comment the scene:

Anna: I said that doesn't matter, I took over power and blocked other's suggestions and explanations. Seeing my behavior frightens me, I did not realize I was doing this.

Thus, her statement in the questionnaire indicates that she was a group leader that did not approve of others' ideas, because she was very convinced of her own. In contrast, Olivia did not participate with her own ideas or took over any other active responsibilities. However, it becomes clear from several statements that she was monitoring the whole process and questioned the process if necessary. But based on her statements in the interview, it becomes clear that she is not aware of doing so herself:

Interviewer: And what about looking about one's own shoulder? [...]

Olivia: I don't think so.

Interviewer: Why not?

Olivia: I don't know. We are a group that simply work. And then, ready.

Thus, Olivia uses metacognitive strategies of monitoring unconsciously. This makes clear that it is sometimes necessary to have further information about the group processes and the different roles of the students. One possibility are ratings by experts. However, those are not sufficient solely, as one can see in regards to Lea. She did not say a word while working on the problem, but states to have monitored the whole process. If her judgement is right, it cannot be proved. But as the answers from the questionnaire do not count regarding marks and it was clear to the students that their math teacher will not get their judgements, you can state that Leas statements are correspondent with her perception of her own behavior.

The students' statements about evaluating the whole modelling process correspond and match with the researchers' analysis completely: The group did not evaluate their working process significantly (except of Julia).

## Conclusion and outlook

The selected results of the pilot study presented above illustrate in a considerable way the importance of sharing metacognitive competencies in a group: Presumably, none of the girls would have solved the task on their own. Even Anna, the "group leader", needed Julia and Olivia for monitoring and validating the modelling process. However, it also becomes clear that measuring students' metacognitive competencies is challenging. Measuring metacognitive group competencies is even more challenging. In this study, different methods for measuring the use of metacognitive strategies while working on a modelling problem in small groups were used: students had to fill in a questionnaire and were interviewed. Furthermore, their behavior was judged by researchers.

The presented results clearly show that some answers in the questionnaire are not consistent with statements in the interviews or with the analysis of the students' working process. In addition, students' judgements about incidents during group work differ.

As presented above, almost all differences could be explained by consulting not only one, but different items or by using all three datasets. However, not all students, who take part in the main study (about 600), can be interviewed nor can their group work be analyzed. Therefore, it should be analyzed next, if there are any key or filter-items in the questionnaire that give information about how to judge other items. In accordance, the items have to be identified that can be rated by experts better than by students themselves and it has to be analyzed whether this is a question of special items in general or a question of students and the role of the students in small groups.

# Product orientation in modeling tasks

Wolfgang Bock, Martin Bracke and Patrick Capraro

KOMMS, University of Kaiserslautern; {bock, bracke, capraro}@mathematik.uni-kl.de

*Keywords: Real-world problems, modelling tasks, client action.*

## Introduction

Beginning with the first Pisa study in 2000 (OECD, 2001) there is a worldwide discussion of an appropriate education in the so-called STEM subjects. One cause was the alarming fact that in many countries the majority of secondary school students fail to reach proficiency in math and science (Kuenzi, 2008). One significant reaction to the above mentioned debate was to strengthen the role of mathematical modeling in teacher training and the curricula. In Germany, this can be seen from the fact that mathematical modeling is mandatory in most of the recently introduced master programs for mathematics teachers. Moreover, there is a strong increase in the number of publications on mathematical modeling of real-world, realistic or authentic problems over the past decade. The following definition is due to Bock & Bracke (2013):

**Definition 1:** *An authentic problem is a problem posed by a client, who wants to obtain a solution, which is applicable in the issues of the client. The problem is not filtered or reduced and has the full generality without any manipulations, i.e. it is posed as it is seen. A real-world or realistic problem, is an authentic problem, which involves ingredients, which can be accessed by the students in real life.*

Real-world problems and authentic problems are used and studied in many different modeling activities such as the TheoPrax method (TheoPrax), modeling weeks and modeling days, the Junior-Engineering Academy (Bock & Bracke, 2013), Fraunhofer-MINTeC<sup>1</sup> Talents (Bracke et. al., 2015). Especially in TheoPrax and also the modeling activities in vocational education (e.g. Wake, 2014) the activities aim towards a specified product from the beginning. In product management a product is a deliverable or set of deliverables that contribute to a business solution. In (Kotler et.al. 2006) it is defined as “anything that can be offered to a market that might satisfy a want or need” (p. 230). In the client-provider situation the product thus is the good sold to the client by the provider. It, therefore, is directly related to the needs of the client meaning the task the client gives to the provider. In the real world, e.g. in industry, an actual client is not really interested in mathematical models – very unfortunate to most of mathematicians - but mostly in a tool or a strategy he can directly use for his purposes. In our opinion for modeling activities having real-world or authentic problems this is a dimension which is to be included into the existing modeling process. For authentic and real-world problems we therefore define the notion of a product.

**Definition 2:** *In a mathematical modeling situation (with an authentic and real-world problem) a product is a deliverable in the language of the client which satisfies the needs incorporated in the*

*task given by the client to the provider in such a way, that the client can use it directly for his purposes.*

## Research questions

At the University of Kaiserslautern modeling activities including products have been performed for years. Even in the first modeling week in 1993 one can find in 3 of 8 projects concrete products such as computer programs and strategies. It is planned to study how modeling tasks and the development of products changed during this time based on the reports of past modeling activities. It is to expect that both changed with the introduction of computers and the increase of programming skills. For this purpose we intend to analyze existing material from the past 23 years on how strong the focus on project orientation in the modeling tasks have been. The use of computers during the modeling weeks is well documented, however the data is not enough for empirical studies. Thus for a more involved study we plan to gather material from other universities involved in modeling weeks. Furthermore we want to investigate how the client action during the modeling process changes the whole process of the modeling cycle and the product itself. A product can in reality be produced without a modeling cycle; on the other hand the modeling cycle can be performed without producing a product. However the quality of the product can be improved by an iterated mathematical modeling process in most cases. The client in this case plays the role of an external control in the sense that he/she will accept or not the product. He/she can also ask for new features or ask for specific extensions. To study this we plan to apply different approaches (with client/without client) to different but similar groups in modeling activities. The performance of the group should be investigated via video analysis, such that we can estimate how often a modeling cycle was performed.

**Keywords:** *Mathematical Working Space (MWS), modeling tasks, modeling cycle.*

In the Mathematical Working Space (MWS) model, an epistemological plane and a cognitive plane are introduced with a focus on their interactions related to semiotic, instrumental and discursive dimensions (Figure 1a). The model is devoted to the analysis of mathematical work with, specifically, paradigms guiding and orienting the work. Numerous researches are based on the MWS model and the reader may refer to special issues in journals such as *Bolema* 30(54) and *ZDM-Mathematics Education* 48(6) in which an introduction to the model is given in the survey paper. Nevertheless, until now, few studies on modeling tasks have been based on the MWS model and we want to highlight recent researches, in particular coming from PhD studies within our team.

Based on the modeling cycle (figure 1b) proposed by Blum and Leiss (2005), we suggest, in the poster, some adaptations which help to understand how MWSs can be used. The whole modeling process is not taken in its whole, and we focus more on how the analysis can be refined, mostly between phases 3 and 5 of the cycle, in relation to activity in different mathematical domains.

Figure 1a: MWS diagram; Figure 1b: modeling cycle (Blum & Leiss, 2005)

Nechache (2016) suggests describing the modeling work in probability situations, with the MWS framework. She identifies the importance of the theoretical referential of the  $MWS_{Proba}$  in the constitution of the real model. Then, for the analysis of the mathematical part, she fully uses the  $MWS_{Proba}$ . In the same way, the MWS model can be used for studying other mathematical domains.

Derouet (2016) proposes a similar type of use for the mathematical part, but she associates sub-phases to the stages of the cycle in order to investigate the progress of the modeling process. She isolates a part of the cycle containing “real model” and “real results” that she names pseudo-concrete. It allows her to identify, in a modeling situation related to continuous probability, a work within the  $MWS_{Proba}$  in various working paradigms.

In these studies, the MWS model allows to refine the analysis of the mathematical part by taking into account a first horizontal mathematization followed by a second vertical mathematization allowing to strengthen the mathematical model. Other types of change, or transition, are possible,

like the change of MWS or mathematical domains. In his study in relativist kinematics, Moutet (2016) suggests an extension of the MWS model to take into account a change of matters. He considers a second epistemological plane for physics, and he studies the interactions between these two planes and the cognitive level.

In these studies, simulation associated with digital models can also be considered as an important stage of the modeling process. It plays two different roles. The first one is in relation to the development of the real model with a simulation close to the initial situation (urn model or a calculator which proposes rolls of dice or coin, in probability). The second role presupposes a stronger mathematical expertise in the MWS of the domain at stake as, for example, the implementation of an algorithm of dichotomy in analysis.

Hence, the use of the MWS framework can enrich and strengthen the analysis of the modeling process based on the study of a cycle (figure 1b) in connection with a first resolution of the problem. It constitutes a first interaction between MWS and the modeling cycle, as a *first cycle*<sup>1</sup>: The modeling problem has been mathematized and it is possible to identify the epistemological and cognitive components of the MWS in relation to the student's activity and realization in the different domains and paradigms. But we can also, in a more didactic way, think of a *second cycle* aiming at a better understanding of the model and of the mathematical objects introduced to solve the problem by students. In that case, the modeling task proposed by a teacher aims not only at solving a real problem but more deeply at exploring and understanding the numerous uses of a mathematical notion, enriching the MWS, in particular the theoretical referential. This is what we are developing in a work on progress on the exponential function.

# Mathematical modeling and competencies for biology students

Yannis Liakos

University of Agder, Kristiansand, Norway; [ioannis.liakos@uia.no](mailto:ioannis.liakos@uia.no)

*The research aims at introducing modeling tasks with an ultimate goal to engage students more actively into learning mathematics through tasks that are biologically ‘colored’. My focus is on the individual progression (if any) of students’ mathematical competencies during a sequence of modeling sessions as part of their first year mathematics. My goal is to explore the nature of progression within the competency profile of participating student, the relation between modeling processes and this progression and what transformations are applied in these sets of competencies.*

*Keywords: Mathematical modeling, mathematical competencies, tasks, progression.*

## Short description of the research topic

The literature provides documentation of learning benefits by engaging students in mathematical modeling: educational benefits (Kaiser et al., 2006); students engaged in modeling may develop a deep understanding of the content and an ability to solve novel problems and that it can bring students into alignment with the epistemic aims of science and help them develop more sophisticated ideas within the area of study they are focused on. I adopt a design based research approach in which an iterative process of design, implementation and analysis takes place.

## The research questions

RQ\_1) What is the nature of progression in a student’s competency profile through the course of the mathematical modeling unit?

RQ\_2) Considering a set of competencies (competency profile) as a body of knowledge, what transformations are applied in the course of the modeling sessions?

## Theoretical and methodological framework

My theoretical approach is informed by the anthropological theory of the didactic (Bosch & Gascón 2014) and, in particular, by the distinction between four bodies of knowledge: scholarly knowledge; knowledge to be taught; knowledge taught; and knowledge learnt. A significant work on mathematical and modeling competencies has been done by many researchers (e.g. Maaß 2006; Blum & Kaiser 1997) while Niss (2003) created an 8-fold (KOM project) system of mathematical competencies. I decided to proceed to an adaptation of the KOM model adjusted to the above mentioned literature and the specific context I am working on: students of a Biology Department. Part of my analysis will be based a 3-D (radius of action, degree of coverage and technical level) model of progression for each competency from Niss and Højgaard (2011). I have also constructed a coding system in order to “attach” specific students’ expressions to a certain mathematical competency. These constructs form a first set of tools for data collection and analysis.

## The context and methods for data generation and analysis

The context (or arena) of this study is the Biology Department of a Norwegian university and a mathematics course for first year Biology students. My main study took place with first year Biology students. Modeling sessions occur weekly during the first semester. These sessions (for groups of 3 to 4 students) are 50 minute in length and supplement lectures to the whole cohort of students. Tasks in the sessions are designed in five 2-week blocks focused on a subset of mathematical competencies that students should bring into action in order to complete the task.

To address RQ\_1 I will, as above, explore selected students' small group discourse activity. Data were collected through audio-visual recordings of students working on tasks synchronized with their writing (using Smartpens which records audio and visual data accompanying written data). At RQ\_2

I am addressing the question: what is the "offered body of competencies" (an a-priori analysis). For the next three steps I will use my data to provide answers or useful directions. A task-design analysis, for example, can provide what the existing literature provides on population dynamics and exponential growth (scholarly knowledge) but also which task was finally decided to be presented (knowledge to be taught) and this will happen for every different modeling block.

## Potential significance and contribution

My research will contribute to the following areas (1) dynamic competencies profiles for students, (2) a critique of Niss' (2003) 8-fold system of mathematical competencies, and (3) a description, in the context of mathematical modeling in the Biological Science, of ATD's four bodies of knowledge.

# Phenomenological analysis of the line: A study based on the Didactical Analysis of mathematical knowledge

Guillermo Ramírez-Montes<sup>1</sup> and Fabián Gutiérrez-Fallas<sup>2</sup>

<sup>1</sup>Instituto de Educação, Universidade de Lisboa, Lisbon, Portugal; [grm1905@gmail.com](mailto:grm1905@gmail.com)

<sup>2</sup>Instituto de Educação, Universidade de Lisboa, Lisbon, Portugal; [fgutierrez92@gmail.com](mailto:fgutierrez92@gmail.com)

**Keywords:** *Phenomenological analysis, line, Didactical Analysis.*

Improving the learning of students has been a concern in research in Mathematical Education. Consequently, didactical aspects and tools for teaching of a successful mathematic, have received a growing attention in different studies. The Didactical Analysis (DA) is considered by Rico, Lupiañez & Molina (2013), as (a) a tool for teaching training; b) an instrument for curricular innovation; and (c) a methodological and research tool, this latter considered in this study. The DA is a cyclic process which implies four sub analysis: content analysis, cognitive analysis, instruction analysis and performance analysis (Gómez, 2002). In the content analysis, we find the Phenomenological Analysis (PA) of a concept, that consist of "describing what are the phenomena for which (the concept) is the means of organization and what relationship has the concept or structure with these phenomena" (Puig, 1997, p.62). Freudenthal (1983) names didactical phenomenology to the phenomenology that is characterized by consider the concept as a cognitive process, as a subject of teaching and to be learned by students, that beside organizes phenomena in the student's world and proposed in the teaching of concept. For this author PA's aims is to serve as the basis for the organization of mathematics teaching.

The intention of this poster is to present results of a PA of line concept on the Cartesian plane, based on the DA of this concept, to answer: what is the knowledge related with the line used for? The data were collected between 2013 and 2014 through a books selection of mathematical and didactics texts of secondary level. The PA of the line was carried out by documental analysis of these texts and its construction was realized in three phases: (i) define mathematical substructures of line concept on the Cartesian plane (mathematical-world), (ii) define the phenomena that each mathematical substructure organizes (real-world), (iii) establish the relationship between substructures and phenomena.

Our proposal consists to show that from this PA, mathematics teachers can organize the teaching of the line on the Cartesian plane promoting the mathematical modelling process of Borromeo Ferri (2006), where phenomena and mathematical substructures are part of different sets, but they are related each other according to the proposed steps in the modelling process. In our study, we identified four contexts that lead to this modeling process, each one referring to phenomena and substructures of how organize the contents of line: (C1) the slope of a linear trajectory with respect to a fixed reference line, (C2) the linear relationship that occurs between two magnitudes, (C3) the behavior between two or more linear relationships, (C4) the distance between two or more objects.

For instance, in C1, a possible real-world model related to the mathematical substructure of the *slope of the line* is as follows:

The picture presents the information of a car when climbing p a road. In this one is showed the position of the car in two different moments, when it has moved 50 m and 350 m respectively.

What is the slope and angle of inclination of the road?

What is the relationship between the slope and the tangent of the angle of inclination?

In relation to C2, a possible real-world model related to the mathematical substructure of *the linear equation of two variables* (or *the equation of two variables of first degree*) is the following:

Carlos has a bank account where he earns 0,5% interest from the initial savings each month. If Carlos opened the account with 2000€ ten months ago, how much money will Carlos currently have? How many months are needed to have 8000€?

In the poster, we would present examples of each context, highlighted the details to consider them like starting points to promote the modelling process in the learning of the line in the Cartesian plane.

## TWG08: Affect and mathematical thinking

## **Introduction to the papers of TWG08:**

### **Affect and mathematical thinking**

Pietro Di Martino (Chair), University of Pisa, Italy

Inés M<sup>a</sup> Gómez-Chacón, Universidad Complutense de Madrid, Spain

Peter Liljedahl, Simon Fraser University, Canada

Marilena Pantziara, Cyprus Pedagogical institute, Cyprus

Stanislaw Schukajlow, University of Münster, Germany

### **Introduction**

This chapter introduces the contributions discussed during the working sessions of the TWG8 “Affect and mathematical thinking” in CERME 10.

In this edition our TWG has been enhanced by the inclusion in the group and the contribution in the discussion of the researchers from the TWG7 “Mathematical Potential, Creativity and Talent”.

The quantitative data about the participation to our group confirms the interest toward affective issues in the field of Mathematics Education: 41 manuscripts were initially submitted to the groups, 26 were accepted for the discussion, and finally in these proceedings 24 papers and 2 posters are included.

Moreover, our group confirms its spirit of inclusion: 12 different countries were represented and 11 newcomers welcomed.

The papers (24) and the posters (2) were presented and collectively discussed in the first six sessions. Presenters had 10 minutes (5 minutes for posters) to introduce the key-ideas of their papers, then we developed a 10 minutes discussion. At the end of each session, 20 minutes were used to discuss the main aspects emerged in the section.

In the fourth section, one hour has been devoted to the presentation of the ERME Chapter about affect: the draft of the chapter was sent to all participants before the conference, and each participants had to share two questions, comments or criticisms about this draft. The collected comments are been the thread of the discussion related to the chapter.

In the seventh and last session, we discussed the main themes emerged during our previous work, developing the structure of the report for the final day.

### **The issues emerged in TWG8 at CERME10 and the related discussion**

The analysis of the affective focus of the papers discussed in our TWG reflects the current diversity of interests and approaches inherent in the field of affect research. Many different affective constructs emerged: beliefs, motivation, values, emotions, needs, relaxed, memory, aesthetic, confidence, meta-affect, identity, self-efficacy, meaning, motivation, values, images, views, flow, perseverance, tolerance, interest.

It is important to underline as many of these constructs are clearly related, sometimes – and this is a well-known critical aspect in the affective research – different labels are used to indicate the same constructs, and vice versa. Sometimes the same term is used in a very different meaning by different

researchers. As we will underline later, this communicative issue is particularly critical for the emotions.

In our discussions, we underlined the lack of conceptual clarity again, and called researchers to use a clear definition in their studies and to label the constructs appropriate.

Despite this variety, we recognized five recurrent and crucial dimensions involved in the discussion of our group: students, problem solving, self-concept, emotions and context.

In the following, we briefly discuss some aspects related to these five dimensions.

## **Students**

Enriched by the contribution of researchers from the TWG7, we have long debated about the so defined “achievement problem”, discussing around the following clearly related questions:

- Looking at school transitions: what are the effects of these transitions on school achievement? How and why do the parameters of the school achievement change dramatically from a school level to the next?
- What is the relationship between school achievement and mathematical talent?
- What is the distinction between low and high achievers in mathematics apart from the grade?

We also argued as it would be interesting to develop research around the above themes, looking at students who are studying mathematics in different contexts (for example modelling, IT environment, etc.).

## **Problem solving**

There is a known and long tradition of research about affective construct and problem solving. This kind of research it is particularly important for our field, since it shows two crucial aspects: the strict relationship between affect and cognition (problem solving activities surely involve cognitive aspects but also strong emotional reactions); the relevance and peculiarity of the research on affect in the specific context of mathematics: indeed problem solving is one of the main activity for mathematicians.

As usual, one of the main issues is how teachers can create the context in order to develop the appropriate mathematical activities and environment for positive affect, increasing motivation and also performance. In several discussions within our group, it emerges as problem solving is not only an essential activity for developing the mathematical competence, but it has also the potential to draw attention and to motivate students, because – in some sense – problem solving is one of the beautiful side of math (the eminent mathematician Ennio De Giorgi used to say: a nice problem, even if you do not solve it, accompanies you).

Many papers presented in our group stressed the relevance of two aspects in order to take advantage of the *affective potential* of problem solving.

The first one is related to the setting: here setting is understood in a broad meaning, on the one hand we mentioned the classroom climate – a positive climate is needed to develop significant problem solving activities, in particular it appears crucial to not identify problem solving activities and

assessment – and the context (for example the spatial organization of the classroom). On the other hand, we mentioned the organization of the problem solving activities with the promotion of collaboration and discussion among students.

The second one is related to the choice of the mathematical problem. It is confirmed as only cognitive demanding (and not routine) problems can foster students' engagement, but, above all, can challenge students shifting their attention from products to processes. In particular, it is also crucial the monitoring of the possible imbalance between skill and challenge that student can experience during problem solving. In this setting, problem solving can be a tool to involve high-achievers, but also low-achievers, in mathematical activities and increase positive affects towards mathematics.

### **Self-concept**

The fact that students/teachers self-concept strongly affects their choices, the effort they devoted and their perseverance in doing some specific activity is one of the fundamental points in our field. Therefore, it is not a surprise that many discussions in our group focus around self-concept and related constructs, such as: self-efficacy, self-perception, self-regulation, identity, personal meaning.

In particular, three aspects related to the self-concept have been analysed and discussed in this edition of the TWG8:

- How students' self-concept influences their interpretation of the *mathematical environment*;
- How the context affects the self-concept, in particular it emerges the idea that context provides available identities;
- The connection between the self and the emotions (in the context of mathematics education). Self has seen as a filter for interpreting experiences.

### **Emotions**

Obviously the study and the discussion around emotions is a must in the group of affect.

In particular, we discussed some crucial dichotomy related to the concept of emotion:

- Emotions sometimes are a cause for some didactical outcomes, but sometimes are a symptom. In the first case, we see positive emotions as an educational goal, in the latter emotions are an indicator;
- Emotions have a double nature: more rapidly changing state-aspect and more stable trait-aspect. The study of state, as opposed to trait, is necessary to give a more detailed description of emotional experiences in the mathematical teaching-learning process;
- Emotions can be the cause for opposite pathways during problem solving, or more in general mathematical activities (go on vs. give up).

As usual, we also discussed how deal with two classical critical issues in the research about emotions: one related to the observation and the other related to the communication.

Emotions, in truth as many other constructs, are not directly observable, therefore we never observe emotions, but we infer them from some indicators. Sometimes we collect information about emotions through self-reports, and – already at this stage – communication issues intervene; studies

developed in different countries stress the level of *emotional illiteracy* of a large part of the population: it is difficult to reflect about emotions, and it is more difficult to have the dictionary to communicate them.

The *communication problem* involves the field of the research not only for the difficulties related to the emotional illiteracy, but also for the *internal* communication (the communication between researchers): as a matter of facts, the labels for emotions have different shades in every language, and sometimes they are associated to a different meaning.

### **Context**

Affective issues are mainly social for their nature: as we have seen, context plays a crucial role in the development of affective reactions. For this reason, context is always been one of the *leading actors* in discussion within TWG8.

A still open problem is the exact definition of context: what is the context? We are convinced that the context is dynamic in nature (it depends on the group/individuals), and this dynamicity makes more complex to circumscribe it.

In the group discussion was observed that in the context of emotion, the term ‘culture’ needs to be ‘unpacked’ and broached not from the assumption that cultures are uniform, but rather from more dynamic conceits such as put forward by identity theories.

Some studies in this edition focus on the difficulties related to the transition from a context to another one (for example in the school transition), analyzing how and how much these *context-transitions* change affect.

# Positioning and emotions in learning algebra: The case of middle-achieving students

Wajeeh Daher<sup>1,2</sup>Osama Swidan<sup>1,3</sup>Amani Masarwa<sup>1</sup><sup>1</sup>Al-Qasemi Academic College of Education, Baqa, Israel [wajeehdaher@gmail.com](mailto:wajeehdaher@gmail.com)<sup>2</sup>An-Najah National University, Nablus, Palestine<sup>3</sup>Kay Academic College of Education, Beer Sheva, Israel

*Mathematics education researchers utilize different theoretical frameworks to study the role of affect in learning mathematics. This paper utilizes a discursive framework (Evans, Morgan, & Tsatsaroni, 2006) to study middle-achieving students' emotions in learning, utilizing technology, the topic of 'the quadratic function as a product of two linear functions'. The students' learning was videoed and then transcribed to be analyzed according to the discursive framework. The research results indicate that members in the middle-achieving groups claimed the collaborator positioning in order to learn the mathematical topic using mainly behavioral, social and cognitive processes. Leaders claimed their positioning through carrying out processes related to the different aspects of learning, mainly the cognitive, metacognitive, meta-emotional, social and linguistic aspects. Dominant emotions in the groups' learning were frustration, enjoyment and content.*

*Keywords: Discursive framework, positioning, emotions, middle-achieving students.*

## Introduction

The affective aspect is a growing area in educational research due to its relationships with other aspects of students' learning, especially the cognitive one. In the present paper, we study middle-achieving students' emotions in relation to their positionings when they learned the quadratic function as a product of two linear functions using dynamic software. In a previous research, we examined students' positioning and emotions in one group learning geometry (Daher, Swidan & Shahbari, 2015), where the group consisted of two high-achieving students and one middle-achieving student. Following that study, we wondered how emotions and positioning are experienced by groups consisting of only middle achieving students. This paper intends to examine this issue, using the discursive framework (Evans, Morgan, & Tsatsaroni, 2006).

## Emotions in mathematics education

Polya (1957) addressed the necessity to consider emotions as they influence the problem solving process. Later, especially in the 1980's, researchers considered affect as a significant component of students' mathematical problem solving (e.g., McLeod, 1988; Schöenfeld, 1985). Emotion is one of the fundamental elements of the affective aspect (Hannula, 2004). Hannula (2004) describes emotions as connected to personal goals. Furthermore, emotions, when managed appropriately, become a potential tool for effective thinking rather than a disturbance to this thinking (Antognazza, Di Martino, Pellandini, & Sbaragli, 2015; Salovey & Mayer, 1990). In the present research, we intend to study, by using the discursive emotions and positioning framework, middle-achieving students' emotions when they utilize technology to study Algebra.

## **The discursive positioning framework for studying students' emotions**

Positioning is defined as “the discursive process whereby people are located in conversations as observably and subjectively coherent participants in jointly produced storylines” (Davies & Harré, 1999, p. 37). Evans, et al. (2006) suggest this discursive positioning framework for studying students' emotions. This framework assumes that meaning making occurs in social practices, using semiotic resources. Social practices have an emotional dimension that helps maintain social identity. Moreover, empirical data in this framework is seen as text, the analysis of which demands attention to its context(s). This analysis entails a combination of structural and textual phases that each informs the other. The structural analysis considers the positions available to or claimed by the participants. Positions are associated with power in relation to others, as well as with differing values within the discourse, which creates spaces within which emotion may arise. Usually, there is more than one available position for a participant, either within a single discourse or several competing discourses. Evans, et al. (2006) describe the positionings taken care of in the structural analysis: Helper and seeker of help, collaborator and solitary worker, director of activity and follower of directions, evaluator and evaluated, insider and outsider.

The textual analysis considers the exchange of meanings. This phase has two functions (Evans, 2006): (a) showing how positionings in social interactions are actually taken up by the participants, and (b) providing indicators of emotional experience. The textual analysis has two stages. In the first stage, the focus is to identify the interpersonal aspects of the text that establish the positions of the participants. Indicators at this stage include reference to self and others, reference to valued statuses (e.g. claiming understanding or correctness), modality (indicating degrees of un/certainty), hidden agency (e.g., passive voice) or repetition. For example, leadership is indicated by demonstrating knowledge or meta-emotional behavior (e.g., trying to change the negative emotions of the group members). The collaborator position is indicated by the activity of a group member, as answering questions or doing actions in response to events occurring during the group learning.

The second stage of the textual analysis attends to (a) indicators of emotional experience that include: direct verbal expression (e.g., ‘I feel anxious’), use of particular metaphors (e.g. claiming to be ‘coasting’), emphasis by words, gesture, intonation, or repetition, body language (e.g., facial expression); (b) indicators suggested by psychoanalytic theory, as indicators of defenses against strong emotions like anxiety, or conflicts between positionings (as ‘Freudian slips’), surprising error in problem solving, behaving strangely (as laughing nervously), denial (e.g., of anxiety).

## **Research rationale and goals**

In spite of mathematics education researchers' acknowledgement of the role of affective aspects in mathematical education in general and mathematical problem solving in particular, research related to this aspect is still not widespread (Antognazza et al., 2015). We intend to study emotions in problem solving using the discursive framework developed by Evans, et al. (2006). In more detail, we intend to analyze the positionings taken by ninth grade students and their related emotions when learning in groups, with the help of GeoGebra, the quadratic function as a product of two linear functions. Doing so, we introduce to the discursive framework the different aspects of learning; as the meta-cognitive and meta-emotional aspects. This will shed more light on the factors that influence middle-achieving students' experiencing of positioning and emotions.

## Research question

- How are positionings taken up by middle-achieving ninth grade students, working in a group to learn the quadratic function as a product of two linear functions, in the presence of technology?
- How are middle-achieving ninth grade students' emotions associated with the positionings that they claim, when learning with technology the quadratic function as a product of two linear functions?

## Methodology

### Research setting and participants

In a previous research (Daher et al., 2015); we analyzed the affective aspect of one group's learning of mathematics, where the members were both high and middle achieving students. We wondered how the affective aspect would be affected in just middle achieving or high achieving groups of students. In the present research, we analyze this aspect in three groups of grade 9 middle-achieving students (ages between 14 and 15 years). One group consisted of three female students (Sana, Amal, Asil), and two consisted of two female students and one male student each (Fairouz, Noura, Salim) and (Alaa, Siham, Amin). All the participating students had not worked with GeoGebra before, and they were introduced to it in two hours' session before learning the quadratic function topic. Furthermore, the students had learned some issues in the topic of the quadratic function (the function's maximum or minimum, the vertex of the function and the domain of increasing/decreasing), but not the quadratic function as a product of two linear functions. The third author taught the three groups in a middle school in Israel.

### Data collecting and analyzing tools

We collected our data using observations of the learning of the three groups. We also conducted interviews with their members. Every group's learning was videoed and at the end of each lesson, the three students in each group were interviewed individually regarding their positionings and emotions during learning. We analyzed the two types of collected data using the discursive analysis framework presented above. Moreover, we combined the analyses of the data collected by the two tools (observations and interviews). The findings section in this paper sheds light on this method.

### Learning material

The three groups of ninth grade students worked with a sequence of activities; all related to the quadratic function as a product of two linear functions. Following is an example of these activities.

In the same coordinate system, we want to draw the three functions:  $y=x$ ,  $y=x+2$  and  $y=x(x+2)$ .

- What are the algebraic characteristics of the linear function:  $y=x$ ?
- What are the graphical characteristics of the linear function:  $y=x$ ?
- What are the algebraic characteristics of the linear function:  $y=x+2$ ?
- What are the graphical characteristics of the linear function:  $y=x+2$ ?
- What are the algebraic characteristics of the linear function:  $y=x(x+2)$ ?
- What are the graphical characteristics of the linear function:  $y=x(x+2)$ ?
- What are the similarities and the differences between the characteristics of the two above linear functions and the characteristics of the quadratic function?

Note: Algebraic characteristics are related to the parameters of an equation, while the graphical characteristics are related to the intersection points with the axes, increasing or decreasing of a function, etc.

## Findings

The present research aimed at characterizing middle-achievement students' positioning and emotions when learning algebra with technology. Doing so, we found that mainly the students had the leader and collaborator positionings during a lesson. We will describe how the students in the middle-achieving groups claimed each of the positionings and experienced their emotions and/or reported them in each positioning. Doing so, we will address the following aspects of learning that the positioning is related to: behavioral, cognitive, meta-cognitive, social and linguistic. The emotional aspect of learning will be considered in light of the taken positioning.

### Collaborator's functioning

The middle-achieving groups utilized collaboration to learn the new mathematical ideas. This is exhibited in that generally the members of each of the participating groups claimed the collaborator positioning to pursue, with the help of the mathematical software, their learning of the quadratic function. This claiming resulted in making the group's members learn enthusiastically to understand the appropriate mathematical relations. This resulted in the group's members enjoying the activity and being content when arriving at its solution. Thus the collaborator's positioning helped make the students' emotions concerning their learning experiences positive ones.

To claim the collaborator positioning, the group members were involved with behavioral processes (working with GeoGebra), social processes (group discussions), as well as cognitive processes (mathematical reasoning). These three types of processes, not only helped the group members claim the collaborator positioning, but at the same time, supported their attempts, as described above, to perceive the new mathematical ideas. In the interview, the students associated their behavioral processes with positive and negative emotions: enjoyment of their work when the software helped them solve the mathematical problem, and frustration when finding difficulty to operate the software. Excerpt 1 shows this claiming the collaborator's positioning.

- |    |      |   |
|----|------|---|
| A1 | Sana | We need to find the intersection with x for the three functions.                  |
| A2 | Amal | What's the first function?  |
| A3 | Asil | $3x-2$  |
| A4 | Sana | [drew the first function in GeoGebra]   |
| A5 | Amal | What's the second function?   |
| A6 | Asil | $2x+3$  |
| A7 | Sana | [drew the second function in GeoGebra] Let's find the intersection points with x. |

#### Excerpt 1: claiming the collaborator positioning

Excerpt 1 shows the claiming of the collaborator's positioning as connected with the behavioral aspect of the group's learning. This aspect is expressed by the students' action with the Geogebra software (A4, A7). However, this positioning also involves the meta-cognitive aspect. The utterances of Sana (A1, A7) are concerned with regulating the processes of the problem solution.

## Leader's functioning

The leader's positioning in the middle-achieving groups was claimed by directing the learning of the group, as well as to advance this learning towards the solution of the mathematical problems and the sharing of the new mathematical ideas. Moreover, leaders in the middle-achieving groups claimed their positioning through carrying out different types of processes, mainly cognitive, metacognitive, meta-emotional, social and linguistic processes. Below, we elaborate on these processes.

The group leader's cognitive functioning was actualized through demonstrating knowledge during carrying out the mathematical activity. For example, Fairouz, a leader in one middle achieving group, argued that they only needed to know the intersection points of the two linear functions with the x axis in order to draw the resulting quadratic function.

The group leader's metacognitive functioning was actualized through asking questions during the group learning as means to decide upon the method of solving a problem. Moreover, the group leader's meta-emotional functioning was actualized through trying to change the negative mood of the group when encountering a difficulty. For example, Alaa, a leader in a middle-achieving group, tried to lessen the anxiety of group members by saying: "Don't worry. It's O.K. Sure we made a mistake. Let's read again our solution to find it".

The group leader's social functioning was actualized through answering other members' questions, asking questions and requesting actions from the group members to keep the group learning going. Regarding the linguistic aspect of the leader's functioning, the leaders in the middle-achieving groups used the first person plural pronoun to talk about the mathematical actions that they needed to perform, which showed them as collaborators with the other members of the group. This indeed happened in the middle-achieving groups but not numerously (See for example excerpt 2).

The leader's functioning resulted in different emotions, but generally speaking this functioning resulted in frustration, when unable to find a way for solving a mathematical problem, enjoyment during the successful solution process, and content when finally solving the activity.

## Difficulties in claiming the positions of leaders and collaborators

The members of the middle-achieving groups, due to the lack of appropriate previous knowledge in the subject matter and sometimes in GeoGebra manipulation, encountered difficulties in claiming the positions of leaders and collaborators during the process of the mathematical problem solving. This led to their experiencing some negative emotions. Moreover, the members of the middle-achieving groups experienced calmness, anxiety and confusion in accordance with their leader.

Working with GeoGebra, the members of the middle-achieving groups encountered at the beginning difficulties related to working with a new technological tool, which could be related to the behavioral aspect of the group's learning. Excerpt 2 describes such a difficulty, where Salim, Noura and Fairouz wanted to draw the function  $(2x-9)(3x-4)$  in GeoGebra [B1], but found difficulty doing that due to not writing correctly the appropriate number of brackets [B2-B6].

- |    |         |   |
|----|---------|---|
| B1 | Fairouz | We should write $3x-4$ multiplied by $2x-9$ .<br>[Noura started to write the expressions] |
| B2 | Salim   | Perhaps the brackets can be put afterwards, wait Noura, wait, it keeps moving.            |
| B3 | Fairouz | Write it from the beginning.  |

- B4 Salim No, no [He takes the mouse from Noura who seemed annoyed by the act of Salim. Salim works on GeoGebra] O.K. Now write it again.
- B5 Noura [Noura puts her hand on her mouth with boredom]
- B6 Fairouz [Fairouz worked on GeoGebra, then she said with annoyance] something wrong with the brackets.
- B7 Teacher Don't get anxious. At the beginning, brackets are tricky. Everything will get O.K.

**Excerpt 2: Students' difficulties in working with GeoGebra and related emotions**

Excerpt 2 shows some of the difficulties encountered by the middle-achieving groups, as a result of their behavioral functioning; specifically when working with a technological tool. Fairouz, in the interview, said they felt out-of-control and thus frustrated not being able to draw from the beginning the graph of the function  $f(x) = (2x-9)(3x-4)$  in GeoGebra. Salim pointed at the teacher's interference as supporting them in getting back control over their work with GeoGebra, which made them satisfied with their work on the mathematical problem.

Encountering difficulties in learning the new topic, not only influenced students' positioning and emotions, but also colored the linguistic aspect of their learning, especially their use of pronouns. This is the case in excerpt 3, where the difficulty is related to simplifying an algebraic expression.

- C1 Siham We want to draw the quadratic function  $y = (2x-9)(-x-4)$ .
- C2 Amin Multiply first the brackets.
- C3 Alaa  $(-x-4)(2x-9) = -2x^2 + 9x - 8x + 36$ , Now we compute  $+9-8$ .
- C4 Amin -17
- C5 Siham Minus 8 plus 9.
- C6 Amin Minus 17, plus .. [He seemed anxious, not sure of his computation]
- C7 Alaa What?
- C8 Amin Minus one or plus one
- C9 Alaa What?
- C10 Siham Plus 1.
- C11 Alaa Write  $-2x^2 + x - 36$ .

**Excerpt 3: Having difficulty in simplifying an algebraic expression**

Excerpt 3 shows that confronting difficulty constrained the group's sense of control and produced anxiety. In this situation, singular pronouns or no pronouns were used.

## Discussion and conclusions

Research of students' emotions in mathematics learning is growing (e.g., Antognazza et al., 2015; Daher, 2011; Hannula, 2004). The present research aimed at characterizing grade 9 students' positioning and emotions when learning algebra with technology. The research findings indicate that to claim the collaborator positioning, members of the middle-achieving group were involved with behavioral processes (working with GeoGebra), social processes (class discussions), as well as cognitive processes (reasoning). These processes helped them reach their learning goal, thus resulting in positive emotions. It could be said that collaboration was associated mainly with positive emotions as enjoyment and content, though negative emotions as anxiety were experienced when having difficulty in solving the mathematical problem; i.e. in arriving at the learning goal.

To claim the leader positioning in a middle-achieving group, the member was involved with different learning processes, as demonstrating knowledge, which was also reported in Evans, et al. (2006), but their functioning was distinguished from the other group members by performing metacognitive and meta-emotional processes, as reported in Daher et al. (2015). These processes helped plan, monitor, evaluate and take decisions regarding the group learning, especially in time of difficulty in arriving at the learning goals. Thus, these processes helped maintain the leader positioning (Black, Soto & Spurlin, 2016), as they supported the leader in advancing the group learning.

In addition, the leader metacognitive functioning was actualized by asking questions as means to decide upon the method of solving a problem. This decision making could be looked at as a social process (Vroom & Jago, 1974) with the goal to advance the group learning. Moreover, it seems that critical thinking skills, actualized in decision making, were needed to claim the leader's positioning. Furthermore, the goal of the leader meta-emotional functioning was to change the negative mood of the group when encountering a difficulty, which motivated the members' work (Leithwood, Louis, Anderson & Wahlstrom, 2004). So, we argue that the leader positioning was claimed by paying attention to different aspects of the group learning, especially the metacognitive and meta-emotional aspects. This leader's functioning resulted in different emotions related to the difficulty and success in performing the mathematical task, which could be associated with Goldin's (2000) emotional pathway, where generally frustration preceded enjoyment and enjoyment preceded content. This emotional pathway included the three dominant emotions in the groups' learning, i.e. no singular emotion was dominant but the emotional pathway was thus. Furthermore, the group members' emotional experience was influenced by that of the leader, which could be related to the emotional contagion suggested by Hatfield, Cacioppo and Rapson (1993), where there is tendency to converge emotionally with others. We say this is especially true in group learning when the other is the leader.

Students encountered sometimes difficulties in learning the new topic. This encounter, not only influenced students' positioning and emotions, but also their linguistic use of pronouns. This was expressed in their use of singular pronouns or no pronoun at all when getting anxious for not being able to proceed with the carrying out of the activity.

Future studies are needed to compare the positioning and emotions of different achievement-groups in solving mathematical problems. Furthermore, research is needed to verify the effect of prior positions of the group members on their current positioning, which the present research did not target.

# The role of affect in failure in mathematics at the university level:

## *The tertiary crisis*

Pietro Di Martino<sup>1</sup> and Francesca Gregorio<sup>2</sup>

<sup>1</sup>University of Pisa, Mathematics Department, Pisa, Italy; [pietro.di.martino@unipi.it](mailto:pietro.di.martino@unipi.it)

<sup>2</sup>University of Pisa, Mathematics Department, Pisa, Italy; [gregorio.francesca@gmail.com](mailto:gregorio.francesca@gmail.com)

*The tertiary transition between secondary school and university appears to be an insurmountable struggle for many students. This is also the case, surprisingly, in a certain sense, of students enrolled in Mathematics degree courses, and therefore students considered “gifted” with respect to mathematics. This case seems particularly interesting from an affective point of view: these students often live failure in mathematics as a tragedy, and – above all – initially they are not able to interpret their failure. For these reasons, it appears crucial to investigate which role is played by emotions in the emergence and management of this crisis, and how the students’ view of mathematics and their self-perception develop in the tertiary crisis period.*

## Introduction and theoretical background

As Nardi (2008) underlines, the teaching and learning of undergraduate mathematics is a relatively new field of mathematics education research.

The most part of the research about this topic focuses on cognitive aspects, highlighting the difficulties related to the learning of advanced mathematics (Artigue, 2001). In particular, Tall (1991) discusses the students’ difficulties in conceptualizing some specific mathematical constructs (for example the notion of limit of a function), and in using the formal definitions of these constructs.

Other scholars focus on the specific difficulties related to the tertiary transition, discussing the enormous gap between secondary and tertiary mathematics (De Guzmàn et al., 1998; Wood, 2001) in terms of cognitive, metacognitive, linguistic and also practical demands.

Alcock and Simpson (2002, p. 33) underline how “certain reasoning strategies are inadequate when applied to university mathematics, although they might be efficient and sufficient in non-technical contexts and in the kind of reasoning with specific objects required by school mathematics”. Schoenfeld (1985) analyzes the undergraduate students’ difficulties in managing with non-routine tasks. Ferrari (2004) discusses the linguistic difficulties related to the shift from an informal approach to mathematics to a formal one. De Guzmàn and colleagues (ibidem, p. 756-757) underline how “many students arriving at University do not know how to take notes during a lecture, how to read a textbook, how to plan for the study of a topic, which questions to ask themselves”.

All the scholars describe the mathematical tertiary transition as a very challenging moment for students: Tall (1991, p. 25), points out that it “involves a struggle (...) and a direct confrontation with inevitable conflicts, which require resolution and reconstruction”.

Nevertheless, affect appears to be the ‘great absent’ in this overview about the factors playing a role in this transition: for example, in the previous editions of CERME, there are no reports of the TWG about affect related to the undergraduate level (with the exception of the study related to the undergraduate course needed to become a primary teacher).

In particular, Clark and Lovric (2008), drawing on anthropological theories, describe the tertiary transition in mathematics as a three-stages rite of passage that includes: separation (from secondary school), liminal (from secondary school to University) and incorporation (into University). This rite of passage is characterized by a real crisis in which the consolidated routines are suddenly interrupted, changed and distorted.

As Bardelle and Di Martino (2012) underline, this crisis appears to be particularly challenging for mathematical high-achievers in the secondary school level: it can be difficult for these freshmen to understand why the reasoning strategies that worked in their previous mathematical experiences suddenly stop working at university level.

Therefore, it becomes interesting to investigate which role emotions play in the arise and management of this crisis, and how the high-achiever students’ view of mathematics and their self-perception develop during this crisis period.

In other words, considering the TMA-model for attitude developed by Di Martino and Zan (2010), it is interesting to study the development of students’ attitude towards mathematics during the *tertiary crisis*.

With this aim, in the AY 2014/15 we developed a narrative study involving different categories of current and ex-students of the Bachelor in Mathematics in Pisa:

- 1) *freshman*: to collect the voice of the subjects during the crisis period;
- 2) *expert students*, i.e. students enrolled in the third year of the Bachelor: to understand what they remember about their transition difficulties, their idea about the causes of such difficulties and about how they overcame them;
- 3) *dropout students*, i.e. students that have left the Bachelor in Mathematics without obtain the degree in Math: to collect their memories about the crisis period, in order to reconstruct their emotions, the motives of their resignation, their theories of success (Nicholls et al., 1990) and causal attributions (Weiner, 1986).

## Context and methodology

**Context.** The Bachelor in Mathematics in Pisa is one of the most prestigious in Italy, the majority of its students is considered excellent in math during secondary school. This fact is confirmed by data collected for our research. We analysed data from AY 2009/10 to 2012/13: Table 1 shows the percentage of the high-rated students in final exam of secondary school (we define high-rated a mark between 90/100 and 100/100). It compares the situation in Pisa with the average from all Italian Bachelors in Mathematics.

	2009/10	2010/11	2011/12	2012/13
Italy	45%	42.4%	44.5%	40.1%
Pisa	73.6%	58.6%	65.7%	60%

**Table 1: Percentage of high-rated students in the Bachelor in Mathematics, in Pisa and nationwide.**

The percentage of high-rated students in Pisa is much higher than the global one. However, the dropout rates of the Bachelor in Pisa are within the national average range.

The high concentration of above the average students and the presence of difficulties, as witnessed by the failure rates, make the Bachelor in Mathematics in Pisa the ideal contest for our research.

**Procedure.** The study was conducted in two different phases.

In the first phase, we developed and administered three online questionnaires (one for each category of the involved students) including open and close questions about the mathematical experience at the University and, in particular, the difficulties encountered. Students were requested to answers in an anonymous way: respondents were invited to share an e-mail address in order to participate in the second, non-anonymous, phase of the research. The participation to this study was voluntary. At the end of this first phase we had collected: 26 answers by freshmen; 75 by students enrolled in the third year of the Bachelor; 52 by students that had left the Bachelor.

In the second phase, 40 students (3 freshmen, 27 *expert students*, 10 *dropout students*) were interviewed by the second author of this report. The time for the interviews varied in a range from 5 to 90 minutes. The interviews were audio-recorded and then fully transcribed.

We will quote the students' answers using an alphanumeric code: F, E or D (which mean freshman, expert student or dropout student, respectively); a serial number (it indicates the order in which the student completed the questionnaire); Q and I (which mean questionnaire and interview, respectively).

**Rationale.** We developed a narrative approach because we wanted students to feel free to express what they consider important, using the words that they consider more appropriate. In particular, we considered the open-ended questionnaire and the interview to be two complementary narrative instruments: according to Cohen et al. (2007), an open-ended question can catch the authenticity, richness, depth of response, honesty and candor which are the hallmarks of qualitative data. On the other hand, questionnaires have their limitations: they are one-way compared with interviews.

## Discussion

In the students' stories the difficulties are often linked to strong and negative emotions, persisting over time. Both questionnaire and interview had specific questions about emotions; for example, a question in the questionnaire was: "*Write a feeling that is linked to your experience at the Bachelor in Mathematics*". E69Q, despite he was able to overcome the initial difficulties, reports: "*unfortunately, now [after having dropped out of the Bachelor in Mathematics] I like math a lot less, or rather, it still fascinates me but it is now linked to very negative emotions that ruin it all*".

The percentage of students who indicate negative emotions changes drastically depending on the category of interviewed students. Only 32% of the freshmen report having bad feelings relating to their experience at the Bachelor in Mathematics and to their difficulties and failures. This fact may be connected with some characteristics of the sample: the questionnaire was published at the end of the academic year, when the students with serious difficulties have already left the Bachelor. The percentage of students that report having bad feelings increases among the *expert students*: as many as 52% write about bad feelings and emotions. Predictably, the percentage increases among the *dropout students*: 75% of these students link difficulties and the experience at the Bachelor in Mathematics with very negative feelings.

Different types of bad feelings are reported, we have identified some categories: anxiety/ distress/ anguish; frustration/ despondency/ hopelessness; fear/ apprehension; sadness/ sorrow/ depression; inadequacy/ insecurity.

The majority of bad feelings are related to the anxiety caused by the Bachelor in Mathematics: “*for the first two years I was in a permanent state of anxiety and distress*” (E6Q), “[my experience in Pisa has been] *angsty*” (E8I). This topic is reported by all three categories of students.

The frustration and despondency category appears despondency among the *expert students*, but also among the dropout students. Many students report they are not been able to reach their goals via techniques and mechanisms that had been successful in the recent past. The persistence of such a situation forces many students in a state of frustration and it brings them to reevaluate their skills: “*I realized that I would go to class and not understand a word of what was being explained. Therefore, I felt some frustration and I thought that I was not intelligent enough, that I was inadequate*” (D49Q).

The category of sadness and sorrow characterizes particularly the students who left the Bachelor in Mathematics. The decision of leaving the Bachelor in Mathematics seems to be linked to a strong sadness: “*I remember [of that period] just a lot of tears*” (D39Q).

Also the category of inadequacy and insecurity is strongly linked to the experience of difficulties, and in particular to their lasting and to the failure in overcoming them. These feelings are new for the students, they never felt them before because they have always been good at math. The consequences, in these cases, can affect the students’ self-esteem and his or her learning abilities: “*I think that my experience at the Bachelor in mathematics left me with less confidence in my ability to study*” (D10Q), “*as far as I’m concerned, low self-esteem kills any productive drive*” (E8Q).

The emotions reported by the interviewed are often felt as negative because they are unexpected: the student shifts suddenly and in unexpected ways from a *mathematical welfare* to a *mathematical malaise*, and he doesn’t understand the causes of the shifts. The persistence of the difficulties causes the growth of bad feelings and the sense of helplessness (“*there were a lot of difficulties and disappointment... I felt like there was no way out*”, E29Q), contributing to foster a downward spiral.

In our study a special attention has been given to the students’ attributions for their difficulties. The students both spontaneously or answering specific questions, have made causal attributions. The narrative data collected have permitted us to identify the more frequent causal attributions, and to organize them in categories:

- *Transition aspects*: differences between secondary school and University (contents, organization, teaching styles, assessment, ...);
- *Low preparation*: insufficient secondary school prerequisites;
- *Low ability*: lower math ability than they thought, inadequate mindset (these factors are often attributed to a faulty way to assess in secondary school);
- *Comparison aspects*: many of these students were considered (and perhaps they really were) the best math-students in their school, and for the first time in their life they are “one of many”. This impacts with their self-perception in math.

The students blame an important part of their failures to the great differences (related to math) between secondary school and University. These differences and the subsequent difficulties often cause significant changes in the students' view of math, and in particular of what it means to be good in math. In particular, most of the students point out that they got good grades in secondary school without significant efforts: “[in secondary school I considered myself good at math] *because I could avoid studying it and still get the highest grades*” (F14Q) and “*I realized that the high learning speed was due to the easiness of the topics we studied in high school, rather than to an above the average skill*” (D51Q). The secondary school's math is regarded as a simplified and procedural math, surely not as the *math* studied at the University: they seem two completely different subjects! (“*Math you do in high school is not the one you do in your first year in University*”, E52Q). Students recognize that in University more formalism, abstraction and proofs are required: math switches from numbers and figures (a practical mathematics) to structures, like vector spaces or groups (a theoretical mathematics), and it involves a radical and hard cognitive shift. Despite the connected difficulties, the discovery of this new math usually is welcomed (“*I think I like the subject even more than I did in high school. I've found topics that I find fascinating*”, E65Q), but sometimes it isn't (“*I've changed Bachelor since I couldn't find the practical math I was expecting*”, D6Q).

Anyway, the crucial point seems to be that this *discontinuity* in the subject is typically unexpected by the students: they choose Mathematics with a clear idea of what it is and of how much they are good in math, and suddenly they have to compare with a new reality.

Among the transition aspects, teachers and style of teaching have a predominant role. There is a shared perception amongst students that at the university level there is not a particular attention to the students' difficulties: it is interesting to underline that this perception is often shared also at secondary school level by students with difficulties in math (Di Martino & Zan, 2010).

Students also underline the fact they are left alone from the beginning: “*in University they gave for granted many notions, or they didn't focus enough on topics they deemed to be easy, creating enormous doubts and flaws*” (D41Q). So students feel abandoned and powerless against apparently insurmountable difficulties, unable to find successful strategies.

From our data, it emerges that students blame responsibility to secondary and university teachers for their transition difficulties. In their view, secondary school teachers did not teach them what math really is and how it needs to be studied, and university teachers do not pay attention to the natural difficulties in the transition.

In this framework, math is seen (often for the first time for these students) as intrinsically complicated, and the transition aspects seem to add up further difficulties. Many students thought, and continue to think, a particular mindset is required to succeed in math, and this “math mindset” is innate (*“from birth you are not cut out for it, as you would need to be”*, E45I).

The great amount of difficulties in the transition and this belief represent an explosive mix: according to the students’ narrations, it is one of the main causes of resignation (to be good in math you need to have an innate talent; now, with the real math, I’m not good in math; so I don’t have the innate talent and I can’t do anything to improve, because I’m not talented).

The above explosive mix is also strongly affected by the comparison with peers. Most of the interviewed were the best of their class, or even of their school, during secondary school. At University, the context is completely different: you are one of many, and – above all – there is a natural reluctance in sharing personal difficulties (this reluctance appears to be linked to the emotional reactions to the difficulties we have commented before). The consequence is the spread of a feeling of loneliness, a lot of students stated that they thought to be the only ones in that context with difficulties: they believed that most of their peers understood all without difficulties. This (wrong) perception affects and quickens the change in the math related self-perception of the students, creating doubts about their own brightness. This has strong effects on the emotional side: *“I have really downsized the opinion of myself I had by seeing that there were way more capable people than myself”* (D33Q), *“I had begun to think that maybe I wasn’t so good as I had thought and that it had all been an illusion. Moreover, I saw geniuses that new everything and understood everything right away and so I felt like an idiot”* (D44Q).

Despite a lot of common themes, there are also some significant differences between the causal attributions for difficulties of the expert students and those of the dropout students.

In particular, most of the dropout students claimed that, despite a hard and extensive study, or even despite the supposed sufficient comprehension of math, they failed the exams. In their opinion, the reasons for the lack of success is therefore linked to their natural inability or even stupidity: they seem to think that a kind of innate ability is needed to succeed in mathematics. Other respondents said that one of the reasons for failure was that some professors seemed to teach only for the excellent students, without taking care of the bulk of the average students. So, the exceptional students’ presence is seen as a problem, as much as the exams’ scale of evaluation.

In the final analysis, the dropout students used especially external and uncontrollable causal attributions.

Also the freshmen and the expert students used external causal attributions but, they reported that after of an initial period in which the difficulties were perceived as uncontrollable, they found a way to turn them in to something controllable. In particular, they refer to a shift in their theories of success or to a change in the strategy they adopted to deal with their pre-existing theories of success.

The students report of some strategies or changes that have led them to the overcoming of their difficulties; the most frequent reasons are relative to the quantity and quality of their study and relative to their study habits. A lot of the interviewed spoke about the cooperation with peers as of being of great help: *“obviously a relevant part of my success is due to the people that have supported me”* (E44Q) and *“Personally it was group study that allowed me to go on”* (E7Q). Peers,

especially better students, also helped to find the right study habits and to create the necessary mindset to succeed in math: *“the older students helped me by convincing me that it was all about getting settled with new ways of reasoning”* (E44Q).

So, as a student said, *“challenging one’s study habits”* (S63I) is important; the first step is to understand that the study habits are amendable and this happens especially after failures and through the comparison with peers or teachers. From this quote, as from many others, it appears that the personal awareness of what is going wrong and what can be improved is a necessary step towards overcoming one’s difficulties. *“Seeing the teachers in action has been fundamental for me, in the sense that it helped me adopt the right mindset. By just studying on the books, I would have never obtained the same results”* (E52Q). Teachers are also fundamental for their emotional support: *“some teachers were fundamental in the process of overcoming my difficulties! In my opinion it is important that the professor lets you know that he believes in you, that he is aware you spent months preparing for the exam, that he is sorry if he fails you and that you are not just a number!”* (E28Q). Moreover, lots of students have found the meetings with peers or teachers very useful, overcoming the fear of the professor’s judgment, which is instead very common in secondary school. Finally, great study and effort are necessary: *“I overcame my difficulties by endeavor and maximum commitment”* (E44Q).

## Conclusions

From our study there thus emerges a path that seems to characterize the experience in the Bachelor in Mathematics. A student which was a high-achiever in high school enrolls in the Bachelor in Mathematics; almost always, in an unexpected and abrupt manner, he faces difficulties; these difficulties are linked to strong negative emotions (such as anxiety, frustration, sadness...) and are combined with a reevaluation of the previous scholastic experience and of one’s skill in math; math is seen under a new light: it is, in some sense, new and it is taught differently; the student produces theories of success and causal attributions: these can be internal or external, but the difficulties are initially almost always perceived as uncontrollable.

Up to this point in the student’s path, most of the stories we have heard agree, regardless of the interviewed student’s category. But from now on there is a definite distinction between the experience of who has abandoned the Bachelor in Mathematics and who has succeeded in continuing his or her studies. The comparison of the experiences of the subjects from different categories has in fact provided us with precious information: those who, for possibly emotional reasons, persevere in producing uncontrollable causal attributions or in implementing the same strategies to reach success, will eventually drop out of the Bachelor in Mathematics; on the other hand, changing one’s theories of success or one’s causal attributions or just identifying them as controllable allows one to overcome difficulties and failure. Our study seems to suggest that what makes the difference between dropping out and overcoming the difficulties are one’s success theories and causal attributions, and in particular the ability to modify them and identify controllable factors.

It thus seems that the processes that lead to changes in the students’ success theories and causal attributions, which bring to light the controllable aspects of one’s difficulties, is worthy of a deep investigation.

# Primary future teachers' expectations towards development courses on mathematics teaching

Silvia Funghi

University of Modena and Reggio Emilia, Faculty of Education, Italy; [silvia.funghi@unimore.it](mailto:silvia.funghi@unimore.it)

*The issue of what teachers need to teach mathematics effectively has been widely dealt with in the past decades; nevertheless, there are still few studies focusing on what future teachers think they need in order to be effective. In order to get a deeper understanding of future teachers' viewpoints about what they need to learn, a narrative study concerning primary future teachers' expectations on a course on Mathematics Teaching was developed. Issues about a lack of connections between theoretical notions provided by university courses and teaching practice were raised, as well as problems about affective dimension in mathematics learning and about mathematics itself.*

*Keywords: Future teachers, expectations, mathematics teaching, professional development.*

## Introduction and theoretical framework

*What do teachers really need to teach mathematics effectively?* In Mathematics Education this question has been mainly addressed by studying the relationship between teachers' knowledge, behavior and attitude, and students' achievements (Ball et al., 2008). Other studies highlight several aspects perceived by different figures (students, administrators, teachers) as necessary for the teacher to be effective, e.g. competence in the subject, teaching style, enthusiasm for teaching, care for students' difficulties and interest in students' lives outside of the classroom (Stronge, 2007).

It emerges that people have different 'ideals' of good mathematics teachers, and this is true in particular in the case of future teachers. This case is interesting because this 'ideal' strongly affects how a future teacher approaches learning opportunities (Liljedahl et al., 2015). From this viewpoint, teachers' development can be seen as an ongoing process nurtured by teachers' desire to "fill the gap" between their current developmental stage as teachers and the "ideal" mathematics teacher they want to become (Sfard & Prusack, 2005). In particular, future teachers' development depends not only on the training planned by teacher educators, but also on individual needs and aims: "teachers do not come to professional learning opportunities as blank slates. Instead, they come to these settings with a complex collection of wants and needs" (Liljedahl, 2014, p. 1). This is crucial for primary level teaching, in which involved people are not specialized in mathematics.

In this framework, it appears relevant to collect future teachers' opinions about what they want to learn in their professional development, and, above all, what expectations they have about the mathematics courses they have to attend. In fact, in the field of mathematics education, *expectations* are quite an unusual focus even for research concerned with affective issues: more often, research regarding the implementation of educational courses or workshops takes into account future teachers' *a posteriori* evaluation of whether their expectations have been fulfilled or not (Bartolini Bussi, 2011).

For these reasons, this paper focuses on a study on narrative data collected from future teachers *at the beginning* of a course dealing with mathematics teaching, in order to bring out future teachers'

expectations and hopes about their education in mathematics teaching before they participate in a specific educational course.

## Methodology

**Population and procedure.** This study concerns the analysis of the answers to one of the questions of a questionnaire that was administered in February 2016 to a class of future teachers during the first day of the course of the third year in Mathematics Teaching (Bachelor's Degree in Primary Teacher Education, University of Modena and Reggio Emilia, Italy; the duration of the whole degree course is 5 years). The answers were collected from a class made up of 49 future teachers.

The choice to consider a class attending the third year of degree course is not irrelevant, because it was strictly related to one of the purposes of the inquiry, which was to study the story of future teachers' relationship with mathematics, paying attention to their perception of the value of their university education. From this viewpoint, a third year class was interesting because future teachers in this university must attend two courses in Mathematics in the first two years and a course in Mathematics Teaching in the third year: in particular, they cannot take the exam for this last course until they take both Mathematics exams. Furthermore, the course in Mathematics Teaching is also the last compulsory course they must attend regarding mathematics. So, it was interesting to investigate what these future teachers expected about this course *after two compulsory courses on Mathematics*.

In order to pursue this goal, an open questionnaire was specifically developed. It was composed of three questions, where the first two aimed to investigate future teachers' relationship with mathematics and its changes during the years of university and pre-university education; the last question on the other hand – “*What are your expectations about the course on Mathematics Teaching?*” – was aimed to grasp also future teachers' viewpoints about their own wants and needs regarding their education as teachers. This last question is the focus of this paper.

The questionnaire was presented and administered at the beginning of the first lesson of the course; the time available to fill it in was about 30 minutes. Since the questionnaire is part of a bigger project aimed to study the development of future teachers' beliefs throughout the years, future teachers were asked to write their I.D. numbers, but it was explained them that it was impossible for the researcher to match these numbers with their personal details.

**Rationale.** Results obtained by previous narrative studies show that the analysis of narratives is a very powerful tool, especially for the purpose of research on future teachers' beliefs, identity and attitudes (Kaasila, 2007). A narrative approach, in fact, permits respondents to focus on the aspects *they* consider most important, and to explain their own thinking with the words *they* consider the most appropriate. This way, the variety of answers produced provides the researcher an amount of details and information that has an enormous value for the purpose of qualitative studies (Cohen et al., 2007).

Regarding more specifically the method chosen to collect narrative data, in this case it was essential to make future teachers not frightened of being penalized for their real opinions. So, the most suitable inquiry tool was undoubtedly an open questionnaire, because it allows respondents to

remain anonymous – a possibility that other inquiry tools, such as oral interviews, do not permit. This is also the reason why future teachers were assured of the confidentiality of their answers.

The data were analyzed adopting a content-categorical approach – e.g. the analysis was focused on the content of collected answers, not on their form, and the unit of analysis was single utterances isolated from the rest of the discourse, and not the whole narrative (Lieblich et al., 1998). This approach, in fact, has been proven to be very appropriate to study phenomena common to a group of people (Kaasila, *ibidem*).

In the discussion, we will use the acronym FT (Future Teacher), followed by a progressive number from 1 to 49, to quote excerpts of protocols.

## Results and discussion

The first interesting feature of the collected data is that there were no answers such as “I don't know”, and no answers left blank: future teachers had *something to declare* about their expectations on the course on Mathematics Teaching. The overall feeling emerging from the answers is a compelling need for courses focused on teaching practices, rather than lessons about theories of teaching (“[...] *I hope that we will deal with things that are more inherent to our future profession, because some courses of our degree course deal with many notions that are difficult to employ in practice*”, FT16). This feeling is well reflected in the high rate of respondents – 40 on 49, around 82% – asking for teaching methods (“[...] *I hope that methods to employ once in class will be illustrated as much as possible*”, FT44), or more generally asking for a course to learn “how to teach mathematics at primary school” (“*I expect a course to understand what and how to teach when I will be faced with children at primary school*”, FT3).

However, after a closer examination of the answers, it emerges that expressed expectations involved mainly two dimensions, the pedagogical one and the affective one, so that it was possible to distinguish with enough clarity two kinds of expectations: those related to *pedagogy and pedagogical content knowledge* (according to Shulman's definition, 1986) and those about *affective issues*. Since most of the expectations fell in one of this two categories, the few ones that were not directly related to pedagogical or affective issues were grouped into a third category that we called *other expectations concerning mathematics or mathematics teaching*. In order to give to the reader a clearer explanation of the features of each category, they will be analyzed one by one in the following subsections.

### Expectations related to pedagogy and pedagogical content knowledge

As one could expect, this is the most recurrent category, since every answer involves at least one expectation related to pedagogical knowledge or pedagogical content knowledge. In most cases, as it was anticipated earlier, the respondent makes a generic wish to expand his/her knowledge about methods and means for teaching mathematics. In particular, our future teachers mainly seek methods that are *efficient* (“*I hope that [...] alternative methods will be proposed to us [...] [that are] significant and efficient for children's learning*”, FT46) and possibly *fun* (“*I hope to learn practical and fun methods to teach mathematics in primary school*”, FT2). In many cases, respondents seem to wish to learn a sort of *recipe for good teaching*, e.g. which method works best according to the situation (“*I expect to learn several methods for teaching mathematics that are*

*suitable for the various difficulties that a child can encounter in learning mathematics*", FT31). Many answers even talk about learning *"the best method to teach mathematics"* (*"I hope to face more topics, for example the best way to teach mathematics in order to make children appreciate it"*, FT34). Sometimes the list of notions the respondent expects to learn is so extensive that it can even be hard to believe that a single course would be enough to fulfill all these expectations (*"I expect to learn to understand children's learning processes, strategies to adopt to present this subject, which methods should be used, how to organize the lessons and the topics"*, FT4).

In some cases, as previous excerpts show, future teachers' main concern is about the *real* teaching practice: this is also confirmed by the rate of answers (17 answers on 49 – around 35%) stressing the practical and concrete nature of the notions that future teachers would like to learn (*"I hope that in the course we will talk not only exclusively about theory, but, on the contrary, mainly about PRACTICE. Practice and advice about how to facilitate [children's learning] and make our way of teaching more efficient"*, FT41, capital letters in the original). Some of them ask more specifically for some practical examples from real experiences of in-service teachers (*"I hope that [...] [the course] will be focused on efficient methods for teaching this subject, perhaps also those based on real experiences of teachers"*, FT32). These answers perhaps point out a lack of connections to didactics of mathematics in previous mathematics courses.

A slightly different kind of expectation regards the enhancement of respondent's *competencies* as a teacher. In some cases, in fact, future teachers seem to be more concerned with personal improvement, rather than with learning a set of "ready-made" methods (*"I hope to join my enthusiasm for the subject to the competencies that are necessary to teach it step by step"*, FT11). However, what competencies they refer to is not clear from these answers. There's just one case where the competencies that the respondent would like to gain are sufficiently clear to be described as organizational competencies, competencies in explaining, and diagnostic competencies (*"[...] I expect that [the course] will be useful from a practical viewpoint, so that [...] I will know how to organize the lessons, how to explain and how to help those who have more trouble"*, FT4). The last competence in particular seems to be quite an important one for our future teachers, since many of them underline their need to learn more about children's learning processes and difficulties, and about ways to make children overcome such difficulties – as can be seen from some of the previous excerpts. It is noteworthy that none of the respondents talks about issues regarding creation of tests and assessment of tests' results – suggesting that, in our sample, future teachers are more concerned with making children *understand* mathematics, rather than *assessing* their learning.

### **Expectations about affective issues**

This category of expectations includes those ones referring to emotional aspects related to the relationship with mathematics. We can distinguish in particular two kind of expectations, according to the subject of this relationship: in some case this subject is *the future teacher itself*, whereas in other cases the subject is *the class*, e.g. the pupils that the future teacher imagines to have.

The first kind of expectations refers to those answers that express the desire to reconcile with mathematics and the hope that the course on Mathematics Teaching could facilitate such reconciliation: such answers correspond, in fact, to narrations of difficult or fluctuating relationships with mathematics in the other answers of the questionnaire. A clear example is given by FT46, who

affirms: *“I hope to stop being stuck with this subject, and to be able then to learn and employ useful strategies to teach this discipline at best”*, and in the other answers tells about her fluctuating relationship with mathematics, and in particular about her rejection for solving problems when she was a young student. In these cases, mathematics is described as far from future teachers’ interests, and a course focused on mathematics teaching, not on the subject itself, seems to be an opportunity to come closer to mathematics (*“I hope that this course will let me come closer to a discipline that has always been too distant from me, but I hope above all that I will be able to look at it and perceive it in a different way”*, FT37), as highlighted also in the investigation by Coppola et al. (2013) on the “math-redemption” phenomenon. It is possible that, beyond the sense of utility of studying teaching rather than the subject itself, for these future teachers plays a role their hope that studying how to teach topics could be also helpful to clarify *their* doubts from primary school. Only in a couple of cases did future teachers claim to expect to continue improving their relationship with mathematics, even if it is already a very good one (*“My expectations are varied. First of all, I hope to renew my interest in the subject”*, FT16).

The second kind of expectations, on the other hand, regards future teachers’ need to learn how to support the growth of a good relationship with mathematics among their future students. The request to learn how to support pupils’ emotional involvement in doing mathematics is quite widespread: it is detectable in 17 answers out of 49 (around 35%). In particular, there are four main emotional responses to mathematics that future teachers wish to elicit into their future students – listed in order of increasing intensity:

- No hate for mathematics (*“I hope that it will teach me how to teach mathematics in order to make sure that children don't hate it”*, FT17);
- Having fun when doing maths (*“I expect to acquire competencies to teach mathematics [...] in a way that my children learn it as adequately as possible, perhaps also having fun”*, FT8);
- Feeling a real interest in the subject (*“I hope to discover new methods to revive children's interest in mathematics [...]”*, FT35);
- Being passionate about mathematics (*“I hope to learn, or at least to get hints and advice [...] about how to make children passionate about mathematics, and to engage those who have more troubles or feel aversion for this discipline”*, FT5).

As we can see from the above quotations, even if these emotional responses could all be interpreted as ways to make pupils have a good relationship with mathematics, they do not seem to have the same importance in future teachers’ eyes. For example, in the answers that talk about *having fun*, it is not clear if future teachers are interested in an amusing emotional climate in the classroom *per se* or if they are just looking for fun methods for teaching mathematics – i.e. if establishing a good emotional climate for them is an *aim* to reach when teaching, or a *means* to facilitate the understanding of some mathematical content (*“Through this course I hope to learn instruments that are necessary to explain mathematics to children. It is not an easy discipline, and I would like to discover methods to make it fun, easy and efficient at the same time”*, FT22). In fact, the importance of the influence of pupils’ emotions on their learning seems to be underestimated in the answers that talk about avoiding making children hate mathematics: the feeling the reader gets is that the quality

of the climate to create in the class stops at a sort of “peaceful coexistence” between the pupils and the mathematics to be learnt – as we can see in the excerpt by F17 above. If so, a “peaceful” emotional climate could be seen not as an aim or as a means for teaching, but rather as a *constraint* for the learning to occur.

### **Other expectations concerning mathematics or mathematics teaching**

**Regarding mathematical contents of the course.** Since the course is expected to address teaching practice, most of the answers do not mention expectations about its mathematical contents. “Less mathematics and more practice” could be a good motto to summarize some claims (*“I hope that there will be less numbers and less formulae with respect to the previous courses, and that it will be focused on efficient methods of teaching this subject”*, FT32). However, when a respondent refers to some mathematical content, generally he/she expresses the need of a course focused more specifically on mathematical contents to be treated in primary school, rather than on new topics (*“I expect that the focus will be on the topics that we will have to teach to children, rather than on topics that actually we will never deal with at primary school”*, FT39). Just in one answer we can find a demand for the explanation of new mathematics topics, but also in this case new knowledge is hoped to be useful in practice (*“I hope to come into contact with topics, materials and teaching methods we have never dealt with, that will constitute a new part of knowledge that I could employ in my future profession”*, FT16).

**Regarding the view of mathematics to communicate.** Another group of answer express the wish to learn to teach in a way that communicates a particular view of mathematics (since the focus is not on teaching methods *per se*, this answers were not included among expectations regarding pedagogy and PCK). It could be possible to identify three main kinds of such demands, which can be summarized as: *I hope I will learn how to teach mathematics in order to make it...*

- ...*“reality-based”*. Some people ask for teaching methods that will make them able to make pupils recognize and use mathematics in real-life situations (*“In this course I'd like to discover new methods and ways of teaching that start to talk about mathematics from the real world, from everyday life”*, FT19).
- ...*“cross-cutting”*. This feature is emphasized in particular in FT1's answer, where she describes her will to set her future lessons in a way to link mathematics to other scholastic subjects: *“[...] But above all I hope that [this course] will help me to understand how I can develop a course on mathematics that crosses other disciplines”*.
- ...*neither mnemonic nor mechanical*. A couple of answers express the will to learn to teach mathematics discouraging a view of it as a subject merely based on memory (*“[...] I'd like it if children could receive an approach to the learning of mathematics which is not mnemonic”*, FT33) or on mechanical techniques (*“[...] I hope to receive hints to dispel the myth of mathematics as a strict and mechanical subject”*, FT46).

**Regarding the reasons for teaching mathematics.** To conclude, I would like to report one answer which is particularly original. In this case the respondent expresses her hope to improve her mathematics education, because she seems to seek for a more complete and interrelated overview of mathematical topics, and for an explanation of the reasons why they are taught at primary school:

*[...] I hope to reach a more organized and coherent way of thinking about mathematical contents. But above all I hope to understand the reasons why we study mathematic, in order to return it to the children of my future classes. [...] Obviously acquiring competencies in the management of tools and communication techniques is important but is secondary; the main goal remains to know why one is studying a certain discipline. [FT10]*

## Conclusions

In the introduction we underlined how long researches in Mathematics Education has been pursuing the goal of establishing what do teachers need to teach mathematics effectively. Initially the efforts were directed to defining aspects related to knowledge – as in the work by Ball et al. (2008). More recently, research has widened its perspective to other aspects as well, as affective aspects of teachers' education (Coppola et al., 2013). Another aspect investigated just in recent years is what future teachers think they need to teach mathematics effectively: as Liljedahl (2014) underlines, it does matter “what the results [of the research] say about teacher autonomy and the role that workshops play in the professional growth of teachers”.

These considerations also suggest another direction of inquiry: future teachers' expectations about courses for professional development. This aspect was the focus of the present study. The results obtained are obviously context-bound, since we are concerned with one class of a specific Italian university; nevertheless, there are some observations rising from our findings that seem to be more apt to be generalized and discussed here.

The first one concerns the shared judgment about the compulsory courses on Mathematics: courses focused only on mathematical contents are generally considered to be too theoretical – sometimes even beyond future teachers' capabilities – and scarcely connected with teaching practice. On one hand, as suggested by Boero and Guala, it could be advisable to incorporate the study of mathematical content with tasks “clearly related to crucial educational issues” (Boero and Guala, 2008, p. 232) aimed at stimulating a deep reflection on mathematics as a social and historical product; on the other hand, we believe that poor preparation in mathematics cannot adequately support the development of knowledge for teaching, e.g. a certain level of content knowledge is absolutely necessary for the development of pedagogical content knowledge. The challenge for teacher educators is to make future teachers aware of the importance of a strong preparation regarding content about this sense.

Another general aspect concerns future teachers' expectation about learning mathematics teaching methods that take into account also affective aspects. This consideration highlights two other issues for teacher educators: one is to develop workshops aimed to restore future teachers' relationship with mathematics; the other is to develop courses providing some space for reflections about affective issues, without losing the connection to mathematical content. The main risk, in fact, is to draw future teachers' attention to children's amusement, and thereby neglecting the activities' mathematical relevance. In our viewpoint, mathematical significance has to come first, and moreover, the focus should be not on fun activities, but rather on the ideal emotional conditions to make the activities work, making children feel free to express their thoughts and make mistakes. The analysis of future teachers' expectations raises serious challenges for us, both as researchers in

mathematics education and as teacher educators: accepting them is the further direction of this paper.

# Regression trees and decision rules applied to the study of perplexity: Issues and methods

Inés M<sup>a</sup> Gómez-Chacón, J. Tinguaro Rodríguez

Universidad Complutense de Madrid, [igomezchacon@mat.ucm.es](mailto:igomezchacon@mat.ucm.es),

*This paper explores the use of the CRT (Classification and Regression Tree) methodology to analyse data from a fuzzy rating scale-based questionnaire. Based upon a questionnaire to assess the state of perplexity in mathematics undergraduate students, the rule structure obtained from the CRT analysis is reported. We anticipate these findings may be of interest both to evaluate the interplay between cognition and affect as well as to researchers in the Fuzzy Logic field.*

*Keywords: Emotions, heuristics, fuzzy set, cognition and emotion, mathematics, regression trees.*

## Introduction

In this paper, we will focus on perplexity in mathematics. In the studies concerning determination of affective pathways during the solving of problems (Goldin 2000; Gómez-Chacón, 2000, in press), the state of perplexity or puzzlement is considered to be one of the interesting emotional states into which the individual can drift along positive or negative pathways when solving the problem. Perplexity does not in itself have unpleasant overtones—but bewilderment, can include disorientation and a sense of having “lost the thread”. If problem solving continues, a lack of perceived progress may generate frustration, where the negative affect becomes more powerful and more intrusive, but where there is still the possibility that a new approach will move the solver back to the sequence of a predominantly positive affect. The studies mentioned above show the need to understand and to know, in depth, the benefits that this state can achieve for the teaching and learning of mathematics.

A big challenge today is to improve the methodological tools for evaluating affect detection systems. This need is motivating studies in trying to explain this gradualness in the processing of affective mechanisms. Further research is necessary to reference the identification, discrimination, and the unclear boundary between the cognitive and affective processes. This paper explores the use of decision trees to analyse data from a fuzzy rating scale-based questionnaire. Thus, here we will report our results in the form of a tree structure providing rules to assess the state of perplexity in mathematics undergraduate students, built upon the basis of the previous questionnaire.

The present research is primarily exploratory for two reasons: 1) perplexity has been scantily analyzed in mathematics and educational psychology; and 2) the use of the CRT methodology to analyse data from a fuzzy rating scale-based questionnaire is a new development. The theoretical background and empirical studies related to perplexity need to be developed.

Theorists of science and mathematics (Lakatos 1976) claim that mathematical reasoning and complex problem solving are typical cognitive tasks in which perplexity is directly involved. However, an analysis of the psychological (cognitive and affective) processes involved in it lacking, in order to clarify the definition. (.Studies about confusion (Silva 2010) indicate an appraisal structure of this emotion of novelty-complexity that is reflected in a state of uncertainty and comprehensibility, reflecting an inability to understand. Smith and Ellsworth’s (1985) appraisal

model maintains that in order to differentiate emotional experiences some dimensions are key (pleasantness, attentional activity, control, certainty, goal-path obstacle and anticipated effort). Taken together in this study, these dimensions and mathematical cognitive processes could provide information about perplexity, a knowledge emotion that is rarely studied, and illustrate the relationships between these cognitive variables and emotion in order to deepen understanding of its nature.

The following hypotheses guided the work: (1) the emotions associated with the perplexity state could be positive, negative, or neutral; (2) those participants with more positive ability to cope with the situation (control), better ability to predict, or with a wider understanding, are those who will better handle their state of perplexity in the reasoning.

### Fuzzy rating method for questionnaires

The method of fuzzy rating scale applied in this research was introduced by Hesketh, Pryor, and Hesketh (1988) and subsequently developed in various studies by Gil et. al., (2015). The fuzzy approach is based on the idea that, in some cases, it is not reasonable to say that an object has to either verify a property or not verify it (Zadeh, 1975). Objects or people may exhibit some properties only partially—i.e. up to a certain extent or degree. In many of the conducted researches the evaluation of the emotion parameters is qualitatively performed through reports, interviews, recording observations or, if it is quantitative, through Likert scales. In the case of Likert scales (based on an implicit subjacent numerical continuum), such kind of imprecise information is lost, since finally just a single category has to be chosen (which excludes the representation of a potential hesitation between categories).

**Fig. 1. Examples of Fuzzy sets valuating emotion**

**Fig. 2. Fuzzy sets modelling linguistic variable**

In this sense, fuzzy logic allows relaxing this constraint by admitting valuations to be given in the form of fuzzy numbers over the subjacent numerical scale. That is, in this setting each possible numerical evaluation is assigned a degree of membership or verification, between 0 and 1, representing the validity of such number as a measure of the observed emotional phenomenon (Fig.1).

The idea of using these fuzzy sets to describe imprecise terms is closely linked to the concept of linguistic variable introduced by Zadeh (see Zadeh, 1975). A linguistic variable is considered one that takes linguistic values, which is less accurate than the use of numbers. For example, a linguistic variable used to evaluate 'confidence' may take the (linguistic) values: never, rarely, sometimes, often and always. Each of the linguistic terms that can take the variable is modeled by a fuzzy set (see Fig. 2, and notice the subjacent numerical scale that accompanies the linguistic descriptions). There are values of the variable that can be assigned up to a degree to two of these fuzzy sets (e.g. through disjunction) and, therefore, the boundaries between two consecutive linguistic values can be made flexible.

In this study, trapezoidal fuzzy sets (or fuzzy numbers) were used to perform evaluation on a continuum, assigning a membership degree between 0 and 1 to each point of the interval [0,100] (see Fig. 2 again). Notice that trapezoidal numbers allow representing a continuum of prototypes (i.e. elements that are assigned membership degree 1) with a linear decay.

## **Regression trees**

The CRT methodology is a data mining approach widely employed to develop ‘IF-THEN’ rule models in order to explain the behaviour of a variable of interest (the dependent variable) in terms of logical conditions over a set of explanatory or independent variables (see Breiman et al., 1984). As such, classification and regression trees have been successfully applied to different data-analysis tasks, such as segmentation, stratification, forecasting, data reduction, variable selection, etc., in wide variety of practical contexts (see Strobl et al., 2009).

Particularly, the CRT methodology allows determining a subset of the available independent variables as well as a set of conditions over these variable’s values that separate the data into groups as homogeneous as possible in terms of the values of the response or dependent variable. To this aim, the CRT method performs successive dichotomous splits of the data by identifying both the independent variable and its cut-point that provide the greatest variability (i.e. variance) reduction at the split data groups verifying either condition (i.e. being greater or lower than such cut-point). This process starts at the root node containing all the available data, and is iterated at the resulting nodes or groups until some stopping criterion (usually concerning the depth or number of splits or the sample size in the undivided nodes) is reached. The nodes that are left undivided at the end of this process, usually known as leaves, provide conditional response-variable distributions (assumed to be as homogeneous as possible) given the conditions or premises formed by the conjunction of the different branches (i.e. splits) that separate each leaf from the root node.

Notice that CRT is a data analysis methodology with almost no assumptions, and particularly that it is a non-parametric and distribution-free model-building method (e.g. no normality or independence assumptions are made). For these reasons, CRT is especially useful as an exploratory tool allowing to uncover some relationships and patterns in the data that may be expressed in logical form.

In this work we apply this regression tree methodology to develop a rule model capturing the relationships between a numerical dependent variable, measuring either the intensity of perplexity or pleasure experienced by students while solving a mathematical problem, and a set of independent variables measuring the intensity of other emotions that may appear in consonance with perplexity. Our aim, at least in a first stage, is basically exploratory; that is, we do not pursue a complex mathematical model of those relationships of perplexity with other emotions, but rather a simple model describing the most significant relationships in terms that may be checked intuitively. In this sense, we found that the CRT methodology fitted this aim quite well.

## **Research questions and methodology**

### **Research Questions**

We particularly pursued the following research questions: Research question 1: What emotions and cognitive appraisal processes have more influence on the state of perplexity? Research questions 2:

How pleasant is being in the state of perplexity? What variables are related to the dimension of pleasantness?

### Participants and instrument

Data was collected in 2014 from 100 (56 women and 44 men, aged between 22 and 23) Caucasian undergraduates working toward a BSc. in mathematics. All of the participants were in their last year of academic study, and were distributed into three training groups established by the academic institution. They were following advanced courses in several areas of geometry, algebra, probability and analysis. With regard to solving problems, the students had been introduced to the problem solving heuristics and they received training as students and in one subject related to advanced professional knowledge, practice and relationship skills relevant to teaching. They had not received any special training about backtracking heuristics.

The work dynamic was individual work and began with a paper and pencil resolution of four tasks (problems), each of one hour and a half duration. One example problem, the results of which will be analysed later in section of results, is shown below:

Paths: How many paths consistent in a series of horizontal segments and / or vertical can be counted in the figure below (Fig. 3) (where we have indicated a possible path) so that each segment links a pair of consecutive numbers, to form, from the beginning to the end the number 1234567?

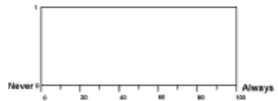

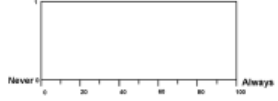

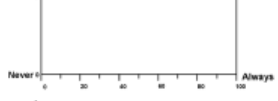

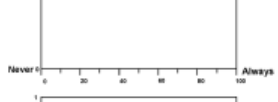

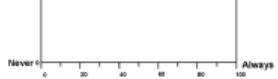

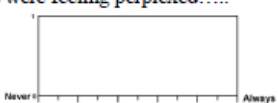

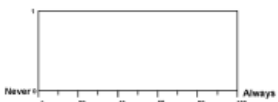

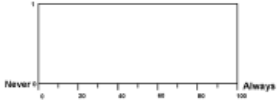

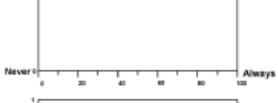

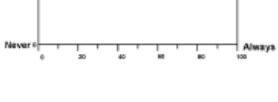

**Figure 3. Possible Path**

In this session, students were given the problem and asked to describe their approaches to resolving the problem using protocols including: steps in the resolution, explanations of the difficulties they might face, and strategies they would use. Afterwards, each problem was followed by a questionnaire based on the measure of fuzzy rating scales and focused on heuristics related to backwards thinking and the difficulties that are generated during the process of solving problems and emotions and cognitive processes (Gómez-Chacón, in press).

The questionnaire is based on the measure of fuzzy rating scales that used a scale of free fuzzy numbers, in which the respondent represents the same fuzzy number that most closely matches their assessment of an interval (Fig. 4). The questionnaire has two parts, one referring to the cognitive dimension and the other, the affective dimension. The cognitive dimension refers to the characterization of the personal meanings of the subjects on the cognitive dimension of heuristic backtracking, or backward reasoning, and the cognitive appraisal processes of the interaction with emotion. The studied emotions were: confusion, uncertainty, hesitation, surprise, frustration, bewilderment, boredom, and confidence. And the cognitive appraisal dimensions to differentiate emotional experiences were pleasantness, attentional activity, control (self-other responsibility/control, situational control), certainty, goal-path obstacle, anticipated effort and mental flexibility.

## Data analysis

Both qualitative and quantitative methods were used to address the subject of this study. This paper presents the quantitative analysis performed on the undergraduate students' written responses to the questionnaire. The first step of the analysis was the defuzzification of data. This refers to converting the trapezoidal numbers provided at the student's responses into usual numbers that can be handled by the CRT methodology. For the purposes of our study, the average centre (also known as the centroid) defuzzification method was used. With such defuzzicated data, different regression tree analysis were performed with SPSS to uncover the prescriptive nature of the variables. Two of these regression trees, together with their associated rule models, are reported next.

<p><b>Emotions</b> Indicate the degree of the following emotions during the solving of problem. Quantify them using a trapezoidal fuzzy set for each case.</p> <p>Confusion</p>  <p>Uncertainty</p>  <p>Confidence</p>  <p>Hesitation</p>  <p>Surprise</p>  <p>Bewilderment</p> 	<p><b>Appraisal Processes</b> Indicate the degree of the following processes during the solving of problem. Quantify them using a trapezoidal fuzzy set for each case. When you were feeling perplexed.....</p> <p>What extent did you feel that circumstances beyond anyone's control were controlling what was happening in this situation?</p>  <p>What extent did you feel that you had the ability to influence what was happening in this situation?</p>  <p>What extent did you feel that you had the ability to influence what was happening in this situation?</p>  <p>How well did you understand what was happening around you in this situation?</p>  <p>How well could you predict what was going to happen in this situation?</p> 
---	--

**Fig. 4** Examples of some items from the questionnaire: Perplexity and backwards reasoning processes (Gómez-Chacón, in press)

## Results

**Research question 1.** For the interpretation of the classification tree, we should go looking at the nodes and branching them until the final leaves. First, we look at the root node 0 that describes the dependent variable: Perplexity of students to solve the problem (P2). It indicates that the group mean is 49.040. Then, note that the data is split into nodes 1 and 2 depending on the variable Bewilderment (P19), indicating that this is the main predictor variable. Node 1 indicates that 22% of students who feel Bewilderment  $\leq 21.37$  has a mean of 25.04 perplexity (P2). This node 1 is again split up into nodes 3 and 4 depending on variable P8, Ability to influence (i.e. Control). We note in node 4 that the students who had Control  $> 67.87$  experience perplexity with an average intensity of 40.28, while students at node 3 have a lower ability to influence and experience a mean perplexity intensity of 16.33. These two nodes 3 and 4 are leaves that allow us to infer rules 1 and 2 below.

Particularly, each path from the root of a decision tree to one of its leaves can be transformed into a rule simply by conjoining the conditions along the path to form the antecedent part, and taking the leaf's mean as the rule prediction or consequent. Similarly, in order to define the rest of the rules, node 2 and the following ones are studied. The profile of students who experience perplexity is defined by nodes 3, 4, 5, 9, 10, 11 and 12 through the following variables: Ability to influence (P8), Bewilderment (P19), Confusion (P13), Boredom (P21) and the ability to solve simpler problems and also goal-path obstacles (P11). The inferred rules are the following:

Rule 1 (node 3): IF ((Bewilderment (P19)  $\leq$  21.37)) AND (Ability to influence (P8)  $\leq$  67.87) THEN the prediction of perplexity (P2) is = 16.33, with a support of 14% (i.e. 14% of the participants verify the premise of this rule).

Rule 2 (node 4): IF ((Bewilderment (P19)  $\leq$  21.37)) AND (Ability to influence (P8)  $>$  67.87) THEN the prediction of perplexity (P2) is = 40.28, with support 8%.

Rule 3: (node 5): IF ((21.37  $<$  (Bewilderment (P19)  $\leq$  64.6)) THEN the prediction of perplexity (P2) is = 48.84, with support 48%.

Rule 4 (node 9): IF (Bewilderment (P19)  $>$  64.6) AND (Confusion (P13)  $\leq$  64.87) AND (Boredom (P21)  $\leq$  12.62) THEN the prediction of perplexity (P2) is = 67.15, with support 5%.

Rule 5 (node 10): IF (Bewilderment (P19)  $>$  64.6) AND (Confusion (P13)  $\leq$  64.87) AND (Boredom (P21)  $>$  12.62) THEN the prediction of perplexity (P2) is = 55.65 with support 5%.

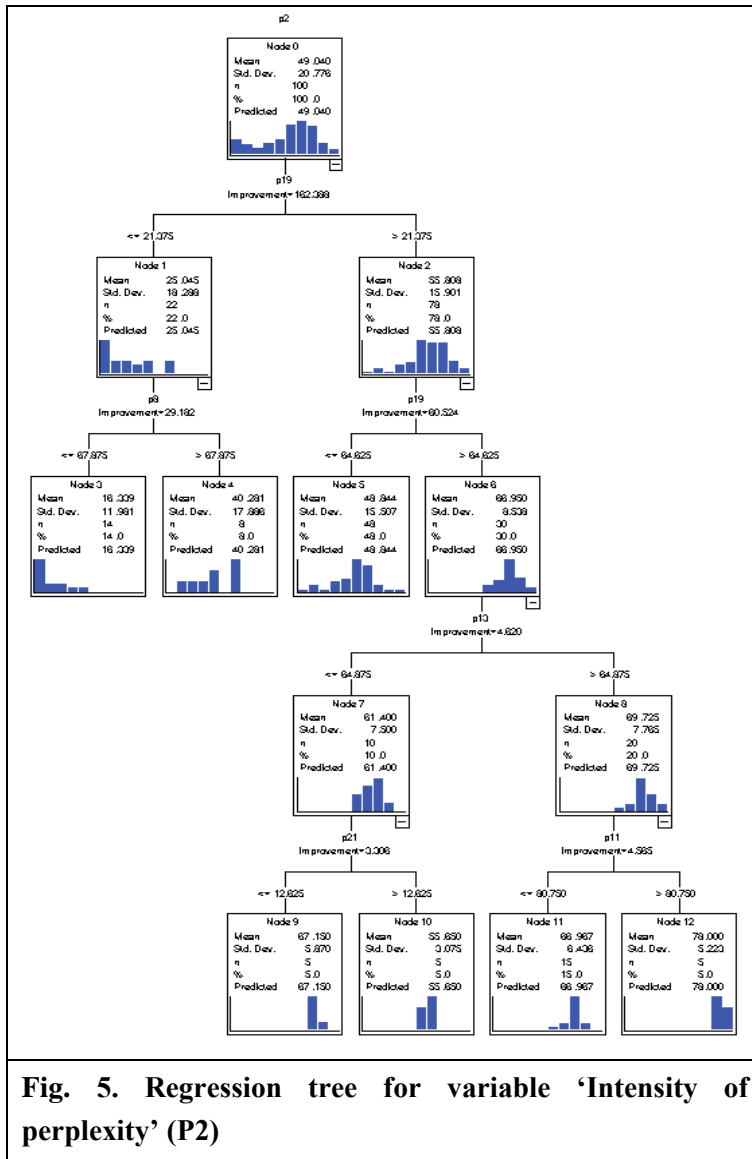

Rule 6 (node 11): IF (Bewilderment (P19)  $>$  64.6) AND (Confusion (P13)  $>$  64.87) AND (the ability to solve simpler problems and goal-path obstacles (P11)  $\leq$  80.75) THEN the prediction of perplexity (P2) is = 66.99, with support 15%.

Rule 7 (node 12): IF (Bewilderment (P19)  $>$  64.6) AND (Confusion (P13)  $>$  64.87) AND (the ability to solve simpler problems and goal-path obstacles (P11)  $>$  80.75) THEN the prediction of perplexity (P2) is = 78, with support 5%.

In summary, the perplexity is closely linked with the emotions of bewilderment and confusion. The bewilderment could generate a fork towards a positive path depending on the ability to influence on the problem and the ability to influence the process of resolving. The perplexity state may stem entail only high novelty, reflecting a state of uncertainty but may entail a searching of understanding when perplexity may share with appraisal dimensions linked to the ability to influence (self-control dimension) and the perception of overcome obstacles and the ability to solve simpler problems.

**Research question 2. Pleasantness.** Pleasantness is considered as an important dimension. It is a function of two appraisals—appraisals of what one wants in relation to what one has, and these are intrinsically pleasant or unpleasant. The mean of the group with respect to pleasure (P5) experienced during the state of perplexity is 40.92. From the classification' tree (Fig.6) can infer the following rules: **Rule 1 (node 2):** IF Confidence (P15)  $>$  55.75 THEN the prediction of pleasure (P5) = 48.07, with support 58%. **Rule 2 (node 3):** IF Confidence (P15)  $\leq$  55.75 and Understanding (P9)  $\leq$  38.37 THEN the prediction of pleasure = 16.63, with support 13%. **Rule 3 (node 4):** IF Confidence (P15)  $\leq$  55.75 and Understanding (P9)  $>$  38.37 THEN the prediction of pleasure (P5) = 37.5, with support 29. In summary, a state of perplexity could not only be a mental perturbation or anxiety, but a pleasure experience given sufficient levels of confidence and understanding.

## Conclusions and discussion

The discussion and conclusions are structured around the objectives of the research, and methodological effectiveness in the use of regression trees for establishing rules.

Relative to the interplay between cognition and affect in the perplexity state the perplexity is closely linked with the emotions of bewilderment and confusion. The degree to which students associate state of perplexity with an emotion of pleasure is linked to the levels of confidence and the understanding of the problem. Likewise the perplexity state shares cognitive appraisal dimensions linked to the ability to influence (self-control dimension) and the perception of overcome obstacles and the ability to solve simpler problems. The relationship shown between cognitive appraisal dimensions and the emotions that make up the state of perplexity highlights conditions about learners who have the ability to appropriately manage their perplexity. This study shows the central role of impasse in mathematics, perplexity it is not a negative event to avoided by intellect, it is responsible for the activation of thinking (Lakatos 1976, Goldin 2000; Gómez-Chacón, 2000). Regarding the methodological adequacy of the present study, the use of a non-parametric, assumptions-free data mining model as regression trees provides a solid basis for the kind of

exploratory analysis aimed at this work. Particularly, this model allows for robust variable selection, as significant variables are identified through a greedy process in which the effectiveness of all the available variables in reducing the variability of the response variable is checked, and that obtaining the greatest reduction (or improvement) is selected. This assures that the selected variables that conform the premises of the obtained rules are relatively good explicative factors of the studied response variables.

# Impact of long-term regular outdoor learning in mathematics – The case of John

Annika Grothérus and Emilia Fägerstam

Linköping University, Sweden; [annika.grotherus@liu.se](mailto:annika.grotherus@liu.se); [emilia.fagerstam@liu.se](mailto:emilia.fagerstam@liu.se)

*This paper reports on a longitudinal study investigating the impact of long-term regular outdoor learning in mathematics in the school-grounds. An interview-based case study of John, a lower secondary school student, will be analysed. The case study will describe John's perceived experience of long-term regular outdoor learning in mathematics and its impact on affective and academic factors. The findings emphasise the positive outcomes of long-term regular outdoor learning in mathematics, indicating enhanced cooperative learning, reduced mathematics-related stress and anxiety, changed self-concept, and enhanced mathematical proficiency.*

*Keywords: Outdoor learning, mathematics anxiety, self-regulation, mathematical proficiency.*

## Introduction

The constant focus on textbooks and formal mathematical practice might invoke a view among students that mathematics is abstract, distanced and only useful in a classroom context, working only in the textbook (Boaler, 1998). If students are not given the opportunity to engage with real-life problems in mathematics they will encounter problems applying their knowledge in an outside school context (Desforges, 1995). Mathematics taught in the classroom will have limited value if it is not transferable to students' everyday life and future academic and career endeavours. Current research on outdoor learning in mathematics demonstrates positive affective outcomes and possible academic benefits (Daher & Baya'a, 2012; Moffett, 2011; Noorani et al., 2010). In this paper, by analysing John's perceived experiences of long-term (3 year period) regular outdoor learning in mathematics, we explore any possible impact on both affective and academic factors. By affective factors we mean mathematics-related stress and anxiety, and motivation. With academic factors we refer to possible academic outcomes such as application and understanding of mathematical knowledge, enhancement of mathematical proficiency, learning strategies, self-regulation and self-concept.

## Theoretical background

### Outdoor learning

Outdoor education can be referred to as organised learning that takes place in the outdoors and is drawn up on the philosophy and theory and practises of environmental as well as experimental education. The embodied and multisensory experiences provided by well-organised outdoor learning are believed to enhance the individual's learning and understanding within a subject, in this case, mathematics. The variation of context between the indoor classroom activities and the outdoor activities enables rich opportunities for cooperative learning in real-life situations (e.g. Jordet, 2007).

### Mathematical proficiency

In the present paper we use the framework of mathematical proficiency presented by Kilpatrick, Swafford, and Findell (2001). According to Kilpatrick et al. (2001), mathematical proficiency has five strands: conceptual understanding (comprehension of mathematical concepts, operations and

relations), procedural fluency (skill in carrying out procedures flexibly, accurately, efficiently, and appropriately), strategic competence (ability to formulate, represent and solve mathematical problems), adaptive reasoning (capacity for logical thought, reflection, explanation, and justification) and finally, productive disposition (habitual inclination to see mathematics as sensible, useful, and worthwhile, coupled with a belief in diligence and one's efficacy) (Kilpatrick et al., 2001, p. 116).

### **Mathematics anxiety, motivation, self-regulation and self-concept**

Mathematics is highly valued by society, and proficiency in mathematics has become increasingly important in order to become a fully functioning citizen, with resulting financial empowerment, making the ability to use mathematics in an out-of-school context even more important (OECD, 2004; Peterson, Woessmann, Hanushek, & Lastra-Anadón, 2011). A variety of studies have shown that many students have negative attitudes towards mathematics, which sometimes results in mathematics-related stress and anxiety (Ashcraft, 2002; Maloney & Beilock, 2012). Within a student, engaged in a mathematical activity, an on-going unconscious evaluation of the situation with respect to the student's self-concept and personal goals is taking place. Depending on the individual's evaluation of the outcome, the student may become emotionally affected being either motivated or not for further mathematical activities (Hannula, 2002; Pintrich, 2004). According to PISA (OECD, 2013), Ryan and Deci (2009) and Wigfield, Tonks, and Klauda (2009) two forms of motivation to learn mathematics within self-regulative skills exist. The two forms are intrinsic motivation and extrinsic motivation. Intrinsic motivation is the motivation to perform mathematics merely for the joy gained from doing mathematics. While extrinsic motivation is the motivation to perform mathematics due to its importance in society, usefulness and the fact that mathematical knowledge will aid future career prospects and further academic studies. An individual with mathematics-related stress and anxiety is emotionally affected in a negative sense and tends to have a low self-concept (self-related cognitions of ability that can explain as well as predict achievement related behaviour, belief in one's abilities) as well as low levels of self-efficacy (a student's belief that he/she has the capability to perform a given mathematics task at a designated level) (Bandura, 1994; Bong & Skaalvik, 2003). Furthermore, these individuals also tend to lack the ability to self-regulate, resulting in avoidance behaviour and a decline in mathematics performance. As a consequence they are assigned lower grades and tend to have limited choices of possible future academic and non-academic career paths (Wu, Barth, Amin, Malcarne, & Menon, 2012).

One important factor to promote learning is students' capability to self-regulate (Pintrich, 2004). If students are provided with guidance on how to self-evaluate their own learning process and how to develop suitable strategies to promote their own learning during formal schooling, such guidance will enable acquired knowledge to remain updated after leaving school and to be used in an outside school context (Pintrich, 2004; Zimmerman, 2002). Self-regulation refers to the degree in which students are active participants in their own learning. It is an individual's ability to set mastery goals, mobilizing the efforts and resources the individual will need in order to achieve these goals. To reach these mastery goals, students use a wide range of self-regulatory processes and display a number of adaptive motivational factors such as self-efficacy and self-concept, where moderate levels of mathematics-anxiety may actually facilitate learning as well as performance (Pintrich, 2004).

## **Cooperative learning**

Procedures in cooperative learning are designed to engage students actively in the learning process through inquiry and discussion with their peers in small groups, which need to be well organised with a clear structure to promote cooperative participation and learning (Davidson & Worsham, 1992, p. xii). Cooperative learning provides students with academic factors such as positive effects in mathematics performance and student achievement (Whicker, Bol, & Nunnery, 1997). Cooperative learning is a preferable method when helping individuals with mathematics-related anxiety to reduce their stress and anxiety. Furthermore, it is also an important feature of self-regulated learning because active participation is a crucial element of the self-regulation construct (Clark, 2012; Daneshamooz & Alamolhodaei, 2012).

## **Focus of the study**

The aim of the study was to investigate John's perceived experience of long term (three years) regular outdoor learning in mathematics in terms of possible impact of integrated outdoor mathematics activities on affective and academic factors.

## **Methodology**

This paper is a part of a larger intervention research project aiming to explore the possible impact of outdoor teaching and learning in lower secondary school (Fägerstam, 2012). Outdoor teaching and learning was implemented on a regular basis as a complement to ordinary classroom teaching during the entire lower-secondary school period of three years. The focus of this paper is to explore the possible impact of long-term regular outdoor learning in mathematics, and the case of John is presented as an example of its possible impact. The research is exploratory to its nature because there are few longitudinal studies on outdoor learning in mathematics. John is 15 years old, attending his third and final year of lower secondary school. John is a fictitious name that has been given to ensure the individual's anonymity. John's class had one of their four weekly mathematics lessons outdoors on a regular basis during the entirety of lower secondary school. The same mathematics teacher taught John during the three years of the intervention project. The school to which John and his class belong was situated in the suburbs of a medium-sized (approx. 85000 inhabitants) municipality in Sweden. The school, grade 7 to 9, was a normal sized school with approx. 450 students in six parallel classes. John was interviewed using semi-structured interview as a method. The interview was audio-recorded and transcribed using verbatim. Data was analysed thematically to identify recurrent patterns and commonalities using thematic coding (Boyatzis, 1998). Aspects of self-regulation skills were analysed based on concepts originally used in the PISA survey (OECD, 2004), namely intrinsic and extrinsic motivation, self-concept and mathematics anxiety. Representative illustrative quotes will describe the possible impact of regular outdoor learning in mathematics on self-regulation in mathematics and mathematical proficiency as well as John's perceived experience. The ethical guidelines and directives stipulated by The Swedish Research Council regarding good research have been followed (Hermerén, Gustafsson, & Pettersson, 2011).

## **The case of John**

John is a fifteen-year-old boy who has had severe difficulties with learning and understanding mathematics since he started school. John was selected as a case due to his low levels of mathematics

self-concept, expressed mathematics-related stress and anxiety and low levels of mathematical proficiency, which were reflected in his mathematical performance.

### **John's overall experience: Well-planned lessons, structure, intelligibility, and time**

John emphasises the importance of well-planned lessons, structure and intelligibility. It is important, he says, that one knows what is expected and that everyone knows what to do.

It is of importance that everyone knows what he or she is supposed to do. It is important that the teacher gives a thorough briefing before the outdoor lesson. It is important that the teacher presents a well-organised picture of the task. You need to have a check before you start as well so you know what to do and that you do not just start directly and miss out on something that is of importance when solving the task that is presented to you and your group.

Through well-organised lessons and well-made tasks, it is easier to understand the mathematics and what is expected of you. John continues:

It is crucial that you understand what you are supposed to do, what kind of theory you need in order to solve the task that is presented to you. If the lessons are not well organised, the head, the brain, you get so, you disconnect, you start to think of other things.

Time is another aspect of John's experience of the long-term regular outdoor learning. He thinks that the teacher who teaches mathematics provides time to work with mathematics outdoors. However, he questions why other teachers in other subjects do not provide time and prioritise time to have some of the weekly lessons outdoors.

I think that you should have outdoor lessons in other subjects too. Take biology for example. In biology there are so many "outdoors and environmental issues" so it would be a great possibility to work more outdoors. But, we are never outdoors during our lessons in biology, which I think is strange.

According to John, outdoor learning in mathematics provides more time and space to understand what and why you do things.

Indoors you seldom receive any help from the teacher. Often you just sit there for like ten minutes waiting for the teacher to have the time to help you. This results in you not raising your hand to ask for help, because it is quite meaningless. On the contrary, during the outdoor lessons in mathematics the group could either help each other or if the group needs assistance from the teacher, the teacher helps the whole group at the same time, which is really great.

### **Impact on affective factors**

John experienced and expressed a change in self-concept.

Outdoor lessons in mathematics make it easier for you to remember what you do and why. When you have your lesson in mathematics outdoors, the teacher explains clearly what to do. You are given a clear picture of what is expected of you and what the task at hand is about and what the aim of the lesson is. You will better understand what you do and why you do it.

Moreover, it seems like the change of learning environment reduces the mathematics related stress and anxiety.

It is relaxing to work on a regular basis with mathematics outdoors. I get really stressed during the regular indoor lessons in mathematics and suffer from mathematics-related panic attacks. However, during the outdoor lesson in mathematics I really enjoy myself, I am more relaxed and do not suffer from mathematics-related anxiety attacks.

John experiences that he is enjoying himself and feeling more relaxed during the regular outdoor lesson in mathematics.

John also indicates that his extrinsic motivation has a tendency to hamper his achievement and performance in mathematics. He brings up the pressure to perform and the stress and anxiety the national tests in mathematics cause. However he also brings up a sense of changed perception of himself and emphasises the positive outcomes of variation of context for the learning of mathematics.

It makes you understand everything much better. You become more engaged and motivated. Regular outdoor lessons in mathematics provide you with more input and understanding of mathematical concepts. In addition, you feel better and enjoy the mathematics lessons more.

John appears to address the idea of losing one's self-confidence, which will lead to low self-concept.

John emphasises the importance of feeling engaged and motivated. To be extrinsically motivated tends to have a negative impact on understanding and learning mathematics. It rather makes you give up because you feel like a loser who cannot manage mathematics. However, by working to engage with real-life problems in mathematics with regular outdoor lessons in mathematics solving these real-life problems together with others provides, according to John, the possibility to become aware of one's true mathematical proficiency and that it might be enhanced. As demonstrated, John experienced that he began to enjoy mathematics more. He changed from being extrinsically motivated to become more intrinsically motivated and was more ready to face new, more challenging tasks because he started to believe in his own abilities.

### **Impact on academic factors**

John also stated that he had difficulties with negative numbers when using them and understanding the concept of them. During one of the outdoor lessons in mathematics they had worked with negative numbers. Before this outdoor lesson they had, during the indoor lesson, talked about negative numbers and worked with them in the textbook.

Well, we had one lesson when we worked with negative numbers, you know plus and minus and that kind of stuff. We did this exercise where you were supposed to run and put a piece of paper next to another on one of these big long things that looks like a row, and then there were also, you know, numbers in between and at the far end there was perhaps minus something and in the middle was zero. After a while you started to realise that it was kind of a huge thermometer. It was almost like the numbers became connected with each other. The visual picture and the practice of actually building the thermometer gave you a better understanding of the concept. It is strange but you actually need lots of self-confidence when it comes to learning and understanding mathematics.

As seen, working more visually and practically with negative numbers, strengthens John's conceptual understanding of negative numbers.

John emphasised the gain of cooperative learning. During the outdoor lessons in mathematics the students were supposed to collaborate when solving different problems they were given. During the outdoor lessons in mathematics, John was given a feeling of participation.

The class cooperated better when working with mathematics outdoors than indoors. Indoors the class seem to be more divided into certain groups. There is that group with the smart kids, who are good at mathematics, then the rest of us who are kind of left behind. During the outdoor lessons there tends to be more cooperative work, because all of us know that you must first begin to solve the given mathematics task on your own to begin with and then help the group by discussing the problem together. It is important that everyone can join in, participate and be given the possibility to explain how to solve the task at hand. Everyone should be given the opportunity to show his or her proficiency and share one's knowledge with others. It is a way to better understand how a given task can be solved. You become more engaged and motivated if you are allowed to participate and speak your mind regarding how you believe that the task at hand can be solved.

John emphasises that cooperative learning opens up opportunities for and development of adaptive reasoning. Through the outdoor lessons in mathematics, the students are given the possibilities to reason with each other. They have the opportunity to explain and try out their logical thoughts as well as justify their thoughts and chosen solution to the task at hand by reasoning with others.

### **Productive disposition**

John expressed experiencing that he began, thanks to the regular outdoor lessons, to recognise and realise the importance of mathematics and that it is worthwhile to make the effort to understand the concepts of mathematics. Through cooperative learning he realised that he actually possesses a certain level of proficiency in mathematics. He realised that a task can be solved in several different ways.

You need self-confidence in mathematics and if you enjoy mathematics then you become more confident and more motivated. Indoors you just sit and understand nothing. But when you work with mathematics outdoors you understand how it all works.

### **Discussion**

John's perceived experiences of regular outdoor learning in mathematics indicate that it is reasonable to assume that students can benefit from regular outdoor learning in mathematics. We may conclude that long-term regular outdoor learning in mathematics shows a tendency to have an impact on affective factors by altering the individual's self-concept, reducing mathematics-related stress and anxiety and resulting in a more engaged and motivated student, which is supported by the findings of previous studies (e.g. Moffett, 2011). In addition, long-term regular outdoor learning in mathematics shows a tendency to have an impact on academic factors and one major feature was the importance of variation of context. It is reasonable to assume that the possibility to work more visually and practically with real-life problems, which had first been presented theoretically during the indoor lessons, might be a key factor for enhanced conceptual understanding (Kilpatrick et al., 2001). We may conclude that engagement and motivation for learning mathematics is enhanced. Accordingly, students tend to become more engaged and motivated by regular outdoor learning in mathematics. Cooperative learning is a prominent part of outdoor learning in mathematics and is emphasised by John as a key feature for the enhancement of his adaptive reasoning (Kilpatrick et al., 2001). Previous findings have indicated that cooperative learning tends to help mathematics- anxious individuals

reduce their stress and anxiety for mathematics (Daneshamooz & Alamolhodaei, 2012). The main feature of cooperative learning is the opportunity to discuss and reason with others and justify one's mathematical thoughts on how to solve different mathematical problems. John stresses that cooperative outdoor learning in mathematics tends to make students aware of their true mathematical proficiency by being given the possibility to observe that a task at hand can be solved in more than one way and that more than one "right" solution to the problem may exist. John experienced that when mathematics became less abstract and more transferable to his everyday life, learning mathematics becomes more joyful resulting in a more positive attitude towards mathematics making him engage instead of avoid learning mathematics (e.g. Maloney & Beilock, 2012). Long-term regular outdoor learning in mathematics gave John the possibility to develop the ability to self-regulate his learning (Wu et al., 2012). Finally, it is reasonable to assume that if a student is provided with a sense of control, that student may enhance the levels of self-concept and reduce mathematics related stress and anxiety.

# Finnish educators' conceptions of the social-emotional needs of mathematically gifted high school students

Eeva Haataja<sup>1</sup> and Anu Laine<sup>2</sup>

<sup>1</sup>University of Helsinki, Finland; [eeva.haataja@live.fi](mailto:eeva.haataja@live.fi)

<sup>2</sup> University of Helsinki, Finland; [anu.laine@helsinki.fi](mailto:anu.laine@helsinki.fi)

*This article presents conceptions of social-emotional needs of mathematically gifted adolescents of certain Finnish educators. The article is based on a qualitative research study conducted with the methods of semi-structured interviews and participant observation in a Finnish high school that offers a special programme for mathematically oriented students. The study shows that the educators considered the most essential social-emotional needs of mathematically gifted students to be the need to be respected as unique personalities, to meet other gifted, to feed and guide the intrinsic motivation.*

*Keywords: Mathematical giftedness, gifted students, social-emotional development.*

## Introduction

The purpose of this study is to present and analyse the conceptions of the social-emotional needs of mathematically gifted students held by certain educators who work in a mathematically oriented high school in Finland. The research is conducted in a unique Finnish school community that is focused on educating students who exhibit particular interest in mathematics. The data of this research was collected by interviewing five educators of the school and by participant observation in the school. The research context provides valuable knowledge as it brings together the practices and theories of research on gifted education (Ambrose et al., 2010; Laine et al. 2016).

Giftedness is a very complex concept and varies both qualitatively and quantitatively within gifted persons (Passow, 2004), and multiple definitions of giftedness have been written over the decades (Ambrose et al., 2010). This chapter presents the theoretical fundamentals on mathematically gifted adolescents and summarises former research on teachers' conceptions of giftedness and gifted education.

Being gifted means possessing promising potential in a certain domain of giftedness and being able to develop this potential into actual high performance. This domain, e.g. mathematics, is the field and the context in which the gifted activity occurs (Cross & Coleman, 2014). Mathematical giftedness in particular means the ability to abstract numbers, variables and functions and the relations between them. For a mathematically gifted person, it also means courage, persistence and intrinsic motivation to go further and deeper in such mode of comprehension (Gardner 1983; Reis & McCoach, 2002; Movshovitz-Hadar & Kleiner 2009; Subotnik, Pillmeier, & Jarvin, 2009). The development of such person is not only affected by personal characteristics, but also by the structure and properties of the individual's particular domain of talent (Coleman & Cross, 2000).

Mathematically gifted students need mathematical activities, and with the support of their surroundings, they are able to take an active role in their own learning and develop into professional mathematicians (Cross & Coleman, 2014; Usiskin, 2000). They have also certain social-emotional needs... A gifted person is able to fulfil his whole potential only if his intrinsic abilities, the support of his social surroundings and the social-emotional dimensions are in balance (Subotnik et al., 2009;

Usiskin, 2000). Exceptionally gifted adolescents often experience dissimilarity and even unpopularity among their schoolmates (Mönks & van Boxtel, 1985; Rimm, 2002), especially when the giftedness takes place in the domain of mathematics (Pettersson, 2008).

Many professional educators still view giftedness as a fixed and innate characteristic of a person (Laine, Kuusisto, & Tirri, 2016). Some of teachers even consider the gifted as students who actually do not need training or instruction (Laine et al., 2016). However, recent theoretical definitions of giftedness have shifted towards contextual and malleable conceptions (e.g. Ambrose, VanTassel-Baska, Coleman, & Cross, 2010; Cross & Coleman, 2014). Various researches illustrate this gap separating the theoretical knowledge of giftedness from the conceptions of professional educators (Ambrose et al., 2010). Research further shows that there is also a gap between the teachers' conceptions of gifted education and the educational practices they conduct. Therefore there is need for in-depth research to further our understanding of teachers' conceptions of giftedness (Laine et al., 2016).

Teachers' conceptions have a significant role in supporting young gifted students in advancing their talent (Mann, 2006; McNabb, 2003; Pettersson, 2008). Teachers tend to favor quite traditional conceptions of giftedness (Moon & Brighton, 2008). Generally, according to teachers, the most determining characteristic of a gifted student in the school context is a specific difference from others, which presents itself as the gifted student's capability to perform fast, intelligent and creative learning (Kaya, 2015; Laine et al., 2016; Mattsson, 2010; Moon & Brighton, 2008). It is interesting to note that teachers also associate mainly positive social-emotional characteristics with giftedness, such as enthusiasm, sensitivity and curiosity (Kaya, 2015; Laine et al., 2016; Mattsson 2010).

There seems to be a gap between the theories and teachers' traditional conceptions of giftedness. Therefore, the purpose of this study was to examine the educators' conceptions of the social-emotional needs of the mathematically gifted adolescents in a school with successful practices. We were especially interested in the conceptions that were also enacted in their practices.

## **Methodology**

In this qualitative research the data was collected by interviewing all the teachers who had regularly supervised the summer schools (two mathematics teachers, the biology teacher) as well as the principal and the healthcare officer. Additionally... by observing, filming and participating in the mathematics classes in the autumn of 2011 and an overnight school session in January of 2012. A qualitative semi-structured interview technique was used in order to give the interviewees the possibility to conceptualize and describe the topic in the way they prefer.

The researcher spent time with the student participants of the overnight school and participated in the social and mathematical activities of the event. Short informal discussions were conducted with the students while participating. As the data was collected in the authentic environment of the research subjects by means of participant observation, this study contains characteristics of ethnographic research (Delamont 2004; O'Reilly 2005).

The data was transcribed and analysed with inductive content analysis. Inductive content analysis means categorizing and combining units of the analysis into larger aggregates (Elo & Kyngäs, 2008). A whole statement was chosen to be the unit of the analysis. The whole statements included one thought, conception or opinion varying in length from a couple of words to several sentences. These

units were first categorized into codes. After that, as is done in inductive content analysis (Elo & Kyngäs, 2008), the codes were connected into categories and such categories into main categories, and finally the results were interpreted in the light of the theoretical background of the study.

## Results

The purpose of the school is to gather together and educate adolescents interested in mathematics. The students of the school are offered a wide range of instruction in mathematics and diverse learning environments such as the Night of Mathematics and an annual summer school in Lapland. The educators interviewed in this study generally described their students as gifted. They defined mathematical giftedness as the ability to picture, learn and remember mathematical causations rapidly and with clarity. They described two types of giftedness appearing in the school: students with multiple talents and those with a single exceptional talent. The students with multiple talents were interested in societal influencing and social activities. On the other hand, the exceptionally talented tended to impress their teachers with their commitment to studying and with their high level of mathematical reasoning skills.

Principal: Roughly speaking there are those Renaissance talents who are widely talented and then those exceptionally gifted, who focus on the area of their deepest interest.

**The uniqueness of the school's students** was emphasized in the interviews. The interviewees were unwilling to stereotype the students and rather described their personalities, interests, social skills and profiles of giftedness as very individual.

Principal: I don't want to give any stereotyped answer here. I don't want to say that they are this kind or that kind.

According to the educators, many of the students have experiences and memories of feeling different and isolated during elementary school. Sometimes a change of school climate can be essential for a gifted adolescent.

Mathematics Teacher2: And we offer a community where you can discuss the Schrödinger equation during a break without being sneered at.

Biology Teacher: I just received a message where the parents were thankful because it has been so great [for him]. To be accepted in the group and let him be himself and encouraged and so on.

According to the interviews, the students with exceptional mathematical giftedness had more challenges in terms of social skills than those who were gifted in various fields. Moderately gifted students are usually relatively popular among their school mates and age peers, while the exceptionally gifted are more prone to being left alone (Gross 2002; Rimm 2002). Any school environment requires various social skills from students (Payton et al. 2008). According to Mathematics Teacher 1, both "social sharks" as well as those who have "obvious problems in that respect" could be found among the students of the school.

Biology Teacher: Some of them have very poor social skills. ...It is often related to this narrow field of giftedness.

Every student was welcome to participate in the social activities of the school to the extent of their own preferences. According to the interviews, one important social skill for the students is tolerating of all kinds of personalities. In the interviews, the diversity among the students was seen as an important part of the school's social climate.

Mathematics Teacher1: Of course one can choose to enjoy small groups or solitude.

Mathematics Teacher1: We have a vast variety of personalities and a tight community, which means that it becomes a tolerant community.

**To study and associate with other gifted students** was considered one reason behind the distinctive solidarity of the school community. These views are congruent with the literature (Gross 2002; Rimm 2002). Even though a variety of social skills existed among the students of the school, the common interests made social interaction easier.

Health-care officer: To find congenial people. And I know how the teachers describe, how they [the students] make experiments in the physics lesson or somewhere, the burning enthusiasm they show.

According to the interviewees, the students of the school were able to form close friendships with each other. The class-based structure and diverse range of informal activities formed the basis for the development of friendships at the school.

Biology Teacher: And then across the groups of each year's class, because on Mondays [when extra courses in mathematics are taught] and at overnight schools, they spend time together, there are no boundaries.

Associating and studying with other gifted students are emphasized both in these results and in the literature (e.g. Subotnik et al. 2009; Rimm 2002). The positive social climate of the school was constructed upon acceptance of the dissimilarities of students, diverse social interaction, shared experiences and interest in learning mathematics. These features were also seen as suitable for enhancing giftedness.

**Intrinsic motivation** is one of the most essential social-emotional characteristics for the development of mathematical giftedness (e.g. McNabb, 2003; Subotnik et al., 2009). The importance of motivation was also emphasized by the mathematics teachers interviewed in this study.

Mathematics Teacher2: They are very motivated. And that is more determining than giftedness. Of course they need some kind of giftedness. But with some kind of basic giftedness you can go very far.

Even though motivation is often seen as a person's inner characteristic (Subotnik et al. 2009), the interviewees highlighted the significance of peer support in connection with maintaining motivation. The shared motivation and interest in mathematics was also apparent in the overnight school, where groups of students solved mathematical problems together while demonstrating amazing enthusiasm.

Health-care officer: It is the passion for [mathematics] that creates common good things in the class or the group or among the students.

Mathematics Teacher2: The social pressure can influence them one way or another... They support each other very much in studying.

The observations of the overnight school showed that the students were able to discuss their perfectionism, too. The conversation was humorous, and the participants were laughing at their perfectionistic characteristics.

Student1: I am not a workaholic at all!

Student2: No you're not. You only scared all the freshmen with your stories last year.

Sometimes high motivation comes with negative phenomena such as unbeneficial perfectionism. The biology teacher and the healthcare officer had seen that achieving certain objectives or failing to do so may cause stress and exhaustion.

Principal: It [exhaustion] does not occur often, but someone every year.

Health-care officer: Often great giftedness and striving for perfection and achievements are a part of the personality. There is a risk of stress and fatigue and exhaustion.

The interviewees tended to see perfectionism as a practical problem of the educational system rather than a problem in the adolescents. The perceptions of the interviewees were summed up by the healthcare officer. According to her, negative perfectionism can be prevented and treated by guiding the students, being adaptive and offering constant care to the students.

Health-care officer: Flexibility and a flexible education system are what secure the path of the adolescents somehow. And also the caring, in particular, daily care.

Studying with the other gifted students in a supporting school climate was described to help the adolescents to form a realistic self-image and a strong self-confidence as people and mathematicians.

Mathematics Teacher1: It is easy to obtain perspective, [because] some really are incredibly good. –  
– But nobody is the best of all.

Health-care officer: It is amazing to notice how they somehow gain self-confidence.

The gifted students were described as both ordinary and special at the same time, as they encounter the common social-emotional challenges of adolescence but also have special characteristics and needs due to their mathematically oriented and ambitious environment. The influence of the domain of mathematics on the development of mathematically gifted adolescents cannot be ignored.

## Discussion

All qualitative research should be subject to realistic reflection on its general reliability (Lincoln & Guba 1985). In this particular study, the use of triangulation of data collection increases the validity of the research. Nevertheless, a longer participatory observation could have offered more profound information on the social interactions of the students. Additional reliability was achieved by presenting the interviewees with the results of this study.

This research studied educators who possess particular experience in the context of Finnish education on teaching students who are recognised as gifted. Therefore its results differ from earlier studies on conceptions of giftedness of Finnish teachers (Tirri & Kuusisto, 2013; Laine et al., 2016). The interviewees of this study described giftedness as advanced performance and a modifiable characteristic of a student as well as of the whole school community. Finnish teachers tend to relate gifted students only with positive social-emotional characteristics, such as creativity and high level

of motivation (Laine et al., 2016). The interviewees of this study were prone to discuss also social-emotional challenges related to lives of the gifted adolescents. Still, the positive attitude to giftedness, enthusiasm for teaching and pride of their students were easily heard within the interviews. Research has also noted that the amount and especially the quality of cooperation with gifted students determines the teachers' conceptions of and approaches to giftedness (Kaya, 2015).

The concept of dissimilarity is widely included in definitions of giftedness as well as in the conceptions of giftedness commonly held by teachers. If someone is thought to be gifted, she is also seen as somehow, although often positively, different from others (Shani-Zinovich & Zeidner, 2009). In this research, the school was described as a meeting place for mathematically gifted students who are, in some way, different from many other adolescents. Therefore it is significant to understand the difference as a subjective experience of a gifted adolescent. Although the society, parents and teachers usually appreciate giftedness, exceptional talents often experience isolation within their age group (Gross, 2002; Rimm, 2002).

The organization and the curriculum of national school systems should meet the needs of every student including the gifted ones (Cross & Coleman, 2014; Kaya, 2015). The school investigated in this research does not represent a common high school in Finland. Neither does it reflect general Finnish attitudes toward special education of highly performing adolescents (Laine et al., 2016; Tirri & Kuusisto, 2013). A person's individual growth and particular social environment determine the social-emotional challenges of a mathematically gifted child instead of the mathematical giftedness per se (Wilson, 2015). Finnish teachers are highly qualified and skilled at differentiating learning contents both for fast and slow learners (Laine et al., 2016). However, this research shows that even the most devoted and competent teacher cannot replace the need of meeting, studying and making friends with other congenial peers. As a conclusion, when planning education for gifted students the social-emotional aspects of gifted education and the gifted students' need for meeting congenial adolescents should be considered.

# The qualitative differences in generative characteristic of the aesthetic sensibility: Analysis of learners' problem solving

Hayato Hanazono

University of Tsukuba, Graduate School of Comprehensive Human Sciences, Japan

[hanazono@human.tsukuba.ac.jp](mailto:hanazono@human.tsukuba.ac.jp)

*There are some discussions about the relationship between creativity and the aesthetic sensibility. It has been a characteristic of mathematician and mathematical gifted that the aesthetic sensibility has a generative characteristic. On the other hand, some studies demonstrated that the generative characteristic also was available even by the non-mathematician or non-mathematical gifted. The purpose of this paper is to clarify the process to produce qualitative differences in the generative characteristic of the aesthetic sensibility through the analysis of learners' problem solving. For this purpose, two pairs of high school students and one pair of college students were observed during problem solving. As a result, it was clarified that it is critical whether learners have their own goal other than the given one to evoke the generative characteristic. Moreover, it was suggested that the difference of one's own goal is associated with qualitative difference in the generative characteristic.*

*Keywords: Aesthetic, generative, creativity, problem solving, qualitative study.*

## Introduction

There are two directions for the term “mathematical creativity” used widely: extraordinary creativity, known as big C, or everyday creativity, known as little c (Sriraman, Haavold & Lee, 2014, p.110). Everyday creativity also is important for mathematics educators. Silver (1997) said,

Although creativity is often viewed as being associated with the notions of “genius” or exceptional ability, it can be productive for mathematics educators to view creativity instead as an orientation or disposition toward mathematical activity that can be fostered broadly in general school population. (Silver, 1997, p.75)

In today's national curriculum in Japan, developing *all* students' creativity is one of the objectives in high school mathematics education. So, this paper uses the term “mathematical creativity” or “creativity” as the meaning used by Silver: everyday creativity.

Since Poincaré (1908/2003) pointed the importance of the aesthetic sensibility in mathematical discovery, the interest in the relationship between creativity and the aesthetic sensibility has risen in the field of mathematics education. Some studies have claimed that the aesthetic sensibility is one of characteristics of mathematician or mathematical gifted student (Dreyfus & Eisenberg, 1986; Hardy, 1956/1992; Krutetskii, 1976; Poincaré, 1908/2003; Silver & Metzger, 1989). As the bases for such a claim, these studies had drawn attention to the process that the aesthetic sensibility worked (Dreyfus & Eisenberg, 1986; Krutetskii, 1976; Silver & Metzger, 1989). In particularly, Silver & Metzger concluded that there were several characteristics of aesthetic sensibility during mathematical problem solving only by mathematicians. On the other hand, other studies disagree with above claims in that general learner, non-mathematician or non-mathematical gifted student, can have the aesthetic sensibility and their aesthetic sensibilities have the similar characteristics with mathematician or mathematical gifted student (Papert, 1978; Sinclair, 2006a). These studies demonstrated that the

generative characteristic of the aesthetic sensibility, which works as a guide in decision making during mathematical discovery, could work in general learners' mathematical problem solving.

If the difference of such a characteristic is not due to the mathematical talent, the questions have remained unanswered what critical factor causing difference is or how such difference is caused. The purpose of this paper is to clarify the process to produce qualitative differences in the generative characteristic of the aesthetic sensibility through the analysis of general learners' problem solving.

## **Theoretical background**

### **The characteristics of the aesthetic sensibility in problem solving**

There is not a clear and widely accepted definition of the term “aesthetic” in mathematics education. Poincaré (1908/2003) explained using both the form of mathematical objects and the sense of the perceiver as following:

It is the harmony of the different parts, there symmetry, and their happy adjustment; it is, in a word, all that introduces order, all that gives them unity, that enables us to obtain a clear comprehension of the whole as well as of the parts. (Poincaré, 1908/2003, pp.30-31)

Hardy (1956/1992) and Dreyfus & Eisenberg (1986) defined it using subjective qualities like “economy”, “simplicity” and “surprise”. Without referring to its subjectivity, Hardy argued that mathematician would share them. In contrast to the above studies, Wells (1990) claimed that the aesthetic qualities are subjective and context-dependent.

On the other hand, some studies paid attention to the working process of the aesthetic sensibility, which is the ability to appreciate and respond to aesthetic qualities of mathematical objects, rather than strictly defining the term “aesthetic” (Papert, 1978; Silver & Metzger, 1989; Sinclair, 2006a, 2006b). Though claims about what the aesthetic is are various, the discussion about what characteristics the aesthetic sensibility have is a convergent as below. Papert (1978) was focused on the process of creation explained by Poincaré. Papert regarded the aesthetic widely and observed non-mathematicians' proving process. As a result, Papert concluded non-mathematician also could be guided by the aesthetic sensibility. Silver & Metzger (1989) classified the role of the aesthetic sensibility into two categories. First is “the guidance of decision making during problem solving” (p. 62). The viewpoint of this category can be regarded as the same as Papert's. Second is “the evaluation of the elegance of a completed solution” (p.62). In addition, Silver & Metzger observed mathematicians' problem solving and identified these roles in their problem solving. Similarly, Sinclair (2006b) classified characteristics of the aesthetic sensibility into three categories: the evaluative characteristic, the generative characteristic, the motivational characteristic. Moreover, Sinclair (2006a) observed learners' problem solving and problem posing and identified these characteristics of the aesthetic sensibility. Sinclair's generative characteristic and evaluative characteristic can be regarded as the same as Silver & Metzger's two roles.

The above results demonstrate that whether the aesthetic sensibility does work in problem solving is due not to only mathematical talent but also to something else. The existence of this “something else” is consistent with the claim of Papert. However, there has been not enough study done concerning this point. In particular, few studies have attempted to observe learners' generative characteristic of the aesthetic sensibility.

Based on the above background, this paper defines the generative characteristic of the aesthetic sensibility (GCA) as a guide in decision making during mathematical discovery, and clarifies the process to produce qualitative differences in the GCA.

#### **Four categories of the generative characteristic of the aesthetic sensibility.**

Poincaré (1908/2003) regarded the aesthetic sensibility as a thing working in the unconscious level. In contrast, some studies limited the discussion to the conscious level (e.g. Papert, 1978; Silver & Metzger, 1989; Sinclair, 2006a). This paper also limits a discussion to the conscious level.

Papert regarded reasoning without conviction or logic but with pleasure as “the problem of guidance” (p.109) by the aesthetic sensibility. Sinclair (2006b) associated such non-conviction reasoning to intuition as “capitalising on intuition” (p.94). Moreover, Sinclair (2006b) identified additional three categories of the GCA based on the mentions by mathematicians. First category is “playing with or ‘getting a feel for’ a situation” (p.94). This means exploration “in that the one playing is seeking to identify organizing themes and structures and to arrange the objects being played with in a meaningful, expressive way” (p.95). That is, it can be interpreted as pursuing these goals without depending on the goals of the given problem. Second category is “establishing intimacy” (p.94). This means, for example, to give a name to the considered subject. Third category is “enjoying the craft” (p.95). This is interpreted as consideration using mastered tools. Although the question remains whether it is reasonable that intuition is regarded as one of the aesthetic generating, this classification by Sinclair (2006b) can be used as viewpoints for extraction of the GCA from one’s behavior in problem solving.

#### **A study on the generative characteristic of the aesthetic sensibility in general learners’ problem solving**

##### **Participants**

Two pairs of high school students and a pair of college students, who had several mathematical knowledge and mathematical experience, were selected as participants, and observed during solving a problem. One pair of high school students belonged to 10<sup>th</sup> grade (Pair H1), another pair belonged to 11<sup>th</sup> grade (Pair H2). One of college students belonged to third year and another belonged to fourth year of mathematics teacher-training course (Pair C). Although they were all better than the average learners in Japan, they were not so good as mathematician or mathematical gifted student.

Pair H1 and Pair H2 belonged to the same high school in Japan. Pair H1 had learned double radical signs. However, they had learned about a particular type like  $\sqrt{3 + 2\sqrt{2}}$  which could be transformed into other form without a double radical sign. In addition, they had not learned the relationship between the roots and the coefficient of the quadratic equation. The other hand, Pair H2 had learned same type double radical signs with Pair H1. This pair had learned the relationship between the roots and the coefficient of the quadratic equation.

Pair C did not belong to the same high school with Pair H1 and Pair H2. They had learned double radical signs and the relationship between the roots and the coefficient of the quadratic equation. Although a student belonged to third year had never “studied” mathematics in college, another student belonged to fourth year had “studied” mathematics in college for a half year. So, fourth grade

student was expected to have experienced mathematical discovery and to show the experience in the process of problem solving.

### Procedure of the study

Because the GCA is “involved in the actual process of inquiry, in the discovery and the invention of solutions or ideas” (Sinclair, 2006b, p.93), participants were observed their problem solving behavior in following process.

Each pair calculated in order to clear some concrete double radical signs like  $\sqrt{3 + 2\sqrt{2}}$  as warm-up. Then, observer showed another type which cannot be cleared double radical signs like  $\sqrt{5 + 2\sqrt{2}}$ . After that, each pair solved a problem about an abstract double radical sign (it is shown below). After they finished to solve, they were interviewed about how to solve it.

In order to analyze verbal report during solving problem as data, participants were asked to solve a problem while consulting in pairs. By this setting, it was expected to provide simultaneous and nature verbal report. All participants’ verbal report was recorded on a IC recorder. (Only Pair H2 was recorded on a video camera, too.)

### A problem

In this study, a following problem was chosen.

Find the conditions for clearance of a double radical sign from  $\sqrt{p + 2\sqrt{q}}$ . However,  $p$  and  $q$  belongs in positive rational number. Moreover,  $q$  is not the square of rational number.

There are multiple conclusions in this problem as following. The participants were not informed what conditions were appropriate as the conclusion. Therefore, they were also asked value judgments for determining their finding as a conclusion. In contrast to that the multiple solution problems need participants to solve problem by more than one way — general learners usually do not so, such open-ended problems need participants’ value judgments more naturally.

(Conclusion 1): If a double radical sign can be transformed into following expression:

$$\sqrt{p + 2\sqrt{q}} = \sqrt{\alpha} + \sqrt{\beta},$$

then right side of above equation can be transformed into following expression:

$$\sqrt{\alpha} + \sqrt{\beta} = \sqrt{(\sqrt{\alpha} + \sqrt{\beta})^2} = \sqrt{\alpha + \beta + 2\sqrt{\alpha\beta}}.$$

From the above transformations, a necessary condition for clearance of a double radical sign from  $\sqrt{p + 2\sqrt{q}}$  is the existence of  $\alpha$  and  $\beta$  belonging to positive rational number such that  $p = \alpha + \beta$  and  $q = \alpha\beta$ . Conversely, if  $\alpha$  and  $\beta$  belonging to positive rational number such that  $p = \alpha + \beta$  and  $q = \alpha\beta$  exist, then the double radical sign of  $\sqrt{p + 2\sqrt{q}}$  can be clear as following:

$$\begin{aligned}\sqrt{p + 2\sqrt{q}} &= \sqrt{\alpha + \beta + 2\sqrt{\alpha\beta}} \\ &= \sqrt{(\sqrt{\alpha} + \sqrt{\beta})^2} = \sqrt{\alpha} + \sqrt{\beta}.\end{aligned}$$

(Conclusion 2): Existence of  $\alpha$  and  $\beta$  belonging to positive rational number such that  $p = \alpha + \beta$  and  $q = \alpha\beta$  is equivalence with that  $\alpha$  and  $\beta$  are the roots of the quadratic equation  $x^2 - px + q = 0$  in  $x$ . From this, the latter condition is also a conclusion of above problem.

In the following,  $D$  expresses the discriminant of the quadratic equation. If  $D = p^2 - 4q \geq 0$ , then

$$x = \frac{p \pm \sqrt{p^2 - 4q}}{2} > 0.$$

From this, if  $D$  can be expressed as the square of rational number like  $k^2$  ( $k \in \mathbb{Q}^+$ ), then  $x^2 - px + q = 0$  has positive rational roots in  $x$ . Conversely, if  $D$  can be expressed as  $k^2$  ( $k \in \mathbb{Q}, 0 < k < p$ ), then the two roots of quadratic equation  $x^2 - px + q = 0$  are

$$x = \frac{p \pm k}{2}.$$

These sum and product are

$$\frac{p+k}{2} + \frac{p-k}{2} = p, \quad \frac{p+k}{2} \times \frac{p-k}{2} = \frac{p^2 - k^2}{4} = \frac{4q}{4} = q.$$

From these,

$$\begin{aligned}\sqrt{p + 2\sqrt{q}} &= \sqrt{\frac{p+k}{2} + \frac{p-k}{2} + 2\sqrt{\frac{p+k}{2} \times \frac{p-k}{2}}} \\ &= \sqrt{\left(\sqrt{\frac{p+k}{2}} + \sqrt{\frac{p-k}{2}}\right)^2} = \sqrt{\frac{p+k}{2}} + \sqrt{\frac{p-k}{2}}.\end{aligned}$$

From above, if  $D$  can be expressed as  $k^2$  ( $k \in \mathbb{Q}, 0 < k < p$ ), then the double radical sign of  $\sqrt{p + 2\sqrt{q}}$  can be clear.

(Conclusion 3): Looking back at the conclusion 2 can provide next developmental conclusion. That is, the conditions for clearance of a double radical sign from  $\sqrt{p - 2\sqrt{q}}$  is that  $D$  can be expressed as  $k^2$  ( $k \in \mathbb{Q}, 0 < k < p$ ), too.

(Conclusion 4): Moreover, seeing  $4q$  as  $(2\sqrt{q})^2$  can provide another perspective. That is, if  $2\sqrt{q}$  in the  $\sqrt{p \pm 2\sqrt{q}}$  is replaced to  $\sqrt{q}$ , then a conclusion of finding the conditions for clearance of a double radical sign from  $\sqrt{p \pm \sqrt{q}}$  is that  $p^2 - q$  can be expressed as  $k^2$  ( $k \in \mathbb{Q}, 0 < k < p$ ).

## Results

Overview of three pairs' problem solving is shown in Table 1.

	Pair H1 (H1-1&H1-2)	Pair H2 (H2-1&H2-2)	Pair C (C1&C2)
Conclusion 1	04:00	H2-1 02:20/ H2-2 06:02	08:16
Conclusion 2	16:20	H2-1 05:37/ H2-2 06:59	
Conclusion 3, 4			
Finish	16:20	51:16	38:00

**Table 1: Overview of three pairs' problem solving**

In Table 1, each of the values show the time participants spent to get to the conclusion shown to far left, and diagonals show that participants did not arrive at the conclusion. Each participant of Pair H2 had got to the conclusion on their own before they started to consult each other. Therefore, each time of Pair H2 was shown in Table 1. Line of the "Finish" shows the time which each pair had spent solving problem. For instance, Pair H2 and Pair C kept pursuing more exact condition than their conclusion in cooperation each other. Solving process of each pair are as follows. However, the symbols used below are the same as those used by participants.

(Pair H1)

After confirming the question, each immediately got to the relationship:  $p = a + b, q = ab$ . H1-1 continued more investigations from the reason that " $p$  and  $q$  cannot be found when these are the large numbers. I want another one easily puts out with only  $p$  and  $q$ .", and continued for a further inquiry. In addition, H1-2 said "it is not good to use the new  $a$  and  $b$ ", and continued to explore. H1-1 associated the factorization from the above equation, and flashed that it will go well if he can factorize as following:  $x^2 + px + q = (x + a)(x + b)$ . H1-1 started to think about that H1-2 had been questioned: the case  $x^2 + px + q = 0$  has the rational solutions. H1-1 paid attention to the discriminant of the quadratic equation, but dismissed this idea. H1-1 dazzled that if the root in the quadratic formula could be clear, it will go well. H1-2 agreed this. They established conclusion that  $D = p^2 - 4q$  is square number, and finished the solving.

(Pair H2)

After confirming the question, H2-1 and H2-2 went ahead the discussion using a specific example. However, they did not use the peculiarities of example, generalized immediately once outlook was obtained. Up to this point, they worked on the problem at each, and got to a conclusion 2 through the conclusion 1. However, they had not been convinced that the condition they got was the one they sought for. When the observer was urged to check the progress of each other, they decided to consider in cooperation about the conditions with the  $p$  and  $q$ , which H2-1 had considered. H2-1 was looking for a simple conclusion than conclusion 2. Ultimately, they made out that  $D$  can be expressed as the square of rational number is necessary and sufficient condition for clearance of a double radical sign without deriving another "simple" conclusion.

(Pair C)

After confirming the question, C1 remembered following condition as a formula:  $p = a + b, q = ab$ . Then, they considered they could regard this formula as conclusion. They made sure that  $a \geq 0, b \geq 0$ , and could regard the formula as conclusion. By the "intervention" of the observer: asking them about example, they began to consider whether concrete double radical signs can be clear based on above "conclusion". C1 noticed that  $x, y$  were rational number when a double radical sign could be cleared, and he said, "I guess I should add another conditions". C2 considered that the example which could not be clear a double radical sign was really not able to clear through a specific calculation. As a result, they confirmed that it could not clear. In response to the results, they concluded as following:

Condition ( i ):  $p = a + b, q = ab$ .

Condition ( ii ):  $a \geq 0, b \geq 0$ .

Condition (iii):  $a, b$  are rational number.

### The analysis

The analysis was carried out in the following procedure. First, making transcripts of participant's problem solving process. Next, judging whether some of the four GCA proposed by Sinclair (2006b) can be seen through the observation of problem solving behavior and the interpretation of the intention of the behavior. The interpretation of the intention is based on the transcripts of the problem solving process and the explanations of their process that the participant did after solution. Finally, comparing the GCA of each pair. As a result, the GCA were seen as following Table 2.

the GCA	Pair H1	Pair H2	Pair C
Removing new symbols (for Conclusion 2)	○	○	
Pursuit of exactness (for Conclusion 2)		○	○
Pursue of simplicity (for other Conclusions)		○	

Table 2: The GCA of three pairs in problem solving process

### Discussion: The qualitative differences in the generative characteristic of the aesthetic sensibility

From a comparison of the three pairs, mainly three of qualitative differences in the GCA in problem solving were observed. First is the point whether they attempt to remove new symbols  $a$  and  $b$ . Both Pair H1 and Pair H2 discussed about this point, but Pair C did not. Second is the point whether they confirm the exactness of the conclusions. Pair H1 did not check it, and the remaining two pairs did. However, there was a difference in the method used by pair H2 and pair C. Pair H2 was showed exactness by considering that the found condition was necessary and sufficient condition. On the other hand, pair C confirmed the exactness by considering a concrete example. Third is the point whether they attempt to further improve the conclusion that  $D$  could be expressed as the square of rational number. This had done only pair H2. However, this pair could not obtain conclusion.

From above results, it can be presumed that the qualitative difference of the GCA in problem solving depends on participants' goal in problem solving. For instance, pair H1 wanted not only to find condition, but also find condition without new characters  $a$  and  $b$ . Pair H2 also had this goal, but pair C did not. As a result, only pair C did not pursue another conclusion. Therefore, in order to evoke the GCA it is critical whether learners have one's own goal other than the given one. In addition, even if

learners have same goal such as exactness, the difference in means of the “exactness” can cause qualitative differences of the GCA.

From above discussion, if we can make learners to have one’s own goal, it is possible that we can evoke learners’ GCA. However, it is not clear in this paper that what kind of goal is desirable for mathematical creation, and how can we make learners to have one’s own goal. Therefore, a further study of these points should be conducted.

## Identifying subgroups of CERME affect research papers

Markku S. Hannula and Enrique Garcia Moreno-Esteva

University of Helsinki; [markku.hannula@helsinki.fi](mailto:markku.hannula@helsinki.fi)

*Research in mathematics related affect uses a variety of theoretical frameworks. Three different dimensions have been suggested as significant to characterize concepts in this area: (1) emotional, motivational, and cognitive aspects of affect, (2) state and trait aspects of affect, and (3) physiological, psychological, and sociological level of theorizing affect. In this study, we used the information in reference lists and graph theory to identify Graph Communities (coherent clusters) of research papers published in the affect groups of CERME conferences. The four main Graph Communities identified in the analysis were Foundation (beliefs, attitudes, emotions), Self-Efficacy, Motivation, and Teacher Development. There were six smaller Graph Communities that may suggest emerging new frameworks: Academic Emotions, Metacognition, Teacher Beliefs, Resilience, Meaning, and Identity. These results suggest that of the three possible dimensions to structure the area, the distinction between cognition (beliefs), motivation, and emotions is the most important one.*

*Keywords: Affect, educational theories, graphs, literature reviews.*

### Introduction

The affect group in CERME has spent a lot of time and energy discussing the conceptual framework and terminology, leading to more extensive theorization of the area. Three theoretical frameworks have been especially influential in CERME for structuring the area of affect. The first is McLeod's 1992 framework that identified three main topics of research in mathematics related affect: emotions, attitudes, and beliefs. Moreover, the framework suggested that emotions are the most intensive, the least stable, and the least cognitive of the three, while beliefs are at the other end of the continuum and attitudes are in the middle.

An important synthesis of discussions in the group was Op 't Eynde's graphic representation of the conceptual field at CERME 5 (Hannula, Op 't Eynde, Schlöglmann & Wedege, 2007, Figure 1). This model identifies some new constructs that had been then discussed in CERME affect group: most importantly, the model identifies motivation as a dimension separate from affect, and meta-affective constructs. Moreover, the model highlights the local (classroom) and socio-historical contexts.

The model was discussed and developed by Hannula in his CERME plenary (2011) and further elaborated in the CERME special issue of RME (2012). This cube model (Figure 2) identified three dimensions that are relevant when discussing affective constructs. The first dimension addresses cognitive, affective, and motivational types of constructs. The second dimension separates the rapidly changing state-type constructs and more stable trait-type constructs. The third dimension identifies three levels of theorizing affect: psychological, social and embodied theories.

These distinctions identify separate research areas of mathematical affect. But how separate are they? Do the studies on attitudes, emotions, and beliefs form three separate research traditions or even 18 separate research areas, as Hannula's cube model suggests? Perhaps the studies on state and trait type affects are separate? Or are the different topic areas partially overlapping with diffuse borders, as Op 't Eynde's figure depicts it?

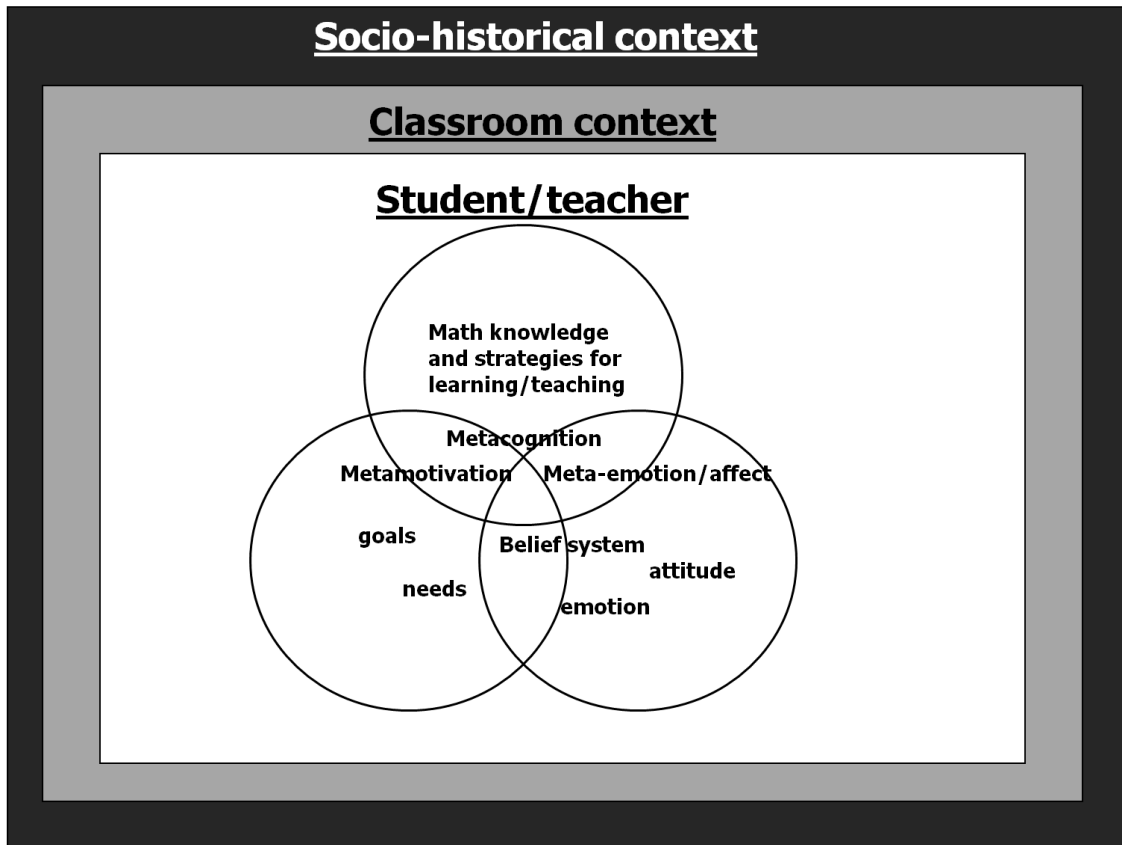

Figure 1. A graphic representation of the different dimensions of mathematics-related affect and their relationships, presented at CERME 5 (Hannula et al., 2007, p. 204)

Figure 2. Hannula's (2011; 2012) cube model of the three dimensions for affective constructs

One way to analyze the question empirically is to analyze the references different research papers share. We are aware that there is a lot of cross-referencing between authors of CERME affect papers and that there are some fundamental articles that keep being cited often. However, there has not yet been any systematic analysis on the cohesion of the research papers. We are going to make a network

analysis of CERME papers in this research area. With this analysis we can identify whether there are some clusters of different research traditions within the CERME affect group. Moreover, we expect to identify important foundation works for each research tradition.

Our research questions are: (1) What possible subgroups can we identify among CERME research papers on affect when analyzing the cited authors of each paper? (2) What are the defining characteristics of each subgroup of papers?

## **Methods**

### **Corpus and measures**

Our corpus for analysis were the 100 research reports published in the affect groups in CERME conferences four to nine. The first two CERME conferences did not have an affect group and CERME3 one was left out because of some difficulties in the formatting that we did not have time to solve. We excluded from our analysis affect papers published in other groups, for example in groups of teacher beliefs or comparative studies.

Knowing the CERME publications in affect group, we knew that some authors had published papers that might fall into different research traditions. For example, many researchers have published papers both on teacher affect and student affect, and it could be possible that these fields would be empirically separate clusters. Therefore, we decided to search for clusters of papers published in CERME rather than identifying clusters of researchers.

When analyzing the lists of references, we had two basic options to identify links between papers. We could identify whether the same reference appeared in the reference lists of two papers, or we could link them whenever they had papers by the same author in their lists of references. Because our data corpus was modest in size, there was high probability that papers using the same theoretical framework might not share the same exact references even if they use papers by the same authors. Therefore, we decided to use the authors in the reference lists rather than the exact references as the method of connecting papers.

As a conclusion, our data consisted of research reports published in the proceedings and the authors appearing in their reference lists. For each of the papers, we created a connecting link from the paper to each of the authors mentioned in the references. For analyzing the connections between papers, we identified CERME papers and cited authors as vertices of a graph. Edges of the graph are the links that connected each CERME paper with the authors mentioned in the list of references, allowing multiple edges when a paper had several references by the same author. Hence, we produced a graph connecting all papers to their cited authors and this was then subjected to a mathematical analysis.

### **Analysis**

The analysis included two stages: (1) To identify Graph Communities, and (2) to identify commonalities within the papers and authors of the selected Graph Communities.

We identified related papers using the FindGraphCommunities algorithm with modularity-based clustering to identify how papers and cited authors are related (Wolfram Alpha LCC, 2016). The modularity approach was originally developed by Newman and Girvan (2004) and the algorithm used in Wolfram Alpha is based on Fortunato's article (2010).

The input for the algorithm was the graph connecting research reports to authors cited in these papers. The output was subgraphs called Graph Communities, each of which consisted of some of the research reports and authors. The algorithm chooses only one Graph Community for each of the graph's vertices. In other words, although the same author may originally appear in the reference lists of papers from many graph communities, in these subgraphs each cited author belongs exclusively to one Graph Community. This accentuates the differences between Graph Communities, especially with respect to those authors who are cited in papers in several communities. In addition, we are aware that the current method does give additional weight to authors cited several times in a paper.

The next stage of analysis was to identify which Graph Communities to include in further analysis. This stage was based on a visual inspection of Graph Communities to see how well they are connected. The five biggest Graph Communities are presented as graphs (Figures 3 – 6), all affect papers published in CERME are represented as vertices with multiple edges. However, authors may have either one or multiple edges, depending on how many times they appeared in references. Another six Graph Communities are described but due to space limitation their graphs are not presented.

In the last stage of the analysis, we examined which papers and authors were represented in each of the Graph Communities.

## Results

The algorithm identified 21 Graph Communities. We shall describe nine of them.

The first Graph Community 1 (29 papers; Figure 3) we call *Foundation*. It was the largest and the most cited authors in it included arguably the most influential researchers in the area of mathematical affect: McLeod (e.g. 1992), Schoenfeld (e.g. 1992) and Goldin (e.g. 2002). The most frequently cited authors in Foundation were active participants of CERME affect group: Hannula, Zan, Pehkonen, and Di Martino. Foundation is perhaps the most difficult to describe and may be best done by contrasting it with other Graph Communities. The Foundation's papers represent a large scope of research topics and theoretical frameworks, including papers that focus on beliefs, attitude, affect during problem solving, and emotions. This group also contains several papers that deal with dynamically changing affective states.

The second Graph Community (11 papers, Figure 4,) was given the label *Self-efficacy*. It had papers mostly from Cyprus and Turkey (e.g. Arslan & Bulut, 2015). The shared theoretical framework of self-efficacy was indicated by numerous references to Pajares and Bandura.

The third Graph Community (11 papers, Figure 5) we named *Motivation*. Philippou and Pantziara were influential authors in this Graph Community. Seven of the papers included at least one of them as the author (e.g. Pantziara & Philippou, 2011). Also Wæge appeared three times in this group as an author. This group shared motivation theory framework, and the most cited authors were well-known motivation theorists Midgley, Deci, Ryan, Pintrich, and Elliot.

**Figure 3. The Graph Community Foundation**

**Figure 4. The Graph Community Self-Efficacy**

The Fourth Graph Community (8 papers, Figure 6) collected together papers on *Teacher Development*. Liljedahl was an important author in this group with four papers and the most cited authors include Liljedahl and Ball.

**Figure 5. The Graph Community Motivation    Figure 6. The Graph Community Teacher Development**

The following six Graph Communities were smaller, each including 3 to 5 papers. Due to space limitations, these will be described only briefly. The four papers in *Academic Emotions* share Pekrun's (e.g. Pekrun, Goetz, Titz, & Perry, 2002) academic emotions framework and all these papers have been published in CERME8 or CERME9. All four papers in *Metacognition* were authored by Panaoura (citing e.g. Flavell, 1987). *Teacher Beliefs* had three papers from CERME8, citing, e.g. Fives & Buehl (2008). *Resilience* included 5 loosely connected papers without any frequently cited author. *Meaning* (citing e.g. Skovsmose, 2005) included four papers, and *Identity* (citing, e.g. Sfard & Prusak, 2005) four papers.

The remaining 14 Graph Communities included one or two papers each, altogether 16 papers. Nine of these papers were by authors who have ever published only once in the CERME affect group. Yet, these included also papers by frequent CERME participants (e.g. Hannula and Philippou).

## Discussion

The analysis identified nine groups of CERME affect publications. Their defining features were a shared theoretical framework and often a research team. The largest group, Foundation, did not hold a theoretical framework clearly separating it from other groups. Rather, this group seemed to rely

more on the seminal works in the field of mathematics related affect and cover a variety of research topics indicating that there is much cohesion in this research field.

How much are these identified groups of papers determined by having the same authors? Most researchers with several papers in the analysis had most of their papers in a single community and only Philippou appears in three different Graph Communities. Often, having publications in different Graph Communities seems to be explained by supervisors co-authoring their students' papers that may often have quite different theoretical frameworks than their own papers.

The current method did not allow overlapping of Graph Communities, which made it difficult to identify possible authors who have a cross-cutting importance across several graph communities. However, looking at the total numbers of citations across all Graph Communities we found some such authors. The clearest examples were Ernest, who was cited 12 times in total, but not more than four times in any Graph Community, and Mason, who was cited 10 times but not more than twice in any Graph Community. Also, most authors described above as defining a Graph Community are cited in many papers of other communities. This suggests that results might identify groups more clearly, if we defined connections through specific cited research papers rather than cited authors. However, our current corpus might not be sufficiently large for that kind of analysis. Such analysis would be recommended when using a data corpus of at least a few thousand articles.

There are some methodological issues that we are aware of. We realized that summaries of the affect group from the previous CERME proceedings were cited often, inflating the number of citations by their authors. A more fundamental question is, that we have no measure for the reliability of The Graph Community analysis. With the current data corpus, our first analysis included an error that excluded 11 of the 100 papers. This was enough to produce a significantly different result: A subgroup of Foundation papers (Pehkonen and his students) was identified as a separate Graph Community and Teacher Development was not identified as a Graph Community. This suggests that the results of the analysis are quite sensitive to changes in data.

The first author of this paper has published several synthesizing articles on research in mathematics related affect. Using the graph analysis was an attempt to overcome possible personal biases in perceiving the structure of the research area. Our method of connecting CERME publications by authors appearing in their lists of references seems to have worked. It confirmed research on motivation research as a specific research domain. The analysis also identified specific research traditions on self-efficacy and academic emotions. While earlier reviews (e.g. Hannula, 2011), identified beliefs and emotions as two areas within mathematics-related affect, the current analysis identified research on beliefs in three different groups: Foundation, Self-Efficacy, and Teacher Beliefs. Similarly, the current analysis identified Academic Emotions as separate group while most emotion papers were part of Foundation. These results suggest that in the Hannula (2011; 2012) model, the distinction between cognition (beliefs), motivation, and emotions is the most important one. On the other hand, one small Graph Community, Identity, can be considered to be characterized by its theoretical background being sociological. A possible new characterizing feature for research could be focus on the dynamics of change, exemplified by the research traditions Teacher Development and Resilience.

# Tracing mathematics-related belief change in teacher education programs

Çiğdem Haser<sup>1</sup> and Işıl İşler<sup>2</sup>

<sup>1</sup>Middle East Technical University, Turkey; [chaser@metu.edu.tr](mailto:chaser@metu.edu.tr)

<sup>2</sup>Middle East Technical University, Turkey; [iisler@metu.edu.tr](mailto:iisler@metu.edu.tr)

*Understanding mathematics related belief change in teacher education programs has been a concern due to the information it presents about the effectiveness of program experiences. The present study investigated how preservice mathematics teachers' (PMTs) mathematics related beliefs changed through a teacher education program by implementing a belief scale to a cohort of PMTs 12 times during 6 consecutive semesters. Comparison of mean scores for different time periods showed that the cumulative effect of the teacher education program is more detectable than year-long or semester-long effects. While such implementation is likely to provide a perspective for monitoring belief change and possible effects of courses, it might also address that the contents of the courses should be connected to ensure the best cumulative effect of the programs.*

*Keywords: Mathematics related beliefs, preservice mathematics teachers, tracing beliefs.*

## Beliefs and teacher education programs

Training teachers with knowledge, skills, and disposition to practice the reform-oriented teaching has been a major goal for teacher education programs as teachers are the key to the success of the reforms aiming constructivist and student-centred mathematics instruction at schools (Handal & Herrington, 2003). Hence, initiating and strengthening mathematics related beliefs parallel to the reform movements have been a concern for teacher education programs (Raymond, 1997). This study aimed to identify possible key courses and experiences in teacher education programs that influence PMTs' beliefs by monitoring the changes in beliefs for three years in a four-year middle grades mathematics education program. The other aim is to gain perspective on the information that continuous monitoring of beliefs can provide. We adopted the identification of beliefs which Muis (2004) used for students' mathematics related beliefs and considered PMTs' beliefs as *availing* if they had the potential to help PMTs to achieve the reform-oriented goals of the teacher education program and middle school mathematics curriculum, and *nonavailing* otherwise.

Preservice teachers generally start teacher education programs by nonavailing mathematics-related beliefs (Szydlik, Szydlik, & Benson, 2003) for their learning in the program. Although programs aim to initiate and strengthen availing beliefs to reach program outcomes and teach through reform when PMTs become teachers, availing beliefs are initiated and developed to a limited extent (Clift & Brady, 2005). However, nonavailing beliefs are carried to the student teaching and teaching profession and they influence teachers' practices and implementation of reform principles in classrooms (Szydlik, et al., 2003). Therefore, teacher educators face the challenge of understanding PMTs' beliefs in the beginning of programs and organize tasks and experiences to develop and strengthen the availing beliefs (Swars, Smith, Smith, & Hart, 2009). This requires monitoring PMTs' beliefs throughout programs and the possible influence of program experiences.

Several studies investigated the effects of teacher education program experiences on PMTs' mathematics related beliefs mostly by emphasizing a single course or set of courses such as the methods courses and student teaching. These studies have shown that course experiences had limited effect in terms of the extent and the duration of the developed beliefs (Szydlik, et al., 2003). Longitudinal studies which documented changes in PMT beliefs through a set of courses are rare. Swars, et al. (2009) investigated 24 preservice elementary teachers' mathematics teaching and self-efficacy beliefs, mathematics anxiety and specialized content knowledge through 3 semesters of a 4-semester teacher preparation program. They implemented the belief instruments at the beginning and end of the 2<sup>nd</sup> semester (1<sup>st</sup> methods course), at the end of the 3<sup>rd</sup> (2<sup>nd</sup> methods course) and 4<sup>th</sup> (student teaching) semesters. The analysis showed that preservice teachers' scores significantly increased after the 1<sup>st</sup> methods course, decreased non-significantly at the end of the 2<sup>nd</sup> methods course, and significantly decreased at the end of student teaching. Yet, there was a significant increase from the 1<sup>st</sup> implementation to the 4<sup>th</sup> showing that preservice teachers gained more cognitively aligned beliefs (as targeted by the program) at the end of the 4 semesters.

The present study attempted to trace PMTs' beliefs through a teacher education program beginning from the semester they were enrolled in the initial pedagogical content knowledge courses (beginning of the 3<sup>rd</sup> semester) until they graduated (end of the 8<sup>th</sup> semester). PMT beliefs were monitored by implementing a belief instrument for 12 times in 6 consecutive semesters. In this paper, we report and discuss the changes based on timing of the implementation through the following research questions: (1) How do PMTs' mathematics related beliefs change through the 2<sup>nd</sup>, 3<sup>rd</sup>, and the 4<sup>th</sup> year of a 4-year mathematics teacher education program (a) in the long term (between academic years and throughout the three years); (b) in the short term (within the academic years)? (2) What kind of information does timing of belief instrument implementation offer about mathematics related belief change for teacher educators?

## Method

A longitudinal survey design was employed and data were collected from the same group of PMTs for 6 consecutive semesters to capture the possible changes in their mathematics related beliefs.

### Participants and context

Turkish education system is centralized at the national level with national curricula implemented at all grade levels at all contents. All students have to take a national examination at the end of high school to attend 4-year degree programs at universities including teacher education programs. The context of the study was a four-year middle grades (grades 6-8) mathematics teacher education program (EME) at a Turkish public university. EME program had three mathematics education faculty members at the time of the study and was placed under the Department of Elementary Education with 10 faculty members. The program had mathematics courses offered by the Department of Mathematics in the first four semesters. Mathematics education courses started in the 3<sup>rd</sup> semester and were offered by the program faculty and pedagogical courses were offered by the Department of Educational Sciences. The participants of the study were a total of 33 female and 10 male PMTs who started the EME program in 2006, referred here as the "cohort".

EME program started in 1998, was renewed in 2006 and the cohort was the first to study the renewed program. The changes in the EME programs were due to a major constructivist curriculum reform in

the national mathematics curriculum in Turkey in 2005. Previous EME program offered a mandatory minor degree in science education which was removed in the renewed program. School Experience course in the 2<sup>nd</sup> semester and Textbook Analysis course in the 8<sup>th</sup> semester were removed, and 1-semester Methods of Teaching Mathematics course was renewed as a 2-semester course, which allowed the dense content be covered in more time and depth. Methods of teaching course content was combined with curriculum issues content in a new course. Two new courses on research methods and nature of mathematical knowledge, and two statistics courses from the Department of Statistics were added to the renewed program. Mathematics courses, field experience courses in the 7<sup>th</sup> and 8<sup>th</sup> semesters and most pedagogical courses were maintained. The previous program experiences were based on constructivist approaches, however, the renewed program provided more opportunities for widened and deepened experiences for PMTs.

Two studies investigated the belief change in the previous EME program. Haser and Star (2009) conducted a cross-sectionally longitudinal study through interviews with 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup> year PMTs. Their findings revealed that PMTs' mathematics related beliefs did not change much throughout the program. However, methods of teaching mathematics course provided PMTs a different understanding of teaching and learning mathematics, which they did not experience in their pre-college education. Haser and Doğan (2012) investigated how mathematics related beliefs differed among PMTs in different year levels. They first surveyed a total of 100 PMTs who were at the beginning of the 2<sup>nd</sup>, 3<sup>rd</sup> and the 4<sup>th</sup> year. Their analysis showed that PMTs who just started the 4<sup>th</sup> year in the program had significantly higher belief scores. Then, they focused on the effect of the general methods of teaching course in the 3<sup>rd</sup> year of the program on PMTs' beliefs.

The major changes in the EME program and the opportunity to monitor the 2006 cohort from the semester they started to take courses from the Department enabled us trace the possible influence of the renewed EME program experiences on PMTs' mathematics related beliefs.

### **Data collection instrument**

The belief scale used in this study was developed and used in the previous study (Haser & Doğan, 2012) in order to investigate Turkish PMTs' beliefs about the nature of mathematics and teaching and learning mathematics. Mathematics-related belief scale (MBS) included 38 five-point Likert type items asking PMTs' agreement with belief statements with responses ranging from totally disagree (1) to totally agree (5). Higher scores in MBS indicated existence of more availing mathematics related beliefs. Some of the MBS items are as follows: "Problem solving should be used as a teaching method within mathematics education", "The aim of mathematics education is to obtain correct answer by using the ways previously shown in the course" and "Visual and concrete materials are used in order to set up an environment for students to investigate their ideas". The Cronbach's alpha coefficient for MBS was calculated as .85 in the earlier study.

### **Data collection and analysis**

MBS was implemented for 12 times at the beginning and the end of each semester in the 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup> year in one of the courses PMTs attended. However, the number of PMTs who took the MBS in each implementation varied due to the number of PMTs present at the implementation time. PMTs completed the MBS in about 15 minutes in each implementation.

Data were analysed to investigate both long-term and short-term changes in mean MBS scores, therefore, separate analyses were conducted. Long-term changes were investigated by comparing mean MBS scores of PMTs in the beginning of 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup> year, and at the end of 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup> year by one-way repeated measures ANOVA. Mean MBS scores in the beginning of 2<sup>nd</sup> year and at the end of 4<sup>th</sup> year were compared through paired-samples t-test. Short-term changes were investigated by comparing PMTs' mean MBS scores at the beginning and the end of each year and semester by paired-samples t-test. Cronbach's alpha coefficient was calculated for each implementation and ranged between .74 and .95.

## Results

The results are presented for long-term and short-term changes. First, for long-term changes, beginning of 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> year scores were compared to see the belief change based on the 2<sup>nd</sup> and 3<sup>rd</sup> year experiences. Then, end of 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> year scores were compared to see the change after 3<sup>rd</sup> and 4<sup>th</sup> year experiences. When there is a significant change in the MBS scores, it is interpreted as the effect of the EME program. MBS scores at the beginning of 2<sup>nd</sup> year and end of 4<sup>th</sup> year were compared to see the cumulative effect of the 3 years in the program. "Cumulative effect" refers to the effect of all program experiences until the mentioned implementation. Short-term changes were explored by comparing beginning of year/semester scores to end of year/semester scores. The aim was to detect possible influence of course experiences on PMT beliefs. The comparisons helped us discuss the information that the timing of the implementation might provide.

### Long-term changes

In order to identify possible change in PMTs' beliefs at the beginning of the academic years through the program a one-way repeated measures ANOVA was conducted to compare scores on MBS at the Time 1 (beginning of the 2<sup>nd</sup> year), Time 2 (beginning of the 3<sup>rd</sup> year) and Time 3 (beginning of the 4<sup>th</sup> year). A total of 19 PMTs were common at all Time 1, Time 2, and Time 3 of MBS implementation. The means and standard deviations are presented in Table 1.

Time (beginning of year)	N	M	SD
Time 1 (beginning of the 2 <sup>nd</sup> year)	19	3.81	.237
Time 2 (beginning of the 3 <sup>rd</sup> year)	19	4.00	.246
Time 3 (beginning of the 4 <sup>th</sup> year)	19	4.08	.318

**Table 1: Descriptive statistics for PMTs' MBS scores at the beginning of the 2<sup>nd</sup>, 3<sup>rd</sup> and 4<sup>th</sup> years**

There was a significant effect for time, [Wilk's Lambda = .550,  $F(2, 36) = 10.379$ ,  $p < .05$ , multivariate partial eta squared = .366]. Pairwise post-hoc comparisons with Bonferroni adjustment ( $p < .05$ ) showed that there was a significant mean difference between Time 1 and Time 2, and Time 1 and Time 3. The difference between Time 1 (beginning of 2<sup>nd</sup> year) and Time 2 (beginning of 3<sup>rd</sup> year) indicated that 2<sup>nd</sup> year experiences in the EME program had a significant effect on PMTs' mathematics related beliefs. Similarly, the difference between Time 1 (beginning of 2<sup>nd</sup> year) and Time 3 (beginning of 4<sup>th</sup> year) indicated that a possible cumulative of 2<sup>nd</sup> and 3<sup>rd</sup> year experiences in the EME program had a significant impact on PMTs' mathematics related beliefs.

We wanted to explore if the effect of the program differed for academic years through the program when the program experiences were rather recent for the PMTs by conducting another one-way repeated measures ANOVA to compare mean scores on MBS at the end of the academic years as Time 4 (end of the 2<sup>nd</sup> year), Time 5 (end of the 3<sup>rd</sup> year) and Time 6 (end of the 4<sup>th</sup> year). A total of 21 PMTs were common at all Time 4, Time 5, and Time 6 implementations of MBS. The means and standard deviations are presented in Table 2.

Time (end of year)	N	M	SD
Time 4 (end of the 2 <sup>nd</sup> year)	21	3.86	.197
Time 5 (end of the 3 <sup>rd</sup> year)	21	4.03	.251
Time 6 (end of the 4 <sup>th</sup> year)	21	4.01	.239

**Table 2: Descriptive statistics for PMTs' MBS scores at the end of the 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup> years**

There was a significant effect for time [Wilk's Lambda = .543,  $F(2, 40) = 5.919$ ,  $p < .05$ , multivariate partial eta squared = .228]. Pairwise post-hoc comparisons with Bonferroni adjustment ( $p < .05$ ) showed that there was a significant difference between Time 4 and Time 5, and Time 4 and Time 6. The difference between Time 4 (end of 2<sup>nd</sup> year) and Time 5 (end of 3<sup>rd</sup> year) indicated that 3<sup>rd</sup> year experiences in the EME program had a significant impact on PMTs' mathematics related beliefs. Similarly, the difference between Time 4 (end of 2<sup>nd</sup> year) and Time 6 (end of 4<sup>th</sup> year) indicated that a possible cumulative of 3<sup>rd</sup> and 4<sup>th</sup> year experiences in the EME program had a significant effect on PMTs' mathematics related beliefs. There was no significant difference between Time 5 (end of 3<sup>rd</sup> year) and Time 6 (end of 4<sup>th</sup> year), which might indicate that the 4<sup>th</sup> year experiences did not have a significant effect on PMTs' beliefs. Indeed, mean MBS scores were slightly lower at Time 6.

The effect of the teacher education courses through the three years of the program was investigated by comparing the MBS scores between Time 1 (beginning of 2<sup>nd</sup> year) and Time 6 (end of 4<sup>th</sup> year) by a paired-samples t-test. A total of 25 PMTs were administered the MBS at Time 1 and Time 6. There was a statistically significant increase in mean MBS scores from the beginning of 2<sup>nd</sup> year ( $M = 3.76$ ,  $SD = .174$ ) to the end of 4<sup>th</sup> year ( $M = 4.05$ ,  $SD = .235$ ),  $t(24) = 5.868$ ,  $p < .001$  (two-tailed). The eta squared statistics (.59) indicated a very large effect size. This showed that a possible cumulative of 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup> year experiences in the EME program had a significant effect on the mathematics-related beliefs of PMTs.

### Short-term changes

Three paired-samples t-tests were conducted to investigate the possible effects of year-long experiences on PMTs' mean MBS scores by comparing the beginning-of-year and end-of-year scores for each year. Table 3 presents paired-samples t-test results and the number of PMTs who were common for in both implementations of MBS for each year.

Year	N	Paired-samples t-test results
2	27	No significant difference between the beginning ( $M = 3.82$ , $SD = .256$ ) and end of 2 <sup>nd</sup> year ( $M = 3.88$ , $SD = .222$ ), $t(26) = 1.035$ , $p > .05$ (two-tailed).
3	25	<u>Statistically significant increase</u> from the beginning ( $M = 3.93$ , $SD = .230$ ) to the end of 3 <sup>rd</sup> year ( $M = 4.07$ , $SD = .262$ ), $t(24) = 2.755$ , $p < .05$ (two-tailed). The eta squared statistic (.24) indicated a large effect size.
4	27	No significant difference between the beginning ( $M = 4.07$ , $SD = .302$ ) and end of 4 <sup>th</sup> year ( $M = 4.05$ , $SD = .240$ ), $t(26) = -.381$ , $p > .05$ (two-tailed).

**Table 3: Paired-samples t-test results for MBS scores and the number of PMTs for each year**

Comparisons of beginning-of-year and end-of-year mean MBS scores showed that only 3<sup>rd</sup> year experiences had a significant effect on PMTs' MBS scores. The scores did not significantly change from the beginning to the end of the 2<sup>nd</sup> and 4<sup>th</sup> year of the program. However, the mean MBS scores increased in each implementation until the beginning of the 4<sup>th</sup> year.

A series of paired-samples t-tests were conducted to investigate the possible effects of semester experiences by comparing the PMTs' mean MBS scores at the beginning and end of the semester for each semester. Table 4 presents paired-samples t-test results and the number of PMTs who were common in both implementations of MBS for each semester.

Semester	N	Paired-samples t-test results
3	29	<u>Statistically significant increase</u> from the beginning ( $M = 3.83$ , $SD = .216$ ) to the end of the semester ( $M = 3.95$ , $SD = .246$ ), $t(28) = 3.027$ , $p < .01$ (two-tailed). The eta squared statistic (.25) indicated a large effect size.
4	26	No significant difference between the beginning ( $M = 3.86$ , $SD = .233$ ) and end of the semester ( $M = 3.92$ , $SD = .211$ ), $t(25) = -1.849$ , $p > .05$ (two-tailed).
5	28	No significant difference between the beginning ( $M = 3.96$ , $SD = .225$ ) and end of the semester ( $M = 4.00$ , $SD = .259$ ), $t(27) = -.973$ , $p > .05$ (two-tailed).
6	32	No significant difference between the beginning ( $M = 4.02$ , $SD = .230$ ) and end of the semester ( $M = 4.05$ , $SD = .263$ ), $t(31) = -1.041$ , $p > .05$ (two-tailed).
7	32	No significant difference between the beginning ( $M = 4.07$ , $SD = .284$ ) and end of the semester ( $M = 4.05$ , $SD = .271$ ), $t(31) = -.747$ , $p > .05$ (two-tailed).
8	26	No significant difference between the beginning ( $M = 4.06$ , $SD = .253$ ) and end of the semester ( $M = 4.03$ , $SD = .244$ ), $t(25) = .656$ , $p > .05$ (two-tailed).

**Table 4: Paired-samples t-test results for MBS scores and the number of PMTs for each semester**

Results showed that semester-long changes in mean MBS scores were not significant except for the 3<sup>rd</sup> semester, while mean MBS scores generally increased at the beginning each semester.

## Summary of the analyses and information given by the timing of implementation

Analyses showed that there was a general trend of increase from the beginning of the 2<sup>nd</sup> year to the end of the 4<sup>th</sup> year of the EME program with slight decrease in the 4<sup>th</sup> year. This increase was significant for long-term comparisons and showed that EME program courses and experiences seemed to help PMTs develop or strengthen availing beliefs through the years.

When the analyses focused on short-term differences, the increase in mean MBS scores was not statistically significant in most of the comparisons. The comparison of mean MBS scores for the beginning and end of each academic year revealed significant increase only for the 3<sup>rd</sup> year of the program. On the other hand, semester-long comparisons of mean MBS scores addressed significant results only for the 3<sup>rd</sup> semester. These results showed that belief change might not always be significantly detectable in shorter periods. PMTs might not fully internalize course experiences only in one semester. The significance of the 3<sup>rd</sup> semester comparisons might show us that the first course on mathematics education was effective on beliefs, probably because it included methods of teaching PMTs had never experienced. The significance of the 3<sup>rd</sup> year comparisons pointed the effect of the 2-semester Methods of Mathematics Teaching courses, whose effects on preservice teachers' beliefs have often been investigated in the literature. Indeed, studies conducted in the previous program showed that courses on methods of teaching and mathematics teaching have influenced PMTs' beliefs in a more availing way (Haser & Doğan, 2012; Haser & Star, 2009). Although the decrease in MBS scores from the beginning of the 4<sup>th</sup> year to the end was not significant, it might signal for the rather undesired effect of the student teaching experiences on soon-to-be-teacher PMTs' beliefs due to the reality of classroom environment, differences in students, and lack of support from program instructors at the classrooms (Swars et al., 2009). These findings showed that detecting belief change for shorter time periods provided rather limited knowledge, but it raised issues about the effects of the program experiences for semesters or years.

The analyses reported here were conducted based on the number of common PMTs in the analysed implementations. When we compared the mean MBS scores at each point of time to the mean scores in the repeated measures ANOVA (Table 1 and Table 2) as well as the paired-samples t-tests (Table 3 and Table 4), we observed minor mean score differences between the mean scores of the PMTs who were common across the implementations and all the PMTs who were administered the survey at that implementation. These results are not given here due to space limitation. Hence, we concluded that missing cases did not impact the results of the study. Yet, it should be kept in mind that the analyses were not conducted with all PMTs for all implementations.

In summary, the results of the analyses showed that change in PMTs' mathematics-related beliefs were more detectable when the change was investigated in the long-term, throughout the program. The nature of the increase in MBS mean scores suggested a cumulative effect of the program as PMTs progressed. The short-term investigations did not give much significant results, yet they might give us clue about how courses might influence PMTs' beliefs. The significant results have addressed the possible influences of certain courses that should be investigated in detail.

## Discussion

The long-term and short-term change analyses results showed that while PMTs seemed to benefit from program experiences and develop more availing beliefs through the years in the program, 3<sup>rd</sup>

year experiences seemed to contribute to the belief change the most. Course experiences were not investigated in-depth in this study, therefore how PMTs made sense of these experiences and how these experiences helped them in forming rather availing beliefs were remained unexplored in this study.

The results suggest that teacher educators should investigate change in beliefs through the teacher education programs in different ways. The first teaching related course in the program, methods of mathematics teaching courses, and student teaching courses might have relatively more weight (either positive or negative) within the cumulative effect of the teacher education programs. Considering the significant cumulative effect of the program, it is possible that this cumulative effect might get stronger when the program experiences are meaningfully related to each other to support the availing beliefs and related practices.

*The purpose of the present study was to investigate whether teaching self-regulation strategies via “Solve it” to students with learning disabilities could affect their problem-solving performance in mathematics. The mathematical problems involved four mathematical operations with natural and decimal numbers. Also, the present study investigated the effect of “Solve it” instruction on students’ self-efficacy and value related to mathematics. It was a single-subject design with a pre-test, four repeated post-tests and a maintenance test. The results indicated that the students’ problem-solving performance was improved and their self-efficacy and value attributed to mathematics were increased.*

**Keywords:** *Self-regulation strategies, mathematical problem solving, LD, self-efficacy, value.*

## Introduction

Learning how to solve mathematical problems plays the most important role in the promotion of mathematical thinking. Mathematical problem solving process is especially complex as it requires the use of cognitive and metacognitive strategies as well as emotional management in case of a failure (Freeman-Green, O’Brien, Wood & Hitt, 2015; Rosenzweig, Krawec & Montague, 2011). Some researchers argue that many students with LDs face difficulties in solving mathematical problems due to their deficits in metacognitive processes, such as prediction and evaluation as well as difficulties in using metacognitive strategies in order to monitor and control their learning (Babakhani, 2011; Rosenzweig et al., 2011). A recent learning approach that combines the selection and use of cognitive and metacognitive strategies, motivation for learning and successful control of emotions is called *self-regulated learning* (Wirth & Leutner, 2008).

This paper is part of a larger study which was conducted for the requirements of a Master’s Degree and explores whether teaching self-regulation strategies with the program “Solve it” can influence problem-solving performance of students with LDs. This program includes the use of seven cognitive strategies and three metacognitive strategies. In this paper, it was investigated if the use of seven cognitive strategies and three metacognitive strategies in combination with self-assessment which plays the role of motivation to students can improve problem-solving performance of two students with LDs in order to reach the mastery criterion of the program. In addition, it was explored if teaching problem solving process with these strategies can affect these students’ self-efficacy and value attributed to mathematics. Also, the study tried to shed further light on the metacognitive and self-regulated learning processes and their interplay with motivation in students with LDs in mathematics.

## Theoretical framework and research questions

It is accepted that learning how to solve mathematical problems plays the most important role in the promotion of mathematical thinking. According to van Garderen & Montague (2003, p. 246)

mathematical problems are challenging problems set in realistic contexts that require understanding, analysis, and interpretation. They are not simply computational tasks embedded in words; instead, they require appropriate selection of strategies and decisions that lead to logical solutions.

Over the last 20 years, a new approach called self-regulated learning has been developed aiming among others at improving problem solving skills. This approach has been successfully implemented in developing problem solving skills as it examines metacognitive, motivational and affective aspects of problem solving activity. A lot of researchers have tried to define the composite construct of self-regulated learning (Wirth & Leutner, 2008). Self-regulated learning is defined as

a learner's competence to autonomously plan, execute and evaluate learning processes, which involves continuous decisions on cognitive, motivational, and behavioural aspects of the cyclic process of learning. (Wirth & Leutner, 2008, p. 103)

Research reveals that many students and especially students with LDs in both primary and secondary education face difficulties in solving mathematical word problems (Rosenzweig et al., 2011). Before proceeding to the description of these difficulties, a definition of the term "learning disabilities" should be provided. Under the Individuals with Disabilities Education Act of 2004 (IDEA), the federal law that protects students with disabilities, a specific learning disability is defined as

a disorder in one or more of the basic psychological processes involved in understanding or in using language, spoken or written, that may manifest itself in an imperfect ability to listen, think, speak, read, write, spell, or to do mathematical calculations, including conditions such as perceptual disabilities, brain injury, minimal brain dysfunction, dyslexia, and developmental aphasia. The term does not include learning problems that are primarily the result of visual, hearing, or motor disabilities, of mental retardation, of emotional disturbance, or of environmental, cultural, or economic disadvantage. (34 C.F.R.300.7[c][10])

These students have difficulties in using metacognitive strategies in order to monitor and control their learning (Babakhani, 2011; Rosenzweig et al., 2011).

International contemporary research has shown that teaching self-regulated learning strategies is associated with the improvement of problem solving performance of students with LDs (Babakhani, 2011; Freeman-Green et al., 2015). A self-regulation program that has been successfully implemented in interventions in order to improve problem solving performance of students with LDs is called "Solve it" (Montague, 1992). This program was introduced by Montague (1992) and it combines the use of three self-regulation strategies: self-instruction, self-questioning and self-monitoring with the following four major instructional techniques: problem solving assessment, explicit instruction of problem solving strategies, process modeling and performance feedback. The program includes the following seven cognitive strategies which correspond to seven instruction phases (Read, Paraphrase, Visualize, Hypothesize, Estimate, Compute and Check). Each of these strategies, **including** three self-regulation strategies: self-instruction, self-questioning and self-monitoring are taught. These strategies rely heavily on metacognitive processes. "Self-instruction implies telling oneself what to do before and while performing actions" (Montague, Warger & Morgan, 2000, p.111). "Self-questioning means asking oneself questions while engaged in an activity to stay on task, regulate performance and verify accuracy" (Montague et al., 2000, p.111). "Self-monitoring requires the

problem-solver to make certain that everything is done correctly throughout the problem-solving process” (Montague et al., 2000, p.111).

The “Solve it” program includes seven instruction phases and it is separated into eight lessons (Montague et al., 2000). Lesson one includes an overview of “Solve it” and a description of the cognitive strategies. In lesson two students are tested for the mastery of seven cognitive strategies. Lessons three, four and five include metacognitive strategy instruction and students solve one mathematical problem in each lesson. For example, for the cognitive strategy “Reading” there were three self-regulation strategies that had to be implemented (SAY, ASK, CHECK). The students said to themselves “Read the problem. If I don’t understand, read it again.”, asked themselves “Have I read and understood the problem?” and checked by saying “Check for understanding as I solve the problem”. The criteria for moving to lesson six are three: remembering cognitive strategies, remembering metacognitive strategies (SAY, ASK, CHECK) and solving problems with relevant confidence. In lesson six, students solve ten mathematical problems and they can consult the diagram with the strategies which had been given to them in lesson one and think aloud. Each problem-solving process is modeled by the students or by the teacher after it has been solved. Lesson seven requires the students to solve all 10 problems before modeling the correct solutions for the problems. Lesson eight is the first Progress Check (test of ten problems). Students plot their “grade” on their performance graph and then model the solutions. From then on there will be more tests and students will plot their performance. Student progress graphs show whether students can make constant progress and move toward mastery. It is important to engage students in assessing their own progress by having them chart their performance in diagrams which motivate them to continue trying (motivation) (Montague et al., 2000). The mastery criterion of the program, which is the ultimate goal, is solving 7 out of 10 problems correct on four consecutive tests (Montague et al., 2000).

It should be noted that this program is more frequently used in secondary education (students with and without LDs) with great success (Montague, 1992; Montague, Krawec, Enders & Dietz, 2014) for solving one-, two- and three-step problems with natural and decimal numbers but as Montague (1992) states, this program can be used with younger students provided that adaptations should be made in processes and materials. In the studies where the program was implemented with younger students, they did not manage the mastery criterion as there were no adaptations. As the participants of this study were sixth grade students of an elementary school, some adaptations regarding “Solve it” were required in order to manage the mastery criterion of “Solve it”. In addition, acronyms were used for the description of the strategies in order to be remembered by the students. The acronyms came from the first letter of each strategy in Greek language. Furthermore, it should be noted that there is no clear exploration of the effects of teaching self-regulation strategies via “Solve it” to LD students’ self-efficacy sense and value attributed to mathematics so this is the novelty of this study.

Consequently, the purpose of this study was to investigate whether teaching self-regulation strategies with “Solve it” could affect students’ with LD mathematical problem solving performance, their mathematics self-efficacy and value. Therefore, the following 4 research questions were stated as follows: 1) Will sixth grade students with LDs improve their mathematical problem solving performance in problems with four mathematical operations with natural and decimal numbers after the implementation of “Solve it”? 2) Will students’ self-efficacy related to mathematics and problem solving activity change after the implementation of the intervention? 3) Will students’ value attributed

to mathematics and problem solving activity change after the implementation of the intervention? 4) Will students with LDs maintain their improved performance one month after the intervention with “Solve it”?

## Method

The present study was a single-subject design as two students with LDs participated in the study. In addition, an experimental design with one experimental group (two students with LDs) was implemented. A pre-test and four repeated post-tests took place. One month after the last post-test, a maintenance test was implemented. In this experimental design, the independent variable was the intervention with the program “Solve it” and the dependent variables were the following three: mathematical problem solving performance, self-efficacy in relation to mathematics and the value which was attributed to this school subject.

## Participants

Two students (a male and a female) with LDs took part in the present study. The students were identified as having learning disabilities based on psychoeducational evaluations from an outside state agency. Specifically, the boy encountered specific learning disabilities of dyslexic type and speech problems and the girl learning disabilities in reading, writing and mathematics. Both students were studying in the 6th grade of an elementary school, in North-West Greece and they had difficulties in mathematical calculations and mathematical problem-solving. Moreover, they attended the subjects of Mathematics and Greek Language in a general education classroom and they additionally received resource room support on these subjects from a special education teacher. Parental consent was given for both participating students.

The students’ teacher (first researcher) taught the self-regulation strategies. The teacher implemented “Solve it”, designed the tests with the mathematical problems, administered and collected the questionnaires. The teacher was 25 years old female and she had met the children six months before the beginning of the intervention. She had completed her practicum with these children in the context of earning Master’s Degree so she had already been acquainted with the students and that was the reason why they were selected to be the sample of the study.

## Procedure

The intervention of the present study began in November 2015 and finished in December 2015. The maintenance test was implemented on 15<sup>th</sup> January 2016. The boy attended 18 sessions and the girl 23 sessions that lasted 35-40 minutes. One week before the beginning of the intervention, the pre-test was implemented. The pre-test included 10 one-, two- and three-step word problems (Montague et al., 2000). Also, the two students responded to the 2 questionnaires assessing mathematics self-efficacy and value attributed to mathematics. Afterwards, “Solve it” intervention began and included 8 lessons. The 8<sup>th</sup> lesson was the first progress check (post-test) and three additional posttests followed. In the last post-test, students responded again to the two questionnaires on mathematics self-efficacy and value. Additionally, as it was mentioned previously, an adaptation took place. Specifically, for the better interpretation of the strategies, the strategies were visualized. Specifically, each of the seven cognitive strategies was displayed with words and small pictures that showed the steps of action implied by the strategy. For example, the strategy “Read” was presented verbally, in a diagram and with this icon. 

## Data collection

The mathematical problem solving performance was measured with tests which were designed by the researcher by following the suggestions offered by the creator of “Solve it”. Each test included 10 mathematical one-, two- and three-step word problems which were based on the mathematical problems that students had been taught in their classroom (e.g. two-step word problem: ‘Nick wants to buy three car-miniatures. Each of them costs 3.6€. He has already collected 8€. How much money does he need in order to buy them?’).

Despite the small number of participants, quantitative methods for the data collection regarding self-efficacy and value were used, as the time for the completion of the intervention was limited and the school principal could not give extra teaching hours for an interview. However, some verbal questions were done for clarifications of some of the students’ answers in the questionnaires. The data concerning self-efficacy regarding mathematics learning were collected with the use of a questionnaire. The questionnaire was developed by Dermitzaki and Efklides (2002) and assessed students’ reported self-efficacy in mathematics with 5 items (e.g. ‘I believe I will have a better mathematical problem-solving performance this year’). Answers were given on a five-point scale from 1-‘Not at all true for me’ to 5-‘Totally true for me’. Because of the students’ difficulties in reading comprehension, the questions were being read by the researcher and students were asked to circle the answer that was true for them. After the completion of the questionnaires, the students were verbally asked some questions in order to clarify some of their answers (“mini interview” for clarifications). These answers were written down by the teacher-researcher at the same time.

The data regarding value which was attributed to mathematics and mathematical problem solving were also collected with the use of a questionnaire which was made by the researcher based on Ames’ scale (1983). This scale assessed students’ value beliefs about mathematics as a school subject. The questionnaire included 3 items (e.g. ‘Learning how to solve mathematical problems is....’) and the answers were given on a five-point scale from 1-‘Not at all important’ to 5-‘Highly important’. Each question was asked verbally by the researcher and the students had to circle the answer that was true for them. After the completion of the questionnaire, the students were asked to clarify some of their answers (“mini interview” for clarifications) which were written down by the teacher-researcher at the same time.

## Data analysis

The quantitative data that were collected from the tests were not statistically analyzed because of the small data number. However, a diagrammatical representation with Microsoft Office Excel 2010 was made. The quantitative data that were collected from the two questionnaires and mini-interviews were qualitatively analyzed. Because of the small number of questionnaires, a statistical analysis could not take place. The careful data reading and the description of the data had as a result two categories deriving from each questionnaire. Two categories were developed based on the first questionnaire. The first category included self-efficacy regarding mathematics and the second included self-efficacy regarding a problem solving activity. Similarly, two categories were derived from the second questionnaire. The first category included value attributed to mathematics and the second category included value attributed to a problem solving activity.

## Results

Regarding to the first research question, the progress graph showed that both students' mathematical problem solving performance improved significantly. Specifically, the boy increased his performance from 2.6/10 on pre-test to 9.65/10 on the first post-test and the girl increased her performance from 0.5/10 on pre-test to 7.89/10 on the first post test. Additionally, both students achieved the criterion of solving at least 7 out of 10 word problems correct on four consecutive word problem tests which is the ultimate goal of "Solve it" according to Montague et al. (2000).

Concerning the second research question, the results showed that both students increased their self-efficacy regarding mathematics and mathematical problem solving activity. The boy reported that he was feeling a little efficacious in solving mathematical problems and towards mathematics before the beginning of the intervention. However, he reported that he felt very efficacious about solving mathematical problems and confident towards mathematics after the end of the intervention. The girl reported that she felt a little efficacious about mathematics and very efficacious about solving mathematical problems before the intervention. When the researcher asked her while she was completing the questionnaire "Why do you think that you will be more efficacious in solving mathematical problems?", she answered "I will read more, I will attend carefully the lessons and I will learn how to solve mathematical problems. " After the intervention, she reported that she felt very efficacious about mathematics and solving mathematical problems.

Additionally, both students attributed important value to mathematics and to the problem solving activity after the intervention with "Solve it". The boy reported that both mathematics as a school subject and problem-solving as a mathematical activity were of little importance for his life before the intervention. After the intervention, he thought that mathematics was highly important and problem solving was very important for his life. The girl attributed very important value to mathematics but she thought that solving mathematical problems was not an important activity for her life before the intervention. When the teacher asked her while she was completing the questionnaire "Why mathematics is very important for you?", she answered "Because learning the multiplication table is very important for our lives". After the intervention, she thought that both mathematics and problem solving activity were highly important for her life.

It should be underlined that both students expressed that they had developed more positive emotions such as happiness, when they solved mathematical problems after the intervention. That happened because according to them, they felt safety with the use of the strategies as the last ones had proved to be very helpful in order to solve a mathematical problem.

Finally, regarding the fourth research question, both students maintained their improved performance on the maintenance test one month after the intervention. The score for the boy was 9.6/10 and for the girl 9.05/10. It seems that the girl not only maintained her performance but also improved it more in relation to the last post-test. This finding has not been found in other studies.

## Discussion

This study aimed to investigate whether teaching self-regulation strategies via "Solve it" affected students' with LDs mathematics problem-solving performance, their maths self-efficacy and reported value of maths. The results of the present study are very encouraging. In agreement with other studies (Babakhani, 2011; Montague, 1992; Montague et al., 2014) both students' mathematical problem

solving performance was considerably improved. Also, they seemed to achieve the ultimate goal of “Solve it” (7 out of 10 problems correct on four consecutive tests). This was a surprisingly good result as there was not such a result in other studies which used “Solve it” with elementary school students. As Montague (1992) states, the sixth grade students have not easily reached the mastery criterion. However, in this study students appeared to maintain this performance on the maintenance test a short while after; maybe as the result of the visualization.

Furthermore, both students reported increased self-efficacy in relation to mathematics as a school subject and in relation to problem solving activity. Additionally, both students attributed higher value to mathematics as a school subject and to problem solving activity after the intervention. As Chatzistamatiou, Dermitzaki, Efklides & Leondari (2015) state, there is a positive relationship between the use of self-regulation strategies and self-efficacy and between the use of these strategies and value attributed to mathematics by typically developing students.

Although, the effect of teaching self-regulation strategies on students’ emotions regarding problem-solving activity was not examined in this study, it is important to mention that both students reported they felt happier when they solved mathematical problems after the intervention with “Solve it”. More particularly, the boy said “Now I do not feel so stressed when my teacher tells me to solve a mathematical problem and I feel happy when I do it, even if I cannot find the solution”. A future research could examine in more depth whether and how self-regulation strategies could influence students’ emotions during problem-solving activity.

In conclusion, this study showed that “Solve it” can improve problem-solving performance not only in older but also in younger students with LDs provided that some adaptations will take place. Furthermore, “Solve it” seemed to affect positively students’ self-efficacy and value attributed to mathematics. However, there are some limitations such as the limited generalizability of the results (case study), the different characteristics of the two students, the short time in which the study was carried out and the absence of a control group. Future studies could use “Solve it” in other mathematical domains such as geometry which students with LDs find quite challenging and difficult. In addition, a future study could test how teaching self-regulation strategies would influence LD students’ emotions in relation to mathematics. Such data would be actually illuminative for educational research and practice.

# To err is human. The management and emotional implications of teacher error

Elizabeth Lake

UCL Institute of Education and UEA, UK

[Elizabeth.lake@ucl.ac.uk](mailto:Elizabeth.lake@ucl.ac.uk)

*Research into errors in mathematics classrooms is often centred on student error. Whilst investigating teacher emotional expressions, using data from experienced teachers and affective pathways, I encountered examples of teacher mathematical error occurring in association with expressed emotions. Similarly, I have observed instances of new teachers making errors and hence have begun exploring the implications of teacher error management. In this paper, after describing illustrative examples, I suggest a model based on a continuum of affectively driven strategies that are likely to be familiar to secondary mathematics teachers. Each affectively driven strategy has implications for teacher student relationships and for the learning of mathematics. I discuss some of these implications in terms of longer term affective impact on classroom climate and for students. I offer the model for further discussion in relation to developing growth mindsets.*

## Introduction

There is no doubt that we all make errors and human instinct is to avoid errors as unpleasant experiences. Yet brain analysis research suggests error, however unpleasant, is essential for effective learning; for creating neural connections. Moser et al. (2011) through studying the neural mechanisms when making numerical mistakes shows that this activity fires synapses. There seem to be two synaptic responses. Firstly, when the brain experiences conflict, without awareness, there is an increase in electrical activity. Secondly, brain signals act to draw conscious attention to the error. Conflict (such as recognising an error), also triggers emotions which means making a mistake triggers an observable emotional response. The emotions may be exaggerated as error provides not only a trigger for emotions, but also requires the person experiencing the error to engage in some form of minimising or regulation. Such a positive view of errors is supported by Boaler (2015) and others who suggest we should go further than just avoiding error; that errors should be attended to as part of addressing misconceptions and hence are necessary for learning. In mathematics teaching errors can take many forms, often numerical. Boaler suggests creating a culture where students are comfortable with handling error is beneficial for learning mathematics. Such a culture depends not only on how a teacher addresses student error, but also on how they model addressing their own errors. There seem to be international and cultural differences that merit discussion in terms of how errors are seen and addressed by teachers, from commonly using error as a teaching tool through to avoiding errors and associated discussion as damaging to self-esteem (Santagata, 2005).

Researchers investigating error focus on teacher responses to student error, and a few explore how students respond to teacher error (e.g. Borasi, 1987, Heinze, 2005; Ingram, 2014b; Santagata, 2005; Steuer et al., 2013; Tainio & Laine, 2015). There is less research on the role of error or how teacher error management occurs in the classrooms of experienced teachers. If error triggers an emotional

response, this has implications for classroom relationships and for students who may not notice error. This is important in mathematics as there are perhaps, more opportunities for error.

The definition of ‘error’ used here, interchangeable with ‘mistake’, is that error is a mismatch. A mistake demarcates the distinction between norms (such as usual behaviours) and a deviation (Borasi, 1987), (the unexpected or different) thereby defining what is false and what is correct (Heinze, 2005). Using the classic constructivist definition of emotion as a response evoked by recognition of a disparity (Mandler, 1989), it seems error cannot occur without an emotional association. This association implies that patterns of individual emotions in mistake situations is indicative of classroom culture. For this reason, Steuer et al. (2013) asked students about their teacher’s handling of mistakes. In addition to identifying ‘mistakes friendly’ environments, they found that perceived mistakes friendly environment resulted in increased effort. Yet as recently as 2014, research suggests that UK teachers still predominantly give the message that errors are to be avoided, often through a variety of teaching strategies that rarely indicate an incorrect solution. “These strategies all give the interactional message that errors are to be avoided, or that errors are undesirable even when the teacher does not explicitly say this, or in fact explicitly states the opposite” (Ingram et al., 2014, p.40). In terms of beliefs, a teacher’s stance on error may be revealed by their response to incorrect answers, but more indicative is their response to public revealing of their own errors. Such responses model expected emotional responses to error for that class. Tainio and Laine (2015) consider this in relation to emotional contagion where “Emotional contagion means that in interactions, emotions are usually shared by participants after one participant has offered public forms of emotion for others to attend to” (p.84). Further, students will mimic or synchronise (Hatfield, 1994) with their teacher’s publically expressed affective pathway. According to Goldin (2000), people experience a series of emotions as they pass through the process of problem solving in mathematics. The result is an error climate. Steuer et al. (2013) see what I refer to as affective pathways as a predominantly positive (adaptive reaction) or negative (maladaptive) patterning which, if public, means displaying certain emotions enhances learning.

Primarily, an adaptive reaction pattern is distinguished from a maladaptive pattern: An adaptive reaction pattern following errors and failure maintains learning motivation and functional affects such as joy; a maladaptive pattern decreases learning motivation and increases feelings of shame and hopelessness. (Steuer et al., 2013, p.197)

Examples of transcript and identified affective pathways (Table 1 & 2) from the classrooms of experienced teachers (> 10 years) illustrate encountering and managing of error. I examine the data from the lens of *affective pathways* (Goldin, 2000) as a potentially useful model to examine the illustrative examples. A pathway structures the interpreted emotional journey by labelling emotions from identifying a problem through to either resolution or abandonment. Examining teacher modelling of how to deal with error in conjunction with how a teacher emotionally manages error may assist in interpreting the affective impression given to students. Mandler (1989) suggests that using and modelling emotional responses to error inculcates a tolerance for error that benefits learning mathematics. How a teacher frames the handling and recovery from error can shape student experiences, and indicated preferred attitudes to error management (Santagata, 2005) especially if we consider error as a stimulus to action (Borasi, 1987).

It seems we need errors to learn, whilst teachers can support learning and affect classroom environments by modelling positive responses to error. The question addressed here is whether developing a model of error management examining how teachers model error is useful. To address this question, the data presented below is from a larger study on teacher expressions of emotion in the classroom. Both extracts are drawn from episodes of emotional expression, deemed as such through observation, measurement of galvanic skin response (GSR), (used to roughly indicate internal emotions) and confirmed in post observation discussions. They represent how experienced teachers might manage error. Other strategies, such as used by novice teachers, are drawn from the literature, collaborated by my own experience of working with teachers.

### Modelling dealing with mathematical error (Adam and Bertha)

In these examples, both Adam and Bertha successfully address a small numerical error, one type of mathematical error. Both express emotions (the dominant emotion is determined by the observer, using standard emotion classifications (Scherer, 2005)), yet differ in pathway from recognising discrepancy to resolution, showing the teachers' disparate ways of modelling error management.

In the first example (Table 1), Adam accidentally writes 2 for the difference between 4.5 and 3.5 when demonstrating upper and lower bounds for  $5 - 4$ . As he reads the four possible answers aloud, '2,0,2,1', he slows, quietens his voice and movements, pauses with pen poised, whilst his head moves from side to side scanning. He then steps back and looks, appearing absorbed. Once he has identified the error, he utters the sound 'uhh', interpreted as 'never mind'. He then engages in an exchange of silly noises with a student, corrects the error, rewards a student who is quick to align, and continues in a faster pace, as at the start of the episode, quickly moving on from the error.

T	You can either do for 5..., 4.5 or 5.5, they're your two options, because that's the lower and the upper bound. So what I have written out on the board is all four different combinations of what can happen.	Confident
	Ok... [pause]	Uneasy
	I'm going to work out all of them. So I am going to get 2, 0, 2, 1. [GSR PEAK]	ERROR
S1	Blast-off...	
S2	It should be 1.5	
	Right, think about this. [pauses]	Confused
	The question was saying upper bound, the upper bound for 5 minus 4. That number is going to be as big as possible. [emphasis and shift in pace into regular time beat 1- and-2- and-3- and-4-] <div style="display: flex; justify-content: space-around; border: 1px solid black; padding: 2px;"> <span>as</span> <span>big</span> <span>as</span> <span>Pos-si-ble</span> </div>	Re-establishing certainty Interested
	Hm. [Pause with pen ready, his head moves as scans writing and then steps back] Looks like 2. [Pause] ... Which 2 is it going to be? Well here... [pauses again, this is in a quieter voice]	Doubt Uncertainty Thoughtful
	Oh, that's right, I've done that wrong, that should be 1, uhh, [faster pace resumed]	Satisfaction
	Who picked up on that? [HANDS UP] Chris [S3]? Gold star[smiling]	Pleased
S2	How about me? Oh. Uh	
	Uh	Humorous
S2	Uh I said one though sir	
	Sorry, that's a 1. The biggest number is 2. How did I get 2? I took the biggest number possible here for 5, but the smallest number possible for 4. That made the difference-as-big-as-possible. 2. [firmly stated] Upper bound.	Confident

**Table 1: Affective Pathway from Adam's lesson, where he makes an error**

Bertha uses a well-known mathematics website to produce questions on the area of a circle (Table 2). Following the students finding the area for a given radius, Bertha enters a volunteered answer, but the website rejects this answer. As Bertha has already calculated the answer herself, agreeing with the student, the website rejection brings an unforeseen problem; she thinks she has made an error but has not. The discrepancy is between using  $\pi$  or 3.14, so it relates to the degree of accuracy.

S1	254.46 [student is providing answer to question on the board]	
T	.46	Neutral
S2	I've got .34 [Different answer which legitimises other students who also have different answer and they start calling out as well]	
T	Ok. Whoa, whoa, whoa, whoa, whoa.	Uneasy
	Does anybody disagree with the 254 bit?	Neutral
Many	No, yes, [some hands up]	
T	NO? Right. Can anybody think of a reason...	Neutral
	...Oh, I don't think if we can... yeah, we have. [GSR PEAK]	Uncertain
	Can anybody think of a reason why you might have different, very slightly different answers? [Terry among others raises his hand] Terry...	Confident
Terry	Is it because like one of us...um...were like... we weren't... um.... I don't know if it's right or....	
T	[Frowning]Well just, Terry, just say it, have more confidence in yourself sweetheart...	Hopeful
Terry	...some people pressed the... the pi button and some people didn't.	
T	Absolutely brilliant, well done you.	Pleased
	That's exactly right.	Satisfied
	When you press the pi button on your calculator, it uses a really accurate version of Pi. If you just put in um... 3.14, [writing something on wall behind teacher desk] then that's not so accurate...	Neutral
	...and that's the only reason.	Satisfied
	But anyway, it's coming up and telling us we're wrong.	Uneasy
	So, it says use the area of the square, we've got the area of the square as 9x9, and then multiply it by 3.14... [Does this on a calculator]	Neutral
S2	It's 254.34	
S4	Error	
T	... 3.14 .... (yeah) 254.34 ....	Satisfied
Many	Yes!	
S4	Error	
T	...2...5...4....point... oh I see, point 3 4. Let's try it again [enters answer which is shown on the projector] Yeah!	Confused to satisfied
ALL	Yeah!	
T	OK	Satisfaction

**Table 2: Affective Pathway from Bertha's lesson, where she makes an error**

## A proposed model of teacher error

Drawing attention to teacher error informs discussions about how such error should and could be managed, as this is not the same as when a student makes an error. Firstly, that there are emotional implications of the choices made by a teacher, including the degree of emotional labour required. Secondly, that the choices are indicative of how a teacher perceives error, both for themselves and for their students. And thirdly, that repeated over time, modelling by the teacher of error management sets the climate for students in terms of their own error management. If it is desirable to challenge behaviourist views of learning mathematics (Boaler, 2015), then discussion of error management provides an accessible route to address teacher beliefs. To support such discussions, the following continuum of error management strategies is proposed. This is derived from both the literature on error and the above data. The continuum moves from negative (associated with a mistake unfriendly environment and maladaptive error patterns) through to positive, and similarly from strategies with perceived reduced benefits, through to those which may have longer term positive impact for learning (mistakes friendly environment and adaptive patterns).

To compare and contrast with the examples above, I draw from research on and observations of trainee teachers. In this cohort, I observed embarrassment at making an error, ignoring the error, even when noticed, and errors on the whiteboard left uncorrected. I also observed surreptitious correcting when the students were engaged in another task. There is ample anecdotal and observable evidence that teachers hide numerical errors. They may later notice and leave it, or notice and amend privately. The communicated message is that errors are dispreferred (Ingram et al., 2014), and should be hidden. Similarly, public error can evoke teacher embarrassment or be corrected rapidly, where the teacher ‘steps out of’ rather than ‘stepping into’ learning through addressing the error. ‘Stepping out’ attaches a negative emotional association to error making. A teacher may respond to revealed error by faking, as in “I meant to do that” and publically amend. Although positive in avoiding misunderstanding resulting from the error, this choice can be negative emotionally, in that frequent repetition erodes trust in the teacher. A further response is to associate self with the error through self-depreciation. A teacher might say something like, ‘What a silly error!’ The effect may be that students view all error as silly, and to be laughed at. This may be positive or negative as context specific, but students may reduce contributions if they feel they may be laughed at.

There are suggestions in the literature on error that using deliberate error as a teaching strategy can be effective. This assumes a constructivist view, that the place of error is a learning opportunity, rather than a culturally located behaviourist view, that errors should be avoided (Santagata, 2005). In constructivist terms, viewing error as a learning opportunity is an ideal, yet how a mathematics teacher might cultivate such an ethos needs further research. Research from Ingram et al. (2014) found examples aimed at this ethos, but that in most cases the errors are still managed as something to be avoided. They identify a role for further strategies when positioning error in this way. They suggest either distancing self from the error since the purpose is for students not to make the same errors themselves, or apologising for an error. A more positive management might dismiss the error, but go on to associate with an emotionally positive outcome, such as thanking the student for pointing out the error. The emotional message is that criticism will not follow from error identification. However, taking the error handling strategy further, the identification may be made into an event through provoking a discussion, or may be acted out. There are many possible options, such as

expecting error due to rapid engagement in doing mathematics or that error is just to be expected. The event could show that corrections are fine, that corrections are neither good or bad, and are just a learning opportunity. The attribution of value to the error communicates a positive message.

In the examples from Adam and Bertha there is a mixture of the above that tend to the emotionally positive end of the continuum. What was not apparent either in the examples of data collection was a view that ‘I never make mistakes’. Although both examples are public, Adam notices his own error as part of the next step, whilst Bertha’s attention is claimed by rejection of her answer by an online website. What may be significant is the emotion work in both cases to turn the event to a positive learning experience. As for similar examples from Tainio & Laine (2015), the teachers take affective stances that display affiliation and humour (p.73). They also evoke emotionally positive responses for the students. Both show happiness in resolution of error, and give praise albeit located differently.

Bertha tells in a later interview of an occasion when a formal observation that went wrong because the questions on the website changed. A repeat experience, when again being observed, albeit for research purposes, is likely to re-evoke emotions associated with insecurity, and a need to check solutions with a form of authority, in this case the website answer. Modelling a need for accuracy, for rechecking, reinforces a product orientated ‘feel’ in the example, where correctness takes precedence. There is also modelling of internal thought processes. In Bertha’s case public thinking out-loud for self, “[muttering quietly] ...2...5...4...point...oh. I see, point 34. Let’s try it again.” Possibly this indicates Bertha seeking mathematical correctness. This corresponds with what she says in interview,

I don't see myself as a mathematician. I see myself as someone who is good at maths and you can teach me anything in maths and eventually get it, which does again sounds obnoxious but that's...you know... it might take me a lot longer with some of the things. (Bertha)

Seeking confirmation of correctness perhaps indicates a belief that ‘real’ mathematicians do not make errors. This example shows an intention to model what she thinks a teacher should be doing, indicating a disparity between real and aim more commensurate with trainee teachers. In contrast, Adam models shifting ownership of error by repositioning from ‘we’ to ‘I’, modelling that gives an impression that it is ok to err. He positively manages the error, moving sequentially from a point of uncertainty into exhibiting positive emotions using humour via exchanging noises and giving praise, which acts to restore lesson balance. His modelling of how to deal with error includes distraction of attention and shifting attention via assigning a social reward for correction of error. In the episode, the error becomes an object unassigned, before it is quickly shifted into a positive outcome. As an observer, it felt as if he was pinning the error somewhere distant from self. However, he included students in his happiness at resolving the error, and hence was rewarded. Either interpretation is a modelling that downplays error. As he says afterwards,

Oh, yeah, did I put a mistake on the board to start off with? (Yeah) Yeah...I’m not fussed with that. It happens quite a lot. I always say to the students... I’ll make mistakes, and they’ll make mistakes...and there it goes...(Adam)

Both teachers seem to experience cognitive conflict, observable in the lesson as uncertainty, and resolve the error for themselves. They both resolve positively for their students, stepping into the error again as part of positive modelling. The data confirms that it is not the error itself but how it is

managed that has implications. Public teacher error has more impact, whereas perhaps students are expected to make errors. Underlying the difference between the examples and trainee teachers lie the issues of confidence and risk with the subsequent implications to learning climate of handling error after and during public exposure. We assume that expert teachers have confidence, but the examples show that the use of emotions is part of the restorative process, perhaps as a distraction. This seems to warrant further investigation, as does the disparity between the expert (who makes no mistakes) and Adam's declared and enacted position on error. Mandler (1989) suggests emotions activate other mental contents to deal with situations perceived as being a mismatch between what is intended and what occurs.

## Conclusion and implications

In the above I have used two short episodes to illustrate teacher error management, since the research suggests that modelling of error responses plays an important role in construction of positive emotional climates in a mathematics classroom. Based on this initially small sample, the use of affective pathways seems to support exploration of the adaptive/maladaptive reaction patterns. There may be potential in exploring adaptive patterns with teachers as part of professional development. It may also be useful, in conjunction with ideas such as positive mindsets (Boaler, 2014), to consider how students might participate in error management to a greater degree, for example as springboards as suggested by Borasi (1987). The different responses of the teachers, although both successfully resolved in that student reward is given as restorative praise in both cases, have different longer term impressions. Adam says, 'gold star' for a student and quickly moves on, whilst Bertha draws attention to the correct answer, and to rewarding the student. The impact on students of repeated modelling of 'not my error, let's move on' (process interruption only) compared to 'we must get this right' (product orientation) may be significant. Shifting attention acts to distance the teacher from the ownership of error, modelling addressing error as positive. This distancing compares to a negative impact that models dealing with errors as an annoying problem, one owned by both teacher and students. There is inevitably a degree of uncertainty in relation to error management. These examples represent extremes of a management continuum from valuing error as a learning experience (modelling an expectation of error into learning), to a belief that errors are obstacles to avoid. Indeed, an emotional risk to a teacher may be in not using positive emotions to manage error.

## Acknowledgments

Thanks to UEA studentship funding for PhD data collection, with thanks as always to Prof. Nardi and to Dr Iannone and to the UCL, IOE Mathematics Education team for valuable discussions.

# Students' images of mathematics: The role of parents' occupation

Ciara Lane

National Centre for STEM Education, University of Limerick, Ireland; [Ciara.Lane@ul.ie](mailto:Ciara.Lane@ul.ie)

*A questionnaire survey was conducted as part of a study investigating post-primary students' images of mathematics in Ireland. A definition of 'image of mathematics' was adopted from Lim (1999) and Wilson (2011). Students' images of mathematics were proposed to include attitudes, beliefs, motivation, self-concept, emotions and past experiences regarding mathematics. This paper focuses on one aspect of the study; the relationship between students' images of mathematics and parents' occupation. Some emergent findings regarding this relationship are presented and discussed.*

*Keywords: Image of mathematics, affect, parents' occupation.*

## Introduction

Mathematics education researchers have come to realise in recent decades the significance of mathematics-related affect, with consequential effects on mathematical engagement and performance (Hannula, 2016; Hannula, Ryans, Philippou & Zan, 2004; Lane, O'Donoghue & Stynes, 2014, 2016; Lim, 1999; McLeod, 1994, OECD, 2016). Affect in mathematics education has also been seen to be influenced by various factors including, but not limited to, gender, teachers, parents, peers, society and prior achievement (Frenzel, Goetz, Pekrun & Watt 2010; Hannula et al, 2004; Lane et al, 2014, 2016; Lim, 1999; Morgan, Thornton & McCrory, 2016, OECD, 2016).

There are various constructs investigated by mathematics education researchers in the field of affect. In this study, we focus on the construct 'image of mathematics'.

Although there is no universal definition of 'image of mathematics', there appears to be a general consensus that the term comprises several affective constructs such as: attitudes, beliefs, emotions, self-concept and past experiences regarding mathematics (Brown, 1995; Ernest, 2004; Lane et al., 2014; Lim, 1999). This paper derives from the author's PhD study that examined the image of mathematics held by post-primary students in Ireland (Lane et al., 2014; 2016). No previous research in Ireland had extensively examined second-level students' mathematics-related affect, although studies such as the Programme for International Student Assessment (PISA) have reported on particular aspects such as students' attitudes and confidence (Perkins, Shiel & Merriman, 2013). Lane et al. (2016) found that, similarly to the international context, statistically significant differences occurred for Irish students' images of mathematics with regards to gender, prior achievement and past experiences. Students' image formation was also reported to be influenced by their teachers, parents and peers (Lane et al., 2014). In this paper, one particular aspect of parental influence is examined, with the aim to establishing whether there exists a relationship between parents' occupation and students' images of mathematics. In particular, the author highlights parents' occupations with a strong mathematics base as a distinct occupation category, hypothesizing that these parents would hold positive views of mathematics e.g. in terms of value, and this paper aims to examine whether this positivity would appear to manifest itself in their children.

## Theoretical framework

In her study on the public image of mathematics in the UK, Lim (1999) examined the influences on a person's image of mathematics. She found that images were influenced by four external factors, namely: teachers, parents, peers and society (listed in descending order of reported influence). While the relationship between students' mathematics-related affect and their teachers/the way in which they are taught, as well as the importance of peers and peer-learning in relation to affective issues, is evident in the literature (Dweck, 1986; Frenzel et al., 2010; Hill, 2008; OECD, 2016; Pantziara, 2016), the relationship between students' mathematics-related affect and parents/family is less visible.

### Parents' occupation

The role of parents as an influence on students' mathematics-related affect and achievement has received some attention in the literature (Fennema & Sherman, 1976; Frenzel et al., 2010; Lane et al., 2014; Lim, 1999; OECD, 2014). Parents' influence can be explained by three underlying mechanisms according to Bosco & Bianco (2005), these being: socialization, modelling and resources. As part of these mechanisms, it is suggested that parents' values, attitudes etc. can be passed to their children, with obvious connotations with regards to students' images of mathematics. Lim (1999) and Lane et al. (2014) found parents to be the second most common influence in forming an image of mathematics. This influence occurs chiefly in the form of support and encouragement, but also indirectly from parents' own images of mathematics. In Frenzel et al. (2010), students' 'interest' in mathematics was found to be higher when his/her parents expressed higher levels of mathematics values. Similarly, ASPIRES (2013) found that a key factor affecting young people's science-career aspirations was the amount of 'Science Capital' a family has. Which includes science-related qualifications, understanding, knowledge, interest and social contacts.

With regards to the role of parents' occupations, this aspect has been found to indirectly impact on children's occupational choices, through their interests and skills (Lawson et al., 2015). The influence of parents' occupation on students' mathematical performance was examined in PISA 2012. Results indicated that across most countries, children whose parents worked as *professionals* (in health, teaching, science, business or administration) had the best results in mathematics (OECD, 2014) indicating a relationship between students' socio-economic background and their mathematics achievement. Furthermore, PISA results indicate that students from disadvantaged backgrounds tend to have a more negative mathematical self-concept than advantaged students, likely linked to lower mathematical achievement (OECD, 2016). Given the influence of parents in terms of students' mathematics-related affect (Frenzel et al., 2010; Lane et al., 2014; Lim, 1999) and also the relationship between affect and achievement in mathematics (OECD, 2016), parents' occupations may impact on student achievement not only in terms of students' socio-economic background, but also in terms of students' images of mathematics.

In this paper, we adapt the definitions of Lim (1999) and Wilson (2011) for her study, with 'image of mathematics' conceptualized as follows: a mental representation or view of mathematics, presumably constructed as a result of past experiences, mediated through school, parents, peers or society. This term is also understood broadly to include three domains:

- The affective domain dealing with attitudes, emotions, and self-concept regarding mathematics and mathematics learning experiences.
- The cognitive domain dealing with beliefs regarding mathematics and mathematics learning experiences.
- The conative domain dealing with motivation regarding mathematics and mathematics learning.

The theoretical framework for the author's study is outlined in more detail in Lane et al. (2014).

## Methodology

A mixed-methodology was employed to investigate the image of mathematics held by 5<sup>th</sup>-year ordinary level mathematics students in second level education in Ireland. The main method used to examine students' images of mathematics was a questionnaire survey. The questionnaire contained both quantitative fixed-response items and qualitative open-ended questions. The quantitative aspect incorporated eight pre-established Likert scales, with a total of 84 items, to examine students' attitudes, beliefs, emotions, self-concept and motivation regarding mathematics – see Table 1. As no single scale existed to measure image of mathematics, the scales were selected that most closely resembled the elements comprising our 'image of mathematics' construct and also that fit with the other scales concisely in terms of length and layout. The five open-ended questions sought to gain further insight into students' images in terms of their influences, prior experience, use of mathematics in everyday life and their causal attributions for success/failure in mathematics. However, this paper aims to address only one aspect of the study with the following research question:

Is there a relationship between image of mathematics and parents' occupation for 5<sup>th</sup> year, ordinary level mathematics students in Ireland?

In order to address this question, we focus on the quantitative data, with students' scores on the eight Likert-type scales examined with respect to parents' occupation.

Author	Scale	Image of Mathematics Element
Aiken (1974)	Enjoyment of Mathematics	Attitude
Aiken (1974)	Value of Mathematics	Attitude
Fennema & Sherman (1976)	Attitude Toward Success in Mathematics	Attitude
Fennema & Sherman (1976)	Effectance Motivation in Mathematics	Motivation
Fennema & Sherman (1976)	Anxiety about Mathematics	Emotions
Fennema & Sherman (1976)	Mathematics as a Male Domain	Beliefs
Gourgey (1982)	Mathematical Self-Concept	Self-concept
Schoenfeld (1989)	Beliefs about Mathematics	Beliefs

*Table 1: Image of Mathematics Scales*

A random stratified sample of 60 schools was selected for this study, although only 23 of these agreed to participate. A total of 356 students completed the questionnaire survey. The students were aged

between 15 and 18 years and were all studying ordinary level (intermediate level) mathematics for the Leaving Certificate (end of second level state examination). The author decided to focus on ordinary level students as it was hypothesized that students in this cohort would provide a wider range of images. In addition, a majority of students (72.14% at the time of the study) took the ordinary level mathematics examination for the Leaving Certificate.

## Findings

In this section, findings are presented in relation to parents' occupation and the relationship with students' images of mathematics. The quantitative data were analyzed using Statistical Package for the Social Sciences (SPSS) (version 19). In acknowledgement of the debate among researchers as to whether parametric or non-parametric methods of analysis should be applied to Likert scales (Jamieson, 2004), both methods were employed with similar findings (see Lane et al., 2014). The internal reliability of the eight scales was examined using Cronbach's alpha, with six scales found to have values above 0.8. The Value scale scored above 0.7, still a good internal consistency but the Beliefs scale was found to have a very low Cronbach's alpha of 0.21, possibly due to the short length of the scale – six items. The 84 items in total – referred to here as the combined image of mathematics scale – had a very high internal consistency of 0.94. Correlation was carried out on the scales, with each scale correlated with all other scales and also with the combined scale. The relationships between the scales was also examined using partial correlation, controlling for the effect of each individual scale on the relationship between the other seven scales. A Principal Components Factor Analysis and Multiple Regression Analysis were also employed. The analyses indicated that the Attitude towards Success in Mathematics Scale and the Mathematics as a Male Domain Scale were not found to correlate highly with the other scales used in this study and so the author has decided to not address these scales here. The median scores on each of the remaining six scales are examined according to parents' occupation. A higher score on any of the scales indicates a more positive attitude, belief, emotion etc.

As parents' occupation was an optional item on the questionnaire, this item received the lowest response rate out of the entire questionnaire with just over half of students providing an answer ( $n=179$ ). Reported parents' occupations were qualitatively reviewed and grouped into categories. Occupations were grouped similarly to Lim (1999) in her study on the public image of mathematics. Due to the fact that the author wished to acknowledge occupations involving a significant knowledge of mathematics, i.e., financial banking, accountancy, mathematics teacher etc. it was decided to include a sixth category relating to this. Initially, parents' occupation was explored with categories that differentiated between one or both parents' occupations being provided. However, as some of these categories contained very few students, groups were collapsed into the 6 categories of: Professional; Managerial and Technical; Skilled (both manual and non-manual); Unskilled and Partially skilled; Mathematics; and Others (unemployed, retired and unclassifiable occupations). Median scores for these categories are also compared with those for students who did not provide their parents' occupations (Not Given).

## *Enjoyment of mathematics*

The re-grouped categories of the parent(s)' occupation variable were first examined with regards to students' enjoyment of mathematics. The highest possible score for this scale was 55. Students with the highest median score for enjoyment of mathematics (40.5) had parents whose occupation involved

mathematics. The lowest median for enjoyment of mathematics (27.0) was found to be students whose parents' occupations were categorized as 'other'. There was little difference between the medians for the other 5 categories.

### ***Value of mathematics***

Parents' occupation was examined in relation to students' value of mathematics (highest possible score being 50) but the range of medians for the Value of Mathematics Scale was quite small with the highest median (38.0) being for students with parents grouped as Managerial and Technical as well parents grouped as Mathematics, and the lowest median (33.0) being for students whose parents' occupations were classified as Other.

### ***Motivation in mathematics***

The highest median score for motivation in mathematics (39.5 out of a possible 60) was found for the Managerial and Technical category. This was closely followed by the Mathematics grouping with a median score of 39.0. The lowest median score on the Motivation scale (30.0) was recorded for students' whose parents' occupations fell within the Other classification.

### ***Beliefs about mathematics***

For the Beliefs scale, the range of median scores was small for the parents' occupation categories. The highest median score on the Beliefs about Mathematics Scale (20.0 out of a possible 30) was found for students whose parents' occupations were classified as either Managerial and Technical or Other. The lowest median score (18.0) was recorded for students' whose parents' occupations fell within the Skilled grouping.

### ***Mathematical self-concept***

It was found that the students with the highest median score for the Mathematical Self-concept scale (43.5 out of 60) were those with parents in the Mathematics category. The lowest median score for the Self-concept scale (33.0) was recorded for students whose parents were classified as Professional. This was the first instance of the Professional grouping scoring the lowest on a scale.

### ***Anxiety about mathematics***

Finally, the parents' occupation variable was examined with regards to the Anxiety about Mathematics Scale. Students with parents who work with mathematics had a much higher median score for the Anxiety scale (43.0) compared with all other groups (meaning these students reported the lowest anxiety levels). The lowest median score for the Anxiety about Mathematics Scale (34.0) was recorded for two groups of students, those with parents in the Skilled and Other classifications.

## **Discussion**

The most significant finding with regards to the relationship between parents' occupation and students' image of mathematics may be with regards to students whose parents are involved in mathematics-related occupations. For most of the scales, and also for the combination of the scales, the Mathematics category of parents' occupation showed the highest median scores and, in some situations, was set apart considerably from the other categories. Students with parents in the Mathematics classification of occupations were found to report the highest enjoyment of mathematics, the highest value of mathematics, a high motivation regarding mathematics, the highest

mathematical self-concept and the lowest anxiety levels with regards to mathematics. Given the suggestion in the existing research that parents can influence students' mathematics-related affect and possibly, their achievement in mathematics (Frenzel et al., 2010; Lane, 2013; Lim, 1999), it is perhaps to be expected that parents employed in mathematics-related occupations will have children with a more positive image of mathematics. In particular, it is not surprising that students whose parents work with mathematics would report a positive value of mathematics, but it would not necessarily be anticipated that these students would report higher enjoyment, higher self-concept or lower anxiety. While the PISA findings (OECD, 2014) indicate a relationship between parents' occupation and achievement in mathematics, the occupation category linked with higher achievement in that study was not specific to mathematics, although it would include mathematics related work. Their findings relating to parents' occupation and achievement are likely due to the better educational opportunities afforded to students whose parents are classified as professionals (the resources aspect of parental influence seen in Bosco & Bianco, 2005), but for the students in this study, there was no significant difference between students' reported images with regards to the type of school attended (Lane et al., 2016). Therefore, it can be hypothesized that the differences come from the parents themselves, and not from the educational opportunities afforded by parents. This ties in with the socialization and modelling aspects of parental influence (Bosco & Bianco, 2005). The significance of this finding lies in the important role parents play in positively influencing their children's mathematics-related affect. Another possibility is that parents involved in mathematics-related careers are more able to provide help with mathematics homework. This extra home support may also positively influence these students in terms of their image of mathematics. Similar findings were observed in the ASPIRES study (2013) in relation to parental influence and engagement with science and science careers. Whatever the case, parents who work in mathematics related occupations would seem to have children with a more positive image of mathematics, and while the possibility of other factors should be acknowledged, the relationship between parental influence and student affect with regards to mathematics is clearly one that requires attention. That students whose parents were employed in mathematics based occupations reported the highest self-concept and lowest anxiety regarding mathematics is particularly of note, as Pantziara (2016) highlights the predictive role of students' self-efficacy in their current and future education and course selection. Thus, the potential benefits of positive parental influence in terms of mathematics-related affect are far reaching.

## Conclusion

Findings from this study suggest a relationship between parents' occupation and students' self-reported images of mathematics exist. The positive image of mathematics found to exist among students whose parents are employed in mathematics-related careers, may offer an insight into the role of parents in the formation of a student's image of mathematics, particularly in terms of the socialization and modelling aspects of influence (Bosco & Bianco, 2005). Parents with positive attitudes, beliefs etc. about mathematics, may pass this positivity to their children, thus creating a cycle of positivity and engagement with mathematics. These parents are likely to be in a better position to provide additional support with mathematics work. Given the role played by parents in terms of their children's education and future occupations (ASPIRES, 2013; Lawson et al., 2015), the influence of parents in students' image of mathematics formation (Lim, 1999; Lane et al., 2014) and the link between affect and future course selection and achievement (OECD, 2016; Pantziara, 2016), it is essential to recognize the part that parents may play in influencing students' engagement with

mathematics education and mathematics related careers. Due to the small number of students in this study with parents involved in mathematics based careers, these findings cannot be taken as conclusive and indeed further research would be necessary to clarify the relationship between parents' occupation and students' images of mathematics, and also the role of parents in influencing students' mathematics-related affect and indeed their current and future engagement in mathematics.

# Emotions and problem solving by prospective primary school teachers

Gareth Lewis

University of Leicester, UK; [gl116@le.ac.uk](mailto:gl116@le.ac.uk)

*This paper reports on a study into the motivations and emotions of prospective primary school teachers and how they change before, during and after a problem solving task. The results highlight the need to build the emotional intelligence or cognitive-affective competences, resources and strategies to overcome negative emotion and to scaffold learning.*

*Keywords: Motivation, emotion, problem solving.*

## Background

The link between emotion and the experience of learning mathematics has long been recognised (Buxton, 1981). In particular, negative experiences, leading to negative emotions, are seen to inhibit or disable the learning of mathematics. Buxton's study provided evidence of the damaging effect of lack of confidence and competence that motivation and emotion play in the learning of mathematics. Skemp (1977) also described the part played by a range of emotions in successful and unsuccessful strategies for learning mathematics. Yet until recently, much research on emotion and mathematics has focussed on anxiety, and particularly test anxiety (Hembree, 1990). Evans (2000, p. 108) claimed "there is still little or no explicit acknowledgement of the importance of the affective – feelings of anxiety, frustration, pleasure and/or satisfaction which attend the learning of mathematics." More recently, there have been attempts to classify emotions related to learning mathematics (Pekrun, Frenzel, Goetz, & Perry, 2007). This characterisation does not account fully for the wide range of emotions reported in other research (Schorr & Goldin, 2008). Schutz and DeCuir (2010) point out the tendency of research to characterise emotion as trait, and that this in turn tends to promote more reductionist interpretations. They note the methodological problems in the attempt to study emotions, since they happen 'in vivo', and in the moment. Although not specific to mathematics, Meyer and Turner's (2010) review of emotions in classroom motivation research argues for the key role of emotions in learning, using terms such as 'essential' and 'pivotal'.

In relation to emotion and disaffection with school mathematics, there have been few studies. One such is Skinner, Furrer, Marchand and Kindermann. They view disaffection as negative engagement, or, more specifically (2008, p. 767): "the occurrence of behaviours and emotions that reflect maladaptive emotional states." Amongst the emotions accounted for are boredom, anxiety, anger and shame. The framework takes account of these emotions, but offers no theoretical account of their genesis. Lewis (2016), using a Reversal Theory structure, has attempted to widen the range of emotions studied, and has reported on the existence of a range of negative emotions that inhibit or disable learning.

Emotions, then, have received less attention than other affective constructs. In particular, emotion-as-state has been under-researched. The importance of state, as opposed to trait, or to more stable, cognitively-mediated constructs such as attitudes and beliefs, has been pointed out by Hannula. He says (2012, p. 155): "There is a clear imbalance in favour of studies that focus on traits over studies that focus on states." He goes on to say (ibidem, p. 155): "In particular, studies that focus on the dynamics of emotional or motivational states in classroom or other learning community are still rare."

More recently, researchers have begun to pay attention to this deficit. The Cerme community, at Cerme 9, 2015, saw a number of papers address issues of emotion, and focussed on emotion-as-state, in rather innovative ways. Liljedhal (2015) collected data from 38 prospective mathematics teachers after an intensely negative experience. The results contribute to work in mathematics education that anchors emotions in a theoretical framework and links them to other constructs in the affective domain, particularly motives. Di Martino and colleagues (Antognazza, Di Martino, Pellandini, & Sbaragli, 2015) look at if, and how, young students' emotions change during problem solving, the factors behind the change, and the potential impact of certain emotional changes on mathematical activity. They investigate young students' problem-solving difficulties, and the links between affective and cognitive factors in context. They note that intrinsic causes seem to be attributed by students to positive emotions, and extrinsic causes to negative emotions.

Despite there being a number of significant differences between the studies, they share a number of features that help to address the difficulties of studying emotion 'in-situ'. They both involve polling participants before, during and after the performance of mathematical tasks, and both make creative use of open-ended responses. These studies can be taken together to form a conversation within the research community, where researchers respond to identified gaps in the field, and cooperate to move the research on at each stage. A number of points seem to me to be particularly worth exploring further. The first is the interaction between affect and cognition, which research is only now beginning to explore. Secondly, as pointed out above, we need to understand more fully how affective and emotional states help to facilitate or inhibit learning. Further evidence is needed of the dynamic progression of motivational and emotional states through the problem solving process, how these interact with cognition and cognitively-mediated constructs such as attitudes and beliefs.

## **The study**

The aim of the study, then, is to investigate the motivations and emotions associated with the performance of a problem solving task. More specifically:

What are the motivational and emotional pre-dispositions of prospective primary teachers to performing a problem solving task? How do these change during the process of the task, and how are they interpreted after completion of the task? What is the role of self-regulatory skills in mediating negative emotions? How do motivations and emotions interact with cognition in the undertaking of the task?

Prospective primary school teachers on initial teacher training represent a category of whom many members are lacking in confidence and a facility in mathematics (See Liljedahl, 2015). There is a lot of interest in this group for this reason. Looking to take and adapt the methods and protocols from the studies outlined above, I ran a session with a group of primary PGCE students in which these ideas can be explored. The protocol involves presenting them with mathematics problems, and polling them both prior to working on them and after the task, about their affective dispositions. The task was actually a set of graduated questions involving working out terms in series in which they were given the first few terms. By using a graduated set of tasks, I was hoping that there were tasks that were simple enough for everyone to get some right, but also some that would stretch the most accomplished.

Seventeen students on the Postgraduate Certification of Education (PGCE) programme for prospective primary school teachers at a UK University volunteered to attend a lunchtime session. They were informed only that I was interested in researching affect in mathematics education. All but two of the volunteers were women, and they were split equally between those who considered being mathematics specialists, and those who did not.

At the beginning of the session, students were briefly shown the task, and then given a questionnaire. Prior to the task, they were asked to rate the difficulty of the task on a 5-point scale from easy to difficult. They were also asked how they felt about the task, what they were thinking, and why. They then undertook the written task. After completion of the task, they were asked how well they did on the task, to describe their emotions and thoughts and feelings as they undertook the task, and about their most negative emotion, and how they dealt with it. The data was content analysed according to the categories of responses, as reported below.

## Results

### Initial thoughts and feelings

Ten respondents assessed the task as quite easy, and no one assessed it as difficult. Consistent with the Antognazza et al. study, students who rated the task easy or quite easy felt positively about the prospect of doing the task. When asked how they felt about the prospect of the task, prior to undertaking it, a range of positive feelings were expressed:

I like a challenge; Excited; Confident; Relaxed; Curious; Anticipation

These all reinforced the apparent perceived simplicity of the task. However, there were a few other responses (and these all came from volunteers who rated the task as of medium difficulty):

It makes me feel excited because I want to get it correct, but scared because I might get it wrong (sc)

I think I will be able to do the first ones and then they will get harder and I probably won't be able to do them so anticipation (ja)

When asked what they were thinking, and why, most volunteers reflected confidence and excitement. The two exceptions were those again, who judged the task to be of medium difficulty.

How can I get it right and not look silly. (sc)

I'm thinking that although maths isn't my strongest subject, I'm not being judged and marked so I feel more relaxed (an)

In terms of the task itself, volunteer scores were evenly distributed between scores of 4, 5 and 6 out of 6, reflecting their evaluation of the task as fairly easy. After the task, volunteers were asked how well they thought they did, and most seemed to judge that they did quite well. What is clear from the narratives is that the motivation to succeed at the tasks was strong. There are multiple mentions of determination and perseverance.

I really wanted to get the answer ..... I didn't want to be defeated (ce)

My main emotion was one of determination (rp)

I was just determined to get the right answer (cp)

Added to this, not only is getting right answers important, but speed in doing so is also seen as a requirement. Thus we hear:

How quickly I could work it out.. (cp)

I wanted to get through it quickly (sj)

I was quite upset when I took a little bit longer to do the last one (id)

Fine until I felt rushed due to time (cw)

A number of responses suggests that getting ANY answer wrong is unacceptable, and causes negative emotion.

I didn't do well because I was unable to answer the last two questions (an)

### **Post task reflection**

Although the questionnaire prompts participants to distinguish between emotions on the one hand, and thoughts and feelings on the other, including how they dealt with their most negative emotion, the responses seem to represent a 'package deal' in which the emotions and cognitions are conflated, thus demonstrating how intimately connected they are. In terms of emotions, a range of words and terms are used. They include: confidence; stress; panic; confused; happy; confident; uncertainty; worried; feeling worse; frustration; anger; annoyed; irritated.

This list seems to indicate quite a narrow range of primary emotions, comprising variations of anxiety and anger, on the negative side, and happiness and confidence on the positive side. Confusion and uncertainty appear to be cognitive conditions with negative valence, that result in negative emotions such as anxiety.

Again, as with Antognazza et al., making progress and getting right answers are seen as a vital condition of satisfaction.

I was just determined to get the right answer, each time I solved one I was happy (cp)

Mainly joy at being able to do the task relatively easy (gh)

The sense of satisfaction and positive emotion continues until the prospect of getting the answer right is perceived to be at risk, when the emotion turns negative. Getting answers right, and then not being able to get an answer, is expressed in emotional dualities:

Happiness, success, proud I could do it. Annoyed when I had to take a few looks at the last one (id)

The negative feelings seem to easily initiate more deep seated negative and disabling thoughts:

I felt quite happy and relaxed at the beginning when I was able to complete the sequences but later on I felt inadequate as everyone else seemed to know the answers (an)

I began to doubt myself (nd)

Frustration stimulating a negative thought process that I am not that great at maths (ao)

I was happy and confident until I reached 'E'. At this point my uncertainty about maths re-surfaced. I have never been confident in maths and so the fact that I struggled on the last 2 questions made this emotion re-surface (nd)

Other categories of narrative expression also emerge from the data. One category relates to the mathematical or heuristic strategies employed by the volunteers either in the search for pattern or answers, or in response to negative emotional conditions. Examples include:

My prior knowledge of sequences helped (cs)

My confidence went up and down as I used trial and error, once I'd figured out the pattern that was fine (cp)

Try out a variety of methods until I found the one that worked (id)

My most negative emotion was before the last question when I worried 'whoa' not sure I can do this, but I dealt with it by trying to think about the problem from a different perspective and take a different approach as I had with other questions (ce)

I approached it very methodically, wrote things down to help remember what I was processing mentally. As I cracked each pattern I felt more willing to try the next (rp)

I was thinking about the possibilities of how to work each one out. What different methods may I need to use? (hr)

Since the tone of emotion changed from pre-task to post-task, and from mainly positive to mainly negative, it is interesting to examine how these students deal with the negative emotion. There is evidence here of significant self regulation, which is often mediated by self-talk:

Can I do it? Can't I do it? (sj)

I had to tell myself that I had tried my best (nd)

Come on you can do better (cp)

It's not a test so it is ok if and when I get it wrong (ja)

Self talk also plays a part in the negative case:

I couldn't find the sequence and therefore must be rubbish at maths (sc)

The following example illustrates such a negative **pathway** or series of responses:

I was confused as soon as I couldn't find an obvious pattern and consequently panicked and guessed. That made me feel inadequate (sc)

Note the sequence (with comments in parentheses):

1. I couldn't find an obvious pattern... [searching for pattern is a cognitive strategy – in this case unsuccessful]
2. This made me confused... [lack of success leads to lack of solution and the cognitive condition leads to high arousal]
3. Therefore I panic... [this induces negative emotion]

4. When I panic I guess...[ this leads to a poor behavioural response]

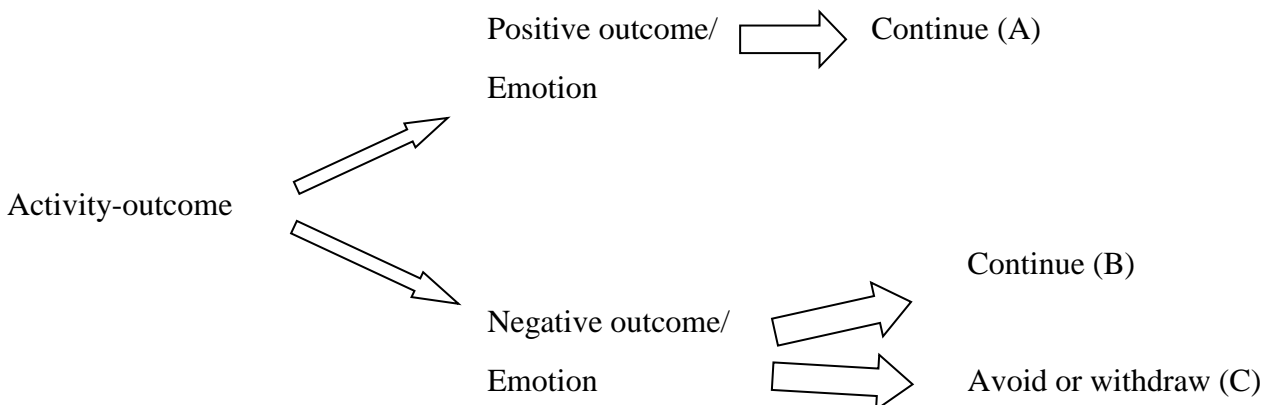

Many of the accounts talk about confusion leading to panic, and the panic relates to the very strong (but unsatisfied) need for progress, often leading to inappropriate strategies for quick solutions:

I felt panicked to try and find a solution as quickly as possible (sc)

### Motivational and emotional pathways in mathematical problem solving

By assembling the evidence, it is now possible to propose a model for the possibility space of the pathways for this motivational-emotional-behavioural nexus. To do this, I will draw on the reversal theory framework, but instantiated by data from this study, and consistent with data from other, similar studies. More details about the eight motivational states, and their associated emotions can be found in Lewis (2016).

The motivational state combination determines how the experience or engagement in the task will be evaluated against the needs of the active states. If the need is satisfied, or if satisfaction is anticipated, it will lead to positive emotion. If not, it will lead to a feeling of frustration, and negative emotion determined by the specific state combinations active at the time. In this case, there is a behavioural dilemma which can be resolved in two ways. Illustrated visually, the space comprises the following pathways:

In the serious self-mastery state combination, which evidence suggests is the dominant motivational disposition of students in problem solving contexts, achieving progress, getting right answers (quickly) and the associated feeling of power or competence, is necessary for a positive affective outcome. The likely behavioural response is attraction, leading to the desire to continue (A).

If progress or positive outcome is not achieved in the serious self-mastery motivational disposition, this will result in anxiety, anger (serious), or humiliation or helplessness (self-mastery, losing), whereas in paratelic (playful) state combinations, boredom or sullenness will result if arousal is low and excitement is unavailable.

From this situation, the student has choices available. One choice is to use strategies to override or mitigate the negative emotions. One such approach is the learnt behavioural response to ‘call down’ mathematical strategies or heuristics, as evidenced above. Another available resource is the application of metacognitive skills such as determination or perseverance. This allows the student to continue, even if it is painful or uncomfortable to do so.

There is also another process that appears to take place. Negative emotions such as anxiety, anger, (possibly in conjunction with helplessness or humiliation) seem to induce a strong need for meaning, significance or explanation for the failure. Since this is unavailable in the situation, it appears to initiate a search of cognitively-mediated constructs (such as attitudes or beliefs) in order to satisfy this need. This search for meaning seems to be strongly mediated by self-talk, and may result, as the evidence shows, in evaluations of self and capability ('You can do it' or, 'I am dumb'), or evaluations or attributions related to the situation ('these questions are too hard', 'mathematics is useless'). But as Antognazza et al. point out, negative emotion is more often associated with explanations extrinsic to the problem at hand.

If such evaluations about self or the situation are positive and enabling, they provide a kind of behavioural override to the negative emotion, and encourage further qualified or reluctant attraction and engagement, as expressed, for instance, in 'come on, you can do better', as illustrated in path (B). If, on the other hand, such evaluations are negative, they result in repulsion and avoidance or withdrawal from the task, as in path (C). We can see this last option in operation in statements of the form 'I am no good at maths', 'I feel less intelligent than the others.'

Since all students will, at times, encounter negative emotions, it is important to understand in more depth what influences the choice between pathways B) and C). It seems clear that having a range of cognitive-affective resources are the key to the likelihood of students choosing pathway C). The evidence here suggests that these resources and strategies fall into three categories:

- A repertoire of mathematical or heuristic processes to enact in seeking progress in tasks and problems.
- Meta-cognitive and self-regulatory resources such as determination and perseverance in order to continue with a task when it is affectively uncomfortable or painful to do so.
- An architecture of positive or enabling cognitively-mediated structures or representations such as attitudes or beliefs, that provide a frame of confidence in which otherwise psychologically risky situations can be tackled.

## Discussion

This study, then, has attempted to contribute to the understanding of affect, and particularly negative emotions and their effect on learning or not learning, mathematics. A number of interesting points arise. Firstly, further evidence to the Liljedahl study of just how prevalent negative emotion is among prospective primary teachers. Secondly, the evidence here shows just how intimately connected affect and cognition are in undertaking mathematical tasks, and the influence of affect on learning, or not learning mathematics, and indeed, the reciprocal influence of learning on affect. I have proposed a model of the mechanisms by which emotion and cognition interact when students are engaged in mathematical tasks, and in particular, ways that aspects of cognition and behaviour can be used to mitigate negative emotion, such that it doesn't disable learning.

This is a modest study which has a number of limitations, especially related to the small sample, and the fact that they were volunteers. Because of this, no attempt has been made to make quantitative generalisations from the data.

One of the key points to emerge that should inform teaching practice and pedagogy is that explicit focus and attention is needed to help students to build the emotional intelligence or cognitive-affective competences, resources and strategies to overcome negative emotion and to scaffold learning.

# On the edges of flow: Student engagement in problem solving

Peter Liljedahl, Simon Fraser University, Canada; [liljedahl@sfu.ca](mailto:liljedahl@sfu.ca)

*Engagement in mathematical problem solving is an aspect of problem solving that is often overlooked in our efforts to improve students' problem solving abilities. In this paper I look at this construct through the lens of Csíkszentmihályi's theory of flow. Studying the problem solving habits of students within a problem solving environment designed to induce flow, I look specifically at student behavior when faced with an imbalance between their problem solving skills and the challenge of the task at hand. Results indicate that most students have perseverance in the face of challenge and tolerance in the face of the mundane, and use these as buffers while autonomously correcting the imbalance.*

**Keywords:** Flow, engagement, perseverance, challenge, tolerance.

## Flow

In the early 1970's Mihály Csíkszentmihályi became interested in studying, what he referred to as, the optimal experience (1990),

“a state in which people are so involved in an activity that nothing else seems to matter; the experience is so enjoyable that people will continue to do it even at great cost, for the sheer sake of doing it.” (Csíkszentmihályi, 1990, p.4)

In his pursuit to understand the optimal experience, Csíkszentmihályi (1990) studied this phenomenon among musicians, artists, mathematicians, scientists, and athletes. Out of this research emerged a set of nine characteristics common to every such experience (Csíkszentmihályi, 1990) – the first three of which are characteristics external to the doer, existing in the environment of the activity, and crucial to occasioning of the optimal experience.

1. There are clear goals every step of the way.
2. There is immediate feedback to one's actions.
3. There is a balance between challenges and skills.

The last of these – balance between challenge and skills – is central to Csíkszentmihályi's (1990) analysis of the optimal experience and comes into sharp focus when we consider the consequences of having an imbalance in this system. Csíkszentmihályi found that if the challenge of the activity far exceeds a person's ability they are likely to experience a feeling of frustration. Conversely, if their ability far exceeds the challenge offered by the activity they are apt to become bored. When there is a balance in this system a state of, what Csíkszentmihályi refers to as, *flow* is created (see fig. 1).

**Fig. 1: Graphical representation of the balance between challenge and skill**

Flow is a powerful way for us, as mathematics education researchers, to talk productively about the phenomenon of engagement in general, and the three aforementioned elements of flow gives us a way to think about the potential environments that occasion engagement in our classrooms in particular.

Williams (2001) used Csíkszentmihályi's idea of flow and applied it to a specific instance of problem solving that she refers to as discovered complexity. Discovered complexity is a state that occurs when a problem solver, or a group of problem solvers, encounter complexities that were not evident at the onset of the task, is within their zone of proximal development (Vygotsky, 1978), and occurs when the solver(s) "spontaneously formulate a question (intellectual challenge) that is resolved as they work with unfamiliar mathematical ideas" (p. 378). Such an encounter will capture, and hold, the engagement of the problem solver(s) in a way that satisfies the conditions of flow. What Williams' frame-work describes is the deep engagement that is sometimes observed in students working on a problem solving task during a single problem solving session.

Extending this work, I argued that engagement was an affective experience and used the notion of flow to look at situations of engagement extended over several days or weeks wherein students return to the same task, again and again, until a problem was solved (Liljedahl, 2006). The results of this work showed that although flow was present in each of the discrete problem solving encounters, what allowed the engagement to sustain itself across multiple encounters was a series of discovered complexities in each session linking together to form what I referred to as a *chain of discovery*.

More recently, I looked at the practices of two teachers through the lens of flow in general and their ability to set clear goals, provide instant feedback, and maintain a balance between challenge and skill in particular (Liljedahl, 2016a). From this a number of conclusions emerged. First, thinking about flow as existing in that balance between skill and challenge, as represented in figure 1, obfuscates the fact that this is not a static relationship. Flow is, in fact, a dynamic process. As students engage in an activity their skills will, invariably, improve. In order for these students to stay in flow the challenge of the task must similarly increase (see fig. 2).

**Fig. 2: Balance as a dynamic process**

**Fig. 3: Too fast an increase in skill**

**Fig. 4: Too great an increase in challenge**

In a mathematics classroom, these timely increases of challenge often fall to the teacher. But this is not without obstacles. For example, if a student's skill increases either too quickly or too covertly for the teacher to notice that student may slip into a state of boredom (see fig. 3). Likewise, when the teacher does increase the challenge, if that increase is too great the student may become frustrated (see fig. 4). How teachers manage these situations of boredom and frustration is important. In Liljedahl (2016a) one of the teachers managed such situations synchronously, either giving hints or extensions to the class as a whole, usually after three groups finished or she got three of the same questions respectively. For most groups the timing of these hints and extensions was off, and not helpful in maintaining flow. The second teacher, however, managed these situations asynchronously, dealing with groups individually as they got stuck or completed a problem. Student engagement in

the second teacher's class was visibly higher as he was maintaining flow through the constant and timely maintenance of the balance between ability and complexity for each group.

What I did not learn from this aforementioned research is how students cope with imbalance when the teacher does not provide help or extensions in a timely fashion. In the research reported here I look closely at exactly this phenomenon in general, and student autonomous actions and reactions in such moments of imbalance in particular.

## Methodology

To get at this behavior I chose to observe students in a problem solving settings where student work was easily visible. To this end I strategically selected two senior high school classrooms belonging to two different teachers (Cameron and Charmaine), both of whom conducted their classrooms according to a teaching framework designed to shape their classroom into a space "that is not only conducive to thinking but also occasions thinking, a space that is inhabited by thinking individuals as well as individuals thinking collectively, learning together and constructing knowledge and understanding through activity and discussion" (Liljedahl, 2016b, p.364).

My earlier empirical work (Liljedahl, 2016b) on the design of such classrooms had emerged a collection of nine elements that offer a prescriptive framework to help teachers build such spaces. For the research presented here, five of these elements are particularly salient:

1. At the beginning of every class, students are assigned to a visibly random group (Liljedahl, 2016b, 2014) of two to four students.
2. These groups work collaboratively to solve a number of problems (usually) right from the beginning of the lesson.
3. This work is done with groups working at vertical non-permanent surfaces such as whiteboards, blackboards, or windows (Liljedahl, 2016b).
4. Students' flow is occasioned and maintained through the teacher's judicious and timely use of hints and extensions (Liljedahl, 2016a, 2016b).
5. At some point within this sequence of tasks the teacher brings the students together to debrief what they have been doing – either by going over one or more of the students' solutions or working through a new problem together with the class as a whole. This is timed so that every group is able to participate in discussion and benefit from the reification.

Taken together, both of these classrooms offered the affordances for me to easily observe students working within an environment designed to occasion flow. The teachers were both managing engagement through the timely use of hints and extensions to maintain a balance between the challenge of an activity and the ability of each group. The student work was visible and there was enough autonomy afforded in the room that the students could take some kind of action when they found themselves in a situation where challenge and ability may be out of balance.

Data for this research were collected in Cameron's grade 12 Pre-calculus class and Charmaine's grade 11 pre-calculus class. Each class was visited five times over a seven week period in the middle of the second semester.

## The data

Because the collection of video data creates such a narrow field of view, I instead used a variant of noticing (van Es, 2011) to scan the classrooms. Csíkszentmihályi (1990) characterizes flow as enjoyment, fluidity, and focus. These characteristics manifest themselves in the physicality of individuals and groups in flow and allows for the easy identification of flow and the absence of flow in a classroom. As per my research question, what I was looking for, then, were moments where an individual or a group was out of flow and where that individual or group was left to cope with this on their own. Once such a moment was identified I would focus in on that individual, or that group, taking detailed field notes and occasional photographs. When these moment seemed to wane I would conduct short, in-the-moment, interviews.

Csíkszentmihályi's theory of flow (1990) predicts that lack of flow is the result of a group of students' abilities exceeding the challenge of the task (see fig. 3) or the challenge of the task exceeding the abilities of a group (see fig. 4), resulting in the groups quitting, respectively, out of boredom or frustration. As such, flow served as the initial framework for analyzing the data. As it turns out, the theory was far from adequate for explaining all of the students' actions and reaction in the data. As such, I also used analytic deduction (Patton, 2002) to look more closely at students' actions and to group these actions into themes.

## Results and analysis

From this analysis a series of six nuanced themes emerged, each marked by a different type of student action or reaction to being out of flow. In what follows I present cases exemplifying each of these themes as well as some general comments about similar cases.

### When skills exceed challenge: The case of quitting

As mentioned, Csíkszentmihályi (1990) found that if a person's ability exceeded the challenge they are apt to become bored, and then quit out of this boredom. I found evidence of such behavior in Cameron's and Charmaine's classrooms.

- |            |  |
|------------|--|
| Researcher | I notice you are not working on the assigned questions. What's up?   |
| Mikaela    | We did some of them.   |
| Researcher | I saw that. I noticed that you did two very quickly. Took a little break from the math and then went back and did another one. I was sort of waiting to see if you would get back to it. |
| Allison    | This stuff is easy. I'll finish it at home on my own.  |
| Mikaela    | It's actually too easy. I don't even think I will bother finishing it at home.   |
| Allison    | ... Yeah. I probably won't either.   |

During the ten lessons I observed in Cameron's and Charmaine's classes I only managed to capture three other instances that I would say fall into the same category – quitting because the students were bored by seemingly too easy a collection of tasks.

### When skills exceed challenge: The case of seeking increased challenge

Quitting out of boredom was not the only reaction to a situation where the skills of a group or of an individual exceeded the challenge of the task at hand. Some students opted, instead, to autonomously

seek increased challenge. To exemplify this I look at a case from Cameron's class captured while students were working at the whiteboards in randomly assigned groups. During this part of the lesson Cameron moved around the room helping groups that were stuck (or had made a mistake) and giving more challenging questions to groups that were done. Before a group would get his help or the next question, however, he engaged the group in conversation to assess where the group's thinking was. This took time and sometimes groups that were done were left waiting.

- Researcher     So, I notice that you guys are now on question 5 and your teacher has not visited you once. How are you getting your questions?
- Ameer           We just look around and see what the next question is and do that one.
- Researcher     What would your teacher say about that?
- Carl             Um ... he'd probably want to check to see that we got the previous one before giving us the next one ...
- Ameer           ... but we are doing that.
- Researcher     Why don't you just wait for your teacher to get here and give you the next question?
- Carl             We're on a roll. And sometimes we have to wait a long time.
- Researcher     Do you realize that you are doing the problems out of sequence from the order your teacher is giving them?
- Colton           Oh really? That's probably why some were so hard.

This was a very common reaction in both Cameron's and Charmaine's classrooms. Rather than wait for their teacher to give them the next questions groups were opting, instead, to move forward on their own by pulling the next question from groups that were ahead of them. This was facilitated by the visible nature of the work on the vertical surfaces.

### **When skills exceed challenge: The case of tolerance in the face of the mundane**

An altogether different reaction to being tasked with doing easy and redundant questions is to just do them – without quitting and without seeking to increase the challenge. I observed such behavior in the case of Jennifer, who always worked at her desk on her own at the end of Charmaine's lessons.

- Researcher     I have been watching you while I have been here. I notice that you always do a lot of questions. Can you tell me about that?
- Jennifer          Yeah. I like to do a lot of questions. It's good practice. It's how I learn.
- Researcher     So, are you looking for harder and harder questions to challenge yourself?
- Jennifer          Not really. I just do all of them. So, if the teacher asks us to do 4a, I will also do 4bc and d and so on.
- Researcher     Do you find them easy?
- Jennifer          Yeah.
- Researcher     How many do you do?
- Jennifer          I just work the whole time at the end of class and then for maybe an hour at home.

I came to call Jennifer's behavior *tolerance for the mundane*. In my time in Cameron's and Charmaine's classes I saw two other girls who I suspect were very much like Jennifer in their approach

to learning and their tolerance for the mundane. These girls also worked alone in their desks in the last part of every lesson.

### **When challenge exceeds skills: The case of quitting**

Csikszentmihályi's framework (1990) predicts that sometimes students quit out of frustration. I found three cases of this in Cameron's classroom – all near the beginning of class.

- Researcher I have been watching your group for a bit and I notice that you aren't working?
- Robert We gave up. This question is stupid.
- Katrina We tried, but we weren't getting anywhere. So we gave up.
- Researcher What do you think the problem is?
- Shannon This question is too hard.
- Robert ... too hard. We don't get it.
- Katrina And the teacher hasn't come over to help us.
- Researcher What kind of help are you looking for?
- Shannon You know, a hint or something.
- Researcher What would a hint do for you?
- Shannon Help us understand the question.
- Katrina ... or remind us a little bit about how to do it.

For this group the question they have been asked to solve exceeded their abilities and without any help from the teacher they gave up. Interestingly, the help they were seeking was not only to reduce the complexity of the task (understand the question), but also to increase their ability (remind us of what we have done in the past). In the ten lessons I observed, I only managed to capture four instances of a group giving up out of frustration.

### **When challenge exceeds skills: The case of seeking help**

A much more common reaction to facing too great a challenge was for students to seek help. What this looked like, however, was much more subtle than simply asking the teacher for help.

- Researcher I notice that you have been moving about the room a bit. Why?
- Michael Oh. We were just stuck so we went over there to get some ideas.
- Researcher Did it help?
- Michael Oh yeah. We got it now.

This sort of behavior was endemic in both classrooms with too many occurrences for me to track. The vertical and visible work spaces facilitated the ability for groups to check their answers and get ideas. The random groups created the porosity (Liljedahl, 2014) that made the more active interactions and movement of ideas possible.

### **When challenge exceeds skills: The case of perseverance in the face of challenge**

But not all groups sought help when they were stuck.

- Researcher Question #5 was a tough one, huh?
- Oliver Yeah, that one took us a while.

- Connor        In the end it wasn't that hard though. We were just missing something.
- Researcher    Oh really. How did you figure it out?
- Connor        We just kept at it and then we saw it.
- Researcher    I noticed that your teacher came over to help. Did she help you?
- Oliver         No, we wouldn't let her. We knew how to do it and we wanted to figure it out ourselves.

In all the lessons I observed I captured four instances where a group or an individual opted to not seek help, either from the teacher or the groups around them. I called this behavior *perseverance in the face of challenge*.

## Discussion

The aforementioned six nuanced student reactions to being out of flow show that for different individuals and different groups the transitions from flow to boredom or frustration has variable immediacy. Some groups became bored or frustrated and quit. For these groups, Csíkszentmihályi's (1990) original representation of flow holds (see fig. 1).

For others, this transition was not as abrupt. Jennifer showed a great tolerance for the mundane as she spent long periods of time within a space where her ability far exceeded the challenge posed by the tasks she was working on. Likewise, Connor and Oliver demonstrating great perseverance while working on a task that presented too great a challenge for her ability. Taken together, these two cases, and the cases like them, indicate that for some students the boundary between flow and boredom and frustration is not as thin as Csíkszentmihályi's (1990) theory of flow would imply and is buffered by tolerance and perseverance (see fig. 5).

Other students used this buffer to avoid frustration or boredom as they sought to correct the imbalance between skill and challenge that they were experiencing. Carl, Ameer, and Colton used the groups around them to check their own answers and to seek out more challenging tasks when they were done. Similarly, Michael's group used the groups around them to access help when they were stuck. These groups, and the groups and individuals like them, managed to autonomously maintain the balance between challenge and ability. When their ability was too great they autonomously sought to increase the challenge (see fig. 6) and when the challenge was becoming too great they autonomously sought to increase their ability or decrease the challenge (see fig. 7). The highly visible and collaborative environments created by the use of vertical non-permanent surfaces and visibly random groups were shown by the data to be instrumental in facilitating these autonomous actions.

*There is not much research on emotions of mathematics teachers other than the wide research on mathematics anxiety of mathematics teachers and pre-service teachers in elementary school. With the goal of beginning to fill this gap, this research pursues the aim of identifying the daily emotions in a classroom of a high school mathematics teacher. Data was gathered through audiotaped self-reports where the participant reported his emotional experiences during 13 mathematics classes. The data analysis show that the participant experienced diverse emotions such as satisfaction, disappointment, appreciation, happy-for, sorry-for, reproach and anger. The triggering situations for the cognitive appraisals are about the achievement of the planned activities for the lessons. The belief of the participant on the “good attitude” of students – perceived as students’ “collaboration”, “independence” and “participation” – supports the appraisals.*

*Keywords: Teachers’ emotions, cognitive appraisal, self-reports of experience.*

### Teachers’ emotions in mathematics education

In the field of mathematics education, most of the research on teachers’ emotions focuses on mathematics pre-service elementary teachers. There is also some research on elementary teachers. Mathematics anxiety—“a set of negative emotions about a state of discomfort, occurring in response to situations involving mathematical tasks” (Bekdemir, 2010) — is the most widely emotional phenomenon studied in pre-service elementary school (e.g. Bursal & Paznokas, 2006; Di Martino, Coppola, Mollo, Pacelli, & Sabena, 2013; Di Martino & Sabena, 2011; Hodgen & Askew, 2007). These investigations show that “mathematics anxiety is a common phenomenon among pre-service elementary school teachers in many countries and it can seriously interfere with students becoming good mathematics teachers” (Hannula, Liljedahl, Kaasila, & Rösken, 2007, p. 153). For example, , Harper and Daane (1998) found that mathematics anxiety persists in prospective elementary school teachers, enrolled in a U.S. mid-sized south-eastern university, and that often, the anxiety was originated in elementary school. Causes for these students’ mathematics anxiety included an emphasis on right answers and the right method, fear of making mistakes, insufficient time, word problems and problem solving.

Some other research focused in the study of specific emotions in elementary school teachers (Bibby, 2002; Di Martino et al., 2013). For example, Bibby (2002) found the presence of shame [a reaction to other people’s criticisms and an emotional response to knowing and doing mathematics] related with epistemological beliefs about the nature of mathematics: absolutist/product conceptions of mathematics provide ideal opportunities for experiencing shame. Bibby found statements relating to the fear or anticipation of judgement against those standards they felt they had to measure up: “These

comments feature notions of trust, lack of trust and self-doubt, doubt, all of which indicate a fear of shame: a fear of (imagined or real) criticism, ridicule or rejection by others” (Bibby, 2002, p. 710)..

The research of teachers’ emotions in mathematics education outlined here shows the strong presence of negative affect towards mathematics on elementary education teachers. There is a consensus among researchers that the main cause of all negative emotions is that most elementary and pre-service elementary teachers are not specialists in mathematics and often had negative experiences with mathematics as mathematics students in elementary or middle school (Coppola, Martino, Pacelli, & Sabena, 2012; Di Martino et al., 2013; Hodgen & Askew, 2007; Philipp, 2007). The appearance of mathematics anxiety in the first years of school is linked with the way in which mathematics is presented to pupils, with the teacher playing a central. Under these negative affective circumstances it is generally recognized that changes in mathematics education is a difficult and sometimes painful process (Hannula et al., 2007; Hodgen & Askew, 2007).

The previous review shows that most of what we know on teachers’ emotions from different scholar levels is almost limited to mathematics anxiety. The intention of this research is to start filling these gaps by following the aim to identify the daily emotions experimented by a high school mathematics teacher in classroom.

### **Theory of cognitive structure of emotions**

The theory of cognitive structure of emotions Ortony, Clore, & Collins, 1988)—known as “OCC theory” for the initials of the surnames of the authors—is an appraisal theory structured as a three-branch typology, corresponding to three kinds of stimuli: consequences of events, actions of agents, and aspects of objects. Each kind of stimulus is appraised with respect to one central criterion, called the central appraisal variable. An individual judges: (1) the desirability of an event, that is, the congruence of its consequences with the individual’s goals (an event is pleasant if it helps the individual to reach his goal, and unpleasant if it prevents him from achieving his goal), (2) the approbation of an action, that is, its conformity to norms and standards, and (3) the attraction of an object, that is, the correspondence of its aspects with the individual’s likes. In terms of the distinction between reactions to events, agents, and objects, we have three basic classes of emotions: “being pleased vs. displeased (reaction to events), approving vs. disapproving (reactions to agents) and liking vs. disliking (reactions to objects)” (Ortony, Clore, & Collins, 1988).

OCC theory describes a hierarchy that classifies 22 emotion types. The hierarchy contains three branches, namely emotions concerning consequences of events, actions of agents, and aspects of objects. Additionally, some branches combine to form a group of compound emotions, namely emotions concerning consequences of events caused by actions of agents. OCC theory provides specifications for each emotion type with three elements: (1) The type specification provides, in a concise sentence, the situations or events that elicit an emotion of the type in question, (2) a list of tokens is provided, showing which emotion words can be classified as belonging to the emotion type in question.

For example, ‘frighten’, ‘scared’, and ‘terrified’ are all types of fear (of course, ‘fear’ is also a type of fear): (1) TYPE SPECIFICATION: (displeased about) the prospect of an undesirable event and (2) TOKENS: apprehensive, anxious, cowering, dread, fear, fright, nervous, petrified, scared,

terrified, timid, worried, etc. In Table 1 we summarized the type specifications of all 22 emotion types.

Appraisals in terms of	Group of emotions	Types of emotions (sample name)
GOALS	Fortunes- of-others	Pleased about an event desirable for someone else (happy-for)
		Pleased about an event undesirable for someone else (gloating)
		Displeased about an event desirable for someone else (resentment, envy)
		Displeased about an event undesirable for someone else (sorry-for)
	Prospect- based	Pleased about the prospect of a desirable event (hope)
		Pleased about the confirmation of the prospect of a desirable event (satisfaction, joy)
		Pleased about the disconfirmation of the prospect of an undesirable event (relief)
		Displeased about the disconfirmation of the prospect of a desirable event (disappointment, frustration)
		Displeased about the prospect of an undesirable event (fear, worry)
		Displeased about the confirmation of the prospect of an undesirable event (fears-confirmed)
NORMS	Attribution	Approving of one's own praiseworthy action (pride)
		Approving of someone else's praiseworthy action (appreciation, admiration)
		Disapproving of one's own blameworthy action (self-reproach, shame)
		Disapproving of someone else's blameworthy action (reproach, rejection)
NORMA/ ATTITUDE	Well- being/ Attribution	Approving of someone else's praiseworthy action and pleased about a desirable event (gratitude=admiration + joy)
		Disapproving of someone else's blameworthy action and displeased about an undesirable event (anger = reproach + distress)
		Approving of one's own praiseworthy action and pleased about a desirable event (gratification=pride+ joy)
		Disapproving of one's own blameworthy action and displeased about an undesirable event (remorse = shame + distress )

**Table 1: Emotion types according to the OCC theory (an extract)**

## Research question

Considering the above theoretical considerations, in this research we have chosen to identify the *emotional experiences* (the individuals' explicit positive or negative appraisals of the triggering situations) of a high school mathematics teacher. Thus, the research question arising from the aim of our investigation —identify the daily emotions experienced by a high school mathematics teacher in classroom— is: What are the daily individual emotional experiences of a high school mathematics teacher in classroom?

## Methodology

### Participant and Context

Christian, our participant and fourth author of this paper, was 35 years old by the time of the data gathering. He studied Communication and Electronic Engineering and has a master degree in mathematics education. From 2010, he ventures into mathematics teaching gaining 5 years of experience in teaching at the university and at a technical high school. High school where Cristian works is part of the national high school Mexican system, which has a dual system: it prepares students for university studies but is also engaged with those who need to enter the labour market and require a technical certificate.

### Data gathering

The source of data was the daily self-informs of Christian's experiences in his high school Integral Calculus course. The diary methods "involve intensive, repeated self-reports that aim to capture events, reflections, moods, pains, or interactions near the time they occur" (Iida, Shrout, Laurenceau, & Bolger, 2012, p. 277). Christian's self-reports of experiences in class followed an event-based protocol (Iida et al., 2012). The focal experience of the participant that triggered the data collection is the emotional experience of teaching a mathematics class. After each of the 13 lessons (from October 14 to December 4, 2015) of his Integral Calculus course Christian send an audio with a smartphone to the second author of this paper via WhatsApp™ with his answers to the questions: (1) Name and date of the report, (2) What course does this report attend?, (3) What mathematics topics did you work at class today?, (4) How did you design your class?, (5) How were your students intended to learn?, (6) What emotions and feelings did you experiment today at class?, (7) Tell us about the positive experiences you lived today at mathematics class, why were they positive experiences? and (8) Tell us about the negative experiences you lived today at mathematics class, why were they negative experiences? Questions 3, 4 and 5 were designed to understand Christian's expectations and goals in each class. Questions 6, 7 and 8 were designed to know the experimented emotions of Christian in each class. The running time of the self-reports of Christian were among 1:40 y 2:54 minutes.

### Data analysis

The data was completely transcribed and repeatedly read for several times. Christian did not participate in the analysis of the data but agreed that the final report adjusted in general to his experience in class. He did not propose any significant change in the interpretation made by the first three authors but made some observations on the interpretations of some fragments of his self-reports and interviews. He also suggested new elements to detail the context of the research.

Following OCC theory, we considered two aspects to identify the type of emotion: (1) ***Concise phrases that express the triggering situations*** of the emotional experiences. We highlight them with ***italic bold***, and (2) *emotional words or phrases* that express the emotional experience from the participants words or phrases that indicate the appraisal of the triggering situations. We highlight these words or phrases in *italics*. R<sub>n</sub> (n from 1 to 13) denotes the number of the participant's report.

For the analysis we only consider excerpts that express emotional experiences; this means that it must contain at least one explicit positive or negative appraisal of the triggering situation. We interpret the

positive or negative valence according to the question reported by Christian (the valence is negative if it corresponds to questions 8 and it is positive for question 7). For example, in:

**Christian-R2:** [The emotions and feelings I experimented in class were] Being *happy* because *the students managed to structure answers to different doubts of their classmates* {satisfaction-appreciation}. [The *positive experience* I lived was] *the interest of the students in helping their classmates* {appreciation} [I consider this experience as positive] *because of the reflected attitude during the class, it was to help them* {happy for-appreciation}.

We interpret “the students managed to solve doubts” as a triggering situation (‘the students managed to solve doubts’) of a satisfaction type of emotion (Pleased about the confirmation of the prospect of a desirable event). We interpret “the interest of the students to help their classmates” as a triggering situation (‘the students help their classmates’) of an appreciation type of emotion (Approving of someone else’s praiseworthy action). Sometimes in the same emotional experience we identify two types of trigger situations and two types of emotions. In “being happy because the students managed to structure answers to different doubts of their classmates” we interpret as a triggering situation (‘the students managed to solve doubts’) of a satisfaction type of emotion and a triggering situation (‘the students help their classmates’) of an appreciation type of emotion.

We build a table with all emotional experiences for each report. The second and third author of this paper identified the triggering situations and the types of emotions for each self-report on separate analysis but using the same table based on the 22 types of emotions proposed the theory of cognitive structure of emotions. They worked the consensus of the triggering situations and the types of emotions with the participation of the first author of this paper. Table 2 shows an example of these analyses.

Emotional experience	Type of emotion	Triggering situation
Being <i>happy</i> because <i>the students managed to structure answers to different doubts of their classmates</i>	Satisfaction	The students managed to solve doubts
	Appreciation	The students help their classmates
[ <i>Positive experience</i> ] <i>the interest of the students to help their classmates</i>	Appreciation	The students help their classmates
[ <i>Positive experience</i> ] <i>because of the reflected attitude during the class, it was to help them</i>	Happy for	The students have a positive attitude in class
	Appreciation	The students help each other
[ <i>Happiness and joy</i> ] <i>when I realize they answered the doubts</i>	Satisfaction	The students solve their doubts

<i>[Happiness and joy] because of the participation and enthusiasm of the students</i>	Satisfaction	The students participate in class
	Appreciation	The students show enthusiasm in class
<i>[Positive experience] because of the interest showed by the students helping their classmates to solve their doubts, letting them to move on and understand the integration techniques</i>	Satisfaction/	Students solve doubts
	Appreciation	Students help their classmates
	Happy for	Students understood the integral techniques
<i>[What I learn in class today] I consider that the help received from their classmates, in the sense that they shared different knowledge about the integration technique studied and this allowed their classmates to advance on the topics of the class.</i>	Appreciation	Students help each other
	Happy for	Students make progress in the topics

**Table 2. Types of emotion and triggering situations of R2 (an extract)**

## Results

We identified 95 emotional experiences from 7 different types corresponding to 4 groups of emotions (Table 3). We found that Christian experimented emotions of satisfaction, disappointment, appreciation, happy-for, sorry-for, reproach and anger triggered by the cognitive appraisal of 6 types of triggering situations: (1) on the achievement of the planned activity, (2) on the students' participation, (3) on the students' collaboration, (4) on the students' attitude, (5) on the students' independence, and (6) on the students' learning and understanding. During the data analysis, we identified the importance of Christian's the notion of "students' (good) attitude". We asked Christian specifically about his. We found that the supports the appraisals is the his belief about the "good attitude" of students—perceived by Christian as students' "collaboration", "independence" and "participation"—is a necessary condition to achieve participant's goals in class and for the students to learn.

Christian's most common experimented emotions were satisfaction ( $F=36$ ), appreciation ( $F=26$ ) and disappointment ( $F=16$ ). These emotions represent 82% of his emotional experiences. More than half of the emotional experiences are *Satisfaction* (pleased about the confirmation of the prospect of a desirable event) and *disappointment* (displeased about the disconfirmation of the prospect of a desirable event). This means that they are the result of the appraisal of situations in terms of the goals Christian expressed for his lessons. On the other, *appreciation* (approving of someone else's praiseworthy action) represent more than a fourth of the emotional experiences. This highlights the

important role Christian attributes to his students' behavior ("good attitude", "participation" and "independence") to achieve their goals.

Types of emotion	Total	F	Triggering situations
Satisfaction	36	21	Students solve exercises
		6	Students participate in class
		4	Students solve doubts
		2	Students propose methods
		2	Students understand
		1	Students must be independent while solving
Appreciation	26	10	Students help their classmates
		6	Students participate in class
		5	Students are independent in solving processes
		4	Students must have good attitude
		1	Students solve doubts
Disappointment	16	8	Students do not do the planned activity.
		3	Students cannot enter the correct results in the platform
		3	Students do not participate in class.
		2	Students do not understand.

**Note:** *F* denotes the amount of times we identified the triggering situation.

**Table 3. Types of emotion and triggering situation (the most frequent)**

## Discussion

Table 4 presents the types of triggering situations. As we said before, Christian considers the "good attitude" of a student in terms of "independence", "participation" and "collaboration". Therefore, we include all the triggering situations expressed in these terms in only one type of triggering situation named "students' attitude". In this way, we obtained that most of the triggering situations (95%) are divided in two types: (1) Students' attitude (52%) and (2) achievement of the planned activity (43%). This means that the success of an activity depends on his students' attitude above all.

Our results are consistent with those investigations that focused on teachers' emotions based on appraisal theories (e.g. Frenzel, 2014; Schutz, 2014). We believe that this consistency results from the hypothesis that emotions are the result of cognitive appraisals about what happens in class, realized in terms of goals. Our research shows that the appraisal of students' behavior, conceptualized as "good attitude", is the main triggering situation of Christian's emotional experiences. This is also highlighted in the Frenzel's (2014) "reciprocal model on causes and effects of teacher emotions". We propose the thesis that the emotional experiences of other mathematics teachers could mostly be triggered by the mathematics behavior of their students.

# The suitability of rich learning tasks from a pupil perspective

Elisabet Mellroth

Karlstad University, Sweden; [elisabet.mellroth@kau.se](mailto:elisabet.mellroth@kau.se)

*The construction of tasks is important to challenge pupils, but the exploration of pupils' perceptions connected to their work with tasks, is rare. This paper presents the results of a study using a tool aimed at measuring pupils' perception of joy and interest connected to 'rich learning tasks' by comparing the views of mathematically promising pupils and others. Two tasks were pre- and post-evaluated, the first by 139 and the second by 106 pupils from grade 4-9. The results indicate that the tool is suited for the exploration of pupils' views, especially as it can be deduced from the comparison that mathematically promising pupils perceived both tasks more positively than the other pupils, and that the non-identified pupils became more positive after working especially with one of the tasks.*

**Keywords:** Mathematically gifted, mathematically promising, rich tasks, pupils' perception.

## Introduction

One of the main goals in research on mathematical giftedness is to identify and foster mathematically promising pupils (Käpnick & Benölken, 2015). The construction of mathematical tasks is seen to be important for both purposes (Fuchs & Käpnick, 2009; Nolte, 2012). It is a consensus that tasks suitable to identify and foster mathematically promising pupils should, for example, be challenging, open-ended, encourage creativity and engagement, and promote enjoyment (Fuchs & Käpnick, 2009; Nolte, 2012; Sheffield, 2003). In Sweden there is no differentiation among students, every classroom is diverse and includes pupils of all abilities. Therefore, it is interesting to explore how the work with specific tasks are perceived by all pupils in the classroom. Of special interest is the perception of the mathematically promising pupils since in a diverse classroom there is a risk that they not are given opportunities to be challenged (Leikin & Stanger, 2011). A task suitable to implement in the whole class should offer a challenge to pupils at every level, which for example rich learning task are said to do (Sheffield, 2003). However, it is rare that the assessment process of the tasks appropriateness is explored, especially from the pupils' perspective. This leads to the question how tasks aimed to support mathematically promising pupils can be evaluated by the pupils. Against the background of this question this paper presents a study aiming to explore a tool in development that investigates pupils' perception of joy and interest connected to specific tasks.

This paper gives a theoretical background on tasks suitable to challenge mathematically promising pupils and other pupils. Further, the aspect of perceived joy and interest for pupils connected to work on mathematics is elaborated. The study and its results are presented and thereafter the tool used and the interpretation of the results are discussed.

## Theoretical background

Pupils in a diverse classroom naturally have different levels of knowledge. Engström and Magne (2006) showed that in Swedish classrooms the mathematical knowledge of the 15 percentage lowest achieving pupils in grade nine are on the level of a grade four pupil. Also in a mathematical classroom there is a mix of pupils, some are highly motivated while others lack motivation, some are high achieving and others are low achieving (Boaler, 2006). All pupils should be given opportunities to learn and develop, and on task level there are ways to differentiate education to meet and challenge

all pupils. One way is for example through the use of rich learning tasks, which also fulfills the criteria for tasks seen to be suitable to identify and foster mathematically promising pupils (Sheffield, 2003). Because of the Swedish context with the diverse classroom the aim is to meet and develop all pupils, however, the mathematically promising pupils are of particular interest in this study. Therefore, it is important to elaborate on what is important in a task for a mathematically promising pupil as well as for pupils in general.

First, considering the mathematically promising, it is important to give them challenging tasks to help them develop according their mathematical potential (e.g. Benölken, 2015; Koshy, Ernest, & Casey, 2009; Nolte, 2012). Open-ended tasks, like rich learning tasks, are examples of tasks known to be challenging for mathematically promising pupils (Nolte, 2012; Sheffield, 2003). In addition, the joy factor is stated as important in the development process for the mathematically promising (Fuchs & Käpnick, 2009). The importance of joy in working with mathematics is further consolidated by being strived for in activities aiming to support and foster the mathematically promising, such as for example math clubs (Benölken, 2015).

Second, considering pupils in general, Taflin (2007) states that it is important that pupils perceive the problem solving process of a task as positive, challenging, and that it stimulates their creativity. Taflin actually writes that if they do not perceive this, then it is better not to implement the tasks. As to the perspective of joy, Mellroth (2014) showed that tasks aiming to evoke joy make some pupils achieve highly, even though they do not achieve highly on traditional mathematics tests. In addition, to further strengthen that pupils' enjoyment in mathematics is important, Chen and Stevenson (1995) showed that positive attitudes and interest are significantly related to mathematical achievement. And the results of Skaalvik, Federici, and Klassen (2015) show that pupils' self-efficacy in mathematics is positively and strongly related to intrinsic motivation which they directly connected to pupils' enjoyment when working with mathematics.

Based on the theory it can be assumed that pupils' perception of interest and their positive attitudes towards the task have effect on their motivation on working with the task. This is valid for both mathematically promising pupils and for others. Therefore, it is interesting and important to explore how pupils perceive working with specific tasks, especially by comparing promising and other pupils. A developed tool, easy to use, could help teachers choosing tasks that challenge and interest all pupils.

## **Aim**

The aim of the presented study is to investigate how to identify mathematical tasks that can stimulate all pupils in a diverse classroom, including the mathematically promising. Utilizing a pupil perspective, which stresses the importance of pupil interest and joy when working with mathematics, the study provides a comparison of data from promising children and others.

The study is conducted in Sweden within the frame of a professional development program on mathematical promise for seven in-service teachers, teaching mathematics for pupils from grade 4 to 9 (Mellroth et al., 2016).

## **Method**

Two tasks that fulfilled the criteria of rich learning tasks were implemented in seven classrooms, i.e. all pupils in "regular" classes worked with the tasks aiming to solve them. The pupils went in grade

4 (age 10) to 9 (age 15), all grades covered. The tasks considered to be suitable to challenge all pupils, specifically mathematically promising, were chosen (Sheffield, 2003), see Figure 1 (*Task 1*) and Figure 2 (*Task 2*). In the first intervention *Task 1* was implemented: 139 pupils responded on the evaluation of the task, among them 32 pupils were identified as mathematically promising<sup>1</sup>.

<table> <tr><th colspan="6">Front</th></tr> <tr><td>R 1:</td><td>1</td><td>2</td><td>3</td><td>4</td><td>5</td></tr> <tr><td>R 2:</td><td>7</td><td>8</td><td>9</td><td>10</td><td>11</td></tr> <tr><td>R 3:</td><td>13</td><td>14</td><td>15</td><td>16</td><td>17</td></tr> </table> <p><i>Level A</i> Ex. Kyla is in Seat 48. What row is she in?</p>						Front						R 1:	1	2	3	4	5	R 2:	7	8	9	10	11	R 3:	13	14	15	16	17												
Front																																									
R 1:	1	2	3	4	5																																				
R 2:	7	8	9	10	11																																				
R 3:	13	14	15	16	17																																				
<table> <tr><th colspan="6">Front</th></tr> <tr><td>R 1:</td><td></td><td>2</td><td></td><td></td><td></td></tr> <tr><td>R 2:</td><td></td><td>4</td><td></td><td>6</td><td></td></tr> <tr><td>R 3:</td><td></td><td>8</td><td></td><td>10</td><td></td></tr> <tr><td>R 4:</td><td>14</td><td>16</td><td></td><td>18</td><td>20</td></tr> <tr><td>R 5:</td><td>22</td><td>24</td><td></td><td>26</td><td>28</td></tr> </table> <p><i>Level C</i> Ex. I am in the last seat in a secret row. Give a rule for finding my seat number.</p>						Front						R 1:		2				R 2:		4		6		R 3:		8		10		R 4:	14	16		18	20	R 5:	22	24		26	28
Front																																									
R 1:		2																																							
R 2:		4		6																																					
R 3:		8		10																																					
R 4:	14	16		18	20																																				
R 5:	22	24		26	28																																				

**Figure 1: Example from *Task 1*, named Where am I? (Sheffield, 2003).**

In the second intervention *Task 2* was implemented: 106 pupils responded, among them were 20 pupils identified as mathematically promising. All pupils did the interventions in the same order i.e. *Task 1* first and *Task 2* second.

**Figure 2: Example from *Task 2*, named Field of dreams (Sheffield, 2003); The number in a circle, denotes the total number of students in all adjoining fields.**

The pupils involved in the two interventions all came from the same seven classes, 44 pupils did *Task 1* but not *Task 2* and 11 pupils did *Task 2* but not *Task 1*. Therefore 95 pupils participated in both interventions, 20 of those were identified as mathematically promising. Since the suitability of the tasks in the classroom was of interest, evaluations from all participating pupils were used in the analysis for each intervention.

Within the frame of the professional development program a tool how to measure pupils' perceptions on interest and joy connected to working with specific tasks was developed. In the development process experts on motivation and attitudes in mathematics education, and in educational psychology were consulted. The tool resulted in a pre-evaluation that utilized an emoji-note, Figure 3, and a post-evaluation, in which the emojis were changed to words, Figure 4. The reason for the change from emojis to words was to decrease the risk that pupils would chose the same emoji twice due to the short time, the time of one lesson, between the pre- and post evaluation.

<sup>1</sup> Selected through a synthesis of different tools, see Mellroth et al. (2016).

To collect data each teacher presented a power point slide with a picture related to each task<sup>2</sup> in their specific classes, without revealing the actual task. Before the task was handed out to the pupils, they were asked to mark how they felt about the task by choosing an emoji on a paper given to each one of them, see Figure 3. Thereafter the pupils were given time to work with the task.

Your teacher has presented a mathematical problem.  
Which emoji best matches your feeling about this problem?

**Figure 3: Evaluation note before starting to work with the task, adapted from Mellroth et al. (2016).**

When the teacher ended the pupils work with the task, but before the task was discussed orally in the whole classroom, pupils were asked to evaluate the task again. This time by choosing words, see Figure 4.

What words best describes how you felt about the task while working with it?

Very interesting  
Interesting  
Neither or  
Uninteresting  
Very uninteresting

**Figure 4: Evaluation note after completing working with the task (Mellroth et al., 2016).**

Data from all classes were collected and summarized. For the summary process pupils identified by the teachers as mathematically promising were separated from the non-identified pupils. The evaluations, see Figure 3 and Figure 4, were translated to numbers from 1 to 5, where 1 was the most positive evaluation and 5 the most negative. Thereafter, a descriptive analysis was conducted. For further details of the method see Mellroth et al. (2016).

## Results

The results from each task are presented in Figure 5 and Figure 6: the graphs show the distribution of pupils' perception of the task before they started to work on it. Each bar in the graph is also split to show pupils change in perception of the task after they completed working with it. For example, in the left-hand graph in Figure 5, the bar on number 2 shows that 12 pupils, identified as mathematical promising, chose the second most positive emoji before they started to work on *Task 1*. Further, the same bar shows that of those 12 pupils, five gave the task a more negative judgement, two gave it a more positive judgement and five still gave them the second most positive judgement after they completed the work with the task.

<sup>2</sup> The process of choosing and analyzing the tasks are described in Mellroth et al. (2016)

**Figure 5: Pupils evaluation of *Task 1*, before starting their work on the task and after they completed their work (Figure adapted from Mellroth et al, 2016, p. 19).**

**Figure 6: Pupils evaluation of *Task 2* before starting their work on the task and after they completed their work (Figure adapted from Mellroth et al, 2016, p. 19).**

As both Figure 5 and Figure 6 show, through the concentration of the bars to the left, pupils identified as mathematically promising perceive both tasks more positively compared to the non-identified pupils before they started to work with the tasks. Considering *Task 1*, the two groups of pupils, identified and non-identified, did not differ much in how they changed their evaluation of the task after they completed it. 28 percent compared to 33 percent judged the task more positively after they completed it, 28 percent compared to 24 percent judged it more negatively, and 44 percent versus 43 percent judged it the same as before. As to *Task 2*, and the results of comparing identified and non-identified pupils and how they changed their evaluation of this task after they completed it show: 15 percent compared to 33 percent gave a more positive judgement afterwards, 25 percent compared to

19 percent gave the task a more negative judgement afterwards and 60 percent compared to 49 percent did not change their judgement of the task.

## Interpretations and discussion

The aim of the study was to investigate how to identify mathematical tasks that can stimulate all pupils in a diverse classroom, including the mathematically promising. The two tasks used in the study were chosen because they were rich learning tasks and said to be suitable to challenge all pupils, including the mathematically promising (Sheffield, 2003). The positive evaluation given by especially the mathematically promising pupils were expected, therefore the results can be seen to verify the developed tool.

For *Task 1* the results show that the majority of the mathematically promising pupils, before starting to work on it, evaluated it as more positive: 63 percent choose the most, or the second most positive emoji, compared to 40 percent of the non-identified pupils. For *Task 2* the comparable percentages are 85 and 63 respectively. This indicates that the mathematically promising, especially, perceived the tasks interesting and joyful already before they knew the associated question. The results show that *Task 2* has this effect to a higher extend for all pupils, also the non-identified. The post evaluation of *Task 2* shows a relatively large shift to a more positive judgement of the task for the non-identified pupils, Figure 6 right graph. Altogether the results indicate that considering pupils' perception of joy and interest, *Task 2* is suitable for all pupils in the diverse classroom, including mathematically promising pupils.

The results also indicate that *Task 1* is not as suitable for all pupils. However, even if *Task 1* is not as good as *Task 2* according to the results, the mathematical promising pupils perceived it relatively positively before starting to work on it. In addition, just as many of them judged the task more negatively as those who judged it more positively afterwards. Also slightly more pupils of the non-identified judged it more positively after the completed work compared to the number that judged it more negatively. Therefore, *Task 1* might also be a suitable task in a diverse classroom even if it is not as good as *Task 2*.

According to the chosen frame for this study, tasks challenging and stimulating for mathematically promising pupils lead to that they feel joy and develop learning (Fuchs & Käpnick, 2009; Nolte, 2012; Sheffield, 2003). The identified pupils positive evaluation of the tasks, especially *Task 2*, can be a sign of that they felt the tasks challenging and stimulating. The results for the promising pupils can also be interpreted as an indication of that the developed tool fulfills its purpose to measure pupils joy and interest in a rich learning task. Furthermore, it is indicated that the tool can grade the suitability of different tasks, concerning joy and interest, in this case *Task 2* is perceived slightly more positive than *Task 1*.

It has been found that teachers rarely provide mathematically promising pupils with learning opportunities that benefit them in the diverse classroom (Leikin & Stanger, 2011), and also that positive attitudes towards working with mathematics make pupils achieve better (Chen & Stevenson, 1995). Based on this, the results show that the tasks might provide mathematical learning opportunities for all kind of pupils. Further development and verification of this tool can provide teachers with a simple way to find tasks that provide learning opportunities for all pupils in the diverse classroom, also for the mathematical promising.

Even if the simple tool has proven its use in principle, there are, of course, several limitations in this study, the investigation is simple and the tool used is not statistically verified. Nor does the investigation consider in depth how joy and interest is perceived by the pupils. In this study, pupils' motivation to work on a task is assumed to be connected to the perceived joy and interest. The teachers' evaluation of how the pupils worked with the implemented tasks is another important aspect, which this paper does not address. Within the frame of the professional development program the teachers observed and interviewed some pupils connected to their work with the investigated tasks; inclusion of this data would have strengthened the results (Mellroth et al., 2016). Also, to be able to compare different groups of pupils like for example mathematically promising and others (non-identified), teachers need knowledge on how to identify the different groups. In this study the teachers who collected the data participated in a professional development program on mathematical promise, their knowledge on how to identify those pupils can be considered as relatively deep. But it is needed to highlight this for someone who wants to repeat the study.

If further research is done to develop and validate the tool used here, it could provide in-service teachers with an easy and quick way to evaluate the suitability of tasks from a pupil's perspective. In turn this might result in mathematically promising pupils being presented with tasks that help them to develop according to their potential. In addition, complex single-case studies might explore specific aspects of tasks that are assessed highly by the pupils applying the tool presented in this study.

### Acknowledgment

Thanks to all teachers who participated in the professional development program and who were the driving force to include pupils' perception in the investigation. Those teachers, Agneta Arwidsson, Katarina Holmberg, Annika Lindgren Persson, Charlotta Nätterdal, Lotta Perman, Sofia Sköld and Annika Thyberg, are also the co-authors to Mellroth et al. (2016).

*This study investigates grade 10-12 mathematics teachers' beliefs about their roles as mathematics teachers through metaphors. These mathematics teachers' metaphors were analysed using the categorization developed in the context of NorBa-TM project. Most of these mathematics teachers described their teaching role as didactics experts. A closer investigation of these mathematics teachers' metaphors and their teaching experience revealed some variation although not statistically significant.*

*Keywords: Upper secondary education, mathematics, teachers' metaphors.*

## Introduction

The study of mathematics teachers' beliefs and their influence on their teaching practices has gained considerable research attention. Research on teachers' thinking reveals that teachers hold coherent educational beliefs that shape their teaching practices (Handal, 2003; Thompson, 1992; Zhang & Morselli, 2016).

Metaphors offer insights into beliefs that are not obviously or consciously held (Oksanen & Hannula, 2012). A teachers' creation of a metaphor could be the result of his/her attempt to conceptualize his/her teaching. As Martinez, Saulea and Huber (2001) state there is a need for a "shared system of interpretation and classification" of the metaphors teachers and prospective teachers hold, in order to communicate these metaphors and thus to develop them further.

Recent studies in mathematics education (Haser, Aslan & Celikdemir, 2015; Oksanen & Hannula, 2012; Oksanen, Portaankorva-Koivisto & Hannula, 2014) have used the extended model of Beijaard, Verloop and Vermunt (2000) to investigate pre-service and in-service mathematics teachers' (grades 7-9) beliefs as expressed through their metaphors. The present study aims to explore whether the extended model suggested by L fstr m et al. (2010) can be used to describe and categorize Cypriot mathematics teachers' beliefs expressed through metaphors.

## Theoretical framework

### Mathematics teachers' beliefs

Teachers' mathematical beliefs refer to those belief systems that teachers hold regarding the teaching and learning of mathematics (Handal, 2003). These beliefs seem to be derived from personal experience, experience with schooling and instruction, and experience with formal knowledge (Zhang & Morselli, 2016).

Studies have shown that each teacher holds a specific belief system which consists of a range of beliefs about teachers, learners, teaching, learning, school settings, resources, knowledge and

curriculum. The importance of them is that they act as a filter through which teachers make their decisions and they do not rely solely on their knowledge about pedagogy and curriculum (Handal, 2003).

### **Beliefs and metaphors**

An important trend on research regarding teachers' mathematical beliefs is the issue of teacher belief change (Zhang & Morselli, 2016). Researchers suggested a variety of methods and activities in order to investigate teachers' beliefs and also to support teachers reflect upon their experiences. One efficient way is through metaphors. Cooney et al. (1998) found that reflection played a significant role in prospective secondary teachers' growth. Researchers aiming to capture the meaning teachers ascribed to their educational experience, assessed preservice teachers' beliefs by collecting multiple data, including teachers' choice and responses to metaphors (e.g. a mathematics teacher is like an entertainer, a doctor, a gardener, a coach etc.).

### **Metaphors**

Metaphors provide a unique way to represent the world by helping people frame the meaning of their experiences (Kasten, 1997; Zhao, Coombs & Zhou, 2010). As Martinez et al. (2001) state, metaphors are not just "figures of speech" but compose an important mechanism of the mind. The word "metaphor" is derived from the Greek word 'metaphora' (transfer) (Kasten, 1997). Metaphors refer to the understanding of one kind of object or experience in terms of a different kind of object or experience which is more familiar, concrete or visible (Lakoff & Johnson, 1980; Zhao, Coombs & Zhou, 2010). As Lakoff and Johnson (1980) emphasized, a major part of the human conceptual system is structured by metaphorical relations, which are rich and complex.

In educational settings, educators are "unconsciously guided by images and metaphorical patterns of thought as recurring in the field, which can be seen as "archetypes" of professional knowledge" (Martinez et al., 2001, p. 966). In this way, metaphors reflect teachers' understanding of teaching and learning which is difficult to access in a verbatim language providing a deeper and more profound insight into teachers' beliefs and affect in relation to their teaching and the wider social context (Zhao, Coombs & Zhou, 2010). Teachers' beliefs about teaching and learning are associated with teaching roles and in this way metaphors are used to encapsulate the teaching roles (Kasten, 1997).

### **Categories of metaphors**

Löfström et al. (2010) investigated university students' metaphors in Estonia using the Beijaard et al. (2000) model of teacher identity. This initial model identifies three distinct knowledge bases of teacher knowledge reflecting teachers' professional identity. According to the model, teachers' professional identity can be described in terms of the teacher as a *subject matter expert*, the teacher as a *pedagogical expert* and the teacher as a *didactics expert*. The results of the study indicated that the model by Beijaard and colleagues could be expanded to include three additional categories. *Self-referential metaphors*, *contextual metaphors* and *hybrids*. A description of each category of this extended model of teacher identity follows: (a) A teacher as a *subject matter expert*: The teacher has a deep and full understanding of his/her subject area and is a transmitter of knowledge to the students. (b) A teacher as a *pedagogical expert*: The teacher is someone who supports the child's development as a human being. Emphasis is on relationships, values, and the moral and emotional

aspects of children development. (c) *A teacher as a didactics expert*: The teacher has knowledge about how to teach specific subject-related content so that students can capitalise on their learning. This kind of knowledge is referred to as knowledge of didactics, and it is discipline- and subject specific in nature. (d) *Self-referential metaphors*: Self-referential metaphors do not refer to acts central to teaching, students or classroom instruction. These metaphors focus on what teaching represents for the respondents as individuals. They describe features or characteristics of the teacher's personality, with reference to the teacher's characteristics (self-referential) without reference to the role or task of the teacher. One might say that these metaphors describe who the teacher is. (e) *Contextual metaphors*: These metaphors describe features or characteristics of the teacher's work/work environment or in other ways refer to characteristics of the environment (contextual). (f) *Hybrids* may include elements of more than one of the above categories.

The above categorization was employed in recent studies investigating teachers' beliefs through metaphors. Specifically, Oksanen and Hannula (2013) used this categorization to investigate 70 Finnish 7-9 grade mathematics teachers' beliefs regarding teaching and teachers as expressed through metaphors. The results revealed that the teacher as a didactics expert was the most frequently used metaphor (49%). The results showed no statistical significant associations between metaphors and age or gender. In the study by Oksanen et al. (2014) including 72 Finish pre-service teachers and 65 Finish in-service (grade 7-9) mathematics teachers, the most common metaphor used by pre-service teachers was self-referential (46%) while the most frequently used metaphor by in-service teachers despite their teaching experience was the category didactics expert (51%). The researchers explained that as in-service teachers gain more teaching experience, this does not affect the metaphor they use to describe their mathematics teachers' role. Finally, in the study by Haser et al. (2015) with 249 Turkish pre-service students, 29.6% used didactic expert metaphor while 26.5% used self-referential metaphors to express their beliefs.

The purpose of the current study was to explore if the categories included in the model by Löfström et al. (2010) can be used to categorize upper secondary school teachers' beliefs expressed through metaphors in Cyprus and whether the categories proposed in this model are exhaustive enough to cover all metaphors.

## Context

According to the Annual Report of the Cyprus Ministry of Education and Culture (2014) the Public Secondary General Education in Cyprus is offered to students between the ages of 12 - 18, through two three-year levels - the Gymnasium (Grades 7-9) and the Lyceum (Eniaio Lykeio) (Grades 10-12). The curriculum includes common core subjects, such as Modern Greek and Mathematics and Optional Subjects. Some subjects are interdisciplinary such as Health Education and Environmental Studies. In the academic year 2000 - 2001, the institution of the Eniaio Lykeio was introduced in all public secondary schools in Cyprus. All subjects in Grade 10 are common core subjects. In Grades 11 and 12 students attend common core subjects and at the same time select optional subjects for systematic and in depth study. In Cyprus there are 38 Lycea and 7 joined Gymnasia and Lycea. Approximately 280 mathematics teachers work in Lycea. These mathematics teachers are also responsible for the preparation of students for their entrance exams in the public University of Cyprus and the public universities in Greece.

## Methodology

### Data collection, instruments and participants

Data for this study was gathered from mathematics teachers working in Lyceum (Eniaio Lykeio) during the school year 2015-2016. The study was conducted in the context of the international comparative study New Open Research: Beliefs about Teaching Mathematics (NorBa-TM) investigating mathematics teachers' beliefs in more than 15 countries.

A questionnaire was developed and culturally adapted in the participating countries in the context of the project NorBA-TM. The questionnaire comprised of seven parts: one of them qualitative and six quantitative (86 items). The current study used data only from two parts of the aforementioned questionnaire: Part A, that collected data on teachers' background variables (age, gender, education, teaching experience, teaching maths at Lyceum etc.) and Part H that collected data on metaphors. Specifically, Part H included two questions that invited the teachers to think and write down a metaphor characterising themselves as upper secondary level mathematics teachers and to explain their metaphor: "As a mathematics teacher I am like....." and "My brief explanation of the metaphor is as follows:....". We assume that the metaphor research is a useful social science methodology that can be used for generating authentic case study evidence in a certain field.

Data collection took place in June 2015. First, informative letters along with the questionnaire and prepaid envelopes were sent to mathematics teachers in all Lyceums inviting them to participate in the study on a voluntary basis. Teachers who wished to participate in the study completed the questionnaire and returned it to the Cyprus Pedagogical Institute without disclosing their personal data (name and school). A total of 147 out of 280 (53%) mathematics teachers completed and returned the questionnaire. Out of these 147, only 49 (33%) completed Part H by presenting a metaphor and providing an explanation.

Data analysis was performed using the categorization of Löfström et al. (2011) which was explained in detail in the manual developed for the NorBa project. The metaphor categorization was judged on a case-to-case basis using three independent raters whose coding were compared at the end. The raters compared their codes and discussed their differences. In the majority of cases, agreement between the three raters could be reached. In three cases though, consensus between raters was not reached and external researchers with experience in mathematics teachers' metaphors were involved.

## Results

### Categorizing teachers' metaphors

The distribution of metaphors used by the Cyprus in-service mathematics teachers is presented in Table 1.

Teacher as a subject matter expert	Teacher as didactics expert	Teacher as Pedagogical expert	Self-referential	Contextual	Hybrid
8 (16,3%)	12 (24,5%)	6 (12,2%)	9 (18,4%)	7 (14,3%)	7(14,3%)

**Table 1: Distribution of metaphors used by Cypriot mathematics teachers**

Teacher as didactics expert was the most common metaphor used (24,5%). Mathematics teachers in this category used metaphors like “a coach”, “a builder”, “an electrical wire”, “a gardener”, “a playmate, play-maker”. In their explanations, teachers emphasized their role as facilitators of students’ learning process, as mediators between students and the discovery of the new mathematical knowledge, as contributors to the construction of the new mathematical ideas. They referred to the communication of ideas and the team spirit, emphasizing a more constructivist view of learning and teaching. They made also reference to the active role of the students in the learning process.

As a mathematics teacher I’m like a playmate in a team game that usually has the role of the play-maker. I’m trying to arrange the learning activities because we function as a team with a preset schedule of the game. I encourage initiatives but I control for the application of certain rules.

Self-referential was the second most common metaphor used (18,4%). Mathematics teachers in this category used metaphors like “a painter”, “a musician”, “a hard-working bee”, “a perfect circle”, “an angle”. In their explanations these teachers refer to their individual characteristics and their personality traits without reference to the role or task of the teacher.

As a mathematics teacher I’m like an angle. Sometimes acute, sometimes obtuse, sometimes convex and sometimes non-curved.

Teacher as Subject matter expert was used by 16,3% of the teachers. Mathematics teachers in this category used metaphors like “a machine of knowledge”, “a guide in a journey”, “a vocation backpack”, “a well of knowledge”. In their explanations these teachers refer to their teaching role as transmitters of ready-made knowledge to the students and organizers of routines. Mathematical knowledge is conceived as predetermined knowledge that can be delivered by the teacher.

As a mathematics teacher I’m like a well of knowledge. When I’m in class I find ways and examples to transmit the mathematical knowledge to students.

A percentage of 14,3% of the teachers provided metaphors that fell within the category Contextual. Mathematics teachers in this category used metaphors like “an actor”, “a salesman”, “the guy for every job”. In their explanations these teachers refer to the characteristics of the teachers’ work, or the characteristics of the environment the teacher works stressing that it is too demanding and multifunctional. They refer to the teacher in a social context but they do not refer to any specific aspect of the teachers’ professional knowledge or teaching.

As a mathematics teacher I’m like a guy for every job. Mathematics teachers are like ping pong balls. They are involved in many tasks and processes in the school setting but these efforts do not lead to something recognizable or efficient.

A percentage of 14,3% of the teachers provided metaphors that fell in more than one category thus they were categorized as Hybrid. Most of the metaphors in this category include the didactics expert’s characteristics along with another category. The following metaphor was categorized as both didactics expert and contextual metaphor.

As a mathematics teacher I'm like a director who writes a movie and participates in it. As a mathematics teacher I design the teaching of a lesson, I decide for the way to implement it in different faces and last like as an actor I perform different roles.

Finally, 12,2% of the teachers provided a metaphor that fell in the category teacher as pedagogical expert. Mathematics teachers in this category used metaphors like “a parent”, “a mother”, “and an eagle”, “a priest”. In their explanations these teachers emphasized the values, the moral and emotional aspects of students' development. They reveal a more affectional relationship and communication with the students.

As a mathematics teacher I'm like a spiritual father (e.g. a priest). I believe that my main goal is to advice students that with hard work, healthy competition and honesty they can be better in mathematics and in society. Just by hard work.

### Metaphors and background characteristics

No statistically significant differences were detected between gender, teaching experience and metaphors. Table 2 presents the distribution of metaphor used according to teaching experience.

Teaching experience	n	Subject-matter expert	Didactics expert	Pedagogical expert	Self-referential	Contextual	Hybrid
0-10	9	2 (22.2%)	2 (22.2%)	3 (33.3%)	1 (11,1%)	0 (0%)	1(11.1%)
11-20	26	2 (7.6%)	9 (34.6%)	3 (11.5%)	4 (15.3%)	5 (19.2%)	3 (14.2%)
21 and more	14	4 (28.5%)	1(7.1%)	0 (0%)	4 (28.5%)	2 (14.2%)	3 (21.4%)

**Table 2: Teaching experience and categories of metaphors**

As it can be observed, the most common category for teachers with the least years of experience is the teacher as pedagogical expert. The most common metaphor category for the second group of teachers is the teacher as a didactics expert. For the group of mathematics teachers with 21 years of experience and over, the most common categories are teacher as subject matter expert and self-referential metaphors. Contextual and hybrid categories are most frequently met in teachers with more years of teaching experience than those with 0-10 years of experience.

### Discussion

The results revealed that the model proposed by Löfström et al. (2010) can be applied to categorize the metaphors provided by the in-service Cypriot mathematics teachers in upper secondary education (Grades 10-12) and that the categories included in the extended model were collectively exhaustive. The results showed that these teachers prioritize *didactics knowledge*, *self-reference* and *subject matter metaphors*. In particular, the findings showed that the teacher as didactics expert was the most common metaphor provided. This finding is in line with the results of other similar studies (Oksanen & Hannula, 2013; Oksanen et al., 2014) which reported that this category was the most common among mathematics teachers teaching Grades 7-9. However, in the current study the percentage of teachers who used metaphors which described them as didactics expert (24.5%) was not as high as in the other two studies (46% and 51% respectively). Self-referential metaphors were also used by participants of the current study (18.4%). This percentage is higher than the

percentages reported by the other studies in the literature, which state that this category reflects the multi-functionality of teachers' role (Oksanen & Hannula, 2013; Oksanen et al., 2014). The emergence of hybrid metaphors has been explained in other studies (Oksanen & Hannula, 2013; Oksanen et al., 2014) by the complexity of a teachers' job.

The investigation of these teachers' metaphors in relation to their teaching experience revealed no statistically significant differences similar to the results of the study by Oksanen et al. (2014). In that study the researches described that the most common metaphor for all groups of teachers was the teacher as didactics expert. In the current study, pedagogical expert and didactics expert were the most common metaphors for the group of mathematics teachers with the least years of experience, didactics expert was the most common metaphor for the group of teachers with 11-20 years of experience and subject matter expert and self-referential were the most common metaphors for the group with 21 and more years of experience. However, these relationships were not statistically significant. Modifications in mathematics education at the university level, as well as modifications in the work context related to the Cyprus Educational Reform of 2011 could be associated with these groups of teachers' perceptions about their roles as teachers of mathematics.

The results indicated that the model suggested by Löfström et al. (2010) is a useful model that can be used to categorize teachers' metaphors. These teachers' metaphors mapped their current practice and understanding of teaching and learning and revealed what they are and how they feel about their work (Zhao et al., 2010). But how stable are these imageries provided? Will these teachers provide the same metaphor if they are asked again under different conditions, working in different school with other students or if they are under the pressure of their students' entrance exams or at the end of a stressful day? How the methodology used could be developed to include teachers' current state? Further studies investigating the stability of these metaphors are needed. Moreover, further studies could investigate the relation between mathematics teachers' beliefs and mathematics teachers' use of metaphors.

# Multiple solutions for real-world problems, and students' enjoyment and boredom

Stanislaw Schukajlow and Kay Achmetli

University of Münster, Germany; [schukajlow@uni-muenster.de](mailto:schukajlow@uni-muenster.de)

*Emotions are important for learning. In a previous study, we found that students who constructed more solutions for real-world problems with vague conditions reported higher enjoyment and lower boredom (Schukajlow & Rakoczy, 2016). In the present study, we had students construct multiple solutions by applying multiple mathematical procedures to real-world problems, and we investigated effects on the enjoyment and boredom. 307 students were assigned to the experimental or control group. Students in the experimental group applied two mathematical procedures, and students in the control group applied one mathematical procedure to solve real-world problems. During the lessons, they were asked to report their enjoyment and boredom. Contrary to our expectations, the results revealed no effects of the intervention on students' enjoyment or boredom.*

*Keywords: Emotion, affect, modelling, word problems, multiple solutions.*

## Introduction

Emotions are important for learning (Zan, Brown, Evans, & Hannula, 2006). Although students' academic emotions are prerequisites, mediators, and outcomes of the learning process in mathematics (Schukajlow & Rakoczy, 2016), they were neglected for decades. Thus, except for the emotion of anxiety, we do not know much about students' emotional development. Moreover, there is a lack of research on how teaching methods influence emotions. As there have been several calls for intervention studies, we decided to conduct a study that was aimed at clarifying the impact of constructing multiple solutions for real-world problems on cognitive and affective outcomes. We chose this teaching method and this kind of problem because constructing multiple solutions and solving real-world problems are emphasized in curricula in different countries. In the present paper, we taught students to construct multiple solutions by applying different mathematical procedures to solve real-world problems, and we investigated how this process affected enjoyment and boredom.

## Theoretical framework and hypotheses

High-quality mathematics teaching implies that students should develop multiple solutions and compare these solutions in the classroom. Empirical evidence for the effects of constructing multiple solutions on cognitive outcomes comes from international comparative studies (Hiebert et al., 2003) and from experimental studies (Levav-Waynberg & Leikin, 2012; Schukajlow, Krug, & Rakoczy, 2015). However, the impact of constructing multiple solutions on affect is an open issue. For high-quality mathematics teaching, both cognitive and affective outcomes have to be taken into account. As we determined in the project MultiMa<sup>1</sup> (Multiple Solutions for Mathematics Teaching

---

<sup>1</sup> This research was financially supported by a grant from the German Research Foundation (Deutsche Forschungsgemeinschaft) allocated to the first author (SCHU 2629-2).

Oriented Toward Students' Self-regulation Learning), apart from students' achievements and strategies, there is also a need to consider their self-regulation, interest, motivation, and emotions.

### Multiple solutions and real-world problems

Previous research on multiple solutions was conducted for the most part on intra-mathematical problems in different content areas such as geometry (Levav-Waynberg & Leikin, 2012) or early algebra (Star & Rittle-Johnson, 2008). Students' ability to solve real-world (or modelling) problems was not previously the focus of research on multiple solutions so far. Solving real-world problems first and foremost involves demanding transfer processes between reality and mathematics (Niss, Blum, & Galbraith, 2007). As real-world problems often include vague conditions and allow students to construct different mathematical models and apply different mathematical procedures, we distinguished between three categories of multiple solutions (Schukajlow & Krug, 2014b). The first category of multiple solutions are typical of real-world problems with vague conditions. In solving this type of problem, students make different assumptions about vague conditions and therefore arrive at different outcomes or results. Another type of multiple-solution problem occurs as a result of applying different mathematical procedures or strategies, a process that typically leads to the same mathematical outcome. The third category combines the first two categories. In the current paper, we explored the effects of applying multiple mathematical procedures while solving real-world problems for the topic of linear functions. We would like to illustrate this type of multiple-solution problem with the sample problem "BahnCard" (cf. Figure 1), which was developed in the framework of the MultiMa Project.

**BahnCard**

Mr. Besser lives in Hamburg. His parents live in Bremen. For the outward and return journeys with the "Deutsche Bahn" (German Rail), Mr. Besser has to pay 100 €. There are two special offers, the so-called "BahnCard 25" and the "BahnCard 50." The prices for each year and the prices for the outward and return journeys from Hamburg to Bremen for owners of the "BahnCards" are listed below.

BahnCard 25	BahnCard 50
Price per year: 59 €	Price per year: 240 €
Price for a round-trip journey: 75 €	Price for a round-trip journey: 50 €
Number of customers: 3.1 million	Number of customers: 1.6 million

Mr. Besser is going to buy a "BahnCard." When is it worth buying the "BahnCard 25" and when the "BahnCard 50"? Write down your solution.

**Figure 1: Real-world problem "BahnCard" (Achmetli, Schukajlow, & Krug, 2014)**

The problem solver is asked to read the problem "BahnCard," and identify the important values: price per year for each card and the amount of a round-trip journey that would be paid with each card. After mathematizing the problem, different mathematical procedures can be applied.

One mathematical procedure that can be applied is called "differences." In order to solve the "BahnCard" problem by using differences, students first have to calculate differences in the prices per year and for each round trip for owners of each card. Whereas the "BahnCard 50" is 181 € (= 240 € - 59 €) more expensive than the "BahnCard 25," each round trip with the "BahnCard 25" is 25 € (= 50 € - 25 €) more expensive than with the "BahnCard 50." The open question is how often Mr. Besser has to take a trip with the more expensive "BahnCard 50" until the cheaper prices for the

journeys pay off. This is exactly after 7.24 ( $= 181 \text{ €} \div 25 \text{ €}$ ) journeys per year. This result has to be rounded up, interpreted—for example, “For up to 7 journeys per year, the ‘BahnCard 25’ is cheaper”—validated, and the recommendation has to be wrote down.

Another way to solve this problem is to apply a mathematical procedure “table.” To apply this procedure, students must compare the costs for owners of the “BahnCard 25” and the “BahnCard 50” for different numbers of journeys per year (e.g. 1, 3, 6...). By performing this comparison systematically, they can identify that the “BahnCard 25” is cheaper for up to 7 journeys. If the owner makes 8 or more journeys, the “BahnCard 50” is preferable for him/her. Finally, students need to validate their result and write down their recommendation.

### **Enjoyment and boredom as achievement emotions**

Emotions are typically defined as complex phenomena that include affective, cognitive, physiological, motivational, and expressive parts (Pekrun & Linnenbrink-Garcia, 2014). In the academic context, researchers are interested in achievement emotions, which occur in learning settings and are related to epistemic processes. Research on emotions in mathematics education has emerged from different philosophical traditions (Hannula, 2015) and has categorized emotions according their value (positive or negative), level of activation (activated or deactivated), or other characteristics. For example, enjoyment is one of the positive activating emotions (Pekrun, 2006). Students who enjoy problem solving are expected to report pleasant feelings. Moreover, when students enjoy mathematics, they feel activated excitement while working on a problem. The opposite behavioral and cognitive patterns are expected for the emotion of boredom. Boredom was suggested to be a negative deactivated emotion because boredom is accompanied by unpleasant feelings, and if students feel bored, they experience a state of deactivating relaxation. Following these considerations, a positive relation between enjoyment and performance and a negative relation between boredom and performance were hypothesized and confirmed in two empirical studies in the domain of mathematics (Schukajlow, 2015; Schukajlow & Krug, 2014a). Moreover, enjoyment but not boredom was found to predict students’ performance in a longitudinal interventional study (Schukajlow & Rakoczy, 2016).

According to the control-value theory of achievement emotions (Pekrun, 2006), emotions are strongly determined by control and value appraisals, which arise in learning situations. In order for a positive emotion such as enjoyment to emerge, students should (1) perceive their problem solving activities as controllable and be confident that they can influence the learning situation and (2) ascribe the problem solving activities a high value. If students think that they do not have any influence over their problem solving activities, or if they view these activities as meaningless, negative emotions will emerge. For example, boredom arises if students ascribe a low value to their activities. The relation between boredom and control appraisals is complex and is proposed to be a curvilinear U-shape. This relation implies that boredom occurs when perceived control is very high (i.e. task demands are very low) or when perceived control is very low (i.e. task demands are very high). However, in the context of problem solving activities, students do not have to deal with routine tasks. Thus, a negative linear relation between control appraisals (e.g. assessed via students’ performance or self-efficacy beliefs) and boredom was expected and confirmed in most empirical studies (e.g. Schukajlow, 2015).

## **Enjoyment, boredom, and multiple solutions for real-world problems**

On the basis of theoretical considerations from control-value theory, we expected to find that constructing multiple solutions would increase students' control appraisals when solving real-world problems. Higher appraisals should increase students' enjoyment and decrease their boredom. Positive effects of constructing multiple solutions on enjoyment and negative effects on boredom were confirmed in our previous study. Students who constructed more solutions enjoyed their classes more and were less bored (Schukajlow & Rakoczy, 2016). In the current study, we sought to confirm these findings for the other type of multiple-solution problem and investigated the effects of applying multiple mathematical procedures for real-world problems on enjoyment and boredom.

### **Hypotheses**

The hypotheses we addressed were: 1) Constructing multiple solutions by applying multiple mathematical procedures for real-world problems has a positive effect on students' enjoyment of mathematics; 2) Constructing multiple solutions by applying multiple mathematical procedures for real-world problems has a negative effect on boredom in mathematics.

## **Method**

### **Sample and procedure**

Three hundred seven German ninth graders from four schools with three middle-track classes each (48.26% female; mean age=14.6 years) participated in the present study. Before and after the teaching unit, students were asked about their enjoyment and boredom. The teaching unit consisted of two sessions with two 45-minute long lessons each. Each of twelve classes was divided into two parts with the same number of students in each part in the way students' mathematical achievements did not differ between the parts. Further, the number of males and females was approximately the same in each part. Eight of twenty-four groups were randomly assigned to the one-solution condition "differences" (OS1), eight groups to the one-solution condition "table" (OS2), and eight to the multiple-solutions condition "differences + table" (MS), taking into account that in each school, there had to be the same number of groups assigned to each condition, and the students in each class had to be assigned to different conditions (more details about the procedure can be found in Achmetli, Schukajlow, & Rakoczy, manuscript submitted for publication). Each group was taught separately by one of six teachers (three female, age: 27 to 60) who participated in the present study. The teachers taught the same number of groups in each condition in order to minimize the differences between conditions that might result from the influence of teacher personality on students' learning. All of the teachers received instruction manuals that included the lesson plans, problems for the students, and the solutions to these problems.

### **Treatment**

The three treatment conditions implemented in the present study (OS1, OS2, and MS) were based on the positively evaluated student-centered learning environment for teaching modelling problems (Schukajlow, Kolter, & Blum, 2015). This student-centered learning environment was complemented by direct instruction at the beginning of the teaching unit. For the purpose of maintaining comparability between the conditions, the same order was implemented for all three treatment conditions. In the first lesson, the teacher demonstrated how real-world problems could be

solved by applying one mathematical procedure (in the OS conditions) or multiple mathematical procedures (in the MS condition). In the three lessons that followed, the students solved real-world problems by applying the demonstrated procedures according to a special procedure for group work (alone, together, and alone), presented their solutions, and discussed these solutions with the whole group in the classroom. At the end of each lesson, the teacher summarized the key points of each treatment condition. In the multiple-solutions condition, the teacher encouraged the students, further, to compare and contrast the two mathematical procedures and the mathematical results.

Students first solved four similar tasks in the one-solution conditions and in the multiple-solutions condition. The only difference between these four problems was that students in the one-solution conditions were required to apply one mathematical procedure (“table” or “differences”), whereas students in the multiple-solutions condition were required to apply both mathematical procedures (“table” and “differences”). The sample problem “BahnCard,” which was given in the one-solution conditions, is presented in Figure 1. In the multiple-solutions condition, the problems were modified by adding the following sentence: “Use two different mathematical procedures to solve this problem.” As the discussion of the connection between mathematical procedures required additional time in the MS condition, one additional task was offered in each OS condition. Thus, in sum, students in the MS condition solved six and students in the OS conditions solved seven problems.

### Measures

Enjoyment and boredom during the teaching unit were measured after the second and fourth lessons with a 5-point scale ranging from 1 (not at all true) to 5 (completely true). Both scales included three items each (see Table 1).

Scale	Item
Enjoyment	I enjoyed task processing. I was happy during task processing. Task processing was great fun for me.
Boredom	Task processing was boring. I got so bored during task processing that I had problems staying alert. I did not want to continue my work because it was so boring.

**Table 1: Items used in the study to assess enjoyment and boredom**

The scales were adapted from the well-evaluated Achievement Emotions Questionnaire (Pekrun, Goetz, Frenzel, Barchfeld, & Perry, 2011). The Cronbach’s alpha reliabilities were .80 and .79 for enjoyment and .81 and .83 for boredom for Sessions 1 and 2, respectively.

### Treatment fidelity

To ensure the fidelity of the treatment, we videotaped the teaching unit, observed the lessons, and analyzed the students’ solutions. The analysis confirmed the treatment fidelity (Achmetli et al., manuscript submitted for publication). For example, we found that students in all classes worked on the respective version of the problem (MS vs. OS) and all teachers implemented the intended methodical order in their lessons. More specifically, we found that students in the MS condition developed significantly more solutions than the students in the OS conditions (MS vs. OS1: effect size Cohen’s  $d=4.97$ ; MS vs. OS2:  $d=3.61$ ).

## Results

### Preliminary results

In order to simplify the analysis of the effects, we combined the OS1 and OS2 conditions into one OS condition. Combining the two conditions did not influence the results significantly, as our statistical analysis did not show a difference at the 10% level of significance between the two OS conditions for motivational variables such as self-regulation (Achmetli et al., 2014) or interest ( $t(186) = 0.182$ ;  $p = .856$ ). Further, in order to ensure that the two conditions were comparable, we compared interest between the MS condition and the combined OS condition as this construct is closely connected to students' enjoyment and boredom (Schukajlow & Rakoczy, 2016). The analysis of interest at pretest revealed no differences between the MS and OS conditions (MS:  $M = 2.39$  ( $SD = .90$ ), OS:  $M = 2.39$  ( $SD = .96$ )). This result indicates that students' emotional prerequisites were similar in the MS and OS conditions.

### Applying multiple mathematical procedures and students' enjoyment or boredom

We hypothesized that constructing multiple solutions by applying multiple mathematical procedures would increase students' enjoyment and decrease their boredom. We tested both hypotheses by computing t-tests. The crucial assumption when using a t-test is that the variances are equal in the two groups. Levene's test of equality of variances was significant for students' boredom measured after the second and third lessons, indicating that the assumption of equal variances in the two groups had been violated ( $F(280) = 4.022$ ,  $p = .046$ ;  $F(279) = 4.851$ ,  $p = .028$ ). Thus, we used the adjusted degrees of freedom, t-values, and  $p$ -values for students' boredom. The descriptive statistics are presented in Table 2.

	Enjoyment first session Mean (SD)	Enjoyment second session Mean (SD)	Boredom first session Mean (SD)	Boredom second session Mean (SD)
MS	3.42 (0.92)	2.96 (0.91)	2.24 (1.05)	2.53 (1.16)
OS	3.43 (0.88)	3.00 (0.96)	2.03 (0.90)	2.30 (1.00)

**Table 2: Means and standard deviations for enjoyment and boredom**

Against our expectations, students' enjoyment during the first and second sessions did not differ between the MS and OS conditions (first session  $t(280) = 0.75$ ,  $p = .940$ , Cohen's  $d = 0.02$ ; second session:  $t(279) = 0.297$ ,  $p = .767$ ,  $d = 0.04$ ). Thus, the enjoyment of students who solved real-world problems by applying multiple mathematical procedures was similar to the enjoyment of students who applied one mathematical procedure.

We did not find support for the second hypothesis. Our analysis did not reveal benefits of constructing multiple solutions by applying multiple mathematical procedures for students' boredom during the first or second session (first session  $t(165) = 1.67$ ,  $p = .097$ , Cohen's  $d = 0.22$ ; second session:  $t(156) = 1.62$ ,  $p = .108$ ,  $d = 0.22$ ). Moreover, there was a slight (but not significant) tendency for students in the multiple-solutions group to feel greater boredom than students in the one-solution condition.

## Discussion

In this paper, we aimed to analyze how constructing multiple solutions by applying multiple mathematical procedures while solving real-world problems would affect students' emotions. On the basis of theoretical considerations from the control-value theory of achievement emotions (Pekrun, 2006) and prior research that found that developing multiple solutions had positive effects on students' enjoyment and negative effects on their boredom (Schukajlow & Rakoczy, 2016), we expected positive effects of the treatment on enjoyment and negative effects on boredom during learning. However, our analyses did not confirm these hypotheses. Enjoyment and boredom in solving real-world problems did not differ between the multiple-solutions and one-solution conditions. Moreover, boredom was slightly lower in the one-solution condition compared with the multiple-solutions condition. One explanation for this finding might involve students' high control appraisals. In the previous study, the mean values for students' experience of competence, which can be taken as an indicator of students' control appraisals (sample item: "I felt confident about my knowledge of the topic today"; range from 1 to 5), were 3.85 and 3.65 in the MS and OS conditions, respectively (Schukajlow & Krug, 2014b). However, in the current study, the mean values for students' experience of competence were nearly one standard deviation higher and close to the theoretical maximum of 5 (Achmetli et al., manuscript submitted for publication). As noted in the control-value theory, if students' control appraisals are too high (or task demands are too low), they can have a negative influence on students' emotions. Thus, a future research question might involve asking whether posing more demanding real-world problems that require students to apply multiple mathematical procedures can increase students' positive emotions such as enjoyment and decrease their negative emotions such as boredom. Another research question that should be addressed in an experimental study is about the non-linear connection between control appraisals and students' emotions. This assumption of the control-value theory needs more empirical evidence from randomized studies. More specifically, the curvilinear U-shape relation between control appraisals and boredom should be addressed in future longitudinal studies. Further, it might be the case that the type of multiple-solution problem makes a difference. Whereas students enjoy making different assumptions about missing information, constructing different solutions, and comparing their results, this enjoyment might not hold when they apply different mathematical procedures. Similar effects (low level of boredom for the first type of multiple-solution problem, but no difference in boredom for the second type of multiple-solution problem) were also found for students' boredom. Another explanation for no effects of the intervention on emotions might be that students in the multiple solution condition were not offered to choose their favorite procedure during three of four lessons. More efforts are needed to clarify the role of multiple solutions for affective measures and more generally, with respect to the effects of teaching methods on students' affect.

*Several studies have looked at either the effects of students' Self-Efficacy Expectations (SEE) on their mathematics performance results, or the effect of previous mathematics performances on students' SEE. Few studies have tested the theoretically proposed reciprocal relationship between mathematics SEE and performance in mathematics. Furthermore, previous studies have not included levels of difficulty, although this is an integral part of the definition of SEE. This study applied a new measure of SEE, which included both test taking facets and levels of perceived difficulty, to investigate their relationships with students' performance on a national test in mathematics. Two models gave very good fit to the data, and supported the reciprocal effects model. These models provided estimates of the relationships between students' test performance and their level and facet-specific SEE, respectively.*

**Keywords:** Self-efficacy, performance, reciprocal effects, levels of difficulty, test taking facets.

## Introduction

Self-efficacy expectations (SEE) are important because extensive research indicates they are related to student learning and performance (Zimmerman, 2000). Studies have demonstrated the effect of mathematics SEE on performance results (e.g. Pajares, 1996) and vice versa (e.g. Pampaka, Kleanthous, Hutcheson, & Wake, 2011), but the proposed reciprocal relationship between SEE and performance (Bandura, 1997) has received little attention. Investigating this relationship empirically is important in order to understand the relationship between SEE and performance in mathematics, and the process by which SEE may influence performance in mathematics and vice versa. Few studies have investigated reciprocal effects between SEE and mathematics performance with longitudinal data, and none that we know of in relation to national tests in Norway.

Bandura (1997) argued SEE vary according to three dimensions, but we know of no studies that have included SEE *level of difficulty* to investigate reciprocal effects with mathematics. As we argued in Street, Malmberg, & Stylianides (2017), including level of SEE is important as it is an integral part of the definition of SEE (Bandura, 1997). We aimed to address this research gap by testing a reciprocal effects model including students' level and facet-specific SEE, and their scores on a Norwegian national test. To this aim, we applied a recently developed measure of mathematics SEE that includes four facets of test taking as well as three levels of perceived difficulty. We included students' SEE responses and test scores as they progressed from grade 8 to grade 9.

## Theoretical background

*Self-efficacy expectations* (SEE) are individuals' judgments about perceived capability to perform on future tasks (Bandura, 1997), for instance students' expectations they are able to carry out the various facets involved with taking a mathematics test. Examples are problem-solving skills such as solving

a certain number of problems or solving tasks of a certain challenge, or skills in self-regulation such as concentrating for a length of time or persevering through difficult problems.

SEE affect future performance through mediating processes, influencing students' behaviors and motivations. SEE may influence individuals' tendencies to approach learning tasks, their effort and persistence while engaged in such tasks, as well as their self-regulatory processes (Zimmerman, 2000). SEE have been found to predict mathematical problem-solving after controlling for factors such as cognitive ability, mathematics Grade Point Average, anxiety, and gender (Pajares, 1996). There is also empirical support for the influence of past performances on SEE (e.g. Pampaka et al., 2011). According to Bandura (1997), SEE are formed through four sources, where mastery experiences is the strongest source. Mastery experiences stem from individuals' appraisals of previous performance situations, for instance their experiences from a previous, similar test. Importantly, previous experiences do not influence SEE directly, but are interpreted and made sense of by the individual (Usher, 2009).

A mutually reinforcing pattern of influence between self-beliefs and academic achievement is supported for several types of self-beliefs (Valentine, Dubois, & Cooper, 2004). Studies have, for instance, investigated reciprocal effects between self-concept and achievement (Marsh, Trautwein, Lüdtke, Köller, & Baumert, 2013), however only few studies have investigated reciprocal effects between SEE and mathematics performance. Williams and Williams (2010) proposed a reciprocal effects model, which fit the data well for PISA results from 26 out of 33 countries. They argued reciprocal effects might be a fundamental psychological process, however the data from Norway was excluded from the analyses due to little variation in the grade-level variable. Hannula et al. (Hannula, Bofah, Tuohilampi, & Metsämuuronen, 2014) investigated the dominant direction of effect between mathematics performance and SEE, as students progressed from grade 3 to grade 9 in Finland. Their results supported a reciprocal effects model, where the effect from performance on SEE (.30) was somewhat stronger than the effect from SEE on performance (.26). Both measures were also relatively stable over time.

Measures of SEE have typically included SEE strength and SEE specificity (also called generality). While Bandura proposed a third dimension of SEE (1997), only few studies have included level of difficulty. Students' SEE may vary between different facets of mathematics, and in regards to different perceived levels of difficulty. In relation to the task 'naming uses for common objects' Locke et al. (Locke, Frederick, Lee, & Bobko, 1984) found that SEE for tasks of medium to high difficulty were most predictive of subsequent task performance.

### **Theoretical model and research questions**

In line with theory and empirical findings discussed, we propose a theoretical model (see Figure 1), where SEE and mathematics performance are reciprocally related. We included Norwegian students' SEE responses and subsequent test scores to investigate this model. In the model, students' SEE in grade 8 and 9 are related to their performance in mathematics in the same year. Furthermore, students' mathematics performances in grade 8 predict their SEE in grade 9. Both SEE and mathematics performance are relatively stable (mathematics performance the most stable of the two), with the grade 8 constructs predicting scores in grade 9. We further propose level and facet-specific SEE have differential relationships with mathematics performance.

**Figure 1: Theoretical model**

RQ1: What is the relationship between SEE and performance on national tests in mathematics in grade 8, and SEE and performance on national tests in mathematics in grade 9?

RQ2: Do the relationships between SEE and performance on national test differ according to levels or facets of SEE?

## Methodology

### Participants

The participants were 95 students (44 female) in Norwegian secondary school who completed self-report questionnaires and took national tests in mathematics at the beginning of grades 8 and 9 (13 and 14 years old). The participants were part of a larger sample, selected for cross-sectional investigations (see Sørli & Söderlund, 2015). Included in the study were schools where students had performed above and below what might be expected on national tests, considering measures of socio-economic-status. For a detailed explanation of this strategy see Langfelt (2015).

### Measures

The Self-efficacy Gradations of Difficulty Questionnaire was applied to measure SEE at the two time points (see Street et al., 2017, for a detailed analysis). This is a recently developed multidimensional measure of mathematics SEE, that includes four test taking facets (facet-specific SEE) related to problem solving (complete a number of problems, solve tasks of a certain challenge) and self-regulation (concentrate, not give up), and three levels (easy, medium, and hard) of perceived difficulty (level of SEE). Each of the 14 items in the measure are related to one test taking facet and one level of difficulty within each facet (see Figure 2 for an example facet, "concentrate", with three levels of difficulty). For each item, students are asked to indicate their confidence (strength of SEE) on an 11-point scale from 0 "not at all certain" to 10 "completely certain". The structural validity of this measure was tested (Street et al., 2017), and the resulting best-fit measurement model included three latent (unobserved) level constructs, with correlated uniquenesses (correlated error terms) specified for each of the four facets.

Some people can find it hard to concentrate when sitting tests. How certain are you that you will be able to concentrate during the national tests in mathematics?											
<b>During the national tests this year I will be able to concentrate:</b>											
	0 Not at all certain	1	2	3	4	5 Moderately certain	6	7	8	9	10 Completely certain
at least a little while											
at least half the time											
the whole time											

**Figure 2: Example from the Self-Efficacy Gradations of Difficulty Questionnaire**

The performance measure was raw scores from national tests in numeracy (Norwegian Directorate for Education, 2016). “Numeracy” is similar to what researchers generally refer to as mathematics. Norwegian students sit these tests at the start of the school year in grades 5, 8 and 9. Students in grades 8 and 9 sit the same test, which involves 58 problems, scored as either correct (1) or incorrect (0). We used unique identifiers to link the national test scores with the questionnaire responses.

### Specification of empirical models

Our modeling choices were informed by the previously established factor structure of our measure, as well as our theoretical model. Street et al. (2017) found that the best-fit models were those that accounted for the multidimensional nature of SEE, through correlated latent constructs and correlated uniquenesses. In order to estimate the relationships between latent constructs in our models we used item parceling technique. Parceling involves aggregating (taking the sum or average) two or more items to manufacture an indicator of a construct (Little, Cunningham, Shahar, & Widaman, 2002, p. 152). While our measure of SEE is multidimensional, the factor structure has been tested and established in a previous study. Item parcels were formed to achieve “clean” latent constructs from each year, through aggregating items in such a way that the secondary loading was spread across parcels (Little et al., 2002). For example, the “easy” parcel contains all items related to the easy latent construct, across four facets. Similarly, the “concentrate” parcel includes all items related to the concentrate facet, across three levels of difficulty. As an example, the “concentrate” parcel in Figure 2 is created through summing the scores of the three items included.

Two reciprocal effects models were specified. Our hypothesized model (Model 1) includes national test scores and item parcels for SEE levels, representing the best-fit model from the previous study. The alternative model (Model 2) includes national test scores and item parcels for facet-specific SEE. In both models, SEE constructs in grade 8 are related to test scores in grade 9. Similarly, SEE constructs in grade 9 are related to test scores in grade 9. Correlations are specified rather than regression paths (see Street et al., 2017). SEE constructs in grade 8 are intercorrelated, as are SEE constructs in grade 9. Furthermore, corresponding SEE constructs are related across the two years (e.g. SEE easy in grade 8 predicts SEE easy in grade 9). Test scores in grade 8 predict test scores in grade 9. Finally, the reciprocal relationships tested are the path from test scores in grade 8 on SEE constructs in grade 9, and the paths from SEE constructs in grade 8 on test scores in grade 9.

## Analyses

We analysed the data with structural equation modeling, using the maximum likelihood estimator in Mplus (version 7.31 for Mac: Muthén & Muthén, 2012). We used fit indices recommended by previous studies (e.g. Morin, Marsh, Nagengast, & Scalas, 2014; Schermelleh-Engel, Moosbrugger, & Müller, 2003), specifically we used the chi square ( $\chi^2/df \leq 3$  acceptable), the Root Mean Square Error of Approximation (RMSEA  $< .08$  acceptable), the Standardized Root Mean Square Residual (SRMR  $< .10$  acceptable), the Comparative Fit Index (CFI) and the Tucker-Lewis index (TLI) (CFI/TLI  $> .90$  acceptable). To assess improvement in fit between models, we used the following cut-offs:  $\Delta RMSEA$  (.015),  $\Delta CFI$  (.010),  $\Delta SRMR$  (.030).

## Results

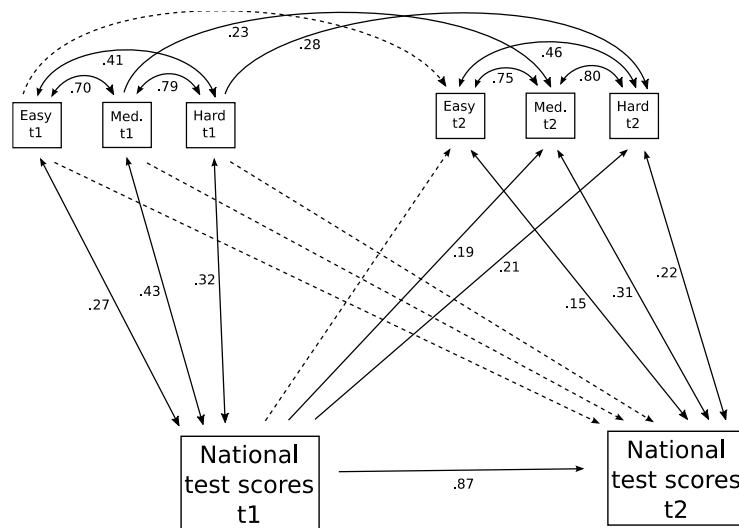

Item cross-correlations for items from the same year were consistent with previous results from the same measure. The correlation matrix indicates items are related to two types of latent constructs; levels (easy, medium, and hard) and facets (no. of problems, solve tasks, concentrate, and not give up). Autocorrelations between items in grade 8 and the same item in grade 9 demonstrate two tendencies. First, autocorrelations are significant for all items, except for two cases, both associated with the easy level (no. of problems\_easy, and concentrate\_easy). Second, the magnitudes of the associations are consistently weaker for items associated with the easy level, than the medium and hard levels. To illustrate this: the strongest autocorrelation of the easy level items is .21, while the weakest autocorrelations of the medium and hard level items is .26 and .29, respectively. Thus, the cross-correlations for each of the years indicate support for a multidimensional construct, while the autocorrelations indicate that students' scores on the medium and hard level items were more stable across time, than students' scores on the easy level items. The non-significant autocorrelations between the grade 8 and grade 9 easy level items might be related to a lack of variability in scores. Most students were highly confident in relation to the easy level items.

*Fit indices for confirmatory factor analyses*

	Model	$\chi^2$	$p$	RMSEA	CFI	TLI	SRMR
1	Correlated levels model, reciprocal relationship with test scores	$\chi^2_{(6)} = 4.397$ $\chi^2/df = 0.73$	$p = .623$	.000	1.00	1.02	.048
2	Correlated facets model, reciprocal relationship with test scores	$\chi^2_{(12)} = 10.890$ $\chi^2/df = 0.91$	$p = .538$	.000	1.00	1.01	.061

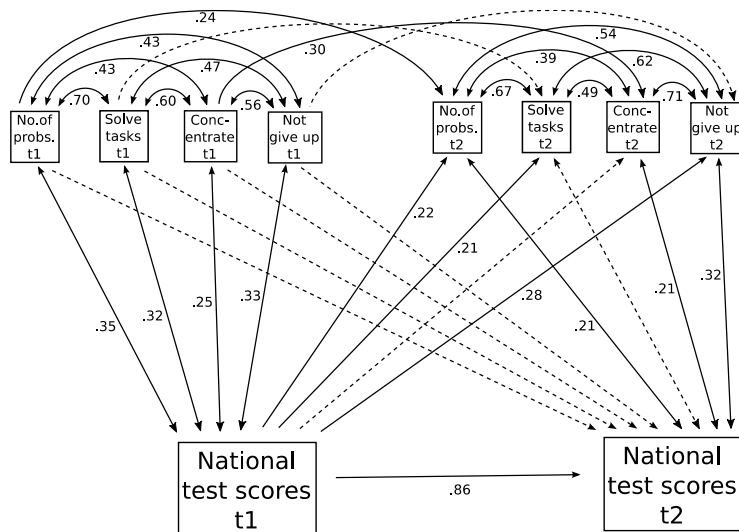

**Table 1: Results from structural equation models**

Results from the structural equation models are presented in Table 1. Both our proposed models resulted in excellent fit. The aim of the present study is not model comparison, but to test a reciprocal effects model, as well as to estimate the relationships between national test scores and level and facet-specific SEE, respectively. Accordingly, parameter estimates from both models are reported (see Figures 3 and 4).

Note: "Easy", "Med.", and "Hard" refer to easy, medium and hard levels of perceived difficulty. "t1" and "t2" refer to time 1 and time 2.  
All estimates are standardized (STYX) estimates from Mplus (Muthén & Muthén 2012).  
Paths are significant at the  $p < .05$  level. Dotted paths are nonsignificant.

**Figure 3: Structural equation model, Model 1 (correlated levels model)**

Note: "No. of probs.", "Solve tasks", "Concentrate", and "Not give up" refer to facets of test taking. "t1" and "t2" refer to time 1 and time 2.  
All estimates are standardized (STYX) estimates from Mplus (Muthén & Muthén 2012).  
Paths are significant at the  $p < .05$  level. Dotted paths are nonsignificant.

**Figure 4: Structural equation model, Model 2 (correlated facets model)**

As can be seen in Figure 3, results from Model 1 partially support a reciprocal effects model between levels of SEE and national test scores. Specifically, national test scores in grade 8 predict levels of SEE in grade 9 in relation to medium and hard, but not easy, tasks. The predicted relationship from SEE level constructs in grade 8 to national test scores in grade 9 is not supported. However, all three levels of SEE are associated with test scores the same year, including when previous test performance is controlled in grade 9. Two further relationships are nonsignificant: the path from SEE easy level in grade 8 to grade 9, and the path from national test scores in grade 8 to SEE easy level in grade 9.

Model 2 results (see Figure 4) are generally consistent with results for Model 1. Test scores in grade 8 predict three facets of SEE in grade 9 (not "concentrate"), while the paths from SEE facet constructs

in grade 8 to test scores in grade 9 are nonsignificant. However, facet-specific self-efficacy constructs are related to performance results in each year, including in grade 9 (not “solve tasks”) when previous test scores are included in the model. Unlike the other facets, the magnitude of the relationship between “not give up” and test scores is very similar in grade 8 and 9. Similar to the easy level in Model 1, the relationships between “solve tasks” and “not give up” from grade 8 to grade 9 are not significant. Finally, we see that test scores are more stable over time than either level or facet-specific SEE.

## Discussion

The current study lent empirical support to a reciprocal relationship between level and facet-specific SEE, and performance in mathematics (RQ1). It was demonstrated that students’ SEE were associated with scores on a test in the immediate future, while national test scores predicted their SEE one year later. All SEE items in our study are explicitly linked with the immediately upcoming test, thus it is reasonable the SEE constructs are associated with performance results of the immediately upcoming tests, but not with the tests one year later. In two previous studies, measures of SEE and performance were collected over the course of a single day (Locke et al., 1984) or three years apart (Hannula et al., 2014). Findings from both these studies indicated the dominant effect was from performance to SEE. The type of test, and whether it is considered important by the students, might influence the relationship between performance experiences and SEE. National tests are quite “talked about” in school in Norway, and students in grades 8 and 9 are likely becoming increasingly aware of upcoming exams (at the end of year 10). This might have provided a particularly memorable context for their test experiences.

Furthermore (RQ2), differential relationships were found between national tests and easy, medium and hard levels of perceived difficulty. The associations with test scores were stronger for medium and hard levels of difficulty, which is in line with previous research (Locke et al., 1984). The relationships with test performance also varied between different facets of test taking, where “not give up” provided the strongest association.

In our sample students’ SEE for medium and hard level tasks had both a stable (SEE regressed on SEE) and a dynamic (SEE regressed on test scores) component, while these estimates differed for the different SEE facets. For instance, in regard to ‘concentrate’, grade 9 SEE were predicted by grade 8 SEE, while in regard to ‘not give up’, grade 9 SEE were predicted by grade 8 test scores. This indicates students drew on their previous test experiences to a larger degree when formulating their SEE for perseverance, as compared to concentrating. This implies it is important to consider how to support student perseverance, particularly after adverse test experiences.

The current findings are limited in that we could not control for other factors that may have influenced students’ SEE and test performance. Also, while the measure of SEE provided interesting information, partitioning the effects of test taking facets and levels of perceived difficulty, further replications are needed with a larger sample, and in different cultural contexts.

# Personal meaning and motivation when learning mathematics: A theoretical approach

Neruja Suriakumaran, Christoph Duchhardt and Maike Vollstedt

University of Bremen, Faculty 3, Mathematics Education, Bremen, Germany;

[neruja.suriakumaran@uni-bremen.de](mailto:neruja.suriakumaran@uni-bremen.de), [christoph.duchhardt@uni-bremen.de](mailto:christoph.duchhardt@uni-bremen.de),

[maike.vollstedt@math.uni-bremen.de](mailto:maike.vollstedt@math.uni-bremen.de)

*Personal meaning, understood as the personal relevance of an object or an action (Vollstedt, 2011), seems to be closely related to motivation. However, the structural relationships between personal meaning and motivation are unexplored yet. Two motivation theories, self-determination theory (Deci & Ryan, 2002) and expectancy-value theory (Wigfield & Eccles, 2000), are used to work out these relations. The focus of this paper lies on theoretical considerations.*

*Keywords: Personal meaning, motivation, self-determination theory, expectancy-value theory, theoretical considerations.*

## Introduction

Students are in the need for meaning when dealing with mathematics in an educational context (Vinner, 2007). As Kilpatrick, Hoyle and Skovsmose (2005) point out, the notion of meaning is blurred in the mathematics education community:

When we consider the question of meaning with respect to mathematics education, the issue becomes even more complex, since philosophical and non-philosophical interpretations of meaning can become mixed. Thus, on the one hand, we may claim that an activity has meaning as part of the curriculum, while students might feel that the same activity is totally devoid of meaning. (Kilpatrick et al., 2005, p. 2)

This paper is interested in the perspective of the students and their individual attribution of personal relevance to deal with mathematics in an educational context. Vollstedt (2011) called this construct *personal meaning*. Theoretical considerations suggest a strong link between personal meaning and motivation drawing on the *basic needs theory (BNT)* and the *organismic integration theory (OIT)* of *self-determination theory (SDT)* (Deci & Ryan, 2002) and *expectancy-value theory (EVT)* (Wigfield & Eccles, 2000).

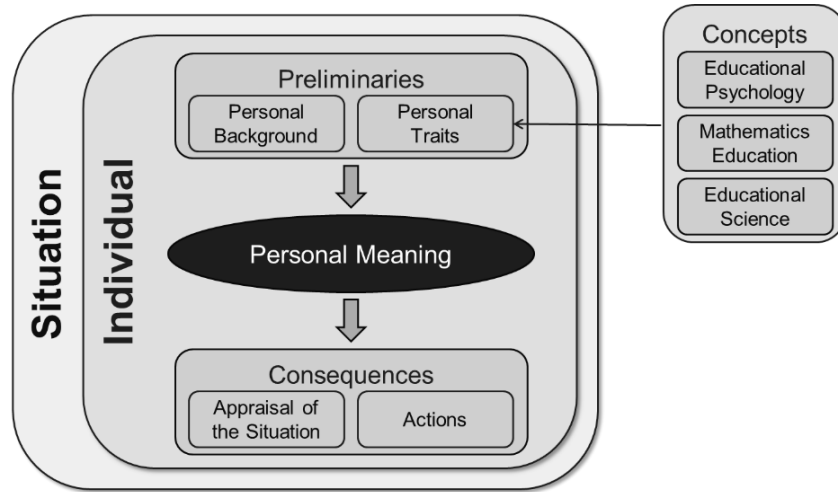

## Personal meaning

With respect to the fuzziness of meaning, Howson (2005) suggests that

one must distinguish between two different aspects of *meaning*, namely, those relating to relevance and personal significance (e.g., “What is the point of this for me?”) and those referring to the objective sense intended (i.e., signification and referents). These two aspects are distinct and must be treated as such. (Howson, 2005, p. 18)

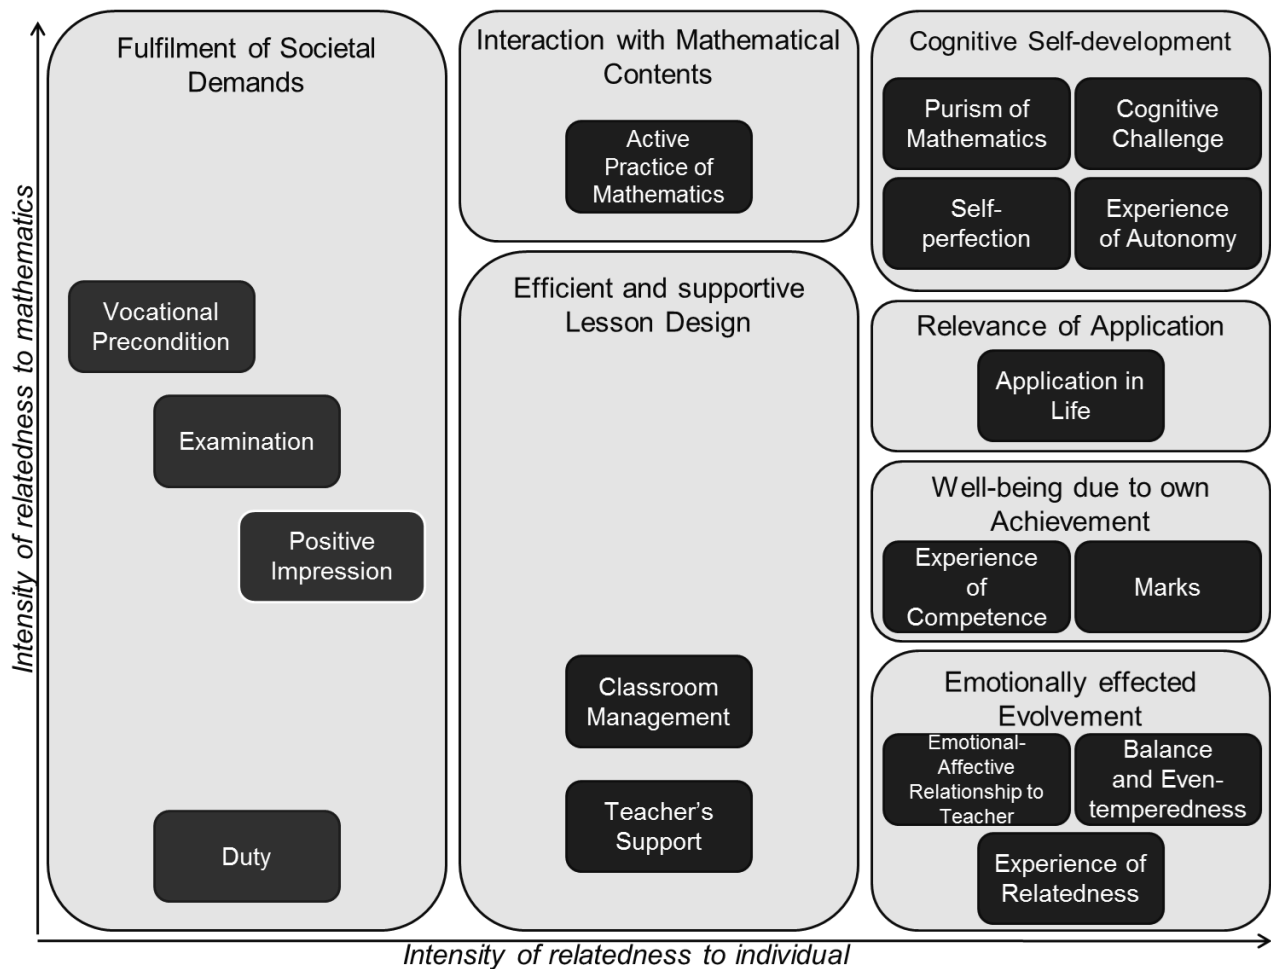

According to Howson (2005), one important interpretation of meaning is the personal one. Personally experienced meaning, again, has a wide notion of concepts: it can be understood as a personal goal, a value, an intention, a purpose, a reference, or a use that an object or an action may have for the individual (Vollstedt, 2011).

Personally experienced meaning depends on the individual and a certain context (see below). It has an endogenous character, i.e. it cannot be provided by the teacher but, on the contrary, must be constructed out of the learner's individual biography (Meyer, 2008). Regarding mathematics, the need for meaning cannot be fulfilled globally: for each mathematical learning content, personal meaning must be constantly interpreted and subjectively constructed (Fischer & Malle, 1985). Therefore, at the same time and in the same context, different students can give different meanings to the same mathematical content (Kilpatrick et al., 2005; Vollstedt, 2011).

**Figure 1: Theoretical framework of personal meaning (Vollstedt, 2011)**

Vollstedt (2011) developed a model of personal meaning when learning mathematics and dealing with mathematical contents in a school context. In her theoretical framework (see Figure 1) she took the student's perspective, as the following two main preliminaries influence the construction of personal meaning: Firstly, the personal background of the student describes aspects which cannot be influenced by himself/herself like his/her socio-economic or migration background. Secondly, personal traits, i.e. aspects that concern the student's self, are relevant. They comprise concepts from various fields like educational psychology (self-concept, self-efficacy), education (developmental tasks), and mathematics education (beliefs). In addition to the individual preliminaries of a student, the situational context, i.e. context of the learning situation in terms of topic as well as classroom situation, is also a crucial factor for the construction of personal meaning. The theory of personal meaning developed by Vollstedt (2011) consists out of 17 different kinds of personal meaning. They were reconstructed based on interview data with students from lower secondary level from Germany and Hong Kong. These kinds vary between the duty to deal with mathematics because it is a school subject, the cognitive challenge that is contained in mathematical tasks, and the experience of relatedness among the fellow students. Note that the experience of the three basic psychological needs for *autonomy*, *competence*, and *relatedness* as described in the SDT of motivation (Deci & Ryan, 2002; cf. *Self-determination theory*) turned out to be meaningful for students. Accordingly, they were also given the status of kinds of personal meaning. The various kinds of personal meaning can be distinguished with regard to the intensity of the relatedness to mathematics and to the individual respectively, giving rise to seven superordinate types of personal meaning (see Figure 2).

**Figure 2: Model of personal meaning (Vollstedt, 2011)**

A relation between the theories of personal meaning and motivation seems likely due to the obvious link via the SDT of motivation. Other links may additionally be assumed (see *Interplay between personal meaning and motivation* for further details). The structural connections between personal meaning and motivation, though, are yet unexplored.

## Motivation

### Self-determination theory

According to the SDT by Deci and Ryan (2002), learners have innate and constructive tendencies to develop an ever more elaborated coherent “sense of self” (Deci & Ryan, 2002, p. 5), i.e. individuals possess a tendency to promote growth or rather integration. They have the primary demand “to forge interconnections among aspects of their own psyches as well as with other individuals and groups in their social worlds”. This general integrative tendency is called the organismic metatheory of SDT. Besides, SDT includes the dialectical tendency, which focusses on the interaction between the active, integrating human nature and social contexts that either nurture or impede human’s effort to “integrate their experiences into a coherent sense of self” (Deci and Ryan, 2002, p. 27).

Those contextual elements can be defined by the basic psychological needs for competence, autonomy, and relatedness, which support or rather thwart motivation, performance, and well-being.

SDT embraces six sub-theories that all contain organismic and dialectic characteristics, two of which have a special significance for our study, namely the basic needs theory for competence, autonomy, and relatedness (BNT; Deci & Ryan, 2002, p. 22) and the organismic integration theory (OIT; Deci & Ryan, 2002, p. 14). These two sub-theories were formulated to clarify the interrelation between “motivation and goals to health and well-being” (Deci & Ryan, 2002, p. 10).

In BNT it is supposed that the basic needs are universal, i.e. they are valid across time, age, gender, situations, and culture. When they are satisfied, they support well-being, however when they are impeded, they might interfere with psychological health.

The OIT focusses on “internalization and integration of values and regulations (amotivated, external, introjected, identified, integrated, and intrinsic)” (Deci & Ryan, 2002, p. 14). Thereby, it defines the development and dynamics of extrinsic motivation in more detail. This process is characterized by “the degree to which individuals’ [sic] experience autonomy while engaging in extrinsically motivated behaviors” (Deci & Ryan, 2002, p. 9). This taxonomy of regulation is neither a developmental continuum by itself, nor do human beings have to proceed through each level of internalization. In fact, it is possible for humans to take in a regulation at any level, when the relevant prior experience and the immediate individual climate encourage the interpersonal basic needs.

### **Expectancy-value theory**

A second theory of motivation that stems from different theoretical roots is the EVT (Feather, 1982; Wigfield, Tonks, & Klauda, 2016). In it, motivation is described as a consequence of an interaction of *expectancy* and *value*. Wigfield and Eccles (2000) conceptualize motivation following EVT in a school context. They argue that “individuals’ choice, persistence, and performance can be explained by their beliefs about how well they will do on the activity and the extent to which they value the activity” (Wigfield & Eccles, 2000, p. 68). Expectancy address the perceived likeliness of achieving a set goal or being successful on a task (self-efficacy). Value represents the extent to which a goal or an activity is desirable (Eccles et al., 1983; Wigfield & Eccles, 1992).

Wigfield and Eccles (2000) describe four subjective task values: *attainment value*, *intrinsic value*, *utility value*, and *cost*. These are also referred to as the components of achievement value. Attainment value is described as the personal importance of doing well on a task, for example on a mathematical exercise. Intrinsic value is characterized by the sense of pleasure in doing that task. Utility value defines how a task suits one’s future plans or goals, such as making an effort during the mathematics lesson in order to be well prepared for an exam. Cost concerns how the decision of putting effort into an activity (e.g. doing mathematics homework) restrains opportunities for other activities (e.g. watching TV). The subjective task values serve the estimation of effort, the likelihood of task achievement, and emotional cost (Wigfield & Eccles, 2000).

## Interplay between personal meaning and motivation

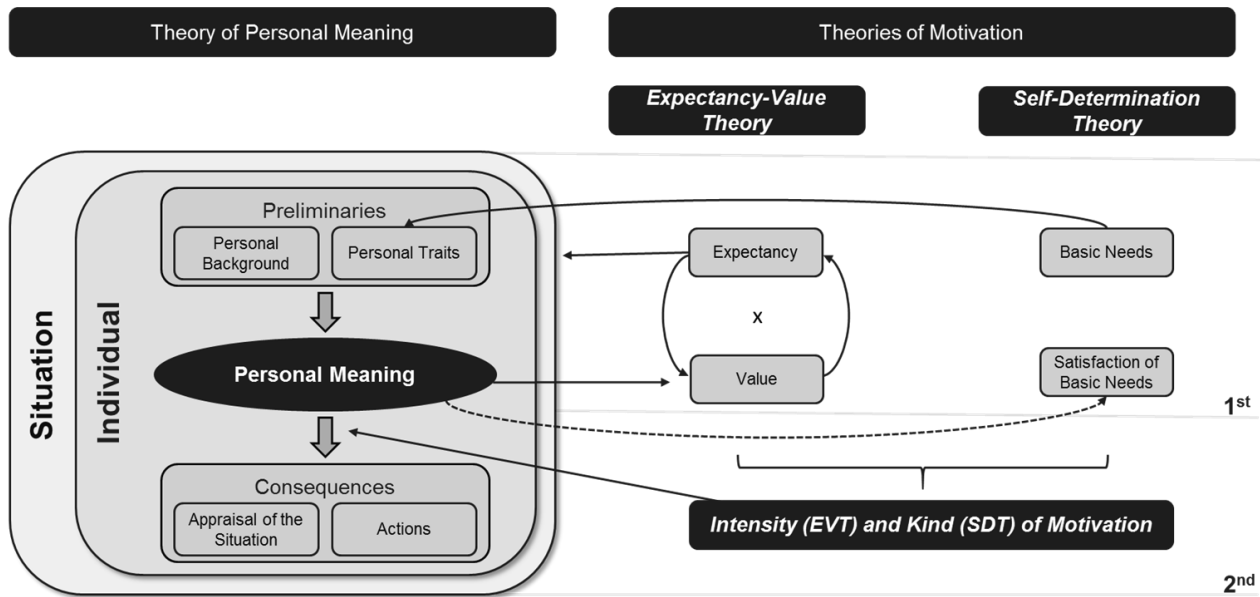

The conceptualizations of motivation introduced above contain various links to personal meaning. In a first approach, several networking strategies *comparing*, *combining*, *coordinating*, and *synthesizing* (Prediger & Bikner-Ahsbabs, 2014) were used to connect the different theoretical perspectives and construct an elaborated theoretical framework of the interrelation between personal meaning and motivation. This process is described below.

Common similarities and differences between parts of theoretical approaches can be identified through the networking strategy of comparing (Prediger & Bikner-Ahsbabs, 2014). Comparing the three theoretical approaches shows that in general, the theories of personal meaning, SDT, and EVT all include organismic and dialectical components, i.e. they consider the learner's biography in detail and the constant interaction with the learner's social environment (Bruner, 1991; Deci & Ryan, 2002; Vollstedt, 2011; Wigfield & Eccles, 2000). This is an essential factor and forms the basis for further elaboration of the concrete interaction between these three theories.

The networking strategy of combining makes it then possible to combine theoretical approaches even from different origin. As EVT-values and intrinsic and extrinsic constructs of SDT are examined from different theoretical perspectives they, thus, have different bases (Wigfield & Eccles, 2000; Wigfield, Tonks, & Klauda, 2016). Nevertheless, close relations could be extracted by combining the theoretical constructs of SDT and EVT: The intrinsic value of EVT is linked to the construct of intrinsic motivation as described in SDT. It refers to behaviors performed out of one's own interest, enjoyment, and the pleasure inherent in these activities (Ryan & Deci, 2002). Utility value describes more extrinsic motives to put effort in a mathematical task, such as doing a task to attain certain outcomes. Accordingly, utility value can be connected to extrinsic motivation (Wigfield & Eccles, 2000). Hence, extrinsic rewards may also help to anticipate individuals' own efforts (Spence & Helmreich, 1983). In addition, SDT points out that the regulation of motivation is important to pursue a certain goal or value. Thus, it differentiates between qualitatively different reasons for action, arguing that different types of motivation will lead to very different outcomes (Ryan & Connell, 1989).

Through the networking strategy of coordinating it is possible to clarify empirical evidence by constructing a conceptual framework grounded in different theoretical ideas. Hence, the three theories were interwoven and synthesized to link equally solid theories in such a way that a new unit of theory arises into, for example, an elaborated new theoretical approach (see Figure 3 below). To begin with, personal meaning and SDT are linked in three ways (cf. also the section *Personal meaning* above): Firstly, the three basic psychological needs for competence, autonomy, and relatedness as described in BNT are part of Vollstedt's (2011) theoretical background for the construction of personal meaning (see Figure 3 below). Secondly, their experience turned out to be meaningful for students so that there are three kinds of personal meaning closely related to the three basic psychological needs (see Figure 2 above). Thus, these two aspects directly link the theory of personal meaning to SDT. Thirdly, there is an indirect link. One of the two overall-dimensions of the model of personal meaning, namely the intensity of the relatedness to the individual, describes the degree of one's subjective involvement in the action or the content respectively. Vollstedt's results (2011) suggest that the intensity of the relatedness to the individual is possibly interrelated with the types of regulation described in OIT. This results from the fact that the intensity of the relatedness to the individual focuses on the personal involvement of the individual with respect

to the action or object in focus. Hence, this establishes a link to self-determined behavior and internalization (Vollstedt, 2011).

**Figure 3: The role of personal meaning in the generation of motivation according to EVT**

With relation to EVT, we also suppose a close link to the theory of personal meaning (see Figure 3 above). We assume that the expectancy as described in EVT is part of the individual's personal traits, i.e. they are contained in the crucial preliminaries for the construction of personal meaning (cf. the section *Personal meaning*). Besides, the subjective values of EVT are embodied in different kinds of personal meaning (cf. the section *Expectancy-value theory*). For instance, the particular nature of intrinsic value is inherent in those kinds of personal meaning which refer mostly to the relatedness to mathematics or the learning of mathematics (e.g. "Purism of mathematics", see Figure 2 above). Another assumption that can be made refers to the relation between utility value and the kinds of personal meaning which have instrumental or functional character (e.g. "Vocational Precondition"). Furthermore, attainment value may relate to those kinds of personal meaning which refer to the knowledge of mathematics being important for one's own identity (e.g. "Self-perfection").

These considerations suggest that motivation may be understood as a result from the interaction between expectancy being characterized by the preliminaries of an individual, and the values being embodied by the different kinds of personal meaning. The resulting motivation influences the consequence that results from the construction of personal meaning. Thus, depending on the kind of personal meaning and its related motivation, an action will follow that may but does not have to do with mathematics (e.g. doing homework instead of playing football – or vice versa). Hence, the inclusion of EVT may provide additional insight into the interplay between personal meaning and motivation.

When looking at the interplay of personal meaning and motivation as a process, with reference to EVT we suggest to think of personal meaning as being constructed chronologically before motivation.

In our understanding, personal meaning is the energizing factor (1<sup>st</sup> in Figure 3 above), which is significant for the students' motivation (2<sup>nd</sup> in Figure 3 above). We even assume that personal meaning is necessarily required for motivation, i.e. that the individual must think that something is

meaningful for him/her and, thus, is motivated to engage in an action that supports his/her goals and values. This suggestion gives personal meaning the status of a key factor for the theory of motivation in general (see Figure 3).

## Conclusion and further perspectives

This paper provides the theoretical background to examine the relationship between personal meaning and motivation when learning mathematics. Hence, personal meaning is linked with motivation through the two motivation theories of SDT and EVT. The results of Vollstedt's (2011) study may suppose connections between personal meaning and SDT, i.e. BNT and OIT (Deci & Ryan, 2002). Three of the subjective values of EVT (attainment value, intrinsic value, and utility value) may be embodied by certain kinds of personal meaning. As cost has a negative connotation, it is not related to personal meaning denominating personal relevance of an object or action.

To conclude, we assume an interrelation between personal meaning and motivation as has been elaborated above. The model sketched above will be elaborated further in an empirical study.

# Mathematical memory revisited: Mathematical problem solving by high-achieving students

Attila Szabo

Stockholm University, Department of Mathematics and Science Education, Sweden

[attila.szabo@stockholm.se](mailto:attila.szabo@stockholm.se)

*The present study deals with the role of the mathematical memory in problem solving. To examine that, two problem-solving activities of high achieving students from secondary school were observed one year apart - the proposed tasks were non-routine for the students, but could be solved with similar methods. The study shows that even if not recalling the previously solved task, the participants' individual ways of approaching both tasks were identical. Moreover, the study displays that the participants used their mathematical memory mainly at the initial phase and during a small fragment of the problem-solving process, and indicates that students who apply algebraic methods are more successful than those who use numerical approaches.*

*Keywords: High-achievers, mathematical memory, mathematical abilities, problem solving.*

## Introduction and background

Despite a growing emphasis on the identification and teaching of mathematically able pupils, much remains unknown about the abilities they display when solving mathematical problems. For reasons of social justice and equality, research has typically focused on low achieving pupils (Swanson & Jerman, 2006) while relatively few studies have observed the abilities of the gifted and high-achievers (e.g. Vilkomir & O'Donoghue, 2009) or addressed those pupils' memory functions during mathematical activities (Leikin, Paz-Baruch, & Leikin, 2013; Raghubar, Barnes, & Hecht, 2010). In particular, just a few studies (e.g. Krutetskii, 1976; Szabo & Andrews, 2017) examined the role of the *mathematical memory* in gifted and talented students' problem-solving activities.

## Mathematical abilities

Our innate ability to estimate quantities, known as the approximate number system, is extremely limited (Dehaene, 1997), but an active contact with the subject may, under favourable conditions, generate mathematical abilities that are both complex and structured (Krutetskii, 1976). The nature of mathematical abilities has engaged researchers for more than 120 years; already at the end of the 19th century, Calkins (1894) presented, based on observations of Harvard students, significant information about the way mathematicians approached the subject. However, the research on mathematical abilities – mainly because of the dominance of psychometric approaches, and thereby considering abilities as innate and static – has not delivered widely accepted results during the first half of the 20th century (Vilkomir & O'Donoghue, 2009). Therefore, of importance for the present paper is the research of Krutetskii (1976), whose longitudinal observational study analysed the problem-solving activities of around 200 pupils. He concluded that able pupils' mathematical ability, while complex and dynamic, typically comprises four broad abilities. These are

- the ability to *obtain and formalise mathematical information* (e.g. formalised perception of mathematic material),

- the ability to *process mathematical information* (e.g. logical thought, flexible mental processes, clear and simple solutions, generalized mathematical relations),
- the ability to *retain mathematical information*, that is, *mathematical memory* (a generalized memory for mathematical relationships) and
- a *general synthetic component* (mathematical cast of mind) (Krutetskii, 1976, pp. 350–351).

However, while these abilities have frequently been associated with mathematical giftedness, Krutetskii (1976, pp. 67–70) argues they can also be displayed properly by high-achievers.

### Mathematical memory

It is largely agreed that memory plays an essential role both in the learning of mathematics and in mathematical problem solving (e.g. Leikin et al., 2013; Raghubar et al., 2010). Thus, what seems to be crucial “is not whether memory plays a role in understanding mathematics but what it is that is remembered and how it is remembered by those who understand it” (Byers & Erlwanger, 1985, p. 261). Calkins’ (1894) early study showed that the memories of mathematicians are more concrete than verbal, that mathematics students do not memorise facts more easily than other students and that, when performing mathematics, there is no difference between men and women. Some decades later, Katona (1940) found that rational methods are easier to memorise than random digits, while Bruner (1962) showed that simple interrelated representations are effective when recalling detailed knowledge. However, Krutetskii (1976) distinguished *mathematical memory* from the *mechanical recalling* of numbers or algorithms, by stressing that it is a memory consisting of generalized methods for problem solving. Hence, the mathematical memory does not retain “all of the mathematical information that enters it, but primarily that which is ‘refined’ of concrete data and which represents generalized and curtailed structures” (Krutetskii, 1976, p. 300). Moreover, he found that able students usually retain the contextual facts of a problem only during problem-solving and forgot it instantly afterwards, but remember several months later the methods they applied. Conversely, low-achievers often remember contextual facts but rarely the problem-solving methods (Krutetskii, 1976). Cognitive psychology studies (e.g. Sternberg & Sternberg, 2012) indicate important distinctions between different memory systems; that is, long term memory can be divided into *implicit* and *explicit* memory, based on the type of the stored information. In a mathematical context, the implicit memory contains automatized procedures and algorithms, while explicit memory retains information about experiences and facts which can be consciously recalled and explained, such as schemas for problem-solving. Thus, according to the cognitive model, we may assume that mathematical memory, as defined by Krutetskii, is explicit. Besides, it is a memory formed at later stages (e.g. Davis, Hill, & Smith, 2000) based on the ability to generalize mathematical material, because at young able pupils “the relevant and the irrelevant, the necessary and the unnecessary are retained side by side in their memories” (Krutetskii, 1976, p. 339).

### The study

The present study had two aims, both based on Krutetskii’s (1976) definitions of mathematical ability. The first was to identify the structure of mathematical abilities when high-achieving students solve non-routine but structurally similar problems. The second was to examine the role of mathematical memory during problem-solving activity.

## Participants

Because young children and low-achievers rarely exhibit mathematical memory (Krutetskii, 1976), participants were 16-17 years old volunteers from an advanced mathematics programme in Swedish upper secondary school who had achieved the highest grade in the Swedish national test. Prior to data collection study, to familiarize students with the study, I spent 30 hours, over a period of four months, as a participant observer in their mathematics classroom. During this period, they came to trust me as an observer of their problem-solving activities. At the end of this process, after consulting their teacher, 6 students, 3 boys and 3 girls, were invited to participate.

## Tasks

The theoretical background indicates that an appropriate way to identify the distinct structure of the mathematical ability is to analyse the problem-solving activities of the individuals (e.g. Krutetskii, 1976). Moreover, the structure of a mathematical problem reveals the mathematical thinking which is required to solve it, because problem solving “is an activity requiring the individual to engage in a variety of cognitive actions, each of which requires some knowledge and skill, and some of which are not routine” (Cai & Lester, 2005, p. 221). However, able students typically forget the context of a problem shortly after solving it, but, as an impact of their mathematical memory, they are several months later able to recall the methods applied to solve it. Thus, in order to complete the aims of the study, the participants solved two problems approximately one year apart. At the first observation, in order to avoid as far as possible the influence of previous experiences, the main criterion was to select a challenging non-routine task, Task 1 (T1). When selecting Task 2 (T2) – in order to emphasize the role of the mathematical memory – the main criterion was to propose a task which was non-routine, but could be solved by methods similar to those used previously.

**Task 1:** In a semicircle we draw two additional semicircles, according to the figure. Is the length of the large semicircle longer, shorter or equal to the sum of the lengths of the two smaller semicircles? Justify your answer.

**Task 2:** In a square we draw two arbitrary contiguous squares, according to the figure. Is the perimeter of the large square longer, shorter or equal to the sum of the perimeters of the two smaller squares? Answer the question without measuring the figure. Justify your answer.

Both tasks underwent substantial a-priori testing with corresponding groups of high-achievers, confirming that they were well-suited for the study and for the mathematical knowledge of the participants. This test confirmed that the students solved the proposed tasks with similar methods, that is, by applying the formulae for perimeters of circles and squares.

## Observations and interviews

To avoid confounding factors during classroom interaction, which may affect pupils' thought process (Norris, 2002), every participant was observed individually and, to avoid stress, given unlimited time to solve each task. T1 was solved and approximately one year later T2 was solved. In

order to avoid participants' memories being activated mostly because of recalling the circumstances for the first observation as an unusual element in their daily activities – that is, not because of recalling the previously solved task – I continued to interact with them during their mathematics classes between the two observations. The students were invited to solve the tasks in a think-aloud manner and encouraged to describe every step in the process. To minimise participants' influence on each other, the tasks were solved during single days. The observations took place in a private room at their school and, when needed, supplementary questions were posed in order to facilitate the process. If a student neither wrote nor spoke for a while, the following questions were posed: What is bothering you? Why do you do that? What do you want to do and why? What are you thinking about? Pupils generally are not used to verbalise their problem-solving process (Ginsburg, 1981), thus, in order to avoid the risk that essential parts of their cognitive activities would not be communicated, every observation was followed by a *reflective interview*. The purpose of the interviews was to display the hidden cognitive processes at problem-solving and to evaluate the levels of competence in those processes (Ginsburg, 1981). Each observation was recorded using a technology that digitises both speech and handwritten notes; the audio recordings were transcribed verbatim. Although they were given unlimited time, no participant needed more than 14 minutes to complete a single task.

### Data analysis

The piloting of the tasks on corresponding groups of high-achievers indicated that the *general synthetic component* – a typical ability of gifted students (Krutetskii, 1976, p. 351) – was unlikely to be observed during problem-solving; consequently, this ability was excluded from the analysis. The analytical framework for this study contained the following abilities from Krutetskii's framework: *obtaining* and *formalizing* mathematical information (O), *processing* mathematical information (P), *generalizing* mathematical relations and operations (G), and *mathematical memory* (M).

The digital recordings resulted in an exact linear reproduction of the students' actions, which was especially beneficial when performing *qualitative content analysis* of the material, inspired by van Leeuwen (2005). The participants' actions were analysed by identifying, coding and categorising the basic patterns in the empirical content. This method highlighted the abilities that were directly expressed in the empirical material; each episode lasting at least one second in written solutions and verbal utterances was scrutinised for the presence of the focused abilities. Next, the data from observations were combined with data from the interviews. I exemplify this with data from Linda, who, when solving T2, didn't say or wrote anything during the initial 62 seconds, before stating:

Linda: I would like to write down, start with writing a... some nice little estimations...

After this episode she drew three squares with sides  $a$ ,  $b$  and  $c$ , and wrote " $a + b = c$ ". Thus, based on the observation, the presence of O was certain, but it was not possible to decide if other abilities were also present in the actual episode. Yet, the following sentences from the reflective interview proved that she recalled another task which could be solved with similar methods:

Linda: I got blocked until I remember similar tasks, because it's a lot more difficult to solve this kind of tasks if one doesn't have a determined way to approach it... I believe I will bring up the same task as last time, with triangles and squares.

The utterances “a determined way to approach it” and “the same task as last time” indicate that Linda recalled a different task and its methods, thereby validating the presence of both O and M in the actual episode. In this way, the analysis revealed both the structure and the sequential order of the focused abilities, that is, every ability which occurred during the 12 problem-solving activities was displayed in a matrix. However, as exemplified above, some abilities (e.g. O and M) occurred closely interrelated during certain episodes and were extremely hard to differentiate.

## Results

When asked, each participant confirmed that both tasks were non-routine, this being a prerequisite for the study. The analysis concluded in a matrix, with every episode of the process related to the focused abilities. As mentioned, certain abilities were closely interrelated during some episodes. As displayed (Table 1), M is present – solitary or interrelated – at 16% during the first and at 10.5% during the second observation. The most manifested ability is P, which increased from 53% to 67% a year later, while O, the second most exposed ability, decreased from 47% to 31.5%.

	<b>O</b>	<b>O &amp; P</b>	<b>O &amp; M</b>	<b>P</b>	<b>G</b>	<b>M</b>
<b>Task 1</b>	31%	4%	12%	49%	0%	4%
<b>Task 2</b>	20%	1.5%	10%	65.5%	2%	0.5%

**Table 1: Average time for the focused mathematical abilities in the problem-solving process**

According to the a-priori testing of the tasks, G could be revealed when numerical results – that is, solutions for particular cases – were developed into general, algebraic solutions. Thus, every student who offered purely numerical results – namely Erin, Sebastian and Larry – was encouraged to consider general solutions. Yet, when solving T1 and asked if their numerical results apply also for arbitrary semicircles, none of them could generalize (G) their findings:

Erin: I don’t know how I should prove this ... if I have to do some general method.

Sebastian: I don’t know if I shall demonstrate that it should be the same thing there, for every measure. But now in my head it sounds like that it should be so.

Larry: Yes, I suppose, but I don’t know how to confirm it, it only feels that way.

Thus, the increase of G from 0% to 2% (Table 1) occurred because during the reflective interview connected to T2, when offered additional opportunities to reflect over the patterns in her numerical results, Erin performed a successful generalization of the obtained solutions, and stated:

Erin: I’ve never made a general solution like this ... But it was fun ... Especially when it concluded in something.

When concerning the efficiency of the applied methods, the analysis shows that Earl, Linda and Heather solved both tasks properly by applying general, algebraic methods. Conversely, purely numerical approaches didn’t lead to fully acceptable results. The most efficient solutions were offered by Linda, who applied the same algebraic model (and its identical steps) at both tasks.

## The role of mathematical memory

The recalling of the applied methods several months after solving a problem is a typical display of mathematical memory (Krutetskii, 1976). Thus, another main criterion for the study was that both tasks could be solved with similar methods. However, only Earl and Larry associated T2 to T1:

Earl: We got a very similar task last year, when we had the circle and that semicircle.

Larry: We did a pretty similar task last time, when it was something like this, something with the radius or diameter on them.

Earl and Larry applied identical methods at the individual level when approaching both tasks. That is, Earl solved both tasks by using the same algebraic method, while Larry approached both tasks with the same numerical method. However, Earl's algebraic method gave accurate solutions while Larry couldn't solve any task properly. The other four students said that they didn't associate T2 to T1. But even though not recalling T1, they approached both tasks in identical ways at the individual level. For example, when Linda solved T2, despite stating that she didn't think at all of T1, she applied the same general method as a year before:

Linda: I will bring up the same task as last time, with triangles and squares. It is a bit the same thing ... I connect very often geometrical tasks to that. I have written that solution many times and I can see every step in the process in front of me.

As seen above, Linda refers to a generalized method which she associates to a geometrical task – about finding the side of a square drawn in a right triangle – which differs considerably from the proposed tasks. Yet, influenced by her mathematical memory (Krutetskii, 1976, p. 300) she states that “It is a bit the same thing” and applies the same method when solving both T1 and T2.

Heather as well used identical algebraic approaches for both tasks a year apart:

Heather (T1): I needed a common variable. Otherwise it will be difficult to calculate.

Heather (T2): I needed some relation among these sides in that and the large square's sides. Otherwise it will be difficult.

Also the individual approaches of Erin and Sebastian were respectively identical; Erin approached both tasks by *reasoning*, testing *numerical values* and applying *particular solutions*, while Sebastian *reasoned* carefully before requesting the use of *numerical values* at both occasions. Thus, every participant approached both tasks identically at the individual level. The analysis also shows that M is displayed mainly at the beginning of the process, for recalling mathematical relations and problem-solving methods; moreover, none of participants modified the initially selected methods.

## Discussion

One of the aims of this study was to display the role of the mathematical memory (M) when high-achieving students solve non-routine tasks, which can be solved with similar methods. Despite its small proportion, M seems to play a pivotal role in problem-solving because the participants selected their methods at the early stages of the process and the methods were not changed later. Thus, by confirming earlier results (e.g. Szabo & Andrews, 2017), it seems that the choice of methods is directly influenced by M and it is critical for the success of the problem-solving.

However, unexpectedly, only two of the six participants recalled the solution process to the earlier task, contradicting Krutetskii's (1976) finding that able students recall the process but not the context of earlier problems. But even when not recalling T1, every participant approached both tasks in the same individual way. For example, Linda's method, connected to a square in a triangle and apparently very different from what is predicted, is a general approach that she uses for non-routine geometrical tasks. And even though the individual approaches of Erin, Larry and Sebastian were not successful when solving T1, they were repeated a year later. Thus, it seems that the participants rely on methods which appear to be inflexible and applied regardless of their success. The general structure of the participants' mathematical abilities indicates that O and M decrease while P increases at the second observation. Hence, it is not unreasonable to assume that the displayed stability of the individual approaches made O and M more efficient at T2, and therefore students had a larger focus on P. And even if none of the students could generalize numerical results at the first observation, Erin generalized her results during the interview after T2. Thus, when additional opportunities were offered, by evolving the patterns in her numerical results, which may be interpreted as a form of convergent thinking (Tan & Sriraman, 2017), Erin could improve the quality of her problem solving. These findings may suggest that some participants are unlikely to have experienced teaching focused on methods of generalization, because the individual structure of the mathematical ability depends on received instructions (Krutetskii, 1976). However, by confirming earlier studies (e.g. Krutetskii, 1976), the methods of this study were not able to differentiate M from O during episodes when students did not say or write anything; thus, a better investigation of the mathematical memory requires further studies. In addition, the study shows that mathematical memory has a key role during the early stages of problem-solving (e.g. Szabo & Andrews, 2017) and that individual problem-solving methods seem to be very stable and apparently independent of their efficiency when high-achievers solve non-routine tasks. Finally, the study indicates that, if given additionally opportunities to reflect over their numerical solutions, some students might be able to display their ability to generalize mathematical relations and operations.

*The present study aimed at investigating the mathematical values embedded in the Turkish Middle School Mathematics Applications Course Curriculum (MACC). For this purpose, MACC was carefully analyzed by considering main components of the curriculum. The findings indicated that all of the mathematical values, namely objectism, rationalism, control, progress, openness and mystery, were embedded in MACC. Although the balance among the embedded mathematical values in MACC was not equal, the findings clearly proved that the mathematical values were taken into consideration by curriculum developers, and thus it might be expected to raise awareness among mathematics teachers, students as well as textbook writers about the values in mathematics education.*

*Keywords: Mathematical values, mathematics applications course, curriculum analysis.*

## Background of the study

In almost all field of human endeavor, astounding developments and advancements are indebted to mathematics to a great extent. Among the other disciplines, "... mathematics was considered the Queen of the sciences." (Gregorian, 2009, p. ii). Mathematical literacy has always been at the heart of nations' capacity for economic growth and social welfare. In other words, there is no doubt that mathematics is not only vital to economic prosperity; but also a fundamental skill for life. Thus, it is essential for all societies to provide learning opportunities in which students will possess and use the understanding of mathematics purposively and interactively. Although mathematics is considered as one of the crucial subjects of school, it is a well-known fact that "...many students leave school with negative attitudes towards mathematics; some dislike the subject, others feel inadequate about it, still others feel it is irrelevant in their lives. This is an unacceptable outcome of school mathematics." (Education Department of Western Australia, 1998, p.9). In many classrooms, mathematics has delivered in a way that follows a textbook under the guidance of a teacher with little emphasis on affective side of mathematics. Thus, most of the students perceive mathematics as a non-creative, mechanical, value-free and teacher- or textbook writer-invented subject (Diamond, 2001). Seah, Andersson, Bishop, and Clarkson (2016) argued that such negative perceptions held by many students are not due to the nature of mathematics itself. It is most likely as a result of developing and implementing a mathematics curriculum which is full of concepts, skills, and procedures but not explicitly include the values of mathematics and the values of mathematics education. Indeed, values are powerful tools for promoting cognitive and affective development in mathematics education since they lead teachers' and students' interests, thoughts, decisions, preferences and behaviors about mathematics (Bishop, 2008; Corrigan, Gunstone, Bishop, & Clarke, 2004). The values expressed by teacher either intentionally or unintentionally in the context of the mathematics classroom may root in his/her personality, pedagogical approach and instructional materials preferred to use, etc. However, the important point is here that "what kinds

of values are embedded in the intended mathematics curriculum?” Because as a teacher, it is his or her responsibility to implement the curriculum as intended. Therefore, analysis of curriculum regarding mathematical values will shed lights on what kind of values that a teacher is expected to convey into instruction as well as what kind of an image of mathematics is going to be presented for students.

Affective issues in mathematics learning and teaching have been a prolonged and persistent interest among researchers. McLeod (1992), attributed to as the pioneer in work on the affective dimension of mathematics education (Gil, Blanco, & Guerrero, 2006), identified three main constructs of affect as beliefs, attitudes and emotions “...representing increased levels of affective involvement, decreased levels of cognitive involvement...” (p. 579). The scope of the mathematics-related affect has broadened with the addition of a fourth construct – values (sometimes including morals /ethics) – by such leading works of Bishop (2001); De Bellis and Goldin (2006); Leder and Grootenboer (2005). Considering the studies on the affective constructs such as beliefs, motivation, anxiety and attitudes, research on values in mathematics education is still insufficient (Zan, Brown, Evans, & Hannula, 2006). Leder and Grootenboer (2005) stated that the field of affective domain has been dominated by the studies on beliefs and attitudes, yet there has been a few number of study concerned with values. Although different conceptualizations of values in mathematics education have been described in the literature, the Bishop’s (1988) classification of the mathematical values provides a widely-used framework while analyzing mathematical values (Hannula, 2012; Seah, 1999). Besides, there is no doubt that mathematics is the sum of the human activities, and thus the Bishop’s framework (1988) not only gives room for discussing the values from the socio-cultural perspective but also corresponds to White’s (1959) three components of culture – ideology, sentiment, sociology. In this respect, the present study is primarily concerned with “mathematical values” and thus the Bishop’s framework was chosen to analyze the mathematical values. According to Bishop (1988), Rationalism-Objectism (the ideological component of mathematical values), Control-Progress (the sentimental component of mathematical values), and Openness/Mystery (the sociological component of mathematical values) are the mathematical values grouped as three pairs of complementary values. Table 1 summarizes each pair of mathematical values.

During the past decade, there have been the bulk of theoretical and research-based arguments on values in mathematics education (e.g. Values in mathematics and science education by Bishop, 2008; Identification of a learner’s value orientations in mathematics learning by Seah, Zhang, Barkatsas, Law, & Leu, 2014), yet the number of the studies on mathematical values embedded in math curricula is still very limited. In this respect, the present study aimed to is to explore the mathematical values embedded in the Turkish Mathematics Applications Course Curriculum (MACC) by addressing the following research questions: (1) What are the mathematical values embedded in the MACC? (2) Where are the mathematical values located in the components of the MACC?

<i>Three Pairs of Mathematical Values</i>	
<i>Rationalism</i>	<i>Objectism</i>
Focuses on the development of students' mathematical reasoning through discussions, explanations, evaluating their way of solutions etc. (Bishop, 1988, p. 62).	Focuses on concretizing abstract ideas through the use of symbols and objects, promoting to use different kind of representations (Corrigan, et al., 2004)
<i>Control</i>	<i>Progress</i>
Focuses on control ensured by the nature of mathematics for the problems related to both natural phenomenon and social environment through application of mathematical knowledge and favors stability (Seah & Bishop, 2000).	Puts emphasis on change and progress in society by means of mathematical knowledge (Seah & Bishop, 2000).
<i>Openness</i>	<i>Mystery</i>
Focuses on transparency/verification aspects of mathematical ideas and conclusions through proofs (Corrigan, et al., 2004)	Focuses on mystique and unclear origins of mathematics and puts emphasis on dehumanized knowledge, intuition, wonder (Corrigan, et al., 2004)

**Table 1: Three Complementary Pairs of Mathematical Values**

In 2012, a comprehensive change took in the Turkish educational system. The length of compulsory education was increased from 8 to 12 years and redefined the system into three levels (12-years compulsory education covering 4-years elementary, 4-years middle and 4-years high school) and this structural reform required for the curricular revision as well. One of the results of the curricular revision was the inclusion of more than twenty elective courses offered for the Turkish middle school students who can able to choose max.6 hours in a week. Along with the fact that mathematics is one of the core subjects of the curriculum, “Mathematics Applications Course” (MAC) is one of the elective courses for middle school students since 2013-2014 academic year. According to statistics, MAC is the most popular elective course among 5<sup>th</sup>-7<sup>th</sup> graders in 2014-2015 academic year (Ministry of National Education [MONE], 2015). The main purpose of MAC is not only to improve students' mathematical knowledge and skills but also to like mathematics and develop positive attitudes towards mathematics through the learning opportunities that allow students to practice mathematics (MONE, 2013).

Keeping in mind that the concept of a value is associated with “what is desirable, preferable, worthy, important, right, or beneficial” (Bishop, Seah, & Chin, 2003, p. 723) by different scholars and they, as cultural products, depend on personal choices, preferences and decisions, the focus of the present study is on the mathematical values of the mostly chosen elective math course by the Turkish middle school students. In this respect, the present study might shed lights on what kind of values about mathematical knowledge and discipline that a teacher is expected to convey into instruction as well as what kind of an image of mathematics is going to be presented for students. Further, the results of the study might raise the awareness of curriculum developers, mathematics teachers, and textbook writers about the values in mathematics education. It is also expected that the results of this study may contribute to the math-related affect studies by giving an example from the values of mathematics in the Turkish Mathematics Applications Course Curriculum.

## Method

This study was designed to explore the mathematical values in the MACC (5<sup>th</sup>-8<sup>th</sup> grade). For this purpose, data were collected through document analysis. The main data collection source of this study was MACC published by the MONE. In this respect, the focus of the present study is on the intended curriculum and limited to the MACC which is available on the MONE's official website.

Before the data analysis process, the framework for curriculum analysis was developed by considering the literature on the mathematical values and the structure of MACC as well as the research questions. In order to portray the mathematical values, namely “Rationalism-Objectism; Control-Progress and Openness-Mystery”, Seah’s outline of the major signals for the mathematical values was adapted (Seah, 1999, pp.110-111). Afterwards, MACC was examined carefully to find out what type of mathematical values embedded in which part of the curriculum. MACC consists of 8 main chapters as (1) Introduction part; (2) Aims of MAC; (3) The developmental characteristics of middle school students; (4) The structure of core mathematics curriculum; (5) Explanations about the implementation process of MACC; (6) Basic principles of MAC; (7) Assessment and evaluation process and (8) Learning objectives of MACC. While locating and analyzing the data, the researchers independently read all chapters line by line and coded all instances of the mathematical value statements in MACC according to the framework. To establish internal consistency, inter-coder reliability was carried out using the formula ( $\text{Reliability} = \frac{\text{Number of agreements}}{\text{Total number of agreements} + \text{Disagreements}}$ ) proposed by Miles and Huberman (1994). A high agreement score (0.92) between the two coders (the researchers) was obtained. Then, the basic descriptive statistics including frequencies and percentages were carried out by means of IBM SPSS.23.

## Results

### *The mathematical values in the Turkish Mathematics Applications Course Curriculum*

The major focus of the content analysis here was to identify all instances of the mathematical values in the written curriculum, namely MACC. The findings indicated that totally 39 value signals of the mathematics embedded in MACC. As given in table 2, it is obvious that objectism ( $f = 10$ ) was emphasized more than rationalism ( $f = 6$ ); progress ( $f = 8$ ) was emphasized more than control ( $f = 2$ ) and openness ( $f = 12$ ) was emphasized more than mystery ( $f = 1$ ). According to the results, while “openness” ( $f = 12$ ) was the most-emphasized value; there is only one reference to the value of “mystery” ( $f = 1$ ) in MACC.

<i>Mathematical Values</i>	<i>Number of value signals (f)</i>	<i>Proportion (%)</i>
Rationalism	6	15.4
Objectism	10	25.6
Control	2	5.1
Progress	8	20.5
Openness	12	30.8
Mystery	1	2.6
<i>Total</i>	<i>39</i>	<i>100</i>

**Table 2: The proportional distribution of mathematical value embedded in MACC**

### *The place of the mathematical values in MACC*

The last research question of the study aimed to portray the parts of MACC in which the mathematical values are embedded. As given in Table 3, the results indicated that the mathematical values mostly located in the learning objectives ( $f = 14$ ). However, both in the introduction part and assessment part of MACC, only three statements referring to the mathematical values were found.

Mathematical values	<i>Introduction</i>	<i>Aims &amp; Principles</i>	<i>Objectives</i>	<i>Teaching &amp; Learning</i>	<i>Assessment</i>
Rationalism	1	2	1	1	1
Objectism	0	2	6	1	1
Control	0	0	1	1	0
Progress	1	3	3	1	0
Openness	1	4	3	3	1
Mystery	0	0	0	1	0
<i>Total</i>	<i>3</i>	<i>11</i>	<i>14</i>	<i>8</i>	<i>3</i>

**Table 3: Frequencies of the mathematical values embedded in the parts of MACC**

Considering the *Introduction part*, it was found that the value of rationalism was embedded in the statements explaining the importance of providing the learning opportunities to develop students' mathematical thinking as well as finding reasonable, rational and logical solutions/answers for problems. It was also found that the value of openness was conveyed in the expressions about the importance of cooperative learning. In addition to rationalism and openness, the value of progress was highlighted in the introduction part through the statements putting emphasis on making connections with mathematics and daily life. Further, the value of rationalism, objectism, openness, and progress were included in part of *the Aims and Principles* of MACC. More specifically, the value of rationalism was embedded in such statements that underline the use of mathematical reasoning; focusing on symbolization and modelling portrayed the value of objectism; putting emphasis on group working, sharing/discussing ideas addressed to the value of openness; and the statements signifying the relationships between mathematics and the other disciplines as well as daily life were found as the indicators of the value of progress. It's also noting worth that in the following statement, the attention aimed to draw on the mathematical values “...it is important for students to develop true values about mathematics” (p. 1). However, there was no explanation related to what are the true values about mathematics provided in this part of MACC. In order to portray the mathematical values, all learning objectives (totally 21) were analyzed in line with the framework. As given in Table 3, the mathematical values embedded in MACC were mostly located in the part of the *Learning Objectives*. The objectives putting emphasis on the use of appropriate mathematical symbols while solving problems were found as the indicators of objectism; asking students to discuss their solutions process through mathematical reasoning were the indicators of rationalism. Additionally, the learning objectives that put emphasis on the development of students' problem solving abilities through daily life math problems were considered as the indicators of progress, and the objectives aimed to promote students' procedural fluency through the tasks asking to test or evaluate the way of solution process were the signs of control. Further, the learning objectives aimed to improve students' problem solving skills through sharing/discussing ideas and pose questions/problems were found as the indicators of openness. Considering the part of *Teaching and Learning Approach*, it was found that while the value of objectism was fostered through the statements suggesting the use of different kinds of representations in problem solving process, the value of rationalism was embedded in the explanations related to the characteristics of problems that should promote students' mathematical reasoning. The indicators of control were found in the sample problem that required using of mathematical knowledge in an attempt to change the environment. The sample problem also indicated the value of progress by means of addressing the relationship between mathematics and daily life. The statements emphasizing the idea of sharing information and collaborative working were found as the indicators of the value of openness.

Besides, the statement suggesting the use of interesting mathematical games was found as the only one indicator of mystery. In the last part of the MACC, *Assessment and Evaluation Process*, three types of mathematical values were found. The value of rationalism was embedded in the statements suggesting the development of students' reasoning and logical thinking skills should be assessed by such methods as classroom observations, self-evaluation reports, etc. Besides the value of objectism was found in the statements that ask teachers to evaluate students' ability to use different symbolizations while explaining their problem solving process. Finally, the value of openness was implied in the suggestions about the assessment of collaborative work.

## Conclusion and discussion

The present study was designed to examine the mathematical values embedded in MACC which is the most popular elective course among the Turkish middle school students in 2014-2015 academic year. For this purpose, the written curriculum was analyzed by the researchers in a detailed manner. In general, it can be concluded that all of the mathematical values, namely objectism, rationalism, control, progress, openness and mystery, are embedded in MACC. Although the balance among these embedded mathematical values in MACC is not equal, the findings clearly proved that the mathematical values are taken into consideration by curriculum developers. Further, the results indicated that the value of openness was the mostly-embedded mathematical value in MACC and thus, it can be concluded that the democratic side of mathematics is intended to be promoted through communicating with the mathematical ideas and questioning the mathematical facts. In other words, the intended implementation process of MAC seems more likely to focus on the appreciating the role of public sharing and discussions in facilitating understanding of mathematics. On the other hand, a considerable amount of the signals were also placed on the value of rationalism and objectism in MACC. This situation might support a widespread image of mathematics as abstract, theoretical, ultra-rational discipline (Ernest, 2004).

One of the more noteworthy findings to emerge from the present study is that both the value of progress and control were rarely mentioned in the curriculum. When considering one of the main aims of MAC that provide learning opportunities for students to experience mathematics through mathematical problems and to develop their mathematical knowledge, it is quite surprising. Besides, there was only one reference related to the value of mystery found in MACC. Such little emphasis on the value of mystery might limit the opportunities indicating the mystical, surprising, and fascinating side of mathematics. Taken together, the results of the present study indicated that the image intended to transmit through MACC might be mathematics as symbolized, open to discussion, theoretical and questionable discipline. What research has found about the mathematical values embedded in math curricula yielded the similar results with the present study (Clarkson & Bishop, 2000; Seah et al., 2016). Moreover, the following statement “...it is important for students to develop true values about mathematics” (MACC, p.1) might be considered as evidence that explicitly mentioned “values about mathematics” in MACC. Nevertheless, it is too vague for teachers to interpret what are the true values about mathematics, so further explanation should be provided in the written curriculum.

Considering the place of the mathematical values, the results indicated that the value signals were embedded in almost all parts of MACC. However, while the value of openness was placed in each part of the MACC, the value of mystery was only mentioned in the teaching and learning approach

part. One of the main reasons behind this situation might be due to MAC itself. In other words, MAC mainly focuses on the development of students' problem solving and mathematical thinking skills through the applications of mathematics. Thus, students are expected to learn collaboratively; to solve and pose problems from daily life and other areas of science; to share and discuss their ideas through mathematical reasoning and to test and evaluate their problem solving process rather than focusing on mystic and fascination sides of mathematics. Taken together, these results clearly indicated that the mathematical values were mostly embedded in the form of implicit statements in the different parts of MACC. Therefore, the reflection of these mathematical values from the intended to enacted curriculum might probably stay as hidden and vague. On the one hand, the image of mathematics embedded in the curriculum will shape students' future choices and career plans about mathematics; on the other hand it will be shaped by the mathematical values hold by the curriculum developers. Therefore, it is essential to raise the awareness about the values in mathematics education as well as to conduct more studies on the mathematical values in the intended, enacted and attained math curriculum.

# A case study on Finnish pupils' mathematical thinking: Problem solving and view of mathematics

Hanna Viitala

University of Agder, Norway; [hanna.l.viitala@uia.no](mailto:hanna.l.viitala@uia.no)

*In this article, the mathematical thinking of four Finnish pupils is reported using two temporally different data sets: problem-solving processes and view of mathematics. While the pupils seem similar on the surface level (high achievers, successful problem solvers, enjoy mathematics, motivated to learn mathematics), a closer look at their problem-solving processes and view of mathematics reveal very different strengths and weaknesses in their mathematical thinking. Most of the similarities in this study were found in individual pupils' problem-solving processes and view of mathematics.*

*Keywords: Problem solving, view of mathematics, affect, metacognition, meta-affect.*

## Introduction

Developing mathematical thinking is one of the key tasks for mathematics instruction in the Finnish curriculum (FNBE, 2014, 2004). And indeed, Finnish pupils have succeeded well in international studies that assess pupils' mathematical thinking (PISA and TIMSS; see e.g. OECD, 2014; Mullis, Martin, Foy, & Arora, 2012). However, the most recent national and international studies show that the mathematics performance of Finnish pupils is descending (e.g. Välijärvi, 2014; Rautopuro, 2013). Additionally to the alarming trend in mathematics performance, we know very little about Finnish comprehensive school pupils' mathematical thinking that go *beyond* paper tests. Thus, a quantitative research study was conducted with the aim of describing what characterises Finnish 15-year-old pupils' mathematical thinking.

On the way to describe what characterises Finnish pupils' mathematical thinking, the study reported in this article examines four high-achieving Finnish pupils' mathematical thinking through the intertwined relationships of problem-solving processes and view of mathematics. While some of the results of individual pupils' mathematical thinking have been discussed in previous publications (Viitala, 2013; 2015; 2016a), the purpose of this paper is to bring the results together, and answer *what similarities and differences related to mathematical thinking can be found between these pupils*. With this question, we can reveal some of the possible trends in skills and competences that the Finnish high-achieving pupils might have in their mathematical thinking.

## Theoretical framework

Developing pupils' mathematical thinking is in the heart of mathematics education, also according to the Finnish curriculum (FNBE, 2014). While research in mathematics education does not seem to have a common understanding of the meaning of mathematical thinking, Schoenfeld (1992) recognised five aspects that are important in a study on mathematical thinking: the knowledge base, problem-solving strategies, monitoring and control, beliefs and affects, and practices. Similar findings have also been found in connection to literature on problem-solving performance (Lester 1994), and are also listed as part of final-assessment criteria in the Finnish curriculum (see FNBE 2014, pp. 433-434).

Similarly as the most recent theories on affect, mathematical thinking can be viewed through two temporally different aspects: state and trait (cf. Hannula, 2011; 2012). On one hand, mathematical thinking is always situational (state). Following Schoenfeld's (1992) categorisation, it is influenced by the pupils' knowledge base and heuristics, and guided by their metacognitive skills, affects and classroom practices. In this study, mathematical thinking is studied through problem-solving processes. In other words, 'pupils' activities, actions and explanations during problem solving are interpreted as visible signs or expressions of their mathematical thinking' (Viitala, 2015, p. 138).

Pupils' problem-solving behaviour is influenced by pupils' metacognition, affect and meta-affect that occur in a problem-solving situation. The successful application of problem-solving activities at the correct moment is a result of metacognitive skilfulness (e.g. van der Stel, Veenman, Deelen, & Haenen, 2010), affect influence the problem-solving situation for instance through the feeling of confidence, and meta-affect transforms individuals' emotional feelings (DeBellis & Goldin, 2006) and directs problem solving behaviour (Carlson & Bloom, 2005).

On the other hand, problem-solving situations can show patterns of thought that can be interpreted as signs of more stable ways of thinking. Some of these patterns can also be revealed through pupils' view of mathematics (see e.g. Viitala, 2016a). View of mathematics draws from psychological theories. It is a mixture of cognitive, motivational and emotional processes that include for instance beliefs, attitudes, values, feelings and motivation (Hannula, 2011; 2012). In this study, view of mathematics is studied through four components: mathematics (as science and as a school subject), oneself as a learner and user of mathematics, learning mathematics, and teaching mathematics (Pehkonen, 1995, cf. Op't Eynde, de Corte, & Verschaffel, 2002).

## Methods

### Data collection

At the time of data collection, the four pupils (Alex, Daniel, Emma and Nora) were 15 years old and in their 9<sup>th</sup> and final year of compulsory school in Finland. Additionally, they were all high achievers (mathematics grades between 9 and 10 on a whole number scale of 4 to 10).

The data was collected in three cycles over the course of three months. In each cycle, one mathematical task was solved in an ordinary classroom situation as a 'main task'. The pupils solved the tasks individually but they were allowed to talk about the tasks with a friend or ask for help from the teacher. In each cycle, the pupils were video recorded while they solved the task(s) in class and their solutions on paper were collected. Below, there is an example of a main task (School Excursion, OECD, 2006, p. 87).

A school class wants to rent a coach for an excursion, and three companies are contacted for information about prices.

Company A charges an initial rate of 375 zed plus 0.5 zed per kilometre driven. Company B charges an initial rate of 250 zed plus 0.75 zed per kilometre driven. Company C charges a flat rate of 350 zed up to 200 kilometres, plus 1.02 zed per kilometre beyond 200 km.

Which company should the class choose, if the excursion involves a total travel distance of somewhere between 400 and 600 km?

In each cycle, the pupils were interviewed individually. The interviews took place either on the same day, or on the next day after solving the task in the classroom. The interviews contained two parts. The first part concentrated on affective traits and treated the following themes: pupil's background, mathematical thinking, and pupil's view of mathematics (following the categorization of Pehkonen, 1995; see example questions in Table 1, Viitala, 2016a, p. 1295). This part of the interview was semi-structured and focused (Kvale & Brinkmann, 2009).

Theme	Example questions
Background	Tell me about your family.
Mathematical thinking	What does mathematical thinking mean? / How do you recognise it?
Mathematics	What is mathematics as a science? / Does it exist outside of school? (How? Where?)
Oneself and mathematics	Is mathematics important to you? / Does it help you think logically? (How?)
Learning mathematics	How do you learn mathematics? / Is it most important to get a correct answer?
Teaching mathematics	Does teaching matter to your learning? (How?) / What is good teaching?

**Table 1: Interview themes and example questions.**

The second part of the interview was about problem solving. The classroom data was used as stimuli when the pupil's problem-solving process was discussed. The pupils were asked to explain their thinking and actions during the problem-solving situation and additional questions were asked (e.g. what are you thinking now? Why are you doing so? What did you feel when you read the task? Did you think about your own thinking when solving the task?).

Finally, in each interview, the pupils were asked to assess their confidence before, during and after solving the problem, as well as their confidence in school mathematics using a 10 cm line segment (scale from 'I couldn't do it at all' to 'I could do it perfectly'). All interviews were video recorded.

### Analysis

Following the state and trait aspects of the study, the analysis was divided into two sections: problem solving and view of mathematics. The problem-solving processes were analysed first by going through the problem-solving phases introduced by Carlson and Bloom (2005): orienting, planning, executing and checking (cf. Polya, 1957). Then the results on problem-solving behaviour were complemented with metacognitive activities (orientation, planning, evaluating and elaboration van der Stel et al., 2010), affect (state and trait, as well as cognition, emotion, motivation; Hannula, 2011; 2012) and meta-affect (DeBellis & Goldin, 2006) emerging in problem-solving processes. Finally, the pupils' confidence to solve the problems was analysed.

The first analysis of the pupils' view of mathematics followed the themes of data collection (Pehkonen, 1995). After condensing the results, a pupil profile was created to be used as background information about the pupil. Pupil profile is a short description of the pupil that is based on the pupil's mathematics grade, motivation to learn mathematics, and the core of his view of himself as a learner of mathematics (ability, success, difficulty of mathematics, and enjoyment of mathematics, following Rösken, Hannula, & Pehkonen, 2011).

In the end, the results of problem solving and view of mathematics were compared to see if there are similarities in pupil's problem-solving skills (state) and competences found through pupil's view of mathematics (trait). More details of the methods used in the study are reported for instance in Viitala (in press).

## Results

On a surface level, Alex, Daniel, Emma and Nora seem quite similar: they are all high achievers in mathematics, they enjoy mathematics, and they are motivated to learn mathematics (see excerpts in Table 2). They are also successful problem solvers, that is, they could solve all the problems given to them in the study and justify their answers and solutions. However, a deeper look at their problem solving and view of mathematics introduce four pupils with a very different skills and competences. In the following, the key results of each pupil will be introduced individually.

Alex is very fluent and thorough mathematics learner and problem solver. He can move naturally between different phases of problem solving. He is aware of his own thinking and fluent in explaining and justifying his cognitive and metacognitive actions in problem solving. Similarly, when explaining his learning of mathematics, he says he is actively seeking for connections between new knowledge and prior knowledge, and he is able to spontaneously give examples of this behaviour. He says he trusts his own thinking more than his calculations, and shows to be able to direct his behaviour according to his affects in problem solving. He is confident in school mathematics but in the interviews, he constantly compares his abilities to mathematics as a science and recognises that there is much more than school mathematics (more results in Viitala, 2013; 2016b).

Whereas Alex seems to be very fluent in every aspect of mathematical thinking studied in this research project, from a similar starting point, Daniel shows somewhat different strengths in mathematics. Unlike any of the three other pupils, he is extremely confident in mathematics. He says that mathematics is easy for him, and he shows to be very aware of his success in mathematics. His confidence seems to guide also his problem-solving processes. He is able to move fluently back and forth between problem-solving phases and is skilful in performing metacognitive acts. However, even though (or because of) learning mathematics and solving problems are easy for him, he cannot explain the processes he goes through in or for learning, and he has problems in explaining his problem-solving actions after the problem-solving situation. An illustrative example of this situation is Daniel's explanation about how he learns mathematics: pieces just click together or things become familiar (more results in Viitala, in press).

Similarly as in Daniel's case, also Emma's learning of mathematics and problem solving are strongly influenced by her confidence in mathematics, or more precisely, her lack of confidence. Because of the uncertainty in mathematics, for Emma, learning takes time and effort. She says she learns every topic as a separate entity, and she is able explain the steps that are needed for her to learn a new thing. Similarly, she uses a considerable amount of time for orienting and planning in problem solving. After understanding the problem and the given data, she is able to follow her plan through and check her solution. It seems that Emma's uncertainty in mathematics makes her work harder, and through hard work, she succeeds in mathematics. Moreover, she says that succeeding in mathematics and understanding it, makes it worthwhile studying. On the other hand, affect can also be an obstacle in her problem solving, since she does not seem to have efficient tools to overcome the feeling of getting stuck (more results in Viitala, 2015; 2016a).

Also for Nora, learning mathematics takes time and effort but after learning something, applying is easy. She says that she is quite confident in mathematics and likes learning mathematics very much.

She is capable in explaining her thinking and problem solving, and connecting mathematics to her own life. She also has a diverse view of mathematics as a science. In problem solving, she is flexible in directing her actions based on the affective states occurring in problem-solving situations. She is also fluent in moving between orienting, planning and executing in problem solving. However, given the choices she had made while planning, she is happy with the first answer she gets, and does not check her results (more results in Viitala, 2015).

	<b>Ability and success</b>	<b>Difficulty of mathematics</b>	<b>Enjoyment of mathematics</b>	<b>Motivation to learn mathematics</b>
<b>Alex</b>	Confident in math; deserves the high grade: knows school math quite thoroughly	Learning ‘a separate thing’ is easy, connecting it to ‘other things’ might take time	Learning math is fun and interesting; routine learning is boring	Good grade and future studies, also understanding the issue at hand
<b>Daniel</b>	Very confident in math; can do math well; deserves the high grade (active learner, succeeds in tests)	Learning math is easy and it does not take much time or effort	Math is enjoyable, even fun	Math is needed through life; the most important school subject
<b>Emma</b>	Not confident in math; could not get a better grade in math	Learning math takes time and effort	Learning math is irritating and tiring; succeeding and understanding is fun	Wants to succeed in mathematics and be proud of herself; future studies
<b>Nora</b>	Quite confident in math; not perfect in math but deserves the high grade in school math (active learner, succeeds in tests)	Math can be easy or difficult, more on the easy side; learning takes time and effort, applying after that does not	Learning math is interesting, likes math very much	Good grade; wants to learn math

**Table 2: Examples of pupils’ own statements about their view of mathematics (cf. pupil profile).**

### Some reflections of the results

In addition to forming descriptions of pupils’ mathematical thinking, and showing pupils’ strengths, the study also revealed issues that pupils could work with in order to develop their mathematical thinking. For instance, even though Alex was fluent in problem solving and school mathematics, he did not relate the problems to real life and his view of mathematics outside school was quite limited (see Viitala, 2013, 2016b). Recognising mathematics more in his own life could enrich Alex’s view of mathematics, and through that, also his understanding of school mathematics might develop. Daniel, on the other hand, had problems explaining his thinking after the problem-solving situation and had similar problems with explaining his mathematics learning (see Viitala, in press). Problem solving and learning mathematics might be easy for Daniel in compulsory school, but what happens if (when) the situation changes? Becoming aware of his own learning and problem-solving processes could help him cope in new situations and develop his metacognitive skills not only in mathematics but also in other school subjects.

Emma's weak point was her uncertainty which she had turned into success in problem solving and learning of mathematics. She had overcome some of the uncertainty with the support of her family (see Viitala, 2016a). However, because she was not confident in mathematics, she learnt every topic in mathematics as its own entity, and did not connect it to prior knowledge. This might also hinder her learning. Hence, supporting Emma emotionally could open doors to more thorough learning and understanding of mathematics. Finally, Nora's results were not always correct, and both her activities and explanations showed that she does not evaluate her problem-solving process or check her results (see Viitala, 2015). Supporting her to look back, and perhaps exposing her more to, for instance, open problems, might help her to become more reflective user and learner of mathematics.

## Summary and discussion

The purpose of the paper was to answer the question what similarities and differences related to mathematical thinking can be found between the four Finnish high-achieving pupils. Mathematical thinking was studied through two temporally different data sets: problem-solving processes (state) and view of mathematics (trait). The results showed that the similarities between the pupils were found to be mainly on a surface level: all the pupils liked mathematics, were motivated to learn it, enjoyed doing mathematics and were successful problem solvers. However, after a deeper look into their problem-solving processes and view of mathematics, the study revealed a great deal of differences between the pupils, and showed different competences: Alex is a very conscious thinker and learner of mathematics, and excellent in justifying his thinking and actions in mathematics. Daniel is extremely confident and metacognitive skills are prominent in his problem solving. Emma is an unsure but very thorough problem solver and learner of mathematics. Nora is fluent in expressing her thoughts and connecting mathematics to real life.

In addition to the strengths found in these four pupils, the framework also revealed some of their weaknesses. The strengths, together with the weaknesses can be used to support individual pupils' development in mathematics. For instance, Alex seemed to see mathematics only as a tool to solve something and his view of mathematics outside school was quite limited (see Viitala, 2013, 2016b). This knowledge can be used to develop pupil's mathematical thinking. Four years after the data collection of this research project, I met Alex again. At this point, Alex was as a university student. He explained that only after realising the tool value that mathematics had for him, and learning that mathematics is not just calculations but also ways of thinking, he began to see mathematics everywhere in his real life, and he began to use his mathematical thinking more creatively (see Viitala, 2016b).

All in all, the results showed that even though the pupils seem similar on the surface level, on a closer look, they have very different skills and competences in mathematics. This is an indication that the framework allows different pupils to show different strengths, and also different weaknesses in problem solving and learning of mathematics. Hence, the framework could assist also teachers to pay attention to the aspects that pupils might need help with in developing their mathematical thinking, which in turn can help the pupils to recognise the knowledge, skills and affects that might need further developing (cf. FNBE, 2014, p. 377; Viitala, in press; see also Viitala, 2015). An example of how teachers can use this framework to support their teaching is presented in Viitala (in press).

# Exploring affective reactions of children to Scratch programming and mathematics: The case of Kim

Johanna Carvajal

UCL Institute of Education, University College London, United Kingdom; [j.benitez.14@ucl.ac.uk](mailto:j.benitez.14@ucl.ac.uk)

*Keywords: Affect, Scratch programming, mathematics.*

## Background

Around four decades ago the use of programming as a medium for mathematical learning became the focus of research for some mathematics educators (Papert, 1980; Noss and Hoyles, 1992). The new computing curriculum in the UK with a strong focus on programming inspired the ScratchMaths project which rescues this idea and aims to exploit the potential of programming in Scratch to support mathematical thinking (Benton et al., 2016). Using this project's designed materials the purpose of my research has been to investigate the kind of affective reactions that emerge from the experience of Year 5 children working with the activities during their computing lessons. Given the connection of the materials with mathematics, and the relationship between mathematical and computational skills, those children that underperform in both subjects have been of particular interest for my study. Three Year 5 classes (sixty 9-10 years old in total) from a primary school in London and taught by the same teacher were observed for sixteen weeks during computing lessons. 11 children were purposively chosen to participate in the research.

Building mainly on the literature on affect and mathematics education (McLeod, 1992; Hannula, 2012) and based on results from the pilot study, three categories concerning efficacy beliefs and emotions were explored: perceived efficacy, general emotion and emotion enjoyment. The three main research questions were:

- What kind of experiences do participants have when working with the activities?
- What changes can be observed (positive/negative evolution of the learner's perspectives)?
- On what might a positive or negative evolution of the learner's perspective depend on?

## Methodology

The research used a case study approach and combined different methods for data collection: questionnaires (a short questionnaire administered lesson by lesson during 12 weeks and the attitudes towards Scratch questionnaire), field notes, students' work and critical incident (CI) interviews. The short questionnaire allowed the researcher to capture systematic information along the three categories explored regarding different types of tasks. Indicators above 5 were considered positive reactions, below 5 were considered negative reactions, and equal to 5 were considered neutral. Key moments were identified and were then triangulated with data from other sources.

## Results

Kim's responses to the short questionnaire (Figure 1, left) suggest that for her, positive affective reactions tended to happen when the activities were of an exploratory nature and negative reactions

when the activities had a more explicit mathematical focus (Figure 1, right). Nonetheless, she had positive or neutral experiences around 80% of the times that the questionnaire was applied.

**Figure 1: On the left, graph of Kim's response to the short questionnaire. On the right, examples of a task with mathematical focus (lesson 5) and a more playful and exploratory task (lesson 6)**

Data from the affect towards Scratch questionnaire administered in January and June of 2016 indicates that she had had a negative evolution of perspectives as a learner in this context. Data triangulation from all sources suggests that Kim had noticed a connection between the activities and mathematics and that this connection might have played a crucial role in her learning experience. Children who struggle with mathematics may be in disadvantage when tackling some of the ScratchMaths activities on their own in classroom conditions. In the case of Kim, the involvement of mathematical skills in the activities seemed to trigger negative affective reactions and the belief that she just could not do it. However, when extra material and individual support was given during the lesson she was able to solve the task, help other students in the class, and moreover, she regarded that particular lesson as her best moment working with the activities.

# Documenting metacognitive activity in qualitative interviews with high school graduates

Sebastian Mungenast

Wuerzburg University, Germany; [sebastian.mungenast@uni-wuerzburg.de](mailto:sebastian.mungenast@uni-wuerzburg.de)

*Keywords: Metacognition, calculus, university.*

## Theoretical background

The poster gives an overview of the research and theoretical background of an ongoing dissertation project the major focus of which is on metacognition in mathematics education. A central objective is the documentation of metacognition during mathematical activity in prospective mathematics university students and using the results of this study to expand upon existing category systems of metacognition – especially for the field of Calculus.

Metacognition is generally understood as knowledge about and cognitive processes dealing with (one's own) knowledge and cognitive processes (Flavell, 1976) as well as regulating those.

Metacognition is usually divided into a declarative and a procedural component and their respective sub-categories. Declarative metaknowledge signifies available, explicable knowledge a person possesses about the workings of their own cognitive functions and knowledge. Further specifying the concept, declarative metaknowledge can be subdivided into the three categories *person knowledge*, *task knowledge* and *strategy knowledge*. Procedural metacognition on the other hand is focused on planning, cognitively monitoring, reflecting and evaluating cognitive activity as well as regulating the latter. (Schneider, 2010)

It is expected here that in order to be metacognitively active during mathematical learning or problem-solving processes two or more of these (and possibly further) subcategories “interact”.

The usefulness of metacognition (for learning and doing mathematics) has been documented in the past.

On the mathematical side of the project, the field of Calculus/Analysis was chosen due to its potential for metacognitive activity. For example, developing a stable idea of the concept of limit demands for a change in perspective when dealing with its dynamic and static aspects and integrating them into a coherent idea. It seems likely that the ability to metacognitively reflect and regulate one's own learning processes is beneficial to enable this change and for mathematics learners and practitioners in general.

## Research questions

- 1) Which kinds of metacognitive activity can be observed in high school graduates/ prospective mathematics students when dealing with mathematics?
- 2) Can these activities be fully described using existing category systems or can they be used to expand those?

- 3) How and where can metacognitive activity be beneficial with regard to the field of Calculus/Analysis? What will a category system look like that classifies the term metacognition for that field and expands existing – and possibly more general – models?

## Empirical study

Prospective mathematics students' pre-existing use of metacognition was documented via a qualitative interview study at Wuerzburg University. As a sample group, eleven prospective students from mathematics study courses were selected on a voluntary basis. Five participants were invited for a single interview (one participant, one interviewer) in order to avoid inhibitors between two or more participants (such as shyness, different levels of extroversion or different levels of (perceived) "competence"). Six participants were interviewed in pairs (two participants, one interviewer) to reduce inhibitors between interviewer and participant (such as shyness, artificiality of the situation or different levels of mathematical experience) and to give the students the possibility to interact with each other – such as mutually explaining ideas and one's understanding of a mathematical concept, motivating each other to go on, detecting each other's errors and correcting them, discussing strategies, etc.. A partially-structured interview design was chosen, focusing on metacognitive activities during high school and on developing problem-solving strategies for a Calculus problem at hand. The interviewer had a manual at his disposal to guide the participants through various metacognitive topics, but in order to reduce influencing effects direct questions were avoided and the conversation was mostly left to the participants. The resulting interview transcripts are currently being evaluated by means of Qualitative Content Analysis methods (Mayring, 2010).

## Perspectives

It is the aim of the project to specify the term metacognition and its sub-categories with regard to the field of Calculus/Analysis, building upon existing category-systems and expanding them. It is hoped that such an expanded category-system can be used as a base for introducing metacognitive activity in Calculus classes (at school and university level) in a structured way and to precisely evaluate students' metacognitive "abilities". Documenting prospective mathematics students' pre-existing metacognition should help to both further specify the afore-mentioned categories and possibly add more sub-categories to the system, as well as to gain information about which metacognitive skills students may already possess and actively apply in their learning practice and which kinds of skills need to be strengthened and/ or introduced into a "metacognitively-supported" curriculum.

## Introduction

Within the context of mathematics education research there is strong agreement on the importance of language for learning and thinking, and on the centrality of being able to communicate mathematically for learning and teaching school mathematics. These standpoints are particularly idiosyncratic of TWG09 and the group of papers presented therein on the occasion of CERME10. It is assumed that developing more knowledge about language and language processes can aid the field in terms of a better understanding of what is involved in mathematics learning, teaching and thinking. In the centre of important debates around which theories and conceptualizations of language to take, there is a growing awareness that dialogue between theories will help to refine our approaches to the various phenomena embedded in mathematics education and language research. Within the context of TWG09, this awareness has been present in many ways over the course of past editions (e.g. Planas, Chronaki, Rønning & Schütte, 2015; Rønning & Planas, 2013). Also in the TWG09 sessions at CERME10 participants did not restrict themselves to ‘defending’ their positions. They were interested in exploring common ground and opportunities to take the field forward.

The T of TWG09 stands for a number of topics, themes and theories. As a group, we cover frameworks drawing on linguistics, cultural and social semiotics, sociolinguistics, positioning theory, functional grammar, theory of didactical situations, social interactionism, and content analysis, to list only a few. The main idea we want to share in this short introduction is precisely the possibilities of dialogue between theories opened up to the group and to the domain by the existence of such theoretical diversification –i.e., the fact that theoretical perspectives mostly construct their identities by differing from others. Biehler, Scholz, Strässer, and Winkelmann (1994) recommend talking about diversification instead of diversity. Dialogue is seen to be one of the positive and productive outcomes of diversification, which can keep the domain moving in several ways.

## Diversification and dialogue in TWG09

In this section, we take the collection of TWG09 papers at CERME10 to illustrate the line of argument of a landscape of diversification and dialogue. By commenting on the joint discussions within different groups of papers, we will claim that both diversification and dialogue were present in our working sessions. Throughout these sessions, the emerging common themes showed that dialogue, even if it sometimes remains elusive, is worth pursuing. Dialogue between perspectives was actually made possible because people from different perspectives worked together.

In the first session, we had a discussion of four classroom-based papers by: Brandt and Keuch; Häsel-Weide; Ingram, Andrews and Pitt; and Tatsis and Maj-Tatsis. All these papers have in common that they represent studies of social interaction, each on the basis of different theories and methods. The number of differences visible in the use of terms competing with each other –e.g., deviations, mistakes and opportunities– turned into a collaborative search for common themes. One theme emerged regarding the relationship between long-term mathematics learning and short-term language accuracy in mathematics teaching and learning. Patterns of corrective responses and markers of authority, as reported in some of the papers, were viewed as indicators of discourses of language accuracy at the intersection with processes of meaning construction and negotiation, as reported in all four papers. A related issue in the discussion was the extent to which the suppression –if possible– of certain discourses of language accuracy was necessary for the development of mathematical activity in classrooms. Either explicitly or implicitly, the different analyses presented in the papers reveal this tension between mathematics learning and language accuracy.

The second session brought many of the methodological issues explored by the group to the fore. Four papers by Farrugia, Schubert-Meyer, Ní Ríordáin, Flanagan and Brilly, and Wessel each highlighted the back and forth flow between conceptual development in mathematics and language learning within classrooms with varying degree of linguistic diversity. The papers were each offering a different perspective on the relationship between word and use, including within which language the word is used, and learning mathematical ideas including subtraction, fractions, relative frequency and undergraduate mathematics. Again each of these papers drew from different theories and methods, and researched different settings, but each raised methodological questions at the core of language research within mathematics education. The discussion focused on how integrative frameworks can be developed that draw upon the different approaches that are grounded in the study of language in mathematics.

The third session included five papers that focused on higher grades in mathematical education. The paper presented by Wille dealt with the topic of the shift from difference quotient to the derivative, moving from algebraic to analytic concept formation explored through imaginary dialogues. With this method, different perspectives (horizontal and vertical) could be identified with preservice teachers, which helped focus on the diversity of conceptions later in class. Related to this topic, Zweidar also worked with the topic of functions and its implicit meanings in the classroom. Her research focused on mathematics lessons through a lens that shows the invisible demands of mathematical discourse. Ulises pointed his research also in the direction of mathematical discourse. He examined the signs of vector quantities and their corresponding gestures in regard to novice teachers and he raised awareness of the semiotic dimension. Schlager examined the connection between language proficiency and achievement in mathematics with 10<sup>th</sup> grade students, who work on tasks with different linguistic characteristics. The results demand further research but suggest that extremely difficult linguistic structures should be avoided to reduce the achievement gap. Finally, Arce, Ortega and Planas researched students' mathematical notebooks. They analysed comments into different groups of knowledge to later conceptualize them as a learning resource. Especially interesting in this session was the focus on higher grade mathematics education. These papers all showed that mathematics and language is not a topic that is solely important in early education. Ideas of interactionistic learning theories of mathematics (Krummheuer 2015; Schütte 2014) are not just about building a foundation for later learning but also can be used in higher classes with exceptionally

more complex topics. As all papers stated, research in the specific fields has to be extended to draw broader conclusions but the results look promising.

All four papers presented in the fifth session deal, in various ways, with learning by participation in practices. Another theme, common to most of them, is that they are concerned with explanation and logical reasoning. Logic is central to mathematics but in the paper by Ludes and Schütte the authors take this out of the context of mathematics when they discuss a project which aims to include computer science in primary education. An important aim is to look for possibilities to integrate computer science and mathematics and in the paper, competencies in mathematics from the German core curriculum are listed alongside relevant competences from computer science. Carotenuto, Coppola and Tortora also report from a project which is about logic. In the project the students are working with logical riddles, which are not about mathematics but where logical reasoning is needed to solve the riddles. Erath is interested in how students learn to participate in mathematical practices, and in particular how they participate in explaining practices in whole class discussions. The paper is based in interactional discourse analysis and builds on data from grade five classes. The paper by Fetzner and Tiedemann is of a more theoretical nature. Their interest lies in reconstructing mathematical learning processes with a special focus on the interplay between language and objects. They discuss and compare three theoretical frameworks: by Aukerman on language and context, by Bauersfeld on domain-specific learning and by Latour on objects as actors.

In the sixth session connections between the modality of the language used and the learning of specific mathematical concepts became the focus. The relationships between informal everyday language and formal mathematical language, between informal gestures and sign language, between visual, dynamic and verbal modes are explored, considering not only how the mathematics is learned, but also how the mode influences how the mathematics is conceptualised. Here the links between diversification and dialogue are readily apparent. Each paper draws upon different frameworks, with Ferrari drawing upon Systemic Functional Linguistics, Khalloufi-Mouza drawing upon the Theory of Semiotic Mediation, Krause drawing upon the Theory of Embodied Cognition, Mizzie drawing upon Cummin's model of language use, and Rønning and Strømskag drawing upon the Theory of Didactical Situations, and indication of the diversification within the field. Yet the dialogue within the group focused on the commonalities between each of the papers, that is the relationship between the mode of language and the conceptualisation of the mathematics.

Four posters were also part of our group. Using a meta-analysis, and a qualitative analysis of its results, Dyrvold investigates demanding textual features of mathematics tasks, and the relevance of these features to the mathematical content. Rauf and Schmidt-Thieme sketch the required linguistic competencies of mathematics teachers, and outline a "language curriculum" recently introduced for future mathematics teachers at the University of Hildesheim. Similarly, Krosanke presents a study investigating the effect of integrating inclusive language teaching into the education of mathematics teachers in Hamburg, using analysis of interviews and video-vignettes. Kenton, meanwhile, examines the role of metaphor and language in the development of individuals' understanding of risk, confirming that this understanding is enhanced when probability is expressed in natural language.

## Old debates, contemporary challenges

Debates regarding dialogue between perspectives are not new and are not unique to our research domain (Bikner-Ahsbabs & Prediger, 2014). In particular, in mathematics and language research, the risks of moving towards a fragmented domain cannot be underestimated. The last decades of increasing research on mathematics and language have provided a serious and valuable diversification of theories and lines of interest, inside (Morgan, 2013) and outside ERME (Pimm, 2014). We are progressively including work of a review nature in the agenda in order to recognize what different theoretical perspectives have in common. As a group, we are mature enough to know that the multiplicity and richness of theoretical positions go with articulation and dialogue.

Throughout the reading of the following collection of papers, we invite you to look for common grounds emerging from contemporary ERME research on mathematics and language. Although it may be easier to grasp differences rather than commonalities between papers, careful attention to questions, approaches and methods will offer evidence of similar problems and theoretical challenges. Hopefully some of these challenges have been discussed in this introduction.

# Rethinking students' comments in the mathematics notebook

Matías Arce<sup>1</sup>, Tomás Ortega<sup>1</sup> and Núria Planas<sup>2</sup>

<sup>1</sup>University of Valladolid, Spain; [arcesan@am.uva.es](mailto:arcesan@am.uva.es), [ortega@am.uva.es](mailto:ortega@am.uva.es)

<sup>2</sup>Autonomous University of Barcelona, Spain; [nuria.planas@uab.cat](mailto:nuria.planas@uab.cat)

*We illustrate and expand some findings from research on students' mathematics notebooks in four classrooms (Arce, 2016). Through methods of interpretive content analysis, we discuss what we call comments and group them into a typology of three regarding whether they are primarily instances of: 1) conceptual knowledge, 2) procedural knowledge, or 3) practical knowledge in which it is difficult to recognize the exploration of either conceptual or procedural knowledge of mathematics. We indicate that comments are relevant in the investigation of: 1) How different they are according to the representation of mathematical knowledge, and 2) How influential they are according to the development of student mathematical activity. We anticipate that the analysis of comments may be essential in the conceptualization of notebooks as tools and resources.*

*Keywords: Student mathematics notebook, written communication, student comments, texts.*

## Introduction

The mathematics notebook of the student (MN) is a common tool in many classrooms and has been an object of study in former CERME papers (see, e.g., Segerby, 2015). This is the material instrument in which lesson notes are taken, and mathematical work is developed and revised. In our study, we deal with contents that belong to the private domain of students (Fried & Amit, 2003). In their notebooks students produce a language for communication with themselves about the contents to be developed and learned, and they are the ones ultimately responsible for the small units of information that conform the written outcome. Thus, notebooks somehow act as windows into student work and understanding in the mathematics classroom. Despite this significance of notebooks, research on them is still rare (together with Segerby, 2015, some exceptions are Fried & Amit, 2003; Yau & Mok, 2016), in part due to an expanded “illusion of transparency” (Villarreal & Borba, 2010). Notebooks are often seen as learning resources *per se* (i.e. MN represents information used in the student learning experience). Our study contributes to research on mathematical communication (Morgan, Craig, Schütte, & Wagner, 2014) by focusing on the under-researched idea of MN as a communicational tool in the relationship between learner and learning content.

We follow up on a larger study with eleventh-grade students in four Spanish mathematics classrooms. The lessons in these classrooms consisted of the initial exposition of contents and tasks by the teacher, followed by student work on the resolution of tasks. A type of notes emerged as distinguishable during the processes of MNs content analysis. Regarding the teaching dynamics, it was expected that the students wrote down blackboard contents –from the stages of exposition and resolution of tasks– and oral contents dictated by the teacher. The students, however, wrote annotations that do not fit into the former types of content. These annotations constitute what we name *comments* (see Arce, 2016; Arce, Conejo & Ortega, 2015). Regarding comments, in this paper we address two research questions:

- To what extent are comments different depending on the mathematical knowledge they represent?

- To what extent do comments seem to have influence on the development of students' mathematical activity?

### **Framework for analysis of comments as texts**

Arce (2016) applied a complex system of ideas to analyse what students seem to be saying and communicating in their mathematics notebooks. In this section, we address the theoretical grounding for some of those ideas in order to cover the notions more directly linked to the present research questions. Before making sense of the students' written comments from the perspective of their implications for learning, we need to organize the information represented in these comments.

Arce (2016) makes use of the first two types of writing out of the three discussed by Britton, Burgess, Martin, McLeod and Rosen (1975): transactional, expressive and poetic. The transactional type is particular of public domains (Fried & Amit, 2003) in that it communicates meanings intended to inform and persuade an audience. In contrast, the expressive type is particular of private domains in that it communicates personal reconstructions of public meanings. Transactional and expressive writing relate to each other in the articulation of theoretical, algorithmic, logical, methodological and conventional contents (Shield & Galbraith, 1998). All these contents are modulated by the language used, either particularized or generalized, and procedural or descriptive. What we have in comments are all sorts of combinations of contents and forms in the writing.

Types of writing, contents and forms intersect with types of knowledge, namely, conceptual and procedural knowledge of mathematics (Hiebert & Lefevre, 1986). This is a distinction that emerged as fruitful in the analysis of how, and how much mathematical concepts and procedures are present and related in MNs. Due to the complex overlap involved, we consider these two types of knowledge as critical in the analysis of comments. By the conceptual type, we refer to mathematics knowledge that is rich in semantic relationships between concepts and propositions, while by the procedural type we refer to mathematics knowledge that is rich in syntactic relationship, often expressed by means of rules and algorithms. Again, what we have in MNs and particularly in comments are all sorts of combinations of types of writing, contents, forms and types of knowledge.

In his analysis of comments in MNs as representational texts, Arce (2016) adds the differentiation of issues not strictly related to the communication of mathematical knowledge. We strategically put these multidimensional issues in one group because they all fit into a type of comments where the focus on either conceptual or procedural mathematical contents is difficult to recognize. All these issues are grouped under the name of practical knowledge to provide visibility to and promote discussion of the use of comments that may be facilitating their role in student learning even though they do not primarily address conceptual and procedural contents particular to mathematics.

### **Context, background and methods**

For the examination of comments under the conceptual-procedural-practical framework in line with the first research question, we scanned data from the MNs of 41 volunteering students that had been collected in four high school classrooms chosen by availability. We selected contents of the teaching units on functions, limits of functions, and derivatives. With inspiration on deductive methods of manifest content analysis (Krippendorff, 2004), the first two authors examined comments according to types of mathematical knowledge (i.e. conceptual and procedural), contents involved in the writing (i.e. theoretical, algorithmic, logical, methodological and conventional), forms involved (i.e.

particularized, generalized, procedural, descriptive), and other issues regarding organizational, pedagogical and personal aspects. These were the codes useful in the initial stage of the current research in order to get a first general picture of comments as tools.

In line with the second research question and together with the findings about differences across comments, the collaboration with the third author helped to rethink the previous analysis with data from eight interviews with pairs of participant students. The selection and pairing of students followed criteria, decided in the context of the larger study, about comparison and contrast among MNs in terms of written contents. By applying inductive methods of interpretive content analysis (Ginger, 2006) to MNs and interview data, some possibilities of comments as sources of mathematical activity for the production of mathematical texts in notebooks were preliminary inferred. When there is mention of or allusion to the comments' impact on either the development of MN contents or the performance of mathematical activity, the third author mentioned the possibility of comments playing a role in the development of student mathematical activity. In the next section, we present some instances of comments to reproduce partially the analyses.

### Are student comments more than texts?

The groups of comments below are not exclusive of each other. The groups may occur in various combinations although we present them separately by choosing comments that more clearly illustrate the dominance of some particular features over others. With their characterization, we want to make the argument that they must be taken into account in student written communication. Moreover, these groups of comments are sufficiently important to be included in the investigation of relationships between the knowledge communicated by students in their writing and the mathematics learning opportunities created and eventually explored by them.

#### Comments related to conceptual knowledge of mathematics

There are comments in which we find the name of the concept, a more or less formal narrative for its definition or an explanation about the concept definition. Figure 1 shows two instances of this: on the left, a generalized comment on the definition of the absolute minimum of a function; on the right, a particularized comment on the definition of constant function applied to  $f(x)=-3$ .

Min. absoluto:  
Valor más pequeño en  
todo su dominio

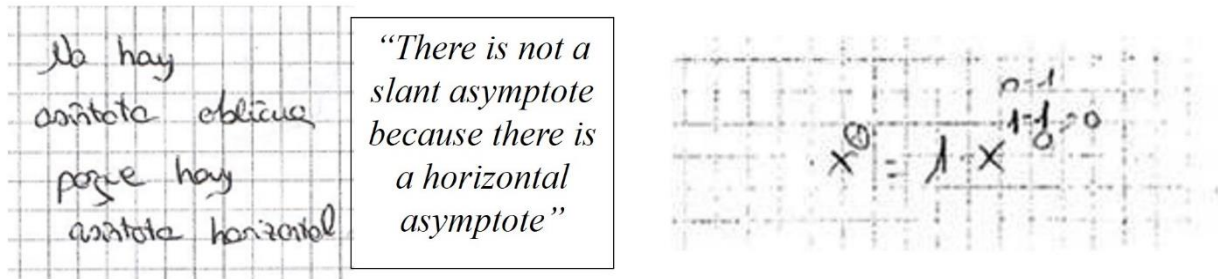

*"Absolute min.: Smaller value in all its domain"*

$f(x) = -3 \rightarrow$  valor constante porque le de el valor que le de a la  
X siempre me sale -3.

*"Constant value because whatever the value I assign to X, I will always obtain -3"*

**Figure 1: Examples of conceptual comments on definitions**

There are other comments from this group with an emphasis on relationships between concepts, properties and rules like those in Figure 2: on the left, a comment on a relationship between different kinds of asymptotes; on the right, a comment on the relationship between the derivative of the identity function and the power rule. In this last case, and different from the comment about asymptotes, as the rules had been independently presented by the teacher, we see expressive writing.

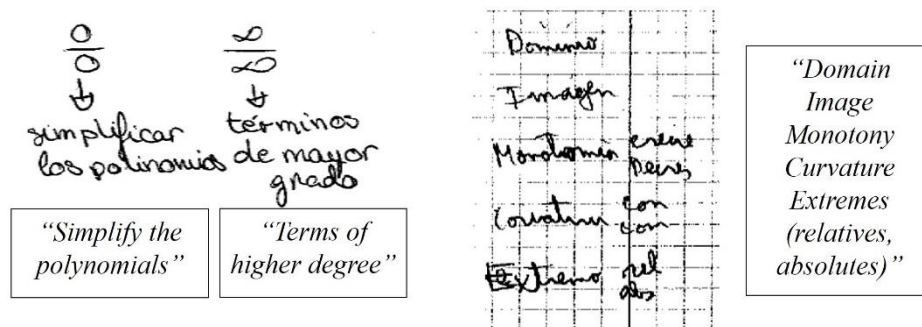

**Figure 2: Examples of conceptual comments on relationships**

Other conceptual comments are centered on the requirement and justification of conditions for a specific process to be applied, and in this way they may express attention to logical aspects of mathematics. Still some other comments anticipate the need to introduce a new concept or technique, and therefore communicate broader networks of concepts and relationships.

In all these comments of a conceptual type, the overall focus becomes student work on concepts and eventually on relationships between concepts involved in the construction of mathematical knowledge. Different uses of these comments by the students emerged in the interviews. Some students said that comments are useful to “clarify”, “evoke” or “remember” concepts, as well as to “support their study at home.” Similarly to the reflections made by Morgan (2005), we see in some of these texts (e.g. Figure 2, on the right) the reconstruction and use of mathematical concepts in ways that allow students to learn mathematics. This is confirmed in the interviews in which students refer to this type of comments as an aid for developing their learning of concepts and relationships.

### Comments related to procedural knowledge of mathematics

In this group, we place the comments in which we see procedural knowledge of mathematics, that is, comments about recalling or clarifying the application of procedures such as algorithms, rules and techniques, as well as the conventions around them. There is an emphasis on algorithmic aspects when mentioning steps or actions that constitute a procedure such as: the calculation of the domain of a function, the resolution of limits with indeterminate forms and the representation of elementary functions. Figure 3 shows on the left, two comments of a student recapitulating how to solve two indeterminate forms, specifically “ $\rightarrow 0/\rightarrow 0$ ” and “ $\rightarrow \infty/\rightarrow \infty$ ”, and on the right, the comment of another student who indicates the steps to be followed to examine any function.

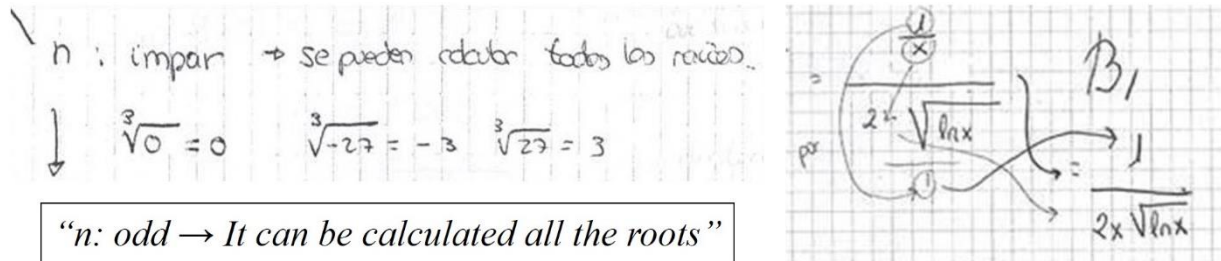

**Figure 3: Examples of procedural comments on methods**

There are comments with verbal and symbolic marks that recall or clarify mathematical properties applied in the development of the steps of a procedure. Figure 4 shows two instances of this kind: on the left, a comment recalling the calculation of the cube root of any real number; on the right, some

marks by means of arrows clarifying how to operate in a quotient of fractions. In all these comments of a procedural type, the overall focus becomes student work on methods and eventually on the symbolic and formal representation of properties and procedures. As said by the students in the interviews, they provide different uses to their procedural comments, namely: highlighting and clarifying procedural aspects found more difficult (Figure 4), and acting as an aid in order to “mechanize” a mathematical procedure (Figure 3, on the right).

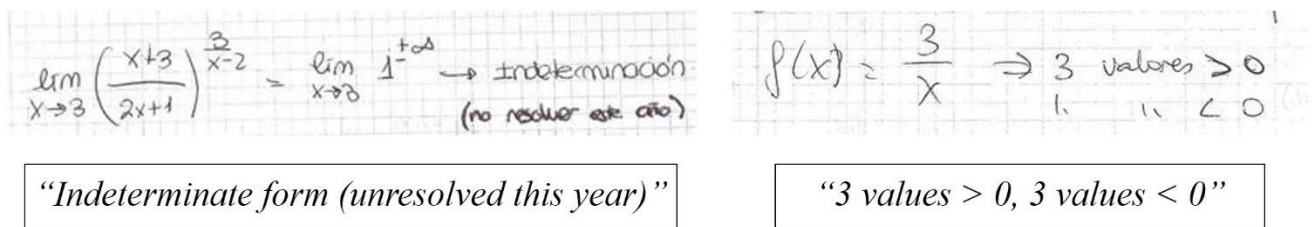

**Figure 4: Examples of procedural comments on properties**

Together, conceptual and procedural comments point to an important presence of expressive writing with modifications and connections to the mathematics communicated by the teacher in the lesson. We interpret the engagement with expressive writing as evidence of some mathematical work. Drawing on this, these comments may be acting as resources in that they develop written representations of student understanding. One could possibly expect to see in representations of understanding at different moments some traces of different learning stages.

### Comments related to practical knowledge

The third group of comments does not directly refer to contents about types of mathematical knowledge communicated in the notebooks; instead, it refers to contents that privilege pedagogical and organizational knowledge, among others. This is a “big” group of comments in this report whose detailed deconstruction in codes can be found in Arce (2016).

Some comments record texts that teachers said during the lessons concerning the organization of curricular issues and other forms of pedagogical support. On the left of Figure 5 there is an instance of an indication about the school time for a curricular content to be considered. Other comments highlight processes that are “tricky” as said by a teacher in a lesson; here we find rules of action as ways to manage difficulty. On the right of Figure 5 there is an instance of a rule for the generation of a table of values in order to represent a function with three positive and three negative values.

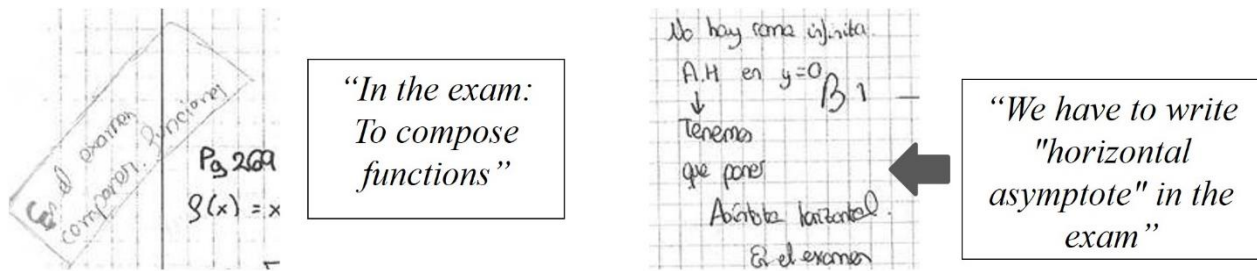

**Figure 5: Examples of practical comments on organization**

There is also practical knowledge in comments about the forms and contents of evaluation in the subject. This is clear in the two instances of Figure 6 with references to an exam and to the expected contents to appear in it. Comments such as those in Figures 5 and 6 are difficult to be recognized as

representations of mathematical understanding. They also contain/are mathematical texts. Some sort of practical knowledge with purposes of optimization of opportunities as learner is communicated.

**Figure 6: Examples of practical comments on evaluation**

Similarly to the instances in Figures 5 and 6, the texts in Figure 7 do not provide evidence of the creation of opportunities for mathematics learning, but rather seem to indicate the creation of opportunities for the student writer as learner. In Figure 7 we find question marks on the left, and sentences to indicate doubts and uncertainty on the right. Other comments documented in Arce (2016) use impersonal forms of language to recommend “reviewing”, “studying”, or “asking”.

**Figure 7: Examples of practical comments on cognition**

There is some evidence of personal meta-cognition and control over the learning process in all these comments. We found in the interviews that some students add comments like those of Figure 7 in the resolution of tasks to focus and increase their attention when the teacher makes corrections in the classroom or to ask directly the teacher about a doubt. However, except for Figure 7 (on the left), there are no concrete initiatives in the MNs aimed at exploring or clarifying what has been indicated as mathematically difficult to understand.

We claim that all these practical comments are also valuable; they communicate part of the knowledge that the student needs to develop, together with particular mathematical knowledge, in the mathematics classroom. These comments provide an opportunity for students to make their own judgments on, for example, what needs to be known (i.e. what is to appear in the exam, what is planned for another school year) and who they are as knowers of mathematics (i.e. what is not mathematically clear to them, which learning requires revision).

## Rethinking comments as more than texts

We are in the position to adventure some initial thoughts and questions about the conceptualization of student comments as resources. Conceptual and procedural comments like those exemplified in this report (Figures 1 to 4) facilitate the exploration of mathematical knowledge, even though there may be some instances of a routine writing activity enabling the development of reproductive or

imitative patterns (also studied by Yau & Mok, 2016). However, our analysis of comments includes one more practical function about prescriptions of what is to be learned (Figures 5 and 6) and about judgments on what is not known (Figure 7). It is not easy to elucidate whether the learning process would be similarly facilitated if particular types of comments were not present. We anticipate that all types of comments –conceptual, procedural and practical – are necessary in order to create learning opportunities oriented to both the creation and communication of mathematics learning.

We agree with Fried & Amit (2003) that there is a need to further investigate the role and use of MNs, and not only of comments, as a learning resource in the mathematics classroom. A significant question for which this area of investigation might provide understanding is why some notebooks are better facilitators of opportunities for mathematics learning. This is an issue related to the broader question of the role of mathematical writing in mathematics learning. As noted already with the analysis of comments, the written elaboration of conceptual and procedural knowledge of mathematics seems to indicate work relevant for the development of student mathematics learning. However, these comments alone may not be enough in the construction of mathematics learning. Other types of comments, like those that constitute what we have called practical knowledge, may be required in the process that goes from student written communication to mathematical understanding and from here to student written communication again. Especially important may be the ways in which all these types of comments appear combined and related.

*This paper deals with aspects of language learning in settings planned for mathematical learning by kindergarten teachers. Using qualitative and linguistic analysis tools, we reconstruct patterns of language use and the language sensitive organization of kindergarten teachers. We mainly focus on the children's language use, particularly on semantic deviations in utterances in relation to the mathematical negotiation process.*

*Keywords: Language usage, measurement, early childhood education.*

## Introduction

The importance of language for cognitive (subject-specific) learning processes is undeniable and well established with regard to research in early mathematics education. Scientific language proficiency is seen as an important factor for successful education and schooling. There are still unsatisfied needs for Germany to appropriately support children with disadvantageous starting conditions (for example migration, socio-economic background, developmental speech disorder), in order to give them an equal chance to participate in education processes (Gogolin & Lange, 2010).

Early education in kindergarten, which puts emphasis on supporting language education, could provide a remedy. Prediger (2015) suggests that academic language education processes start as early as possible, to design them age-appropriately and to orientate it to specific contents. However, Germany is particularly lacking language education approaches that integrate subject-related learning processes and not only selective training single academic language terms. Rudd, Satterwhite and Lambert (2010) describe how mathematical learning and language learning can be combined in (natural) kindergarten situations. They introduce the concept of Math-Mediated Language (MML). This means that mathematical learning is embedded in dialogues, which include mathematical as well as linguistic knowledge (Rudd et al., 2010). They give examples for different mathematical topics, e.g. how to foster complex counting strategies by modeling them in concrete situations or by requesting them from children using corresponding questions. Even though the concept of MML emphasizes mathematical learning in kindergarten, it points to the need that kindergarten teachers consider both the mathematical context and linguistic effort involved in the dialogues – and address this connection in their planning as well as in spontaneous situations. Thus, MML deals with the integration of language education and subject learning in everyday activities for kindergartners.

MML requires a certain amount of language awareness. For pre-service early childhood educators, Moseley (2005) found out that their perceptions of MML is restricted to technical terms and basic mathematical terminology. In our qualitative-empirical project, we are interested in kindergarten teachers' language awareness in everyday situations. We put our focus on the support of language

learning in settings planned for mathematical learning. This idea corresponds to the underlying idea of supporting language development within the subject (Leisen, 2013; Prediger, 2013; Prediger & Wessel, 2013) as it is discussed in the schooling context. Often, these concepts trace back to the Immersion Model for bilingual education for children with migration background in school contexts (e.g. Cohen & Swain, 1976).

Kindergartners are not only 'subject learners' but, independently from their language background, always 'language learners'. Hence, they sometimes have difficulties expressing complex facts and their language productions often show deviations from the standard language (Volmert, 2005). In this paper, we want to deal with deviations from standard expressions that can have an impact on mathematical learning processes. Since we are dealing with spoken language, which often includes aspects of dialectal variation and language change phenomena, it is not always trivial or even possible to decide whether one utterance is correct or not. In German for example, there are nouns with locally varying genders (cf. *der Joghurt*: male or *das Joghurt*: neuter, both possible in standard German; and in eastern parts of Austria *die Joghurt*: female).<sup>1</sup>

In principle, mistakes can be divided into lexical (neologisms and wrong pronunciation), syntactical (wrong conjugation or flexion, word order) and semantic (inappropriate choice or combination of words) ones. In this paper, we concentrate on semantic deviations, which we list as a separate category since the meaning of utterances does not always depend on the choice of single words or grammatical constructions alone. Meanings rather tend to exceed verbal boundaries, which also has to be taken into consideration when looking at inappropriate utterances (Brandt & Keuch, in Press).

In particular, our aim is to reconstruct the empirical language in use, to detect aspects of language support, and to show the connection to specific meanings and concepts that are negotiated in certain situations. In our prior analyses, we found different kinds of language support and correction strategies (Brandt & Keuch, in Press). Similar to Moseley's results (2005), when using language in everyday situations, kindergarten teachers put special emphasis on technical terms and only a limited focus on complex language structures. Thus, in this paper we will concentrate on semantic aspects of the empirical language and the corresponding questions:

- What kind of semantic deviations can we identify in the field of measurement?
- Which impacts for negotiation processes about measurement can we deduce from these deviations?

## Research design

The data basis for our analysis consists of mathematical situations designed by kindergarten teachers and taken from the project *erStMaL* (early Steps in Mathematical Learning) (Acar Bayraktar, Hümmer, Huth, & Münz, 2011). Methodologically, our project is based on grounded theory (Glaser & Strauss, 1967). We figure out the negotiation of meaning in the interaction processes through the interaction analysis (Krummheuer, 2007), which is a sequential analysis and is organized as an extensive turn-by-turn interpretation. Further, we determine linguistic features

---

<sup>1</sup> Duden, 2013; 26. Aufl., Dudenverlag, Berlin.

that originate from a linguistic valence analysis (Herbst & Götz-Votteler, 2008) by looking at the relation between verbs and their objects (Brandt & Keuch, in Press)<sup>2</sup>. Our aim is to create a category system of difficulties and deviations, and their corresponding reactions and support from the kindergarten teachers. According to qualitative content analysis (Mayring, 2000), these categories are generated inductively. Based on these analysis methods, we will present case studies that point out the empirical language use in this partial corpus in the following paragraph.

In this paper, we refer to five situations, which kindergarten teachers designed and realized to support mathematical learning. Besides the general topic *measurement* and the involved children, there were no content-related or structural prompts for the realization of mathematical situations.

<i>Situation</i>	<i>Teacher</i>	<i>Children</i>	<i>Magnitude</i>
A	Doris (MA <sup>3</sup> )	Nikola (f): 4;2 / BL <sup>4</sup> ; Orania (f): 3;10 / L1 (Greek); Regina (f): 4;4 / L1; Uwe (m): 3;11 / L1	length
B	Sabine (MA)	Mona (f): 5;5 / L1; Omara (m): 4;11 / L2 (Tamil); Sadira (f): 5;11 / L2 (Urdu); Theresa (f): ? / L2; Oslana (f): 5;3 / L2 (Croatian)	length and volume
C	Berna (L2 / unknown)	Bella (f): 6;0 / L1; Can (m): 6;0 / BL (Turkish); Denis (m): 6;0 / L1; Friedel (m): 6;0 / L1	length
D	Johanna	Ona (f): 5;6 / L2 (Turkish); Tamila (f): 4;10 / L2 (Pasto / Afghan)	length
E	Linda	Irvin (m): 5;0 / L1; Torben (m): 5;5 / L1	weight

**Table 1: Basic information on the focused situations**

## Difficulties and deviations in language usage

Example from situation D: The kindergarten teacher and the two girls are building towers with colored rods and building blocks of different sizes. One tower of the teacher's construction falls down, which she comments on: "huu jetzt is es gefallen \'" (huu now it has fallen). Ona takes up this structure: "deiner war nicht gut meiner hat nich gefalln." (yours was not good mine has not pleased). Her utterance is grammatically correct. However, using the auxiliary "hat" (to have) instead of "ist" (to be) like the kindergarten teacher for the perfect tense, Ona expresses the meaning of 'pleasing' instead of 'falling'. Certainly, this was not Ona's intention. Thus, semantic deviation can only be determined by focusing one's attention to the context.

<sup>2</sup> For more details see our analyses in the next paragraph.

<sup>3</sup> MA: trained in mathematics.

<sup>4</sup> L1 means, the child learned and uses German as a first language; L2 means, the child learned another language than German as a first language, now learns, and speaks German as a second language; bilingual (BL) means, the child learned German and another language as first languages and now uses both languages at home.

According to Bishop (1988), “measuring (...) is concerned with comparing, ordering, and with quantifying qualities” (p. 34). Comparing, ordering, and quantifying qualities ask for a differentiated language usage, including certain technical terms and grammatical structures. In the next sections, we illustrate semantic deviations in this context. That means we look for language productions that are syntactically correct but their initial meaning does not fit with the context of actions.

### **Verbal constructions with *to measure*: Measuring (yourself) with something or someone**

In Brandt and Keuch (in press) we explain how linguistic valence (Herbst & Götz-Votteler, 2008) can be used to explain the emergence of a cognitive concept of measuring and the acquisition of case endings in relation to the verb *to measure*. With the verb *to measure*, you normally use a subject (someone who measures), something that is measured (the accusative object) and a tool you use for measuring (the dative object). There are, however, situations in which children as well as kindergarten teachers use this expression in a slightly different way.

In situation C, measuring the children’s body lengths occupies most of the situation. The children lie down on the floor and have the position of their head and their feet marked with chalk on the floor. Subsequently, the distance between those two chalk lines is measured with different devices:

- |       |  |
|-------|--|
| Berna | you can actually measure it with all those things here   |
| Can   | wait . I measure it with the chalk \ here it starts (draws a line from one limiting line to the other) |
| Berna | so Can / now wait \  |
| Can   | sooo \ (.) up to my line \   |
| Berna | up to your line  |

While Can’s utterance is syntactically correct, his actions do not fit with its meaning. If he was measuring a certain length with the piece of chalk he carries in his hand, he would aim to find out how often that piece of chalk fits into that length. The group had used a building block before in a similar way. What he does, instead, is to draw a line from one point to another. Since he incorrectly uses the verb *measure* in this context, probably synonymously to *draw* or even *connect*, we consider his utterance as a semantic deviation.

In German, as well as in other languages, certain words used as a collocation in combination with certain prepositions or complements can have a different meaning than the original word, often metaphorical or figuratively. For the verb *measure*, if used with a reflexive pronoun, it gets the meaning of competing with someone (in any possible way, not limited to magnitudes). In situation B, the kindergarten teacher Sabine asks Oslana to stand back-to-back with Sadira and compare their sizes. She accompanies her request with the words “Willst du dich jetzt mit der (.) Sadira messen?” [Do you want to measure yourself / compete with Sadira?]. Sabine does not seem to notice the ambiguity in her utterance on the one hand and the children do not seem to notice the figurative meaning on the other hand. In the course of the situation, Sabine leaves out the reflexive pronoun. She now asks Omara “Whom do you want to measure with?” While the meaning is probably relatively clear due to the unambiguous situation, the dative object is no longer a measuring tool but a person, which could lead to confusion. One could also argue whether the sentence is really any

longer syntactically correct. Mona (the only child whose mother tongue is German in this situation) finally takes up Sabine's sentence structure and says, "I want to measure with you". In contrast to the usual valence, the dative object ("with you") does not represent the measuring device but it rather works as an adverbial phrase, expressing the kind or manner how the activity of measuring shall be done.

### The use of personal pronouns with comparisons
